Impact Factor (2023): 3.5
Volume 11 (2025) ISSN 2369-2960 Editor in Chief: Travis Sanchez, PhD, MPH

Contents

Original Papers

Engagement With Digital Adherence Technologies as Measures of Intervention Fidelity Among Adults With Drug-Susceptible Tuberculosis and Health Care Providers: Descriptive Analysis Using Data From Cluster-Randomized Trials in Five Countries (e62881)
Jason Alacapa, Amare Tadesse, Natasha Deyanova, Tanyaradzwa Dube, Andrew Mganga, Rachel Powers, Job van Rest, Norma Madden, Egwuma Efo, Salome Charalambous, Kristian van Kalmthout, Degu Jerene, Katherine Fielding. . . . 19

The Impact of a Mobile Money–Based Intervention on Maternal and Neonatal Health Outcomes in Madagascar: Cluster-Randomized Controlled Trial (e70182)
Lisa Bogler, Bítia Vieira, Harizaka Andriamasy, Zavaniarivo Rampanjato, Sebastian Vollmer, Till Bärnighausen, Andriamampianina Ralisimalala, Julius Emmrich, Samuel Knauss. . . . 34

Leveraging Administrative Health Databases to Address Health Challenges in Farming Populations: Scoping Review and Bibliometric Analysis (1975-2024) (e62939)
Pascal Petit, Nicolas Vuillerme. . . . 268

Health Equity of Hypertension Management Between Local Residents and Internal Migrants in Shenzhen, China: Cross-Sectional Study (e65548)
Jinyu He, Yanjun Li, Huatang Zeng, Haoran Sun, Liqun Wu, Zhenzhen Zhu, Ning Zhang, Wannian Liang. . . . 395

Accessibility of eHealth Before and During the COVID-19 Pandemic Among People With and People Without Impairment: Repeated Cross-Sectional Survey (e64707)
Linda Pettersson, Stefan Johansson, Ingrid Demmelmaier, Lena von Koch, Jan Gulliksen, Per-Olof Hedvall, Karl Gummesson, Catharina Gustavsson. . . . 411

Facilitated Telemedicine as a Patient-Centered, Sociotechnical Intervention to Integrate Hepatitis C Treatment Into Opioid Treatment Programs and Overcome the Digital Divide Among Underserved Populations: Qualitative Study (e68854)
Andrew Talal, Arpan Dharia, Marianthi Markatou, Lawrence Brown Jr, Kenneth Bossert, Zakiya Grubbs, Raktim Mukhopadhyay, Boatemaa Ntiri-Reid, Elisabeth Houtsmuller. . . . 426

Changes in Epidemiological Characteristics of Varicella and Breakthrough Cases in Ningbo, China, From 2010 to 2023: Surveillance Study (e71691)
Xingqiang Pan, Yan Zhang, Xuefei Zhao, Dandan Zhang. . . . 442

Epidemic Trends and Spatial Distribution Characteristics of Hepatitis B in China: Surveillance Study (e70888)
Xiaoxue Li, Jie Liang, Lanqing Ma, Shijie Shen, Xueying Han, Tao Sun, Heng Guo. . . . 457

Spatiotemporal Trends in Deaths From External Causes in Brazil: 23-Year Ecological and Population-Based Study (e68002)
Lucas Andrade, Wandklebson Silva da Paz, Luís Santos de Melo, Débora dos Santos Tavares, Alvaro Lopes de Sousa, Emerson Silva Camargo, Carla Arena Ventura, Regina Silva Souza, Karina Gomes Machado de Araújo, Carlos Freire de Souza, Allan dos Santos, Fagner Campos, Márcio Bezerra Santos. . . . 471

Epidemiology and Treatment Outcomes of Pulmonary Tuberculosis in Dazu District, Chongqing, China, 2005-2024: Surveillance Study (e78564)
Yu Yu, Xiu-juan Hu, Xiao-man Fang, Jing Wu. . . . 487

Impact of Primary Health Care Data Quality on Infectious Disease Surveillance in Brazil: Case Study (e67050)
Pilar Florentino, Juracy Bertoldo Junior, George Barbosa, Thiago Cerqueira-Silva, Vinicius Oliveira, Marcio Garcia, Gerson Penna, Viviane Boaventura, Pablo Ramos, Manoel Barral-Netto, Izabel Marcilio. . . . 509

Effectiveness of Frequent Point-of-Care Molecular COVID-19 Surveillance in a Rural Workplace: Nonrandomized Controlled Clinical Trial Among Miners (e59845)
Akshay Sood, William “Cotton” Jarrell, Xin Shore, Nestor Sosa, Alisha Parada, Nicholas Edwardson, Alexandra Yingling, Teah Amirkabirian, Qiuying Cheng, Ivy Hurwitz, Linda Cook, Shuguang Leng, Orrin Myers, Douglas Perkins. . . . 518

Updated Surveillance Metrics and History of the COVID-19 Pandemic (2020-2023) in East Asia and the Pacific Region: Longitudinal Trend Analysis (e53214)
Alexander Lundberg, Alan Soetikno, Scott Wu, Egon Ozer, Sarah Welch, Yingxuan Liu, Claudia Hawkins, Maryann Mason, Robert Murphy, Robert Havey, Charles Moss, Chad Achenbach, Lori Post. . . . 534

Wastewater Monitoring During the COVID-19 Pandemic in the Veneto Region, Italy: Longitudinal Observational Study (e58862)
Honoria Ocagli, Marco Zambito, Filippo Da Re, Vanessa Groppi, Marco Zampini, Alessia Terrini, Franco Rigoli, Irene Amoruso, Tatjana Baldovin, Vincenzo Baldo, Francesca Russo, Dario Gregori. . . . 554

Monitoring Public Health Through a Comprehensive Primary Care Database in the Netherlands: Overview of the Nivel Syndromic Surveillance System (e58767)
Christos Baliatsas, Jojanneke van Summeren, Sander van Beusekom, Amy Matser, Mariette Hooiveld. . . . 589

Balancing Human Mobility and Health Care Coverage in Sentinel Surveillance of Brazilian Indigenous Areas: Mathematical Optimization Approach (e69048)
Juliane Oliveira, Adriano Vasconcelos, Andrêza Alencar, Maria Cunha, Izabel Marcilio, Manoel Barral-Netto, Pablo P Ramos. . . . 597

Analyzing Satellite Imagery to Target Tuberculosis Control Interventions in Densely Urbanized Areas of Kigali, Rwanda: Cross-Sectional Pilot Study (e68355)
Mauro Faccin, Caspar Geenen, Michiel Happaerts, Sien Ombelet, Patrick Migambi, Emmanuel André. . . . 604

Statistical Relationship Between Wastewater Data and Case Notifications for COVID-19 Surveillance in the United States From 2020 to 2023: Bayesian Hierarchical Modeling Approach (e68213)
Masahiko Haraguchi, Fayette Klaassen, Ted Cohen, Joshua Salomon, Nicolas Menzies. . . . 616

Experiences and Perceptions About Death Reporting and Notification Among Rural Communities on the Islands of Lake Victoria, Uganda: Qualitative Study (e77135)
Steven Kabwama, Douglas Bulafu, Rawlance Ndejjo, Rose Nampeera, Christine Kihembo, Chukwuma Umeokonkwo, Simon Antara, Sheba Gitta, Caroline Kyozira, Allan Muruta, Jean-Edgard Nguessan, Rhoda Wanyenze. . . . 627

Comparison of Virus Watch COVID-19 Positivity, Incidence, and Hospitalization Rates With Other Surveillance Systems: Surveillance Study (e69655)
Wing Fong, Vincent Nguyen, Sarah Beale, Thomas Byrne, Cyril Geismar, Ellen Fragaszy, Jana Kovar, Alexei Yavlinsky, Ibrahim Abubakar, Andrew Hayward, Robert Aldridge. . . . 638

Equivalence of Type 2 Diabetes Prevalence Estimates: Comparative Study of Similar Phenotyping Algorithms Using Electronic Health Record Data (e79653)
Muchiri Wandai, Katie Allen, Ashley Wiensch, John Price, Brian Dixon. 654

SARS-CoV-2 Detection in International Travelers Through Wastewater-Based Epidemiology at the Kigali International Airport: Genomic Surveillance Study (e71104)
Rwagasore Edson, Robert Rutayisire, Ziad El-Khatib, Olivier Nsekuye, Hugues Mucunguzi, Raissa Muvunyi, Esperance Umumararungu, Eric Remera. 665

Identifying Gaps and Challenges in Acute Hepatitis B Surveillance in the Country of Georgia: Comprehensive Surveillance System Evaluation (e72888)
Lika Karichashvili, Ketevan Galdavadze, Khatuna Zakhashvili, Maia Tsereteli, Ekaterine Ruadze, Sophia Surguladze, Pawel Stefanoff. 674

Transforming One Health in India: National Multisectoral Mixed Method Study on Prioritization of Zoonotic Diseases (e77850)
Simmi Tiwari, Indranil Roy, Monal Daptardar, Ruchi Singh, Anshuman Mishra, Richa Kedia, Ananta Bhat, Harmesh Manocha, Mayank Dwivedi, Amlesh Dwivedi, Gaurish Shukla, Ajit Shewale, Tushar Nale, Dipti Mishra, Ravi Sharma, Daniel Garcia, Runa Gokhale, Meghna Desai, Sujeet Singh. 683

Assessing Usefulness of the Dashboard Instrument to Review Equity (DIRE) Checklist to Evaluate Equity in Public Health Dashboards: Reliability Study (e71094)
Paulina Sosa, Emir Syailendra, Harold Lehmann, Hadi Kharrazi. 697

Nonrandom Missingness in Child Race and Ethnicity Records and the US Federal Data Standards: Pooled Analysis of Community-Based Child Health Studies (e65660)
Danielle Krobath, Norbert Wilson, Adolfo Cuevas, Elena Naumova, Jennifer Sacheck, Sydney Tyler, Christina Economos. 713

Identifying Predictors of Cervical Cancer Screening Uptake in Sub-Saharan Africa Using Machine Learning: Cross-Sectional Study (e71677)
Nebebe Baykemagn, Mekuriaw Aweke, Amare Mesfin, Lemlem Baffa, Muluken Agimas, Habtamu Abuhay, Dagnew Adugna, Tewodros Alemu, Alemu Bicha, Gebrie Getu Alemu. 729

Dietary Risk Factors and Associated Disease Burden Among Chinese Adults Aged 25 Years and Older: Systematic Analysis of the Global Burden of Disease Study 2021 (e72978)
Yuze Xin, Dong Shui, Guangcan Yan, Wei Tian, Ning Tang, Jinyu Liang, Junyi Peng, Hongru Sun, Anqi Ge, Xinyan Liu, Katrina Kissock, Kathy Trieu, Jing Zhang, Xinyi Zhang, Pengpeng Ye, Maoyi Tian. 744

Characterizing US Spatial Connectivity and Implications for Geographical Disease Dynamics and Metapopulation Modeling: Longitudinal Observational Study (e64914)
Giulia Pullano, Lucila Alvarez-Zuzek, Vittoria Colizza, Shweta Bansal. 757

Behavioral and Demographic Profiles of HIV Transmission and Exposure Networks in Florida: Network Analysis of HIV Contact Tracing Data (e65573)
Yiyang Liu, Christina Parisi, Chaoyue Sun, Rebecca Fisk-Hoffman, Marco Salemi, Diego Viteri, Brandi Danforth, Mattia Prosperi, Simone Marini. 767

COVID-19–Relevant Insights Into the Elevated Risk of Accidental Injuries in Survivors of SARS and Their Relatives in Taiwan: Retrospective Cohort Study (e70608)
Chieh Sung, Chi-Hsiang Chung, Chien-An Sun, Chang-Huei Tsao, Daphne Ng, Tsu-Hsuan Weng, Li-Yun Fann, Fu-Huang Lin, Wu-Chien Chien. 781

An Explainable Artificial Intelligence Text Classifier for Suicidality Prediction in Youth Crisis Text Line Users: Development and Validation Study (e63809)
Julia Thomas, Antonia Lucht, Jacob Segler, Richard Wundrack, Marcel Miché, Roselind Lieb, Lars Kuchinke, Gunther Meinlschmidt. 796

A Cloud-Based Platform for Harmonized COVID-19 Data: Design and Implementation of the Rapid Acceleration of Diagnostics (RADx) Data Hub (e72677)
Marcos Martínez-Romero, Matthew Horridge, Nilesh Mistry, Aubrie Weyhmiller, Jimmy Yu, Alissa Fujimoto, Aria Henry, Martin O'Connor, Ashley Sier, Stephanie Suber, Mete Akdogan, Yan Cao, Somu Valliappan, Joanna Mieczkowska, Ashok Krishnamurthy, Michael Keller, Mark Musen, RADx Data Hub Team. . . . 814

Prevalence, Risk Factors, Disease-Related Knowledge, and Vaccination Attitudes and Behaviors for Long COVID Among French Civil Servants: Cross-Sectional Survey (e83323)
Florence Carrouel, Virginie-Eve Lvovschi, Benjamin du Sartz de Vigneulles, Maryem Rhanoui, Roger Salamon, Michel Lamure, Corélie Salque, Romain Lan, Claude Dussart. . . . 836

Using the Health Belief Model to Examine Parental Knowledge and Health Beliefs About Human Papilloma Virus (HPV) and iHPV Vaccine in Kuwait: Cross-Sectional Survey Study (e75818)
Ahmad Abuzoor, Md Jabin, Cyril Eshareturi, Rae Nesbitt, Cor Jonker. . . . 854

Using Social Media Marketing to Improve Retention of Children in the Special Supplemental Nutrition Program for Women, Infants, and Children: Implementation Study (e77172)
Eriko Robinson, Carla Sabugo, Carolina Crisafi, Susan Gross, Yunhee Kang, Elisabet Eppes, Marycatherine Augustyn, Karen Castellanos-Brown, David Paige, Laura Caulfield. . . . 875

Workplace-Based Glucose Screening for Type 2 Diabetes in French Civil Servants: Prospective Observational Cohort Study (e87695)
Solène Petit, Florence Carrouel, Benjamin du Sartz de Vigneulles, Claude Dussart, Roger Salamon. . . . 889

Clustering of Lifestyle Behaviors and Their Association With Risk of Metabolic Syndrome Among Adults in Taiwan: Nationwide Cross-Sectional Study (e73114)
Ya-Hui Chang, Chung-Yi Li, Hon-Ping Ma, Chien-Yuan Wu, Yann-Yuh Jou, Chiachi Lee. . . . 899

Temporal Trends in Cervical Human Papillomavirus Prevalence Among Females in Xiamen, China (2016-2023): Cross-Sectional Study (e70507)
Zhuju Chen, Erjuan Lin, Mo Chen, Shihan Wang, Qiuyuan Lin, Qingquan Chen, Heng Xue, Guanbin Zhang. . . . 910

Development of Machine Learning–Based Risk Prediction Models to Predict Rapid Weight Gain in Infants: Analysis of Seven Cohorts (e69220)
Miaobing Zheng, Yuxin Zhang, Rachel Laws, Peter Vuillermin, Jodie Dodd, Li Wen, Louise Baur, Rachael Taylor, Rebecca Byrne, Anne-Louise Ponsonby, Kylie Hesketh. . . . 922

Prevalence of Chronic Back Pain and Associated Factors in Children and Adolescents: Secondary Analysis of the 2001–2019 Health Behavior in School-Aged Children Study (e67960)
Camila Miño, Héctor Gutiérrez-Espinoza, Jorge Olivares-Arancibia, Rodrigo Yáñez-Sepúlveda, Daniel Duclos-Bastías, Felipe Araya-Quintanilla, Lee Smith, José López-Gil. . . . 936

How Healthy and Unhealthy Lifestyle Behaviors Affect Cognitive Function—Evidence From Older Adults in Chinese Communities: Cross-Sectional Study (e73398)
Huixiu Hu, Yajie Zhao, Yuqing Hao, Huanhuan Luo, Lanying Xie, Chao Sun. . . . 950

Tenofovir to Prevent HIV Infection in Western China: Pragmatic Randomized Controlled Trial (e71494)
Yi Tao, Yan Zhang, Bin Peng, Aizhong Zeng, Jianghong Dai, Hao Liang, Juying Zhang, Huarui Shao, Shihan Feng, Xiaoni Zhong, Ailong Huang. . . . 963

Knowledge, Attitudes, and Practices to Periodontal Health of the Northeast Chinese Public: Cross-Sectional Study (e72069)
Chengde Jin, Ming Chi, Chunxiao Li, Yushan Li, Wanting Wang, Yushi Zhang, Qiao Liu. . . . 979

Gender-Specific Moderating Role of Physical Fitness and Cardiovascular Risk Factors in the Relationship Between BMI and C-Reactive Protein: Cross-Sectional Study (e76485)
Chunyuan Lai, Yunqing Liu, Yue Yan, Boli Cheng, Yakun Liu, Fanshu Yu, Chengyuan Hu, Liqiang Su, Fanghui Li. . . . 990

Epidemiological Features, Clinical Symptoms, and Environmental Risk Factors for Notifiable Japanese Encephalitis in Taiwan From 2008 to 2020: Retrospective Study (e63053)
Fu-Huang Lin, Yu-Ching Chou, Chi-Jeng Hsieh, Chia-Peng Yu. . . . 1010

Effectiveness of a Health Education Program to Reduce Recurrence of Stroke by Controlling Modifiable Risk Factors in a Specialized Hospital in Bangladesh: Randomized Controlled Trial (e72233)
Mahabuba Afrin, K Huq, Sharif Khan, Subir Das, Mohammad Chowdhury, Yasuko Fukuoka, Yasuko Fukushima, Michiko Moriyama. . . . 1026

Impact of Commercial Food Environments on Local Type 2 Diabetes Burden: Cross-Sectional and Ecological Multimodeling Study (e70045)
Kurubaran Ganasegeran, Mohd Abdul Manaf, Lance Waller, Nazarudin Safian, Muhammad Mohd Rizal, Wye Chiew, Feisul Mustapha, Khairul Abdul Maulud. . . . 1040

Behavioral Profiles and Sociodemographic Predictors of Planetary Health Diet Engagement Among Health Care Professionals to Inform Public Health Promotion: Cross-Sectional Study (e67633)
Florence Carrouel, Rita Nugem, Laurie Fraticelli, Yohan Fayet, Lama Basbous, Corélie Salque, Claude Dussart, Marie-Thérèse Charreyre, Romain Lan, Audrey Murat-ringot. . . . 1060

Assessing COVID-19 Mortality in Serbia's Capital: Model-Based Analysis of Excess Deaths (e56877)
Dane Cvijanovic, Nikola Grubor, Nina Rajovic, Mira Vucevic, Svetlana Miltenovic, Marija Laban, Tatjana Mostic, Radica Tasic, Bojana Matejic, Natasa Milic. . . . 1074

Digital Survey–Based Tracing of COVID-19 Over the Early Pandemic: Comprehensive Geospatial and Symptomatic Analysis in Lebanon (e80331)
Youssef Bassim, Abir Abdelrahman, Amal Iaaly, Gavin Douglas, Patrick Daou, Mayda Finianos, Rim Hassan, Ibrahim Nassif, Layal Greige, Liza Dib, Jean Mardirossian, Mira El Chaar. . . . 1086

Social Media Use, Influencer Status, and Outdoor Risk-Taking in Australian Adults: Cross-Sectional Survey (e73089)
Samuel Cornell, Amy Peden. . . . 1126

Assessing the Dissemination of Federal Risk Communication by News Media Outlets During Enteric Illness Outbreaks: Canadian Content Analysis (e68724)
Hisba Shereefdeen, Lauren Grant, Vayshali Patel, Melissa MacKay, Andrew Papadopoulos, Leslie Cheng, Melissa Phypers, Jennifer McWhirter. . . . 1134

Mindfulness Intervention for Health Information Avoidance in Older Adults: Mixed Methods Study (e69554)
Chenyu Gu, Liquan Qian, Xiaojie Zhuo. . . . 1147

Alternative Presentations of Overall and Statistical Uncertainty for Adults' Understanding of the Results of a Randomized Trial of a Public Health Intervention: Parallel Web-Based Randomized Trials (e62828)
Christine Holst, Steven Woloshin, Andrew Oxman, Christopher Rose, Sarah Rosenbaum, Heather Munthe-Kaas. . . . 1163

Evaluation of a Digital Media Campaign to Promote Knowledge and Awareness of the GPFirst Program for Nonurgent Conditions: Repeated Survey Study (e66062)
Rebecca Ong Hui Shan, Hong Oh, Priscilla Goh Sook Kheng, Lyndia Lee Sze Hui, Mas Riza Bte Mohd Razali, Edris Ahmad, Jagadesan Raghuram, Choon How, Steven Lim Hoon Chin. . . . 1183

Validation of the Perceived Barriers to Antiretroviral Therapy Adherence (PEDIA) Scale Among Gay, Bisexual, and Other Men Who Have Sex With Men and Transgender and Nonbinary Persons: Cross-Sectional Study (e67005)
Victor Matos, Dyego Araújo, Thiago Torres, Paula Luz. . . . 1215

Intention to Use Pre-Exposure Prophylaxis Among Age Groups of Brazilian Men Who Have Sex With Men: National Cross-Sectional Study (e58405)
Alvaro Sousa, Caique Ribeiro, Guilherme Santos, Emerson Camargo, Herica Carvalho, Guilherme Schneider, Leticia Vieira, Liliane Carneiro, Ana Fernandes, Talita Fernandes, Márcio Bezerra-Santos, Rita Nascimento, Lucas Andrade, Anderson Sousa, Inês Fronteira, Isabel Mendes. 1 2 3 5

Impact of Knowledge Access on Risky Sexual Behaviors Among Chinese Youths to Improve HIV Prevention: Cross-Sectional Study (e68339)
Yun Zhang, Jie Jin, Feng Cheng, Xingliang Zhang, Junfang Xu. . . . 1252

HIV Incidence and Associated Risk Factors Among Young Men Who Have Sex With Men in Tianjin, China: Retrospective Cohort Study (e66487)
Yan Guo, Hui Gong, Xiangyu Yan, Xinying Zhang, Tielin Ning, Zhongquan Liu, Long Li, Jie Yang, Liu Li, Changxu Ma, Zhuang Cui, Maohe Yu. . . . 1266

Impact of Disclosing to Patients the Use of Antiretroviral Resistance Testing Results for Molecular HIV Surveillance: A Randomized Experiment in 2 National Surveys (e64663)
Jeremy Sugarman, Juli Bollinger, Jose Agostini, Kevin Weinfurt, Gail Geller, Sheethal Jose, Marissa Hannah, O. Edwards, Leslie Henry, Travis Sanchez. . . . 1280

The Effect of a Brief Video-Based Intervention to Improve AIDS Prevention in Older Men: Randomized Controlled Trial (e65674)
Tian Huaju, Xie Rendie, Xiao Lu, Li Mei, Luo Yue, Zhang Daiying, Chen Yanhua, Ren Jianlan. . . . 1289

Awareness of Sexual Partner's HIV Status Among Men Who Have Sex With Men in China: Cross-Sec. tional Survey Study (e66139)
Qian Ma, Tingting Jiang, Wanjun Chen, Shaoqiang Jiang, Jinlei Zheng, Hui Wang, Lin He. . . . 1307

The Effects of MyChoices and LYNX Mobile Apps on HIV Testing and Pre-Exposure Prophylaxis Use by Young US Sexual Minority Men: Results From a National Randomized Controlled Trial (e63428)
Katie Biello, Kenneth Mayer, Hyman Scott, Pablo Valente, Jonathan Hill-Rorie, Susan Buchbinder, Lucinda Ackah-Toffey, Patrick Sullivan, Lisa Hightow-Weidman, Albert Liu. . . . 1320

Perceptions of Long-Acting Injectable Pre-Exposure Prophylaxis Among Men Who Have Sex With Men and Transgender Individuals in Europe Using Structural Text Modeling Technique: Cross-Sectional Study (e72491)
Haoyi Wang, Johann Kolstee, Julio Martinez, David van de Vijver, Jonathan Tosh, Melanie Schroeder, Ama Appiah, Hanne Zimmermann, Kai Jonas. . . . 1369

Secondary Distribution of Dual HIV/Syphilis Self-Testing Among Men Who Have Sex With Men: Pragmatic Randomized Controlled Trial in China (e70775)
Min Wang, Yun Zhang, Weiyi Tian, Jinli Mo, Haimei Huang, Jiawen Zhu, Sumin Tan, Yingqiong Huang, Li Jiang, Ping Cen, Guanghua Lan, Hao Wang, Wei Pan, Joseph Tucker, Chuanyi Ning. . . . 1383

Effects of Maternal Use of the Continuum of Care on Complementary Feeding Practices in Bangladesh: Cross-Sectional Study (e76666)
M Rifat, Rokibul Islam, Rinath Didar, Joya Bhowmick, Plabon Sarkar, Md Amin, Sanjib Saha. . . . 1396

Use of Cigarettes, Cannabis, and Alcohol Among Asian American, Native Hawaiian, and Pacific Islander Adults: Community-Based National Survey Analysis (e76465)
Vuong Do, Van Ta Park, Nhung Nguyen, Pamela Ling, Marian Tzuang, Bora Nam, Marcelle Dougan, Oanh Meyer, Janice Tsoh. . . . 1408

Diagnostic Testing Preferences in Rural and Vulnerable Populations During a Pandemic: Discrete Choice Experiment (e68734)
Eline van den Broek-Altenburg, Jamie Benson, Yvonne Jonk, Abimbola Leslie, Jan Carney, Gary Stein. . . . 1423

Association Between Social Distancing Compliance and Public Place Crowding During the COVID-19 Pandemic: Cross-Sectional Observational Study Using Computer Vision to Analyze Surveillance Footage (e50929)
Lasse Liebst, Wim Bernasco, Peter Ejbye-Ernst, Nigel van Herwijnen, Thomas van der Veen, Dennis Koelma, Cees Snoek, Marie Lindegaard. 1 4 3 6

Mapping Key Populations to Develop Improved HIV and AIDS Interventions: Multiphase Cross-Sectional Observational Mapping Study Using a District and City Approach (e56820)
Pande Januraga, Endang Lukitosari, Lanny Luhukay, Rizky Hasby, Aang Sutrisna. . . . 1445

Trends in Prescription of Stimulants and Narcoleptic Drugs in Switzerland: Longitudinal Health Insurance Claims Analysis for the Years 2014-2021 (e53957)
Tamara Scharf, Carola Huber, Markus Näpflin, Zhongxing Zhang, Ramin Khatami. . . . 1513

Assessment of Bidirectional and Threshold-Response Associations Between Cognitive Function and Physical Performance: Nationwide Cross-Sectional Study (e80575)
Huixiu Hu, Lanying Xie, Yuqing Hao, Yajie Zhao, Huanhuan Luo, Kang Yu, Chao Sun. . . . 1525

Knowledge, Perception, and Attitude Toward Voluntary Counseling and Testing for HIV Among Secondary School Students in Iringa Rural District: Descriptive Cross-Sectional Study (e66739)
Maiko Mkwambe, Shakilu Kayungo, Youping Deng. . . . 1541

Severity Classification of Anxiety and Depression Using Generalized Anxiety Disorder Scale and Patient Health Questionnaire: National Cross-Sectional Study Applying Classification and Regression Tree Models (e72591)
Andre Faro, Julian Tejada, Wael Al-Delaimy. . . . 1553

Trends in Avoidable Hospitalizations Before and During the COVID-19 Pandemic: Multiple Cross-Sectional Study Using Administrative Data From Beijing, China (e69768)
Xiangzhen Wang, Yin Chen, Yuqi Ta, Moning Guo, Hongqiao Fu. . . . 1570

Factors Influencing the Maintenance of Public Health Behaviors After an Epidemic: Cross-Sectional Study (e66535)
Xingmin Wang, Hongli Yan, Lushaobo Shi, Ting Li, Yi Xia, Dong Wang. . . . 1585

Impact of Perceived Unfairness, Uncertainty, and Life Stress on Urban Residents' Health in China: Cross-Sectional Study (e72094)
Jinsong Chen, Shuhan Jiang, Mingli Pang, Huan Zhou, Weifang Zhang. . . . 1600

Knowledge and Beliefs Toward Mammography Screening Among Jordanian Women: Cross-Sectional Study (e75384)
Ahmad Abuabed, Hana Taha, Luz Garcia-Valdes, Mohammad Al-Share, Hadi Al-shar'e, Carmen Amezcua-Prieto. . . . 1616

Health Indicators as Measures of Individual Health Status, Their Perceived Importance, and Associated Factors: Cross-Sectional Observational Study (e65616)
Temiloluwa Sokoya, Yuchun Zhou, Sebastian Diaz, Timothy Law, Lina Himawan, Francisca Lekey, Lu Shi, Sarah Griffin, Ronald Gimbel, Xia Jing. . . . 1631

Migrant-Local Differences in the Relationship Between Oral Health, Social Support, and Loneliness Among Older Adults in Weifang, China: Cross-Sectional Study (e66061)

Abstract

Background: Digital adherence technologies (DATs) are promising tools for supporting tuberculosis (TB) treatment. DATs can serve as reminders for people with TB to take their medication and act as proxies for adherence monitoring. Strong engagement with DATs, from both the person with TB and health care provider (HCP) perspectives, is essential for ensuring intervention fidelity. The Adherence Support Coalition to End TB (ASCENT) project evaluated 2 types of DATs, pillboxes and medication labels (99DOTS), in cluster-randomized trials across 5 countries.

Objective: This study aims to investigate participant and HCP engagement with DATs for TB treatment, stratified by DAT type and country.

Methods: This study is a subanalysis of data generated through the ASCENT trials, which enrolled adults with drug-susceptible TB. A digital dose was defined as either a pillbox opening (for pillbox users) or a dosing confirmation SMS text message sent by the participant (for label users), both of which were recorded on the adherence platform. Descriptive analysis was used to provide an overview of dose-day outcomes. DAT engagement was assessed from both participant and HCP perspectives. To enhance participant engagement, we summarized the frequency of digital engagement overall and by treatment phase, as well as the frequency of consecutive days without engagement. For HCP engagement, we summarized the frequency of doses added manually, the number of days between the actual dose day and when a manual dose was added, and instances of consecutive manual dosing lasting more than 3 and more than 7 days, where doses were added more than 1 week after the dose day.

Results: Of the 9511 participants included, 6719 (70.64%) were using the pillbox, 3544 (37.26%) were female, and the median age was 40 years. Across DAT types, there were 1,384,879 dose days, with 973,876 (70.32%) contributed by pillbox users. Of all dose days, 1,165,195 (84.14%) were recorded as digital, 156,664 (11.31%) as manual, 59,045 (4.26%) had no information, and 3975 (0.29%) were confirmed as missed. Digital dosing decreased slightly from the intensive to the continuation phase. The percentage of digital dose days was higher among pillbox users (851,496/973,876, 87.43%) compared with label users (313,699/411,003, 76.33%). Among label users, manual dosing was most common in the Philippines (37,919/171,786, 22.07%) and least common in Tanzania (11,108/76,231, 14.57%). Among pillbox users, manual dosing was most common in the Philippines (24,015/208,130, 11.54%) and Ukraine (13,209/111,901, 11.80%). Overall, 512 out of 2792 (18.34%) label users and 588 out of 6719 (8.75%) pillbox users experienced a run of more than 7 consecutive nondigital dose days that were resolved more than 1 week after the dose day. The highest occurrence was observed in the Philippines (368/1142, 32.22%, for label users and 224/1351, 16.58%, for pillbox users).

XSL•FO
RenderX

Conclusions: There was considerable variation in DAT engagement across countries and DAT types, reflecting differences in how the intervention was implemented. Further refinement of the intervention and improvements in its delivery may be necessary to enhance outcomes.

KEYWORDS

tuberculosis; digital adherence technology; DAT engagement; intervention fidelity; manual dosing; digital dosing

Introduction

Ending the tuberculosis (TB) epidemic is one of the globally agreed-upon development goals, with a target of reducing TB deaths by 90% by 2030 compared with the 2015 baseline [1]. However, poor treatment outcomes continue to pose significant challenges in high TB–burden settings [1]. Several interventions have been designed and implemented to improve treatment outcomes, including early diagnosis and treatment, counseling and psychosocial support, and managing comorbidities and coinfections [2]. These interventions are articulated within the broader directly observed therapy (DOTS) strategy, which emphasizes maximizing opportunities for direct observation of treatment. The standard treatment duration for drug-susceptible TB (DS-TB) is 6 months, comprising a 2-month intensive phase with 4 drugs followed by a 4-month continuation phase with 2 drugs. Treatment is taken daily during both phases, and direct in-person observation of dose intake remains the predominant recommendation worldwide [3].

With the increasing availability of technologies that facilitate remote treatment observation, alternatives to DOT, such as digital adherence technologies (DATs), have emerged as viable options. Several types of DATs have been used to support TB treatment, including SMS text message–based reminders, smart pillboxes, and video-supported therapy. A recent systematic review suggested that DAT use improves adherence in both DS-TB and drug-resistant TB treatment, although its effect on treatment outcomes remains mixed [4]. Scoping reviews of DAT implementations have documented intervention fidelity challenges, including technological and provider-facing issues, as well as complex cellular accessibility barriers [5,6]. While studies have summarized engagement with DATs from the perspective of individuals with TB, the perspective of health care providers (HCPs) has rarely been explored. A recent scoping review reported the weighted mean of digital engagement over dose days among people with TB as 87% (12 studies) for pillbox users and 61% (4 studies) for "99DOTS" users [6]. An analysis of 11 projects across 10 high TB-burden settings found that electronic doses added manually by HCPs (referred to as "manual doses") accounted for 21.6% of reported doses in the DS-TB population [7].

Under the Adherence Support Coalition to End TB (ASCENT) project, we conducted pragmatic cluster-randomized trials in 5 countries to determine whether the use of DATs can improve treatment outcomes [8,9]. In these studies, eligible participants in the intervention arms received either pillboxes or medication labels (similar to "99DOTS" [10]), with the latter requiring participants to send a toll-free SMS text message each time treatment was taken. These DATs were integrated into a digital adherence platform, where participants' digital engagement with the DATs (pillbox opened/SMS text messages sent) served as a proxy indicator of treatment adherence. Failure to engage with the DATs triggered a cascade of care actions, including automated SMS text message reminders, phone call reminders, and home visits, with escalating actions documented in response to higher levels of DAT nonengagement.

The objectives of this study were to describe the engagement of people with TB and HCPs with the DAT interventions, by country and DAT type. Our findings provide valuable insights into the implementation challenges of DAT interventions aimed at improving treatment adherence and outcomes for individuals with TB.

Methods

Study Design

We conducted pragmatic cluster-randomized trials in Ethiopia (PACTR2020087766949990), Ukraine, Tanzania, South Africa, and the Philippines (4 countries under ISRCTN17706019) to assess the effectiveness of DATs on TB treatment outcomes. The trial designs have been reported elsewhere [11,12]. Clusters, defined as health facilities (rayons in Ukraine), were purposively selected in consultation with the national TB programs based on previously notified TB cases, willingness and capacity to participate, and achieving a reasonable balance of urban and rural settings as well as large and small facilities. Clusters were selected from 5 oblasts in Ukraine, 4 regions in Tanzania, and 2 provinces in each of South Africa and the Philippines. Clusters were randomized (1:1:2 and 1:1:1 in Ethiopia) to receive either a smart pillbox, medication labels, or standard of care in all countries except Ukraine. As fixed-dose combinations were not available in Ukraine, the medication labels, which required fixed-dose combinations, were not used in the trial.

All adults with drug-sensitive TB starting the standard treatment regimen in facilities randomized to a DAT were offered enrollment into the study at treatment initiation by routine HCPs at the facility, following consent, using the DAT type allocated to their facility. Access to a mobile phone was a prerequisite for participation in the labels intervention. As such, participants in the medication labels arm without mobile phone access were offered the pillbox instead. Treatment supporter phone numbers could also be used in either DAT arm for participants without

XSL•FO
RenderX

personal mobile phone access. Designated HCPs at each health facility responsible for TB care were trained in enrollment and in delivering the intervention, including the use of the digital adherence platform [13].

Participants using pillboxes were asked to keep their medication in the pillbox, which provided a daily audio/visual reminder at a predefined time based on participants' preferred time to take their treatment. Box opening, a proxy for dose taken, was captured in real time on the cloud-based adherence platform, which could be viewed by HCPs at each facility. Participants using medication labels were asked to send a unique toll-free SMS text message code daily when taking their dose, with these data also captured on the adherence platform. A box opening or an SMS text message sent by a participant using labels was referred to as a digital dose. At a prearranged time, if no box-opening signal (for pillbox users) or SMS text message code (for label users) had been received, an automated SMS text message reminder to take and log the dose was sent from the adherence platform to participants with mobile phone access. No SMS text message reminders were used in Ukraine, based on a decision by the Ukrainian research team. HCPs reviewed dosing data on the adherence platform and employed strategies such as phone calls and home visits to promote medication adherence, based on a differentiated response algorithm. A dose not recorded digitally on the adherence platform but self-reported as taken by the participant following a phone call required manual adjustment of the recorded dose by the HCP on the adherence platform. Manual entries were expected to be completed promptly to meet adherence criteria and maintain the integrity of the treatment monitoring process, enabling timely intervention when needed.

Adults starting TB treatment in the standard-of-care arm received care according to their country's guidelines, which could have involved facility-based or treatment-supporter–observed therapy, or self-administration.

In this analysis, we constructed a cohort of trial participants from the intervention arms of the 5 trials and used longitudinal data on their engagement with the DAT during their 6-month treatment period.

Setting and Participants

We included adult participants enrolled in the trials who received either the pillbox or medication labels from June 1, 2021, to May 31, 2022. In South Africa, medication labels were discontinued early due to feasibility challenges; all participants enrolled after October 2021 were offered the pillbox. We excluded participants who switched from medication labels to pillboxes during their treatment. Participants were analyzed according to the DAT type received.

Dosing Data

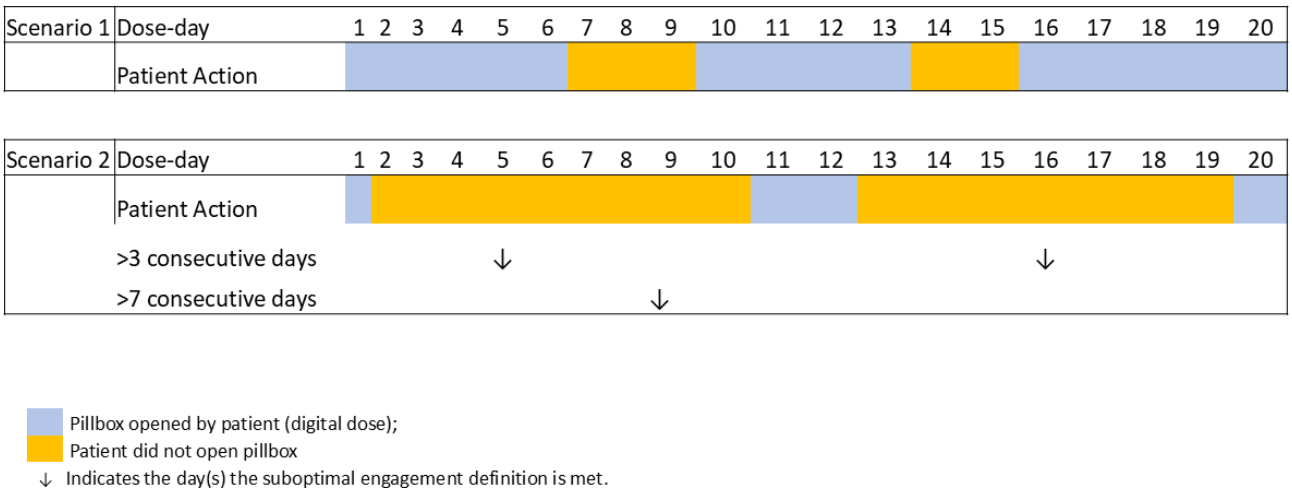
Data from the adherence platform were used to construct a profile of DAT engagement for each participant over their treatment period, from the DAT start to the earliest of (1) the treatment outcome date or (2) 168 days after treatment start (assuming 6 months of treatment). We excluded dose-day records with errors where either the date the dose was received was missing (10 records) or the date the dose was received preceded the dose day (36 records).

For each dose day, the adherence platform documented 1 of 4 mutually exclusive outcomes: digital dose, manual dose, dose missed, or no information. A digital dose-day confirmation refers to when the participant opens the pillbox/sends an SMS text message on the dose day. A manual dose refers to when the pillbox was not opened or an SMS text message was not sent on the dose day, but the HCP confirmed with the participant that the dose was taken and marked it as such on the platform. This confirmation of the dose being taken could occur on or after the actual dose day, with the date of confirmation recorded on the platform. A missed dose refers to instances when the pillbox was not opened or an SMS text message was not sent on the dose day, and the HCP later confirmed with the participant that the dose was not taken. Confirmation of both manual doses and doses not taken was based on participant self-report. "No information" for a dose day refers to instances when the pillbox was not opened or an SMS text message was not sent on the dose day, and no further information was available from the HCP regarding whether the dose was taken.

In real time, participants' DAT engagement data were displayed in a calendar format on the platform, accessed by the HCPs (Figure S1 in Multimedia Appendix 1). Digital doses were shown in dark green. "No information" days, when the box was not opened or an SMS text message was not sent, were displayed in light red, starting from midnight the following day. If a "no information" dose day was later updated to a manual dose by the HCP, it was shown in light green. For confirmed missed doses, the dose day was changed to dark red. There were instances in the labels arm when participants correctly opened their pillbox or sent an SMS text message, but due to temporary connectivity issues, this information was not synced to the platform. As pillboxes maintain an on-device log of all openings, once connectivity was restored, the record of digital dosing would overwrite any interim activity, such as manual dosing entered by the HCP. This was not possible for medication labels, as the system did not support automatic resending of unreceived SMS text messages. There was no standardized approach to logging connectivity issues (except in Ethiopia), and when such issues did occur, they were generally facility-dependent.

The dataset used for the analysis was based on the last dose day recorded on November 15, 2022, and the data extract was dated December 7, 2022. A 3-week window was therefore allowed for any HCP activity, such as adding manual doses or overwriting data due to connectivity issues, to occur.

Analyses



Descriptive analysis was used to provide an overview of dose-day outcomes. DAT engagement was categorized into 2 areas: participant engagement, represented by digital doses recorded on the platform; and HCP engagement, represented by dose days added manually. For participant engagement, we summarized the frequency of digital dosing overall, and separately for the intensive and continuation phases. For HCP engagement, we summarized the frequency of participants with manual dosing, as well as the timing of manual dose entries,

XSL•FO
RenderX

defined as the number of days from the actual dose day to when a manual dose was added.

We further defined scenarios reflecting "suboptimal engagement" with the DAT from both participant and HCP perspectives. From the participant's perspective, suboptimal engagement was characterized by inadequate, timely interaction with the DAT, indicated by nondigital doses, defined as manual, missed, or no information dose days. We considered suboptimal, timely interaction to be present when there were more than 3 or more than 7 consecutive nondigital dose days. Figure 1 illustrates a case where suboptimal engagement criteria were met (scenario 2), whereas scenario 1 does not meet these criteria.

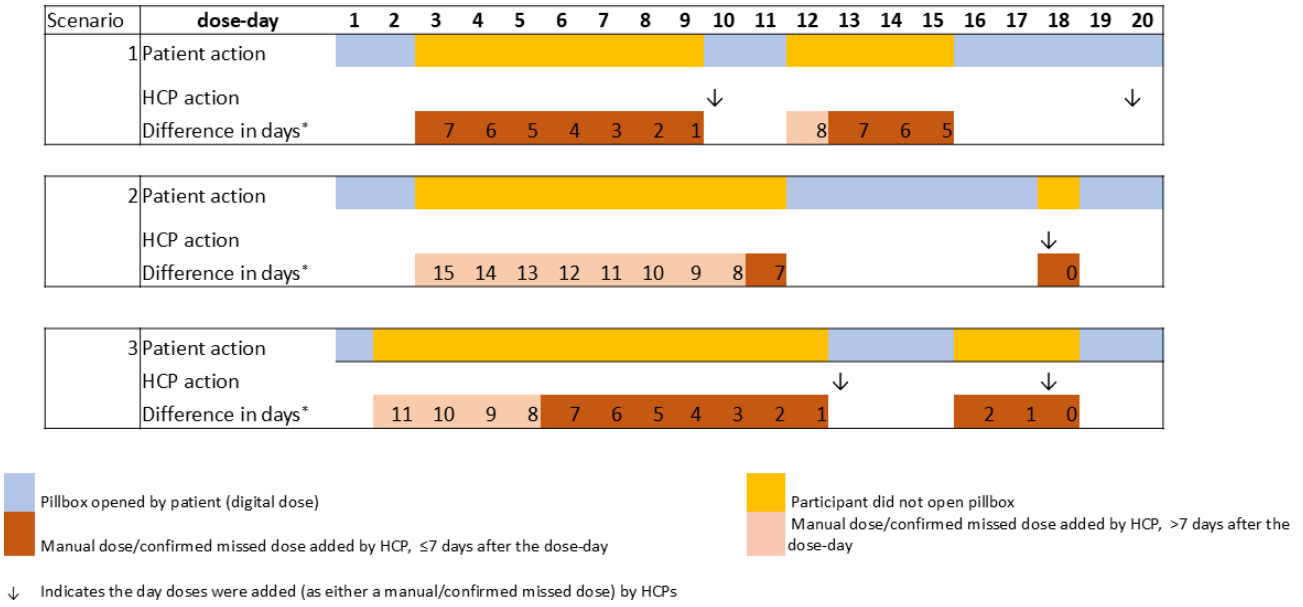


Figure 1. Illustration of 2 scenarios showing suboptimal engagement by person on tuberculosis treatment. Acceptable engagement is defined as ≤3 consecutive days with no digital confirmation. Suboptimal engagement is defined as (1) >3 consecutive dose days or (2) >7 consecutive dose days with no digital confirmation. Scenario 1: The patient had consecutive nondigital confirmation on days 7 to 9 (3 days; inclusive) and days 14 to 15 (2 days; inclusive); the suboptimal engagement condition of either >3 or >7 consecutive dose days is not met. Scenario 2: The patient had consecutive nondigital dose days on days 2 to 10 (9 days; inclusive) and days 13 to 19 (7 days; inclusive); the suboptimal engagement condition of (1) >3 dose days is met twice (on day 5 and day 16) and (2) >7 consecutive dose days is met once (on day 9).

From the HCP perspective, the scenario reflecting suboptimal engagement with the DAT was defined based on a combination of (1) delayed action, where manual or missed dose was added by the HCP, or there was no information about a dose; and (2) this occurring for periods of consecutive nondigital dose days. The first component was defined as a manual or missed dose added more than 7 days after the dose day, or the absence of any information more than 7 days after the dose day. A threshold of more than 1 week was chosen, as this was considered a sufficient time for the HCP to have successfully contacted the participant. For the second component, we considered periods of consecutive nondigital dose days, specifically more than 3 and more than 7 days, as instances when timely HCP interaction (ie, contact with the participant) would have been expected. See Figure 2 for illustrative scenarios. Scenarios 2 and 3 meet the criteria for suboptimal engagement, whereas scenario 1 does not. Analyses, stratified by country and DAT type, were conducted using Stata version 17 (StataCorp).

XSL•FO
RenderX

Figure 2. Illustration of 3 scenarios showing suboptimal engagement by health care professionals (HCPs). Suboptimal engagement is defined as (1) delayed action of manual/confirmed missed dose added by the HCP or no information about a dose and (2) this occurring for periods of consecutive days where non-digital dosing occurred. All scenarios show periods when the patient opened and did not open the pillbox. Scenario 1: HCP added manual/confirmed missed doses on days 10 and 20; of 11 doses added, 10 were within (≤) 7 days of the dose day; dose day 12 was added on day 20 (8 days late); the suboptimal engagement condition is not met. Scenario 2: HCP added manual/confirmed missed doses on day 18; of 10 doses added, 8 doses added were >7 days from the dose day; there is a run of 8 days where doses were added late (dose days 3-10; inclusive); the suboptimal engagement condition is met (consecutive dose days >3 and >7). Scenario 3: HCP added manual/confirmed missed doses on days 13 and 18; of 14 doses added, 4 were >7 days from the dose day; there is a run of 4 days where doses were added late (dose days 2-5; inclusive); the suboptimal engagement condition is met (consecutive dose days >3). *From actual dose day to when the dose was added (either as a manual or confirmed missed dose) by HCP.

Ethical Considerations

Written informed consent was obtained from all participants initiating a DAT in the ASCENT trials. The main trials were approved by the World Health Organization (WHO) Ethical Review Committee, Switzerland; Institutional Review Boards in Ethiopia (Addis Ababa City Administration Health Bureau Public Emergency and Health Research Directorate Institutional Review Board, and Oromia Regional Health Bureau Public Emergency and Health Research Directorate Institutional Review Board); the Ethics Committee for the Philippines (Single Joint Research Ethics Board), South Africa (University of the Witwatersrand Human Research Ethics Committee), and Tanzania (Tanzania Medical Research Coordinating Committee at the National Institute for Medical Research, Dar es Salaam); and the London School of Hygiene & Tropical Medicine Ethics Committee, United Kingdom. The analyses presented here are covered by the original ethics approvals and did not require additional consent. All data were deidentified and contained no personal identifiers. Trial participants did not receive any compensation for their participation.

Results

Participant Characteristics

Overall, 9511 participants from 163 health facilities/rayons contributed to the analysis, of whom 6719 (70.64%) were using the pillbox: 1243 out of 2268 (54.81%) in Ethiopia, 1698 out of 1759 (96.53%) in South Africa, 1611 out of 2185 (73.73%) in Tanzania, 1351 out of 2493 (54.19%) in the Philippines, and 816 out of 816 (100%) in Ukraine. In total, 3544 (37.26%) were female: 936 out of 2268 (41.27%) in Ethiopia, 676 out of 1749 (38.65%) in South Africa, 824 out of 2185 (37.71%) in Tanzania, 845 out of 2493 (33.89%) in the Philippines, and 263 out of 816 (32.23%) in Ukraine. The median age was 40 years (29 years in Ethiopia, 41 years in South Africa, 45 years in Tanzania, 45 years in the Philippines, and 44 years in Ukraine; see Table 1).

[a]DAT: digital adherence technology.

[b]Q1: lower quartile.

[c]Q3: upper quartile.

Description of Dosing Type

During the follow-up period, a total of 1,384,879 dose days from 9511 participants—across both DAT types—contributed to the analysis. The median number of dose days per participant was 168 days. Of all dose days, 973,876 out of 1,384,879 (70.32%) were among participants using pillboxes. Overall, 1,165,195 out of 1,384,879 (84.14%) dose days were recorded digitally, 156,664 out of 1,384,879 (11.31%) manually, 59,045 out of 1,384,879 (4.26%) had no information, and fewer than 3975 out of 1,384,879 (0.29%) were confirmed as missed. A higher percentage of dose days were recorded digitally among pillbox users compared with label users (851,496/973,876, 87.43% vs 313,699/411,003, 76.33%), with patterns varying by country (Table 2). Manual dosing for labels was most common in the Philippines (37,919/171,786, 22.07%, dose days) and least common in Tanzania (11,108/76,231, 14.57%, dose days). Among pillbox users, manual dose days were most common in the Philippines and Ukraine (24,015/208,130, 11.54%, and 13,209/111,901, 11.80%, dose days, respectively) and least common in South Africa (9075/235,417, 3.85%, dose days). No information for the dose day was most common among participants using labels (1190/6154, 19.34%, dose days) and pillboxes (18,711/235,417, 7.95%, dose days) in South Africa. Manual doses were added a median of 4 (lower quartile-upper quartile 1 - 16) days after the dose day for participants using labels, and 6 (lower quartile-upper quartile 2 - 21) days for those using pillboxes. The median time from the dose day to manual dose being added was shortest for participants in Ethiopia (2 days for labels and 3 days for pillboxes) and longest for participants in the Philippines (9 days for labels and 12 days for pillboxes). The Philippines had the highest percentage of manual doses added more than 7 days after the dose day (20,831/37,919, 54.94%, for labels and 14,708/24,015, 61.25%, for pillboxes), followed by South Africa (541/1149, 47.08%, for labels and 3966/9075, 43.70%, for pillboxes) and Ukraine (6858/13,209, 51.92%, for pillboxes). Ethiopia had the lowest proportions (6016/28,783, 20.90%, for labels and 5075/16,845, 30.13%, for pillboxes; see Table 2).

Digital dosing decreased slightly from the intensive compared with the continuation phase (see Figure S2 in Multimedia Appendix 1). The median number of days to add manual doses increased slightly during the continuation phase compared with the intensive phase for label users in the Philippines (from 8 to 10 days) and for pillbox users in Ukraine (from 7 to 10 days). For other countries and DAT types, the median number of days remained similar (see Table S1 in Multimedia Appendix 1).

Participant and HCP Suboptimal DAT Engagement

Participant suboptimal engagement analysis is summarized in Figure 3. From the participant's perspective, the Philippines had the highest number of episodes of more than 3 consecutive nondigital dose days for both pillboxes and labels, while Tanzania and Ethiopia had the lowest frequency. For episodes of more than 7 consecutive nondigital dose days, the Philippines again showed the highest frequency for both DAT types, with the lowest frequency observed in Ethiopia and South Africa.

XSL•FO
RenderX

Figure 3. Bar charts showing the distribution of the total number of participant-level episodes (grouped) of consecutive nondigital dose days lasting >3 and >7 days over the 6-month treatment period, stratified by country of enrollment and type of digital adherence technology received. Top panels: summary at the participant level of the number of episodes (grouped into 0, 1, 2, 3, and ≥4 episodes) where >3 consecutive non-digital dose-days were observed for pillbox (left) and labels (right), by country. Lower panels: summary at the participant level of the episodes (grouped into 0, 1, 2, 3, and ≥4 episodes) where >7 consecutive non-digital dose-days were observed for pillbox (left) and labels (right), by country.

Suboptimal engagement by the HCP is summarized in Table 3. Of the 2792 participants using labels, 820 (29.37%) and 512 (18.34%) met the criteria for suboptimal engagement of more than 3 days and more than 7 days, respectively, at least once. The Philippines had the highest percentage of HCP suboptimal engagement, with 501 out of 1142 (43.87%) and 368 out of 1142 (32.22%) participants experiencing suboptimal engagement, at least once, of more than 3 days and more than 7 days, respectively. South Africa ranked second, with 19 of 51 (37%) and 15 of 51 (29%) for suboptimal engagement of more than 3 days and more than 7 days, respectively. Combining across the 4 countries, 909 out of 1698 (53.53%) episodes lasting more than 3 days also met the criterion for more than 7 days.

[a]Suboptimal engagement was defined as (1) delayed action by the provider—either manually adding a missed dose or providing no dose information—more than 7 days after the dose day, and (2) this delay occurring during runs of more than 3 or more than 7 consecutive nondigital dose days.

[b]For doses added more than 7 days after the dose day.

[c]Q1: lower quartile.

[d]Q3: upper quartile.

Among participants using the pillbox (n=6719), 1062 (15.81%) and 588 (8.75%) met the criteria for suboptimal engagement of more than 3 days and more than 7 days, respectively, at least once. Ukraine had the highest proportion of participants with more than 3 days (217/816, 26.6%) and more than 7 days (117/816, 14.3%) of suboptimal engagement, followed by the Philippines (347/1351, 25.7% and 224/1351, 16.6%, respectively). Combining across the 5 countries, of the 2087 episodes lasting more than 3 days, 939 (45.0%) also met the definition for more than 7 days of suboptimal engagement. Typically, participants experienced a median of 1 episode of suboptimal engagement, except in the Philippines and South Africa. In the Philippines, the median number of episodes lasting more than 3 days was 2 for both DATs. In South Africa, the

XSL•FO
RenderX

median number of episodes lasting more than 7 days was 2 for the label DAT.

Discussion

Principal Findings

This study sought to understand the complex interactions between adults on DS-TB treatment, HCPs, and the DAT intervention, using daily DAT engagement data from 2 DAT types across 5 countries. We found a higher percentage of dose days recorded as digital among pillbox users compared with label users, with digital dosing lowest among pillbox users in Ukraine and the Philippines. The time taken by HCPs to add manual doses varied across countries: the Philippines had the longest intervals for both DAT types, followed by Ukraine and South Africa. Combining across DATs, 34,537 out of 45,628 (75.69%) manual doses in Ethiopia and 18,140 out of 25,669 (70.67%) in Tanzania were added within a 7-day time frame. There was also a lack of dose-taking information recorded on the adherence platform, most frequently observed in South Africa, reflecting another marker of poor HCP engagement with the intervention. Finally, our marker of suboptimal DAT engagement by HCPs showed variation by DAT type and country. Across countries, a range of label users (92/574, 16.0%, to 501/1142, 43.9%) and pillbox users (138/1698, 8.13%, to 217/816, 26.6%) experienced at least one run of nondigital dosing lasting more than 3 days, which was either resolved more than 7 days after the dose day or not resolved at all (no information). The Philippines had the highest percentage of participants experiencing this issue for labels (501/1142, 43.87%) and, along with Ukraine, the highest for pillboxes (347/1351, 25.7%, and 217/816, 26.6%, respectively).

We observed differences in our indicators by country, which may be explained by variations in participants, health care systems, and external factors and are consistent with our process evaluation [13]. The findings from the Philippines stand out, reflecting a pattern of lower engagement with the DATs by both participants and HCPs. Higher levels of manual dosing and more frequent episodes of consecutive nondigital dosing suggest lower participant engagement in this setting. This is further supported by findings from the ASCENT acceptability substudy, where participants in the Philippines reported lower mean scores for Capability, Opportunity, and Motivation, key domains of the Theoretical Domains Framework used to assess acceptability, compared with participants in other countries [14]. Participants also reported lower HCP engagement in the acceptability substudy, as indicated by a lower percentage reporting that HCPs showed them their adherence data during routine clinic visits. In the Philippines, intervention delivery was affected by the reassignment of TB focal staff to COVID-19 vaccination programs in 2021. This led to a decline in participant enrollment during that period and likely posed challenges in delivering the DAT intervention to those already enrolled. In a qualitative study involving people with TB and HCPs participating in the Philippines trial, HCPs cited insufficient training and lack of refresher training at the program design level, as well as power issues at the community level, as barriers to DAT implementation [15]. In South Africa, missing dose information on the platform may have been due to difficulties in contacting participants, such as changes in phone numbers, loss of phones, or provision of incorrect contact details, hindering HCPs' ability to confirm doses. Additionally, some participants were lost to follow-up due to mobility-related issues, such as relocating for work, which resulted in unsuccessful home visits for dose confirmation. During the study period, frequent power outages in South Africa may have contributed to suboptimal HCP engagement with the intervention. In Ukraine, the study coincided with disruptions caused by the military invasion by Russia, which likely affected the timeliness of HCP contact with participants following missed doses recorded on the platform. Regional differences in dosing patterns were observed within Ukraine; Mykolaivska and Donetska oblasts, occupied by Russia early in the invasion, had higher levels of manual dosing added late compared with other regions [16]. Furthermore, in Ukraine, the DAT intervention was implemented by HCPs within the context of staff reductions in TB care delivery, a challenge not reported in other countries. By the midpoint of trial implementation, fewer HCPs were providing DAT support than had been trained at the start of the trial, which may have contributed to suboptimal engagement with the DAT.

In the acceptability substudy, regular access to a mobile phone was identified as an important aspect of the intervention from both participant and HCP perspectives. Shared phone ownership may hinder timely dose taking in response to automated SMS text message reminders in either arm, as well as limit HCPs' ability to successfully contact participants following nonengagement. Ownership of a nonshared phone was lowest among participants in the Philippines compared with other countries, potentially contributing to suboptimal engagement from both participant and HCP perspectives [14]. Disparities in phone ownership are well-known challenges in implementing digitally mediated interventions [17,18].

Poor connectivity poses a significant barrier to optimal DAT engagement, particularly affecting the label intervention. Unlike the pillbox intervention, where box openings are transmitted once connectivity is restored, the label intervention cannot "correct" for periods of nonconnectivity. This limitation may have contributed to lower recorded digital doses for labels compared with pillboxes, as missed or delayed transmissions could not be retrospectively updated. Consequently, participants using labels may appear less engaged, even if their actual adherence was higher than reflected in the data. This discrepancy can also affect health care workers' engagement with DATs, as they may become less motivated to rely on or use the technology if they perceive it as unreliable [5,19,20]. Addressing connectivity issues and incorporating features to mitigate their impact are crucial for ensuring accurate data capture and improving overall engagement from both participants and health care workers.

Comparison With Prior Work

Various levels of participant engagement have been documented across different DAT types in various settings. A recent scoping review reported lower participant engagement with 99DOTS (similar to our labels interventions) compared with pillboxes

XSL•FO
RenderX

[6]. Furthermore, factors such as suboptimal DAT functionality, complex cellular acceptability, and less accurate adherence data may have contributed to these discrepancies [5]. This could be partly explained by differences in ease of use: pillbox users received an optional daily audio reminder, as well as an automated SMS text message reminder if the system did not receive a pillbox opening signal or SMS text message dose confirmation from the participant within a set time. Ready access to a phone among label users may have been a challenge for documenting dose-taking. In the 99DOTS stepped-wedge trial in Uganda, the median percentage of digital dosing was 58.4%, peaking in month 1 at 71.4% and declining to 46.4% by month 6. When manual dosing was included, the median percentage exceeded 99.4% [21]. Digital dosing among label users in the ASCENT trials was generally higher compared with this study. The percentage of digital dosing recorded in pillbox intervention arms in other trials ranges from 84.2% to 88%, aligning with the ASCENT trial data [22-24].

Few studies, however, have summarized digital/nondigital dosing patterns from both participant and HCP perspectives. A meta-analysis of data from 11 projects provided a valuable overview of DAT engagement patterns over the treatment period, but did not explore the nuances of manual dosing frequency and timing. This may be due to differences in how manual dosing was defined across studies, as well as limitations in data capture that prevented clear distinctions between digital and manual dosing [7]. The significance of consecutive nondigital doses, particularly when frequent and prolonged, may indicate participant nonengagement with the DAT. In such cases, manual doses added late by HCPs could also reflect poor HCP engagement. High fidelity in intervention delivery by HCPs is essential for the success of DATs. A multicomponent intervention conducted in Tibet among 276 individuals starting TB treatment, which included pillboxes and a switch to video-supported therapy for those with adherence challenges, reported high fidelity to the transition to video-supported therapy, with at least 89% maintained over the treatment period [25]. In our trials, the calendar format on the adherence platform provided HCPs with a clear visualization of patients' dose taking, intended to support timely action. However, concerns have been raised about the use of this format, particularly in busy health facilities. There may be a temptation for HCPs to manually record doses in the digital calendar without clear confirmation from the participant, similar to critiques of adherence documentation in TB register calendars used in standard care.

Limitations

Limitations of our study include the fact that DAT engagement reflects only dosing as recorded on the adherence platform; therefore, digital dosing should not be directly equated with actual pill consumption. What was recorded were proxies (either via SMS text messages or pillbox signals) of medication intake. Manual doses added late may have resulted from HCPs being unable to successfully contact participants, rather than from delayed action or lack of attempt. However, we were unable to distinguish between these possibilities. Hence, caution should be exercised when interpreting the findings. Furthermore, the external validity is limited, as the sampled participants and collected data were specific to the ASCENT trial. Nonetheless, the strengths of our study are its coverage of 5 countries, each with distinct epidemiological, socioeconomic, geographical, infrastructural, and health system contexts. Data were generated by routine staff delivering the intervention across 163 health facilities/rayons and included 9511 participants.

Conclusions

This study highlights the role of DATs in TB treatment, focusing on how adults with DS-TB and HCPs interact with the technology. We observed considerable variation in DAT engagement across countries and DAT types, reflecting differences in how the intervention was implemented. These findings underscore the need for further research to assess whether variations in DAT engagement affect the overall effectiveness of these interventions. Such research could help inform improvements in DAT design and implementation to foster higher engagement among people with TB and HCPs, thereby potentially enhancing intervention effectiveness.

Acknowledgments

This study was conducted as a part of the Adherence Support Coalition to End TB (ASCENT) trials funded under the ASCENT Consortium through a grant from Unitaid (Grant Agreement Number 2019-33-ASCENT).

Data Availability

The datasets generated or analyzed during this study are available in the DataCompass LSHTM repository [26].

Authors' Contributions

JA, AWT, SC, DJ, and KF developed the study concept. JA and KF contributed to the study design, with KF providing statistical expertise for the analysis. JA, AWT, ND, TD, and AM implemented the study. JA and KF wrote the first draft of the manuscript. All authors provided intellectual input into the research and its implications, contributed to revising earlier versions of the manuscript, and approved the final version. Generative artificial intelligence was not used in any part of the manuscript writing.

Abstract

Background: Financial barriers to accessing obstetric care persist in many low-resource settings. With increasing use of mobile phones, mobile money services appear as a promising tool to address this concern. Maternal health care is particularly suitable for a savings program using mobile money due to the predictable timing and costs of delivery. The mobile money–based Mobile Maternal Health Wallet (MMHW) intervention aimed to ease the burden of out-of-pocket expenses related to maternal health care by providing an accessible savings tool.

Objective: This study aimed to assess the impact of the MMHW on maternal and neonatal health outcomes.

Methods: We used a stratified cluster-randomized trial to assess the impact of the MMHW on maternal and neonatal health outcomes in the Analamanga region of Madagascar. All 63 eligible public sector primary care health facilities (*Centres de Santé de Base* [CSBs]) within 6 strata were randomized to either receive the intervention or not. We estimated intention-to-treat effects and contamination-adjusted effects following an instrumental variable approach. The primary outcomes included (1) delivery at a health facility, (2) antenatal care visits, and (3) total health care expenditure. Between March 2022 and December 2022, a total of 6483 women who had been pregnant between July 2020 and December 2021 were surveyed.

Results: Among women in catchment areas of treated CSBs, 38.79% (1297/3344) had heard of the MMHW, and 37.42% (485/1296) of them registered for the tool. There was considerable variation in uptake across treated CSBs. Descriptively, women in the catchment areas of treated CSBs were more likely to deliver in a facility and had more antenatal care visits and higher total health expenditures compared to women in control CSB catchment areas in the intention-to-treat and contamination-adjusted analyses. However, none of the effects were statistically significant.

XSL•FO
RenderX

Conclusions: While this study did not identify a statistically significant impact, the estimated contamination-adjusted effects suggest that the MMHW has potential to improve access to maternal care for women who are receptive to such a mobile money–based savings tool. Estimated population-level effects were much smaller, and this study was underpowered to detect such effects due to lower-than-anticipated uptake of the intervention.

Introduction

Background

In several sub-Saharan African countries, health care continues to be primarily financed through out-of-pocket payments, exposing households to the risk of catastrophic health expenditures and impoverishment [1,2]. Household savings can mitigate the financial strain caused by unforeseen health care costs [1,3]. However, economically disadvantaged households frequently encounter unexpected and irregular expenses that hinder their efforts to achieve long-term saving goals [4]. Consequently, obstetric care access is often hindered by limited financial resources [5]. Expectant mothers from low- and middle-income households frequently refrain from seeking birth assistance or emergency obstetric care due to the substantial expenses associated with childbirth [6,7].

In Madagascar, ensuring access to and acceptance of health care services for pregnant women remains an ongoing challenge. The national health policy of Madagascar stipulates the free provision of antenatal care (ANC) and uncomplicated deliveries in all public health care facilities. Nevertheless, charges are often imposed for folic acid, iron supplements, laboratory tests, medications, and treatments, as well as for complications during delivery. These charges act as barriers limiting women's access to quality maternal care, particularly for those in economically disadvantaged circumstances [8,9]. The maternal mortality rate in 2020 was 392 per 100,000 live births [10] but is estimated to be up to 3 times higher in the poorest districts of the country [11]. Only approximately half of pregnant women in Madagascar complete 4 ANC visits as recommended by the World Health Organization, and over half of deliveries take place without qualified personnel [12].

Over the past 10 years, there has been astonishing growth in mobile phone subscription rates and mobile money (MM) accounts in Madagascar, as in several other sub-Saharan African countries [13-15]. MM, a commonly used term for mobile payment systems, allows individuals to securely store, send, and receive electronic money through a digital platform operated by a mobile phone carrier, serving as a viable alternative for physical cash. By leveraging simple technologies such as unstructured supplementary service data, these MM services can facilitate monetary transactions even in the absence of a traditional bank account, internet connectivity, or advanced smartphone features. It has been shown that providing a secure place for storing money can increase savings [16]. MM services could act as such a simple, accessible tool.

MM platforms do offer users the option to sign up for additional financial services, such as savings, credit, or insurance, either through mobile operators or third-party service providers. Given that nearly 80% of adults in sub-Saharan Africa lack access to formal banking services, economies in the region are increasingly reliant on mobile payment systems [17]. This technological advancement is also being harnessed to introduce mobile payment–based hospital insurance or savings mechanisms, allowing economically challenged households to allocate funds specifically for health care needs [14,18,19]. The swift accessibility of cash, remittances, electronic savings accounts, and insurance plans provided by MM is driving its growing use in the health care sector across sub-Saharan Africa [17]. MM users have a lower risk of catastrophic health care expenses during emergencies and are less prone to reducing expenditures on education or food [20-24]. This presents an opportunity for inclusive solutions to address health care coverage gaps.

Maternal and childbirth-related health care emerges as a particularly suitable candidate for a savings program due to its relatively predictable timing and costs.

In Madagascar, a significant proportion of pregnant women rely on personal cash savings to financially prepare for giving birth in health care institutions. However, this approach is particularly arduous for impoverished populations [8]. Addressing this issue, the nongovernmental organization Doctors for Madagascar developed a tool known as the Mobile Maternal Health Wallet (MMHW) to ease the burden of out-of-pocket expenses related to maternal health care [25]. Accessible via the unstructured supplementary service data menu on any mobile phone, this software platform offers expectant mothers the capability to save, pay, and receive MM and electronic vouchers for maternal health care services at participating health care providers. The personal information and funds stored in the MMHW are linked to an individual SIM card, which functions on any type of mobile device regardless of whether it is a smartphone or has internet connectivity. Additional incentives provided through the MMHW encompass access to free ambulance services in case of referrals and a free obstetric ultrasound checkup. To encourage pregnant women to save using the MMHW, Doctors for Madagascar offers 50% matching to all deposits made. Collaborating with the Malagasy Ministry of Public Health, Doctors for Madagascar randomly selected 31 out of 63 public

XSL•FO
RenderX

primary care health facilities and 4 reference hospitals in Antananarivo, located in the Analamanga region of central Madagascar, for the implementation of the MMHW. To facilitate the integration of this digital payment system within health care facilities, tablets or mobile phones were distributed to the health care providers operating in the participating facilities.

Objectives

In this study, we evaluated the impact of the MMHW intervention on maternal and neonatal health outcomes among women living in the catchment area of the health facilities. The evaluation strategy closely follows the analysis strategy outlined in the published study protocol [26].

Methods

Study Design

This cluster-randomized controlled trial was implemented in 3 districts of the Analamanga region in Madagascar (Antananarivo Renivohitra, Atsimondrano, and Avaradrano). Eligible for inclusion in the trial were all 63 public sector primary care health facilities (*Centres de Santé de Base* [CSBs]) that provided ANC at the time of the intervention. Due to budget constraints, not all of these could receive the intervention. Therefore, CSBs were randomized within 6 strata to either receive the intervention or not. The control group consisted of 32 CSBs, and the intervention group consisted of 31 CSBs as well as 4 public reference hospitals for maternal care. All health facilities in the intervention group received the intervention package by May 2020. Since then, registration for MMHW was open, and activities to encourage registration were ongoing until December 2022.

For the evaluation of the intervention, we used several data sources. A quantitative population-based survey was conducted during household visits between March 2022 and December 2022. For this survey, women who had completed their pregnancy between July 1, 2020, and December 31, 2021, were interviewed. They answered questions about socioeconomic characteristics, pregnancy, delivery, expenses, saving behavior, decision-making, postpartum depression, and their use of the MMHW. In addition, in households in which there was a woman matching the eligibility criteria but she was not present at the time of the visit, a short interview was conducted with 1 household member present to capture socioeconomic characteristics. This allowed us to compare the sample of women interviewed with those women who were absent but matched the eligibility criteria. The second data source was health facility records. Between August 2022 and September 2022 (with 3 exceptions for whom data were gathered in April 2023), a survey of all health facilities included in the randomization was conducted. Health facility staff was asked to share records on ANC visits, deliveries, and expenses from 2020 and 2021. In addition, respondents at facilities where the MMHW was implemented answered questions about their use of and satisfaction with the MMHW.

This trial was registered with the German Clinical Trials Register (identifier: DRKS00014928) on March 12, 2021. Registration took place after randomization and intervention implementation but before the start of data collection and outcome assessment. A study protocol outlining the evaluation design and estimation approach followed in this analysis was submitted on March 22, 2021, and published in October 2021 [26].

Participants

For inclusion in the randomization, all CSBs in the study region that provided ANC at the time of the intervention were eligible. Eligibility was determined based on 2017 records obtained from health authorities. In addition, the 4 public reference hospitals for maternal care in Antananarivo, as defined by the Malagasy Ministry of Public Health, were included in the intervention group. Each health facility represented 1 cluster.

All health facilities included in the randomization, as well as the reference hospitals, were included in the survey of health care providers.

For the quantitative population survey, we randomly selected 4 census enumeration areas (*fokontany*) in each catchment area of the included health facilities. In catchment areas with ≤4 *fokontanys*, all were included for data collection. In each *fokontany*, data collectors mapped out the area and knocked on every second door to identify women eligible for survey participation. Women were eligible for survey participation if they had completed their pregnancy between July 1, 2020, and December 31, 2021; were aged ≥18 years; and provided verbal consent to the interview.

Randomization and Masking

The unit of randomization for the intervention was the CSB. There was previous evidence suggesting that ANC and delivery quality varied significantly with a facility's patient volume and capacity to perform deliveries [27]. Therefore, all health facilities were stratified into 6 subgroups according to the facility's ANC visit volume (<1750, 1750-3500, and >3500 ANC visits per month in 2017) and the capacity to perform deliveries (none vs any deliveries). Within each stratum, the facilities were sorted in descending order of reported ANC visits. A senior biostatistician then performed pairwise randomization. Pairing 2 health facilities following each other in the ordered list, one was randomly assigned to the intervention and the other to the control group. In addition, 4 reference hospitals were assigned to receive the intervention to ensure that women could use the MMHW in case of referral for complications. Due to their nonrandom assignment to the intervention group, reference hospitals were excluded from the analysis of facility-level outcomes. As they do not have their own defined catchment areas as CSBs have from where women respondents were sampled, the reference hospitals do not affect the analysis of individual-level outcomes. During the intervention rollout, 3 CSBs assigned to the intervention group turned out not to have the technical capacity for the intervention. Of these 3 CSBs, 2 (67%) did not have the required internet connection, and the third (33%) did not manage any pregnancies. Therefore, 2 additional CSBs that were semiprivate and, therefore, ineligible for trial inclusion in 2017 and became fully public only in 2019 were added to the intervention group. These 2 additional CSBs were excluded from analysis as their

XSL•FO
RenderX

assignment to the intervention group was not random. At the individual level, women living in the catchment area of these 2 CSBs were excluded from analysis. Due to the nature of the intervention, neither health facility staff nor patients visiting the facilities were blinded to intervention allocation.

Procedures

The MMHW package consisted of 2 major components. The main component was directed at pregnant women attending ANC visits at health care facilities. Women who registered with the MMHW received a SIM card with which they were able to save in the MMHW and to pay using these savings at the health care facilities in the intervention group. Deposits could be made and used at any time during pregnancy and up to 30 days after childbirth. Additional benefits were provided for those who registered—costs for preventive drugs such as iron and folic acid tablets and mebendazole received during ANC visits, as well as costs for transfer via ambulance in the event of obstetric and neonatal emergencies to the reference hospitals, were covered. A savings incentive of 50% of the saved amount to be used for any pregnancy-related and newborn care up to 30 days after birth was provided through external donors. In addition, users could receive a free obstetric ultrasound checkup. Pregnant women were encouraged to register with the MMHW through a sensitization campaign. Sensitization took place in communities through awareness-raising mass sensitization events and home visits to pregnant women by community health workers and during group meetings organized by workers of Doctors for Madagascar at health care facilities during the facilities' official dates for ANC visits.

The second component was directed at CSBs and provided maternal and neonatal health training, capacity-building, and refresher courses for health workers in maternity wards and ANC departments. The trainings were conducted by trainers from the Ministry of Public Health. The goal of these trainings was to ensure quality of care matching the expected increased demand for health care services. Financial incentives to participate in the intervention were also provided. For each delivery of a beneficiary, the health care professional in charge of the delivery received a bonus of MGA 10,000 (US $2.44 according to the OANDA currency converter rate for January 1, 2021). The pharmacists responsible for taking photo evidence of claims received a bonus of MGA 2000 (US $0.51) per patient and month for each claim sent via the MMHW platform. In addition, medical equipment, including blood pressure monitors, stethoscopes, examination beds, bedpans, and baby scales, was distributed to the corresponding maternity units.

Outcomes

In this study, we analyzed the outcomes as described in the published study protocol, which are based on the quantitative household survey and the health facility records [26]. Primary outcomes were (1) facility-based delivery; (2) number of ANC visits per woman; and (3) total health expenditure during pregnancy, delivery, and the neonatal period per woman. Secondary outcomes at the individual level were related to ANC (number of diagnoses received and whether they had ultrasound checkups or received iron and folic acid tablets or syrup), the delivery process (whether they had complications, planned or emergency cesarean section, or neonatal mortality), finances (health savings, contributions to savings, relative health care expenditure, and indication of financial distress), and satisfaction after delivery (with the health facility, the health system, and life), as well as postpartum depression score. Secondary outcomes at the facility level included maternal and neonatal mortality, number of ANC drugs distributed, and public sector costs. Compared with the full list of proposed outcomes in the protocol, we excluded those outcomes that could not be analyzed sensibly following the planned estimation approach as they would only be relevant for women who actually registered with the MMHW (ie, MMHW use, recommendation of MMHW, and time of sign-up). Furthermore, maternal mortality was only analyzed based on data from health facility records as the outcome was not captured accurately in the quantitative household survey. A full list of outcomes and details regarding their coding can be found in Tables S1 and S2 in Multimedia Appendix 1.

Statistical Analysis

The analysis in this study followed the estimation strategy outlined in the published study protocol [26]. The primary analysis was an intention-to-treat (ITT) estimation of all outcomes. We regressed each individual-level outcome on an indicator of living in the catchment area of either a treated or control health facility and clustered SEs at the facility level. Outcomes at the facility level were regressed on an indicator of treatment assignment. For both individual- and facility-level outcomes, we added strata dummy variables to account for stratification during randomization. Because of the randomized treatment assignment, a comparison of postintervention outcomes between the intervention and control group, on average, provided the unbiased ITT effect. This ITT effect captured the real-life policy impact of the intervention. As a secondary analysis, we conducted a contamination-adjusted analysis for outcomes at the individual level using the random assignment to the intervention versus control group as an instrumental variable (IV). This estimation of the local average treatment effect provided a measure of the effect size that would have been attained without contamination assuming that those who did not take up the intervention would behave similarly once registered for the tool as those who did take up the intervention. Contamination in this case would occur if women living in an intervention area did not register for the MMHW and women living in a control area did. This is very possible in this context in which women do not necessarily choose the facility in the catchment area they live in. Actual registration with the MMHW was instrumented with treatment assignment in the IV analysis. In addition, we instrumented having heard of the MMHW and having used the MMHW for paying with treatment assignment. For ease of interpretation and comparison between ITT and IV estimation, we used linear regressions for all outcomes. We present absolute and relative effect sizes (relative to the mean of the outcome in the control group). As a robustness check, we reran estimations excluding the 3 CSBs that were assigned to the intervention but could not use it. As a further robustness check on individual-level outcomes, we reran estimations with controls for individual characteristics that were imbalanced (employment status, access to a mobile

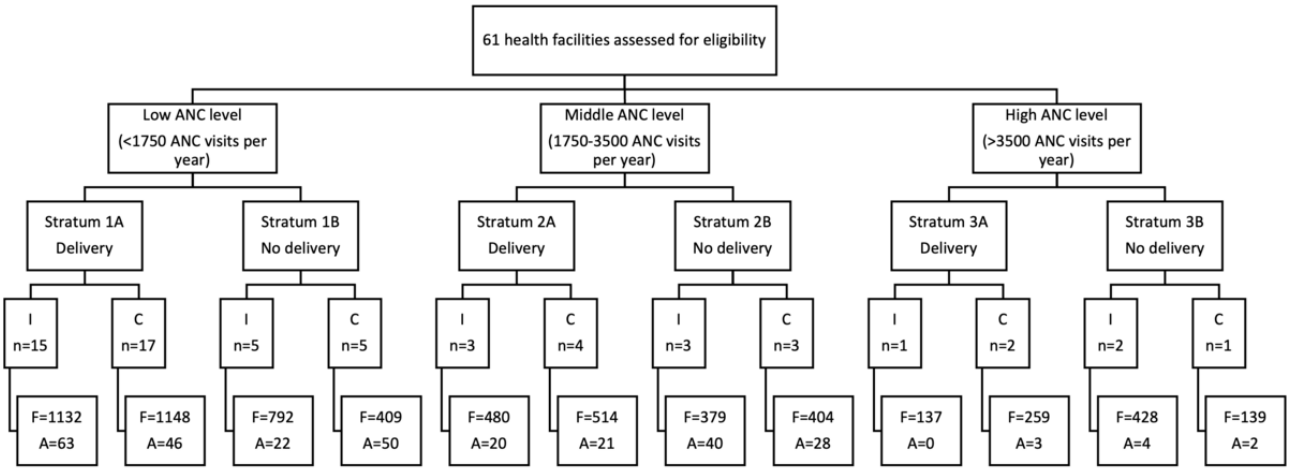
XSL•FO
RenderX

phone, and television ownership). We assessed statistical significance at the 5% level. All statistical analyses were conducted using Stata (version 16; StataCorp).

Power Calculations

A power calculation was presented in the study protocol [26]. Minimum detectable differences between the intervention and control groups were calculated for the 3 primary outcomes using methods for cluster-randomized controlled trials. We assumed that 50% of survey participants in the catchment areas of intervention health facilities would adopt the MMHW. Power calculations showed that the study would have 80% power to detect a 4–percentage point increase in the rate of facility-based deliveries, an increase of 0.08 average ANC visits per woman, and an increase in total health expenditure of MGA 1700 (US $0.41 according to the OANDA currency converter rate for August 16, 2022) if 2300 women were surveyed per group. However, intervention uptake differed from this assumption, as discussed in the following sections.

Ethical Considerations



This trial was approved by the Institutional Review Board of Heidelberg University on February 3, 2020 (S-428/2019). The study was conducted in accordance with the WMA Declaration of Helsinki. Informed consent was obtained orally from all study participants before their interviews. Privacy and confidentiality of survey participants' data and identity was maintained. Survey participants received a bar of soap as a locally appropriate in-kind compensation for their time.

Results

Sample Description and Balance

A total of 6323 women in the catchment areas of the CSBs in the control and intervention groups were identified as eligible for participation and present at the time of the home visit, of whom 6243 (98.7%) completed the full interview. The interview about eligible women who were not present at the time of the visit was completed by 300 respondents (ie, household members who were present and could answer questions capturing the basic characteristics of the eligible women). Figure 1 provides a flowchart of the sample.

Figure 1. Flowchart of sample selection. A: number of interviews for absent eligible women; ANC: antenatal care; C: control group; F: number of full interviews; I: intervention group; n: number of facilities.

Most women surveyed were aged <35 years (2673/6243, 43.82% between 17 and 24 years; 2741/6243, 43.91% between 25 and 34 years) with 1 or 2 children (2282/6235, 37% with 1 child; 1990/6235, 31.92% with 2 children), and the large majority was married (see Table 1 for a summary of socioeconomic characteristics). Some women reported no children as their children had passed away and the eligibility criteria were based on the timing of past pregnancies and not childbirth. A large share of women (4437/6240, 71.11%) had completed secondary or higher education, but less than half (3061/6230, 49.13%) reported receiving regular income. Almost half (2820/6242, 45.18%) were currently not working, which was likely driven by the fact that these were women with very young children. Access to a mobile phone, a requirement for using the intervention, was common but not universal as 58.09% (3626/6242) reported having access to a mobile phone and 77.96% (2827/3626) of those with access reported that the phone was their own. The large majority of respondents (5634/6239, 90.3%) were not covered by any health insurance.

[a]This table shows the shares of respondents for each characteristic in percentages, for the sample who took part in the full interviews (total sample, control, and intervention), and the sample who gave interviews for women absent at the time of the visit. The columns Number of observations per characteristic, n (%) provide the number of women in the respective sample for whom the information was available. The *P* values for the full interviews correspond to a 2-tailed *t* test of the difference between the control and intervention group. The *P* values for absent interviews correspond to a 2-tailed *t* test of the difference between the interviews about absent women and the full interviews.

[b]Information not available for absent sample.

[c]NGO: nongovernmental organization.

The sample of respondents who completed the full interview slightly differed from the eligible women who were absent at the time of the visit (Table 1). Absent women were less likely to be aged <25 years and more likely to be aged 25 to 34 years than women present at their household residence; more likely to have access to a mobile phone; and more likely to own a television, motorcycle, or car. This suggests that absent women were more likely to be working, possibly because it had not been their first birth as they were older and they were slightly wealthier.

Randomization of health facilities led to a balanced sample of health facilities (Table 2) and of respondents in terms of most characteristics (Table 1). However, some statistically significant differences between the control and intervention groups emerged at the individual level, especially regarding type of employment and asset ownership. Respondents in the intervention group were more likely to be self-employed or not working and less likely to work on a family farm or in livestock or fishing. Access to a mobile phone was slightly higher in the intervention group, as was the probability of owning a television.

[a]Data from the health facility survey excluding 2 *Centres de Santé de Base* (public sector primary care health facilities) and 4 reference hospitals assigned to the intervention group nonrandomly. The number of observations and means in the total sample are split by year and by control and intervention group. *P* values correspond to 2-tailed t tests of the difference in means across years and treatment.

[b]ANC: antenatal care.

[c]Values for the two groups, which are being compared, are equal.

Uptake of the MMHW Intervention

A total of 35 health facilities, including the 4 reference hospitals, received the intervention, whereas 32 facilities did not. Of the 35 health facilities that received the intervention, including the reference hospitals, 2 (6%) were dropped from the analysis because their assignment was not random. In the survey of health facilities, 3% (1/32) of the respondents in the control group reported that the MMHW was usable in their facility, whereas 12% (4/33) of the respondents in the intervention group reported that it was not usable. Of the latter, 75% (3/4) were those CSBs that could not implement the intervention due to technical issues. The fourth facility seemed to have stopped using the MMHW since intervention rollout.

Intervention uptake was lower among surveyed women than assumed in the power calculation. Among women in the catchment areas of treated CSBs, 38.79% (1297/3344) had heard of the MMHW (372/2891, 12.87% in the control group). Registration rates were at 14.51% (485/3344) in the intervention group and 3.46% (100/2890) in the control group, corresponding to 37.42% (485/1296) and 27% (100/371) of those who had heard of the MMHW, respectively. Among those who registered for the MMHW, 66.7% (320/480) in the intervention group and 65% (65/100) in the control group actually used it to pay for maternal care services. Uptake varied considerably across treated CSBs; the share of women who had heard of the MMHW ranged from 4% (1/24) to 78% (25/32), and the share of women who registered ranged from 0% (0/24) to 69% (22/32).

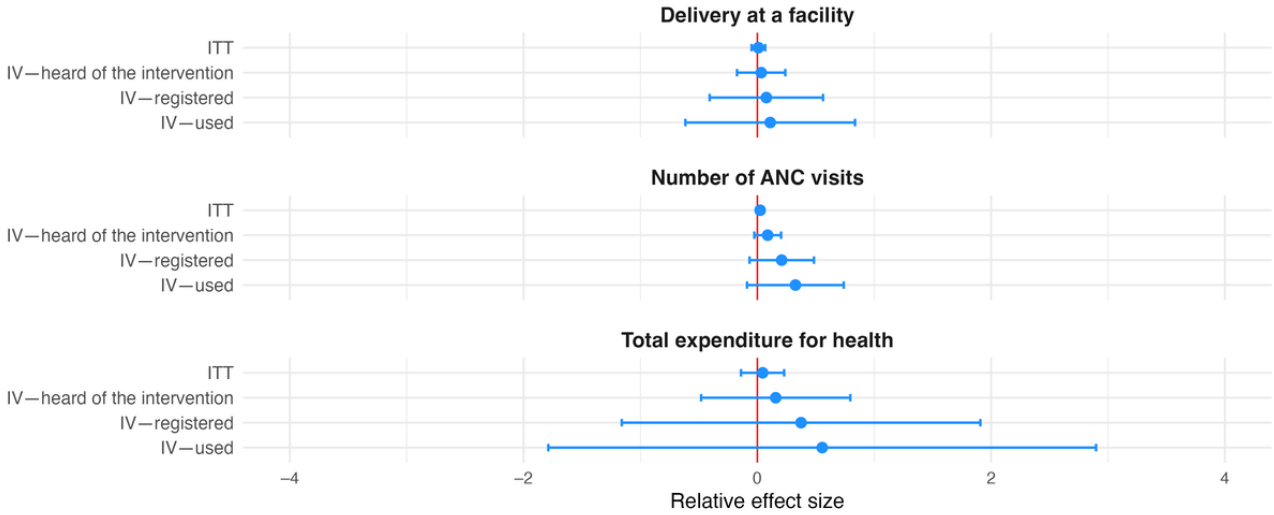
Impact on Primary and Secondary Outcomes

Results of the ITT and IV estimations for outcomes on the individual level are shown in Table 3 for primary outcomes, Table S3 of Multimedia Appendix 1 for secondary outcomes, and are illustrated in Figures 2-6. None of the coefficients for the 3 primary outcomes—delivery at a facility, number of ANC visits, and total expenditure for health—were statistically significant. Relative effect sizes were larger in the IV analysis than in the ITT analysis, and they were larger the stricter the instrumented indicator was (Figure 2). For delivery at a facility, the relative effect size in the ITT analysis was 0.009, meaning that the share of women delivering at health facilities increased

XSL•FO
RenderX

by 0.9% of the control mean (95% CI −0.049 to 0.067). When treatment was used as an instrument for having heard of the MMHW, the relative effect size increased to 0.033 (95% CI −0.174 to 0.239). When treatment was used as an instrument for having registered for the MMHW, the relative effect size was 0.077 (95% CI −0.408 to 0.562). When treatment was used as an instrument for having used the MMHW, the relative effect size was 0.110 (95% CI −0.616 to 0.836), suggesting an increase by 11% of the control mean. For the number of ANC visits, the respective relative effect sizes were 0.024 (95% CI −0.009 to 0.056) in the ITT analysis, meaning an increase of 2.4% over the control mean ANC visits, 0.088 (95% CI −0.026 to 0.203) for IV—heard of the intervention, 0.208 (95% CI −0.067 to 0.484) for the IV—registered with the intervention, and 0.326 (95% CI −0.088 to 0.739) for IV—used the intervention. For total expenditure for health, the respective relative effect sizes were 0.045 (95% CI −0.140 to 0.229) in the ITT analysis, meaning an increase of 4.5% over the control mean of total expenditure for health, 0.157 (95% CI −0.481 to 0.795) for IV—heard of the intervention, 0.374 (95% CI −1.160 to 1.908) for IV—registered with the intervention, and 0.555 (95% CI −1.789 to 2.898) for IV—used the intervention.

Figure 2. Relative effect sizes of intention-to-treat (ITT) and instrumental variable (IV) estimations for primary individual-level outcomes. The graph shows the estimated relative effect sizes with 95% CIs from the ITT analysis as well as the IV analysis where assignment to treatment was used as an instrument for having heard of the Mobile Maternal Health Wallet (MMHW), having registered with the MMHW, and having used the MMHW to pay. ANC: antenatal care.



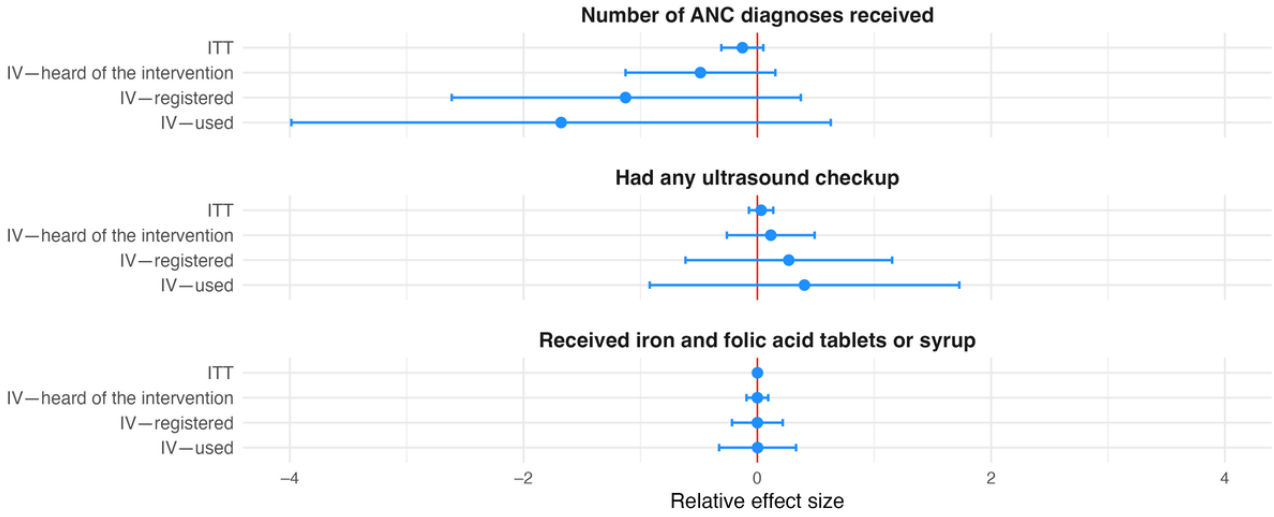


Figure 3. Relative effect sizes of intention-to-treat (ITT) and instrumental variable (IV) estimations for secondary individual-level antenatal care (ANC)–related outcomes. The graph shows the estimated relative effect sizes with 95% CIs from the ITT analysis as well as the IV analysis where assignment to treatment was used as an instrument for having heard of the Mobile Maternal Health Wallet (MMHW), having registered with the MMHW, and having used the MMHW to pay.

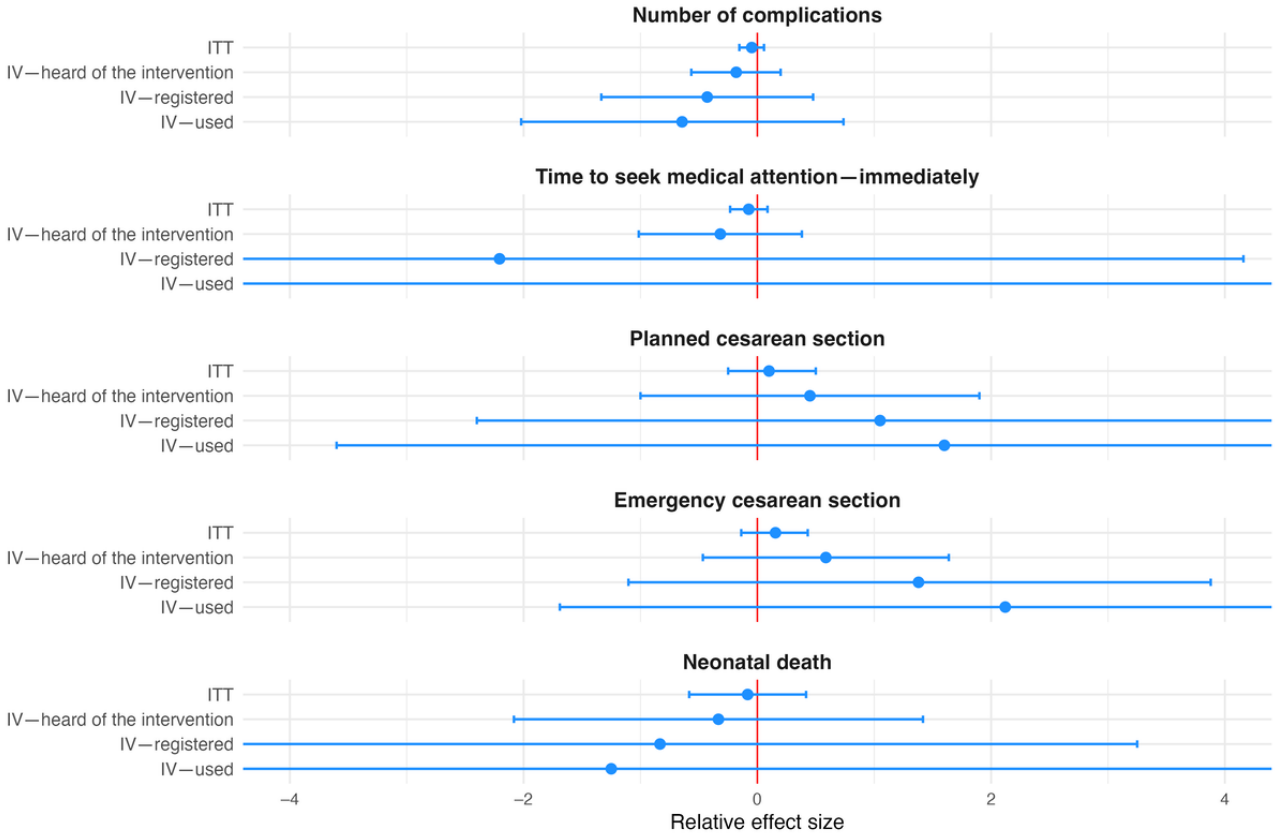
[a]This table shows the regression results of the ITT and IV estimations for primary outcomes. It reports the number of clusters and observations used for each outcome, the intraclass correlation coefficient, the mean value and SD of each outcome in the control group, the coefficient of being in the catchment area of a treated Centre de Santé de Base (CSB; public sector primary care health facility) with the corresponding *P* value, and the relative effect size (calculated as the coefficient divided by the mean) for both ITT and IV models. In all models, indicator variables for strata were included as controls, and SEs were clustered at the CSB level.



[b]ICC: intraclass correlation coefficient.

[c]ANC: antenatal care.

We grouped secondary outcomes into 4 categories. Coefficients for ANC- and delivery-related outcomes were all statistically insignificant. With the exception of the indicator for having received iron and folic acid tablets or syrup, they all followed the pattern described for primary outcomes (ie, larger relative effect sizes in the IV analysis; Figures 3 and 4). The same held true for the 4 outcomes grouped as being related to finances, including the amount of contributions to health savings, amount of health savings, relative health expenditure, and indication of financial distress (Figure 5). All coefficients for these outcomes went in the direction intended by the intervention, showing positive associations with the amount of savings and contributions and negative associations with relative health care expenditure and indication of financial distress, but no coefficient was statistically significantly different from 0 at the 5% level. The last group combined outcomes related to satisfaction and the postpartum depression score. None of the coefficients were statistically significant. Apart from the coefficient for life satisfaction, effect sizes increased across specifications, as described previously (Figure 6).

XSL•FO
RenderX

Figure 4. Relative effect sizes of intention-to-treat (ITT) and instrumental variable (IV) estimations for secondary individual-level delivery-related outcomes. The graph shows the estimated relative effect sizes with 95% CIs from the ITT analysis as well as the IV analysis where assignment to treatment was used as an instrument for having heard of the Mobile Maternal Health Wallet (MMHW), having registered with the MMHW, and having used the MMHW to pay. Elements not visible on the graph: time to seek medical attention in the IV—registered estimation (−2.206, 95% CI −8.573 to 4.159), time to seek medical attention in the IV—used estimation (−5.783, 95% CI −29.899 to 18.332), planned cesarean section in the IV—registered estimation (1.050, 95% CI −2.400 to 4.500), planned cesarean section in the IV—used estimation (1.600, 95% CI −3.600 to 6.850), emergency cesarean section in the IV—used estimation (2.121, 95% CI −1.690 to 5.931), neonatal death in the IV—registered estimation (−0.833, 95% CI −4.917 to 3.250), and neonatal death in the IV—used estimation (−1.250, 95% CI −7.417 to 5.000).

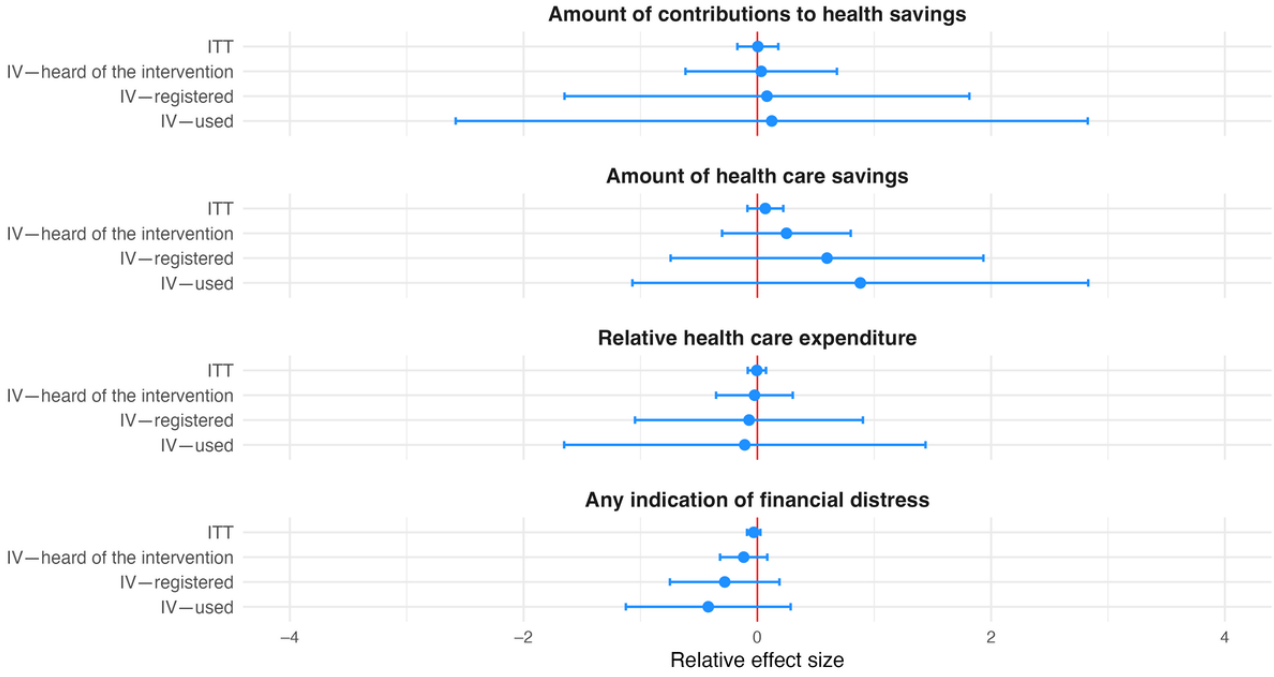
Figure 5. Relative effect sizes of intention-to-treat (ITT) and instrumental variable (IV) estimations for secondary individual-level finance-related outcomes. The graph shows the estimated relative effect sizes with 95% CIs from the ITT analysis as well as the IV analysis where assignment to treatment was used as an instrument for having heard of the Mobile Maternal Health Wallet (MMHW), having registered with the MMHW, and having used the MMHW to pay.



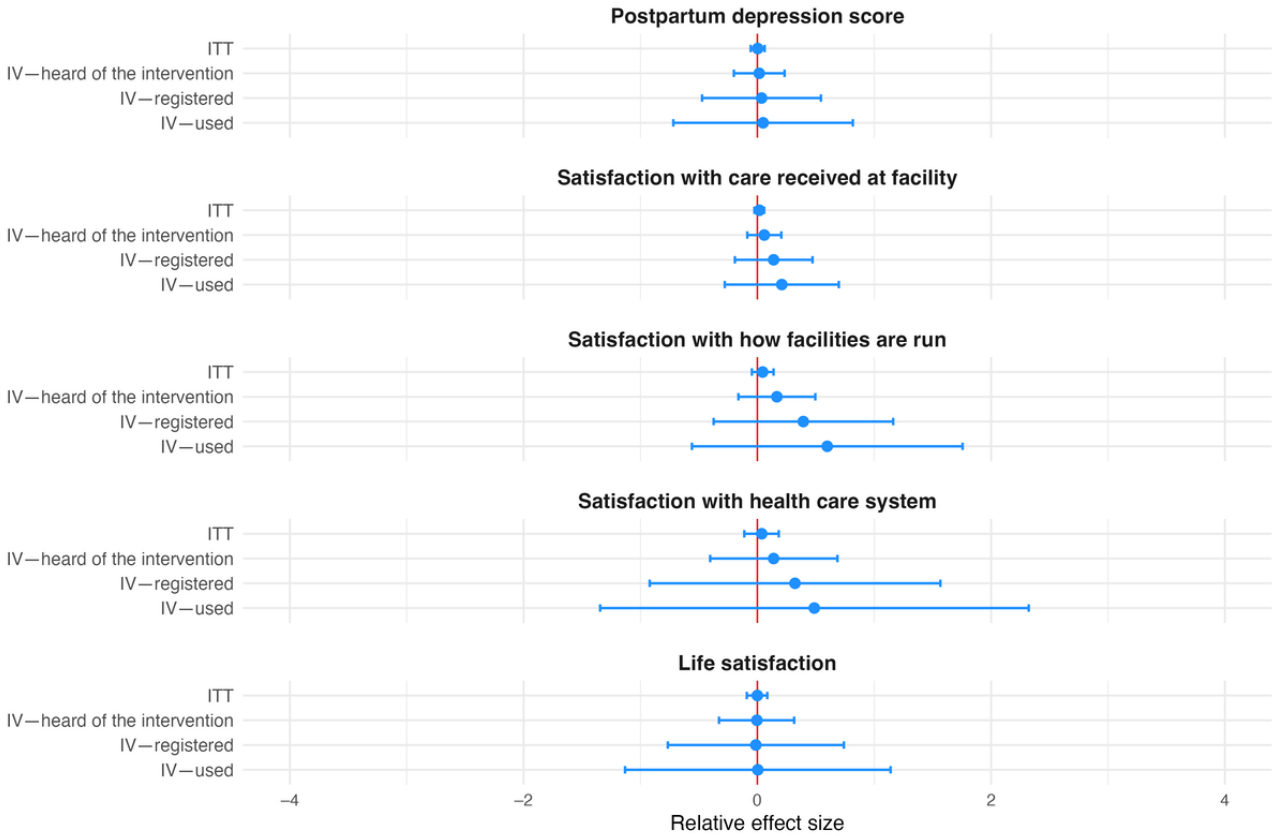


Figure 6. Relative effect sizes of intention-to-treat (ITT) and instrumental variable (IV) estimations for secondary individual-level satisfaction-related outcomes and postpartum depression score. The graph shows the estimated relative effect sizes with 95% CIs from the ITT analysis as well as the IV analysis where assignment to treatment was used as an instrument for having heard of the Mobile Maternal Health Wallet (MMHW), having registered with the MMHW, and having used the MMHW to pay.

XSL•FO
RenderX

In a robustness check, we excluded those CSBs that did not implement the MMHW for technical reasons. The results are shown in Table S4 in Multimedia Appendix 1. For all primary outcomes and several secondary outcomes (whether the women had any ultrasound checkups, whether they received iron and folic acid tablets or syrup, the number of complications, the time to seek medical attention, planned and emergency cesarean sections, the amount of health care savings, and postpartum depression score), the effect sizes went in the same direction as and were larger (in absolute terms) than in the full sample, but the coefficients were still not statistically significant. For other outcomes (number of ANC diagnoses, amount of contributions to health savings, indication of financial distress, and all indicators of facility and health care satisfaction), effect sizes were smaller but of the same sign. The effect sizes for relative health care expenditure and life satisfaction went in the opposite direction to that in the main specification. The effect size for children passing away before their first birthday was still negative but closer to 0.

In a further robustness check, we controlled for variables that appeared imbalanced. The results are shown in Table S5 in Multimedia Appendix 1. For 2 of the primary outcomes, delivery at a facility and total expenditure for health, the signs of the coefficients changed, indicating a reduction from the control mean. Among several secondary outcomes (whether the women had any ultrasound checkups, planned cesarean sections, 3 of 4 finance-related outcomes, and postpartum depression score), the sign of the coefficients also changed. Again, coefficients were not statistically significant.

The results of the ITT estimations at the facility level are shown in Table 4. Regarding outcomes at the individual level, no statistically significant impact on facility-level outcomes was found for outcomes either in 2020 or 2021. Effects on the number of iron and folic acid supplements and antiparasite medications went in the opposite direction of what was intended by the intervention. In the robustness checks excluding the CSBs in the intervention group that did not implement the MMHW, there were also no statistically significant effects (Table S6 in Multimedia Appendix 1).

[a]This table shows the regression results of the ITT estimations for secondary outcomes at the facility level. Centres de Santé de Base (CSBs; public sector primary care health facilities) and reference hospitals assigned to the intervention group nonrandomly are excluded. The table reports the number of observations used for each outcome, the mean value and SD of each outcome in the control group, the coefficient of being treated with the corresponding *P* value, and the relative effect size (calculated as the coefficient divided by the mean). Indicator variables for strata were included as controls.

[b]ANC: antenatal care.

[c]Calculation of *P* value or relative effect size was not possible.

Discussion

Principal Findings

In this analysis, we quantitatively assessed the impact of a mobile savings tool for maternal and newborn care in the Analamanga region in Madagascar. With this tool, users could save money and pay for services at participating health facilities, including primary care health facilities as well as reference hospitals. The intervention was evaluated using a cluster-randomized controlled trial.

In the ITT analysis, we did not detect any statistically significant impact of the MMHW intervention on maternal and neonatal health outcomes. The lack of statistically significant effects could be due to the study being underpowered to detect these effect sizes given that the realized knowledge about the intervention and the uptake among the survey participants was below what was assumed in the initial power calculation. It could also mean that the intervention did not achieve population-level effects.

Relative effect sizes were larger in the contamination-adjusted analysis than in the ITT analysis, and they were meaningful though also statistically insignificant, especially when treatment was used as instrument for having used the MMHW for paying. The larger effects in the contamination-adjusted analysis indicate that the intervention potentially had an impact on those who were receptive to it and used the tool. Coefficients for the 3 primary outcomes were all positive, suggesting a higher likelihood of delivery at a facility, a higher number of ANC visits, and higher health care expenditure among MMHW users. The latter could indicate that, due to financial barriers, these women previously did not purchase all the services they required, leading to an initial increase in expenditure after

XSL•FO
RenderX

financial barriers were eased [9]. However, when controlling for employment status and asset ownership, the direction of the association changed for several outcomes, including delivery in a facility and health care expenditure. This could indicate a potential confounding bias in the main analysis.

A striking finding of this study was the level of expenditure for maternal care, which is in theory free in Madagascar. On average, women in the control group spent MGA 208,021 (US $48.45 according to the OANDA currency converter rate for August 16, 2022—middle of data collection) on health care during pregnancy and delivery. This amount could pose a barrier to many women who might be deterred from delivering at a health facility [8]. Given that MMHW use was associated with higher expenditure, women might actually limit their expenditure compared to their needs. As women continue to face charges for essential medication, treatment, and services beyond what is provided for free, this calls for demand-side financing solutions for maternal care.

Related Evidence

Relative effect sizes for an increase of 11%, 32%, and 55% compared to the control group for the 3 primary outcomes (in-facility delivery, number of ANC visits, and total expenditure for health, respectively) when treatment was used as an instrument for having used the MMHW were in line with effect sizes previously reported for general demand-side and mobile health (mHealth) interventions for maternal care [28,29]. However, mHealth is broadly defined and covers a range of interventions beyond MM interventions. Evidence on MM interventions specifically is much more limited.

Several studies have assessed the association between use of MM and health outcomes. They suggest that users of MM services are more likely to use formal health care services as a response to health shocks than nonusers [30] and that their health care use may be better [31,32]. However, these studies look at MM services in general, which are mostly not focused on saving tools and are not targeted at health spending, as is the case for the MMHW. Moreover, their identification is often not causal.

mHealth technologies have become frequently used tools to address challenges related to maternal and newborn health in low- and middle-income countries [33]. Many of these technologies aimed at improving ANC access seem to have informational functions through messaging and notification alerts [34]. Few seem to have functions related to financial transactions and incentives [35] that could be directly compared to the MMHW intervention assessed in this study. A systematic review of mHealth interventions and their impact on maternal and newborn health identified 1 study evaluating an intervention with the aforementioned financial-related functions [28]. In a randomized trial in Kenya, financial incentives paid through participants' mobile phones increased women's probability of attending ANC, whereas they did not increase the probability of delivering at a facility [36]. This intervention was primarily a conditional cash transfer that was paid for each health visit, whereas the mobile phone was the mode of payment of the transfer. Other studies have also shown that cash transfers and vouchers can have a positive impact on the use of maternal care services [37]. In Western Kenya, a program offering a full voucher and a conditional cash transfer to expectant mothers led to an increase in institutional delivery rates by 33% [38]. Similarly, a conditional cash transfer program in Nigeria paid pregnant women to deliver at a health facility and resulted in a 41% increase in facility deliveries [39].

The MMHW was primarily a savings tool, with a conditional cash transfer in the form of vouchers and matching of deposits made by the user as an incentive to use the tool. It did not constitute a full voucher, meaning that copayment and cosaving by the user was required. This may have reduced its effectiveness compared to a full voucher [38]. Instead, this tool added an aspect to mHealth technology interventions that has not been studied previously, namely, saving. A study protocol of a randomized controlled trial in Kampala, Uganda, described the use of an MM health savings account in their intervention, but the evaluation focused on the effect of SMS text messages to encourage saving behavior and did not analyze the uptake and use of the health savings account itself [40].

The Innovative Partnership for Universal Sustainable Healthcare intervention in Kenya provided fully subsidized, digital health insurance through women's own SIM cards to low-income women of reproductive age [41]. While saving was not a component of the intervention, the goal was to improve access to health insurance using mobile technology and increase the use of maternal health care services. All women in the treatment group received the digital health insurance on their mobile phones. This intervention did not improve maternal health care use [41].

To the best of our knowledge, this was the largest trial of a digital financing solution for maternal health. This trial was implemented in 63 CSBs and 4 reference hospitals in a central region of Madagascar. The evaluation of the intervention rigorously followed a randomized controlled trial protocol for a public health intervention. By conducting a large population-based survey instead of focusing on women visiting health care facilities, the evaluation used the highest possible bar to measure the relevant outcomes.

Limitations

Despite these strengths, this study faced several limitations. The main concern is related to statistical power. While the original power calculation assumed uptake of 50% of women in the intervention area, actual awareness of the intervention and uptake were lower. Uptake among women who had heard of the intervention was 37.42% (485/1296) and, thus, closer to the initially anticipated uptake. We addressed the lower-than-assumed uptake by increasing the sample size of the survey during data collection. However, given an uptake of 14.51% (485/3343), we would have needed to increase the sample size 44-fold to reach a power of 0.8 compared to complete uptake (1/[compliance rate]^2). We conducted a post hoc power analysis based on the collected data and realized uptake rate following the study by Duflo et al [42] for power calculations with grouped errors and imperfect compliance. Given the 14.51% (485/3343) registration rate in intervention areas, 31 clusters in each group, and an average of 103 respondents per cluster, we can only reject effect sizes at the

population level larger than a 69–percentage point increase in delivery at a health facility, larger than an increase of 2.5 ANC visits, and larger than an increase of MGA 558,731 (US $132.80 according to the OANDA currency converter rate for August 16, 2022) in health expenditure. This study was underpowered to detect smaller yet still meaningful effects. Therefore, we cannot reject that the study did not have the observed effect. One possible approach to address low uptake and the resulting low power in future studies would be to sample eligible individuals at health care facilities, randomly assign registration among this sample, and survey only these individuals before and after the intervention. This approach does not allow for an analysis of uptake in a real-world scenario of program rollout. We particularly chose the population-based design to be as close as possible to the real-world effect of the intervention. However, we are aware that this is a composite evaluation of the intervention itself and its implementation, which could have led to the observed lower-than-anticipated uptake. Further research is needed on how the implementation could have impacted uptake, but this is out of scope for this analysis.

No baseline data collection was conducted, which would have strengthened the power of the analysis. The lack of baseline data also meant that it was not possible to assess changes over time and control for potential confounding factors. Our estimation approach solely compared outcomes between the intervention and control groups at endline and relied on the randomized treatment assignment for causal identification.

The larger effect sizes in the IV analysis suggest that the intervention might have been beneficial for MMHW users. Unfortunately, the IV analysis had even greater demands on power, and no statistical significance was achieved. Assuming that all potential users behaved similarly when registered for the tool, the local average treatment effect showed the effect under full uptake. However, this is a strong assumption that may not be valid in the study context. Women who did not register for the tool voluntarily might have behaved differently once registered than those who did. The decision to register with the MMHW may have been influenced by characteristics that are also associated with the measured outcomes or how individuals may respond to the intervention. The factors that are associated with the decision to register have been analyzed quantitatively and qualitatively elsewhere (Schäfer, L, et al., unpublished data, June 2025). Therefore, the results of the IV analysis should be interpreted with caution. Moreover, the IV analysis assumed that treatment assignment affected outcomes only through MMHW uptake. This assumption may be violated if sensitization campaigns influenced health-seeking behavior independently of registration with the MMHW. However, sensitization activities strongly focused on information about the MMHW and did not include general messages such as a call to deliver at a health facility. Therefore, it seems implausible that health-seeking behavior was influenced independently of registration.

Our analysis was an evaluation of the entire intervention package, which combined financial, patient-focused components (eg, savings incentives and free ultrasound checkups) with nonfinancial, health care provider-level components (eg, health care worker training). We are not able to clearly disentangle the effects of these different components. However, when treatment was used as an instrument for having registered with the MMHW, effect sizes were often larger than when treatment was used as an instrument for having heard of the MMHW. This indicates that the components that were dependent on registration (eg, access to free ultrasound checkups and savings incentives) were more relevant than those that were not dependent on registration (ie, health care worker training). Similarly, the larger effect sizes when treatment was used as an instrument for having used the MMHW to pay compared to having registered with the MMHW suggest that the ability to save and collect contributions using the tool may be more beneficial than the vouchers for ultrasound checkups.

Further limitations relate to intervention assignment at the individual level and sample selection into the population-based survey. The analysis treated women in the catchment area of the intervention CSBs as treated. However, these women did not necessarily attend the CSB of their *fokontany* (administrative unit) for various reasons. This CSB might not be the one closest to their residence, they might visit another CSB for other personal reasons irrespective of the CSB's ability to offer payment through the MMHW, or they might not visit any CSB during pregnancy or for delivery. We only observed visits to the CSB after the intervention, and the decision to visit any CSB or a particular CSB might be affected by the intervention. Therefore, it is not possible to capture where women would have attended in a scenario without the intervention, and assigning treatment status through residence in the catchment area was the only option to link women with CSBs given our data.

Furthermore, the analysis was based on survey data from women who were home at the time of the visit, which took place during daytime on weekdays. These women were different from eligible women who were not present at their home, as shown previously. The latter were found to be slightly older and wealthier and have a higher probability of having access to a mobile phone. Studies of MM adoption have shown that wealthier and better educated individuals and those who own a mobile phone are more likely to adopt MM [43]. Therefore, it is possible that uptake of the MMHW might have been higher among those eligible women who were not found at their home at the time of the visit and, therefore, did not participate in the survey. While this means that we potentially underestimated intervention uptake, it is unclear how the sample selection bias impacted the estimated effects of the intervention. On the one hand, wealthier and better educated individuals who own a mobile phone could be in a better position to use the MMHW, leading to an underestimation of the effect using the available survey sample. On the other hand, slightly poorer individuals might benefit more from the MMHW as their financial barriers are more severe, resulting in an overestimation of the population-level effect. A population-based survey always faces difficulties in surveying individuals who are not present at their homes. An alternative approach would be sampling at health care facilities. However, this would lead to a different selection bias as women who do not visit health care facilities for ANC or delivery would not be included. Our study had the explicit goal of measuring the ITT effect at the population level.

RenderX

A last concern relates to the quality of facility-level data based on facility records, which seemed rather imprecise, particular regarding expenses for medication and deaths during delivery. Expenses were not tracked consistently in facility records, and respondents often reported estimates, which was indicated by respondents reporting the same values for 2020 and 2021 and reporting intervals instead of a single value. Deaths of mothers or children were often not reported at all. This limits the usability of the health care provider record data. Underreported maternal and neonatal deaths could underestimate true mortality rates, thereby masking differences between facilities in the intervention and control groups. Imprecise reporting of expenses may negatively affect the precision of effect estimates on ANC and delivery drug expenses. While we followed the published protocol [26] and analyzed the facility-level data, our interpretation puts a larger weight on the data from the population-based survey.

Conclusions

While this study did not identify a statistically significant impact, the estimated contamination-adjusted effects suggest that the MMHW has potential to improve access to maternal care for women who are receptive to such an MM-based savings tool. Estimated population-level effects were much smaller, and this study was underpowered to detect such effects due to lower-than-anticipated uptake of the intervention. It is now of great interest to investigate the reasons for low uptake and strategies to increase adoption of the MMHW or similar tools. The MMHW intervention consisted of several components that could be adjusted to increase the tool's suitability and attractiveness to potential users. Further research could explore which information channels are most effective in informing potential users about the tool, which information sources are locally trusted by potential users to encourage uptake, and whether different incentive schemes could increase saving among users. Adding reminders to save as a function of the MMHW could potentially increase its use and, eventually, its effectiveness. On the health care providers' side, a better understanding of their perception of the tool and their motivation for its use is required. While health care providers received monetary incentives to file claims via the MMHW platform, these incentives might have been insufficient to compensate for the perceived increased workload or adjustment to the new process. Similar interventions should include health care providers in the design of tools and use processes to ensure their acceptance of and comfort with the interventions. In conclusion, while the potential of the MMHW lies in its promise to lower barriers to accessing obstetric care, this potential is not yet fully realized.

Acknowledgments

This trial was financially supported by the German Federal Ministry of Education and Research (01DG21036GA). The intervention was funded by the Else Kröner-Fresenius Foundation, the Berlin Institute of Health, and Doctors for Madagascar. The funders had no role in the study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Data Availability

The individual-level datasets analyzed during this study are available in the Göttingen Research Online repository [44]. The facility-level data analyzed during this study are not publicly available due to identification risks.

Authors' Contributions

SK and JVE developed the intervention and study design and defined the analysis plan. AR, HEA, and BV were responsible for organizing the data collection. LB, in collaboration with HEA, ZR, and BV, designed the data collection tools. LB conducted the data analysis. LB, SK, JVE, and SV interpreted the findings with contributions from TB. LB and BV wrote the first draft of the manuscript. SK, JVE, and SV critically revised the manuscript. All authors read and approved the final manuscript.

Conflicts of Interest

JVE and SK are shareholders of the nonprofit company mTOMADY and co–principal investigators on the Federal Ministry of Education and Research–funded 4MOTHERS trial. All other authors declare that they have no conflicts of interest.

Microorganisms Linked to Health Care–Associated Infections: Modernization of Terminology Resources for Reporting to the National Healthcare Safety Network

Sheila Abner[1], PhD; Shuai Zheng[1], PhD; Caroline Macumber[2], MS; Shaun Shakib[2], PhD; Jonathan Edwards[1], MStat; Andrea Benin[1], MD

Abstract

The National Healthcare Safety Network (NHSN) of the Centers for Disease Control and Prevention (CDC) needed a modernized approach to manage resources containing standardized terminology that specify microorganism data submitted electronically for legacy reporting. Health care–associated infections (HAIs) reported to NHSN require the submission of data regarding specific microorganisms attributed to the patient's condition. Data on microorganisms submitted to the NHSN electronically must use the SNOMED CT terminology standard. Terminology artifacts that guide submission of microorganism data have been maintained in spreadsheets that have become increasingly challenging to manage. This case report details the initial use case for the implementation of off-the-shelf software within the NHSN to modernize the maintenance of terminology assets. Resources that guide reporting microorganisms for HAIs were used as a prototype to demonstrate how a software application can be practically implemented to streamline the maintenance of complex terminology assets. Mission-critical artifacts have been reconciled and consolidated into a single source of truth knowledgebase using an off-the-shelf software solution. This report shares progress and lessons learned regarding the modernization of NHSN's *Pathogen Codes* resource and its derivative artifacts. A model is now available that can be replicated across other NHSN legacy artifacts. Our experience can be applied to other public health use cases and information systems facing similar challenges with attachments to legacy terminology resources and systems.

SNOMED CT; terminology; microorganisms; health care–associated infections; public health surveillance

Introduction

The National Healthcare Safety Network (NHSN) of the Centers for Disease Control and Prevention (CDC) is the nation's surveillance program for health care–associated infections (HAIs) and other conditions, patient safety events, and antimicrobial use and resistance [1]. The NHSN collects and processes surveillance data for the purpose of promoting efforts to prevent adverse events in health care by enabling facilities and governance agencies to determine problematic areas and formulate corresponding corrective actions.

The NHSN was launched in 2005 as a web-based application, succeeding the smaller DOS-based National Nosocomial Infection Surveillance (NNIS) system that had been in operation since the 1980s [2]. A bellwether for the adoption of HL7 data standards and electronic public health reporting, the NHSN implemented its first clinical document architecture (CDA) data submissions in 2008. As of November 2024, there were more than 165,000 users and over 38,500 health care facilities across the health care continuum reporting to the NHSN. More than 59 CDA vendors have established the capacity to submit data electronically on behalf of facilities.

When the NHSN first enabled electronic reporting, specifications for value sets from standardized vocabularies were needed to guide CDA vendors. Spreadsheets became the de facto solution for managing those resources because terminology software was not available. Additional attributes of metadata and relationships to other artifacts were incorporated into the spreadsheets to meet business needs. Maintaining these assets became labor-intensive with the growth of the NHSN expanding beyond its original functions.

As part of the CDC's Data Modernization Initiative, the NHSN has adopted a new software platform for the maintenance of terminology assets. This paper highlights the NHSN's early

XSL•FO
RenderX

successes in modernizing resources that guide standardized data collection of microorganisms attributed to HAIs while preserving backward compatibility with legacy business processes.

Evaluation of Legacy State and Transition Approach

Terminology resource management processes and products were qualitatively evaluated before and after the adoption of an off-the-shelf solution. An assessment of the historical state was performed by terminologists and informaticists skilled in the laboratory data domain. Stakeholders—including data scientists, database administrators, system developers, in addition to epidemiologists and infection preventionists authoring surveillance protocols—were questioned in focus groups to determine pitfalls and pain points in legacy processes. Feedback and insight from those interviews guided the overarching business and technical requirements for the transition activities.

The deployment of the new platform has been approached with three major features. First, the required servers have been constructed in the cloud environment of the CDC, followed by integration and performance testing with other infrastructural systems and existing NHSN applications. Various data provisioning methods have also been explored and merged into the roadmap of the NHSN.

Second, a corresponding standard operating procedure (SOP) has been developed to guide usage of the platform and facilitate communication among collaborators. A Terminology Committee, including physician informaticists, has been assembled to centralize discussions of terminology-related topics and requests, providing convenient consultation services to all stakeholders. After requests are conceptualized, they are formally itemized into specific requirements and documented in standardized terminology asset management (TAM) request forms. The SOP improves the efficiency of communication and streamlines coauthoring and maintenance of terminology resources into the new platform.

Third, necessary training sessions have been scheduled for the software users and stakeholders. In addition to the basic operations of the software platform, fundamental informatics and terminology principles have been taught in the form of training videos, webinars, and workshops to educate the workforce of NHSN. Subgroups have also been defined to offer additional domain-specific trainings based on different roles in the workflow.

Historical State and Drivers for Implementing Improvements

The NHSN has developed an extensive collection of terminology assets, including 2 code systems and more than 80 value sets from various reference terminologies for electronic data specifications conformant to the HL7 CDA standard [3]. In addition to value sets in the value set authority center (VSAC), a publicly available authoring and provisioning tool hosted by the National Library of Medicine [4], CDA vendors are also dependent on the NHSN information data model (IDM), which combines business rules with standardized terminology content. The IDM has been maintained in spreadsheets that evolved into a multi-faceted resource and was well-positioned for modernization. The first proof of concept for such modernization focused on a high-priority table in the IDM, *Pathogen Codes* [5], that catalogs criteria for reporting microorganisms linked to all HAI events in the existing NHSN surveillance portfolio.

The NHSN retained approximately 1000 microorganism terms from its NNIS predecessor and established a methodology to create unique and human readable codes for analysis purposes. These short representations for pathogen concepts were challenging to curate after being coupled to SNOMED CT [6] concept identifiers required for the electronic reporting option. Although the naming conventions for NHSN codes became less intuitive as the number of terms increased to keep up with growth of NHSN over the years, these conventions remained mandatory for analyzing data.

By 2019, the *Pathogen Codes* resource had amassed more than 3500 rows of terms that included subsets of synonyms. Synonyms were particularly challenging to manage due to the ever-changing landscape of microbial nomenclature [7]. More than 35 columns of metadata were needed to characterize the reporting criteria across a growing number of complex HAI events. The sheer number of mixed-term types with manually curated mnemonic codes and business logic attributes managed in spreadsheets led to the need for comprehensive terminology software for the most effective maintenance.

Although the SNOMED CT U.S. Edition releases occur biannually (March and September), updates to the *Pathogen Codes* resource have coincided with annual NHSN application major releases in January. Because the NHSN development life cycles also need to accommodate the development cycles of CDA vendors, the offset timing of NHSN releases and SNOMED CT updates meant that it was challenging to maintain up-to-date SNOMED CT content in distributed NHSN resources.

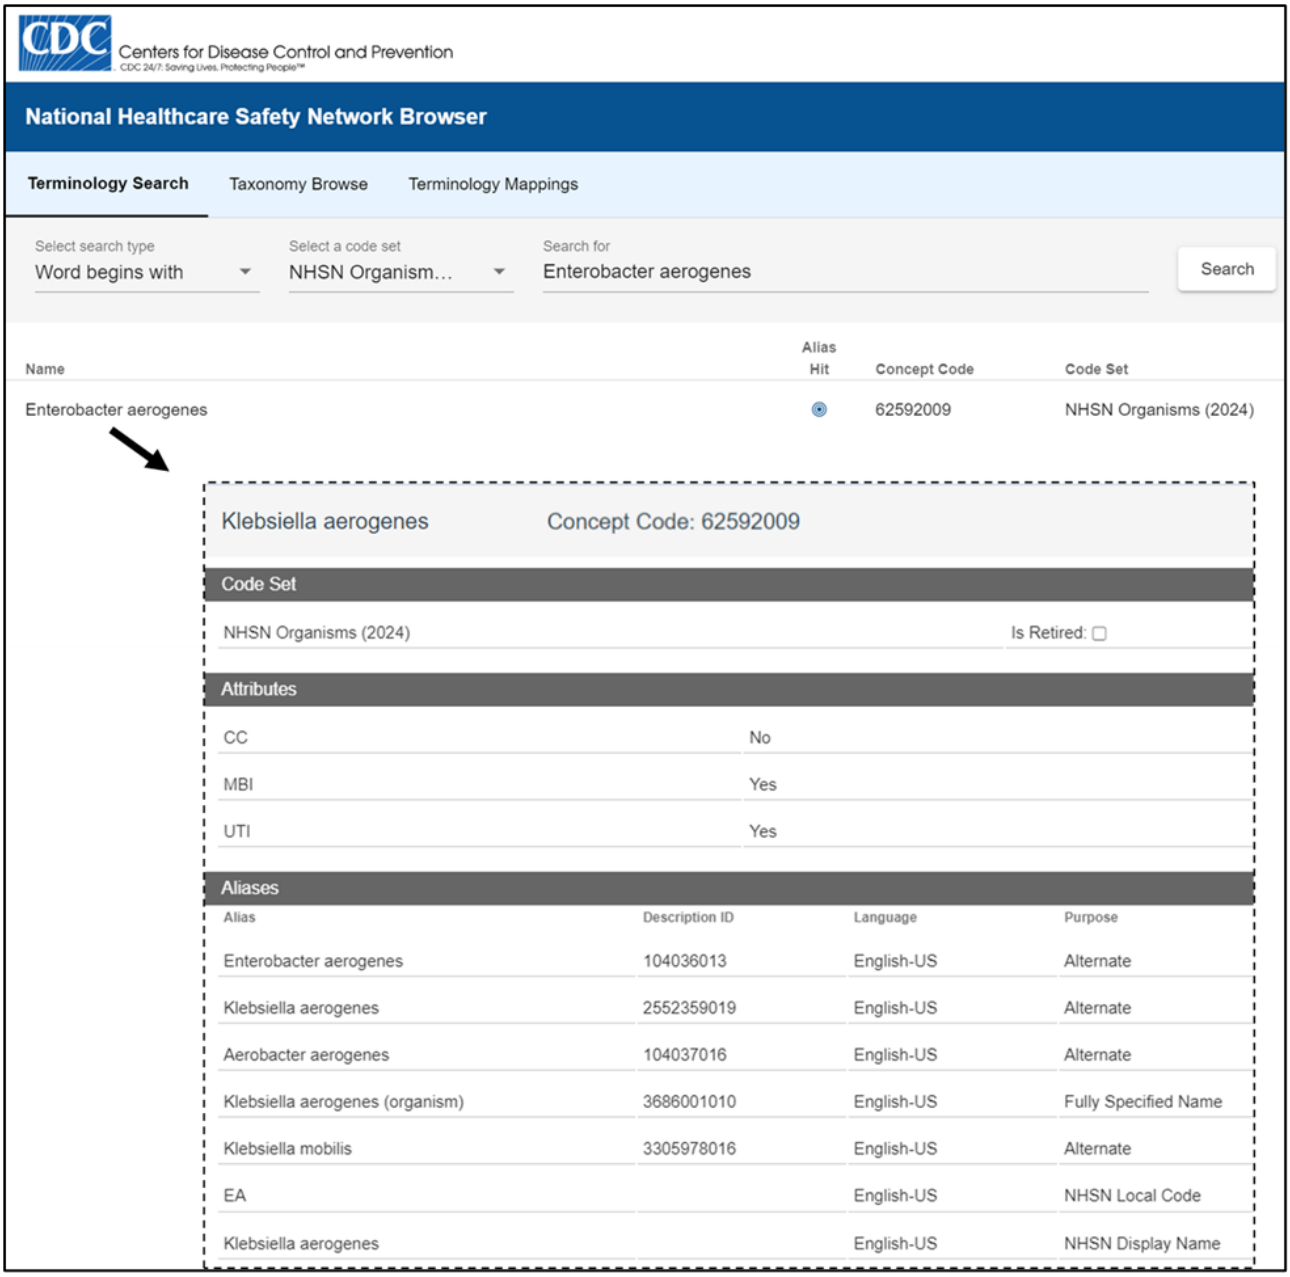
Updating the *Pathogen Codes* resource was so labor-intensive that the task needed to be started on a version of SNOMED CT that preceded the NHSN application release by more than a year. The terminologist prepared enumerated lists of SNOMED CT concepts in VSAC, and exported files were manually compared to existing *Pathogen Codes* content to identify inactivated codes, name changes to term descriptions, and additions being considered. The resulting marked-up spreadsheet that highlighted proposed updates was shared with protocols and data analysis stakeholders to reach consensus on changes to microorganism membership and associated attributes. Following that reconciliation, the annotated spreadsheet was submitted to business analysts with enough time for the development team to implement the changes for the January NHSN application releases. Overall, the maintenance process relied heavily on manually processed spreadsheets and email communication which intensified the workload and prolonged the path to completion. The fragmented process caused challenges to version control and rigorous traceability.

In addition, supplemental spreadsheets derived from the master *Pathogen Codes* table were required to support the divergent

XSL•FO
RenderX

needs of the two different approaches available for data submission. Subsets of content needed to be parsed and simplified in a companion spreadsheet for users entering one event at a time into the web application. In contrast, almost 1000 additional terms needed to be curated separately to expand a subset of content (eg, more than 700 *E. coli* serotypes in SNOMED CT) to support users submitting data via CDA files.

Evolution of Technology Advancement



Migrating the *Pathogen Codes* resource from a spreadsheet to an off-the-shelf software product has modernized how NHSN is maintaining and provisioning this critical terminology asset. The SNOMED CT code system now serves as the core structure for *Pathogen Codes*, and the standard content is enriched with NHSN-specific metadata. Key principles relevant to this effort are derived from the *Desiderata for Controlled Medical Vocabularies* that have influenced the design of several modern code systems [8].

Identifying changes to SNOMED CT concepts and all associated NHSN-specific attributes in the *Pathogen Codes* resource is automated using the terminology software. Microorganism concepts that have moved to inactive status and updates to term descriptions due to changes in nomenclature are automatically flagged for review by subject matter experts from the protocols and data analysis teams with each new release of the code system. Maintenance is substantially more streamlined since the NHSN-specific metadata is now bound to SNOMED CT concept identifiers. Display names of microorganisms in dropdown lists in the web application are identical to the SNOMED CT Preferred Terms. All synonyms (ie, former and alternate names) for the microorganism concepts in the *Pathogen Codes* resource are automatically updated and are now searchable using a customized NHSN terminology browser (Figure 1). This simplified browser has eliminated the need to maintain a separate supplemental spreadsheet for users entering one event at a time into the web application. In addition to identifying synonyms, selected attributes that define reporting criteria for bloodstream infections and urinary tract infections (eg, the Common Commensals column in the *Pathogen Codes* asset) are displayed in the terminology browser for easy reference [9].

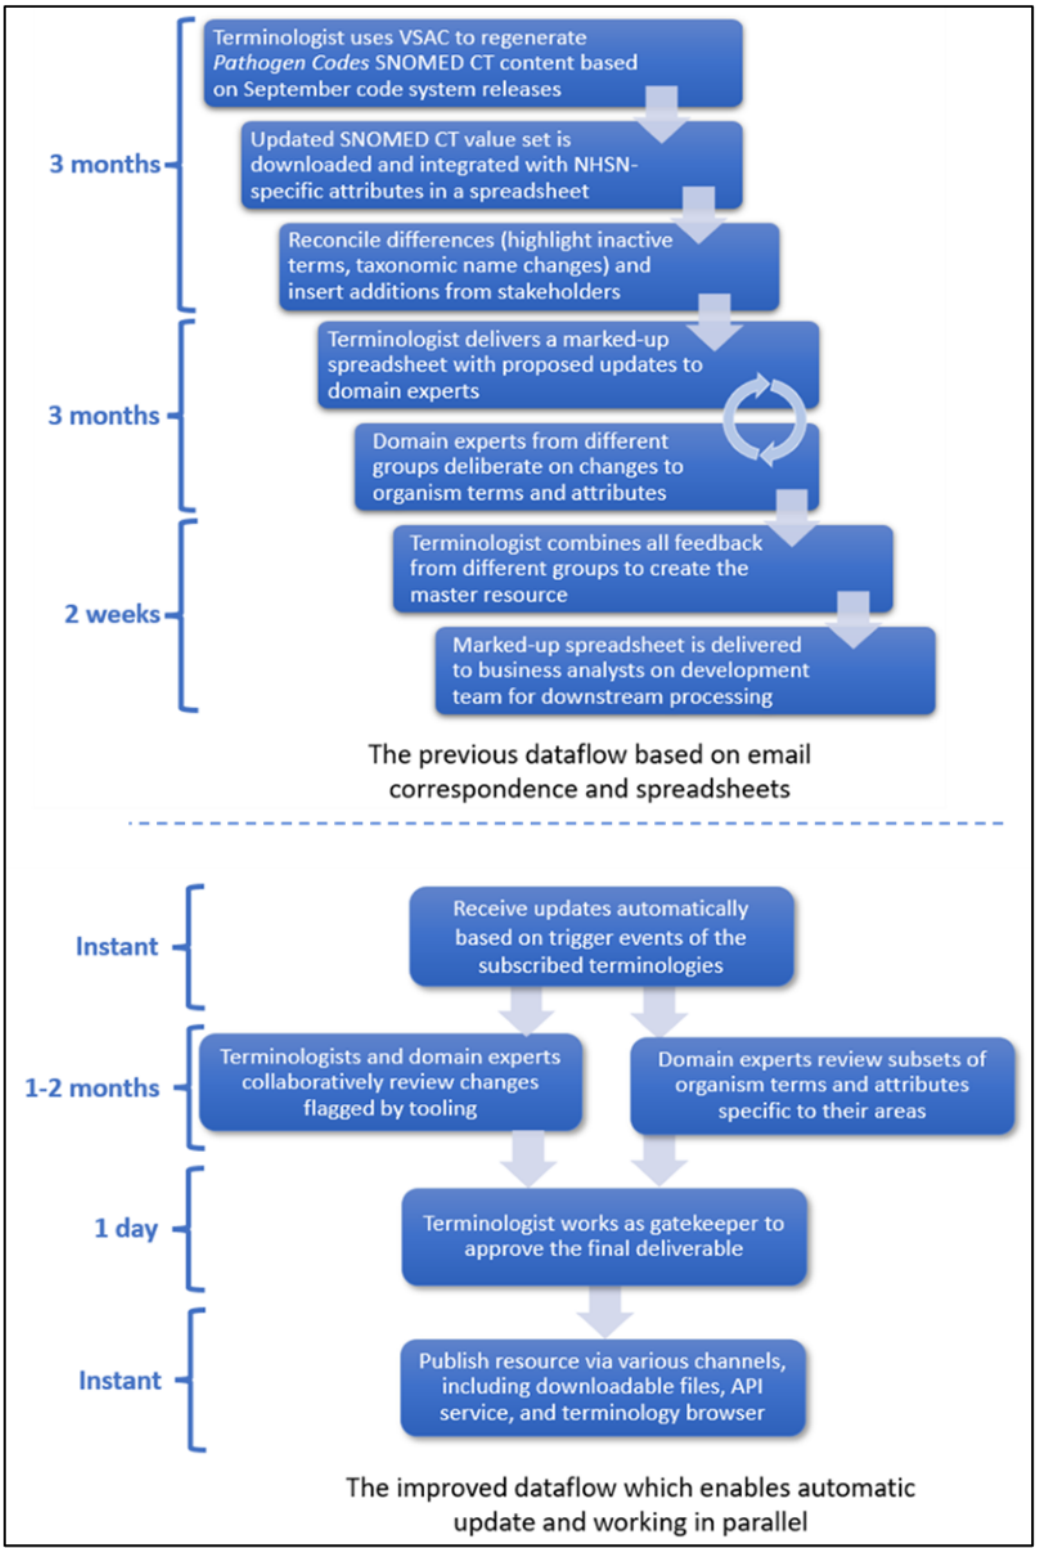
Since the NHSN codes are integral to analyzing data, change must be strategic to minimize disruptions among stakeholders. For maintenance purposes, existing NHSN mnemonic codes will persist as short alternate names (eg, EA for *Klebsiella aerogenes* that was formerly in the genus *Enterobacter*). Current analysis of electronically submitted data depends on translating standard codes from CDA files to NHSN codes. However, future-facing data aggregation and analysis will directly leverage the SNOMED CT ontology and non-semantic concept identifiers without the need for NHSN codes.

XSL•FO
RenderX

Figure 1. The National Healthcare Safety Network (NHSN) terminology browser for the Pathogen Codes SNOMED CT resource. CC: common commensals; MBI: mucosal barrier injury; UTI: urinary tract infection.

Overcoming Challenges From Consequences of Program Expansion

Due to the considerable growth and success of the NHSN, legacy approaches to maintaining terminology assets were no longer sustainable. These challenges placed a demand on adopting a more automated solution to manage all terminology-related resources.



As a result of transitioning to the new terminology platform, reports can be configured to streamline export of customized assets derived from the master *Pathogen Codes* resource. This change will obviate the need to maintain separate companion spreadsheets for different use cases. In addition, the inherent version control and audit trail functionality will enable automated traceability.

Figure 2 illustrates the streamlined maintenance processes. Compared to the previous workflow, a major improvement is that reconciliation with new releases of SNOMED CT is essentially automated. After subscribing to a reference terminology in the platform, changes to NHSN vocabulary assets are applied seamlessly when triggered by new releases of the code system. Alleviating that burden of human intervention is amplified by features of the tooling that allow multiple domain specialists to work simultaneously on subsets of content related to their areas of expertise (eg, bloodstream infection or ventilator-associated events). Another feature that will standardize and streamline the maintenance process is the rich functionality for authoring rule-based value sets. This framework bridges the knowledge gap between domain experts and terminologists to apply rigorous inclusion and exclusion criteria for authoring and automatically refreshing value sets.

XSL•FO
RenderX

Overall, the maintenance timeframe has been reduced from more than 6 months to less than 2 months.

Figure 2. Streamlined data flow with the new approach.

In addition to an application that can automate and streamline the terminology maintenance procedures, the corresponding workflow design and education of the workforce are equally important. Enabling multiple collaborators to cohesively work in parallel on different aspects of a terminology asset not only fast tracks the overall processing time, but also reduces the risk of miscommunication. Meanwhile, training materials on essential terminology principles and methodologies should be offered to the workforce involved in defining requirements for terminology resources to transform routine processes. For example, a basic understanding of the approaches to building rule-based value sets is a fundamental step towards automating updates.

XSL•FO
RenderX

Preliminary progress with the NHSN terminology modernization efforts has been productive and promising. Our experience and lessons learned can be applied to similar use cases relying heavily on terminology resources that are subject to frequent updates. Further integration with other NHSN and CDC applications is a major future direction. A fully automated data pipe will be implemented based on the terminology services offered by the new platform, allowing systematic data provisioning to internal and external stakeholders. Meanwhile, all existing terminology resources will be migrated from the IDM to the new platform for improved maintenance and data sharing procedures. The NHSN is moving in the direction of maximizing electronic submission of data [10,11], but support for manual data entry in the web application and the current IDM will persist indefinitely to accommodate facilities with varying technical capacities and to support legacy surveillance reporting.

Summary

In conclusion, the preparations and directions outlined have drastically eased the adoption and deployment of the new technical solution. Migration of the *Pathogen Codes* asset to the new terminology platform has been a proving ground for updating additional resources in the IDM containing standardized terminology content coupled to the NHSN codes. Being able to tether business rules for HAI reporting criteria to the SNOMED CT concepts of interest and repurposing NHSN codes as short, alternate-term descriptions are pivotal gains from implementing the new approach. Directly using the framework of terminology standards extended with NHSN-specific attributes will streamline maintenance tasks and keep the content more current. Although this use case is restricted to the SNOMED CT organism hierarchy for microorganisms identified in laboratory test results, benefits of this work will scale to other clinical, medications, and laboratory data elements critical for the next generation of NHSN reporting.

Abstract

Machine learning (ML), a subset of artificial intelligence, uses large datasets to identify patterns between potential predictors and outcomes. ML involves iterative learning from data and is increasingly used in population and public health. Examples include

XSL•FO
RenderX

early warning of infectious disease outbreaks, predicting the future burden of noncommunicable diseases, and assessing public health interventions. However, ML can inadvertently produce biased outputs related to the quality and quantity of data, who is engaged and helping direct the analysis, and how findings are interpreted. Specific guidelines for using ML in population and public health have not yet been created. We assembled a diverse team of experts in computer science, statistical modeling, clinical and population health epidemiology, health economics, ethics, sociology, and public health. Drawing on literature reviews and a modified Delphi process, we identified five key recommendations: (1) prioritize partnerships and interventions to support communities considered structurally disadvantaged; (2) use ML for dynamic situations, such as public health emergencies, while adhering to ethical standards; (3) conduct risk assessments and bias mitigation strategies aligned with identified risks; (4) ensure technical transparency and reproducibility by publicly sharing data sources and methodologies; and (5) foster multidisciplinary dialogue to discuss the potential harms of ML-related bias and raise awareness among the public and public health community. The proposed guidelines provide operational steps for stakeholders, ensuring that ML tools are not only effective but also ethically grounded and feasible in real-world scenarios.

(JMIR Public Health Surveill 2025;11:e68952) doi:10.2196/68952

KEYWORDS

population health; public health; machine learning; artificial intelligence; guideline; algorithmic bias; AI; health equity

Introduction

Machine learning (ML) is a form of artificial intelligence (AI) that is now used for a range of problems across many fields. ML involves a machine "learning" as it processes more data, improving predictive performance over time [1]. ML, as a set of tools, can be used for prediction, clustering, and causal inference. While prediction models are commonly used in public health to examine associations between potential predictors and outcomes, ML can also be used to identify groups with shared characteristics (clustering) and to identify potential causal associations between interventions and health outcomes [2,3]. However, these methods are often limited by the quality and quantity of the available data in public health [4].

As methods advance and as the availability of data increases, ML-based innovations are playing a central role in population and public health [5]. Key areas include the surveillance of infectious diseases [6]; predicting the burden of noncommunicable diseases (NCDs) [7]; and assessing public health interventions, including those focused on modifiable risk factors [8]. Awareness that ML could help improve population health is tempered by a growing understanding that it has risks and potentially negative consequences [9]. An important concern for the application of ML models is the perpetuation and amplification of biases reflecting patterns of societal inequality, when the accuracy of model predictions differs systematically across subpopulations, potentially leading to decisions that exacerbate health inequities [10]. This issue is rooted in differences in the amount and quality of data from different populations [11].

Bias in ML as it is applied to population and public health problems has been identified previously [12]; however, guidelines for ML applied to population and public health are limited. Without such guidelines, ML could exacerbate inequities and fail to adhere to methodological standards. For example, during the COVID-19 pandemic, ML models were used to predict infection rates and allocate health care resources. These models were found to be biased, particularly when data from underrepresented communities were either scarce or of lower quality, impacting the accuracy of predictions [13]. Public health organizations may lack the resources and expertise to thoroughly evaluate the ML models they use. While ethical frameworks for AI in health have emerged, they primarily focus on clinical settings. Public health involves unique applications, including population-level interventions, real-time surveillance, and communicable disease control, which require field-specific guidance. Our guidelines aim to address this gap by focusing on the distinct operational, ethical, and equity considerations involved in applying ML to public health. We aim to provide recommendations to those creating or revising ML tools for population and public health purposes, offer guidance to users of ML tools, and outline approaches on how to address bias. We centered our recommendations on the following questions: (1) What are best practices to identify and mitigate biases for those developing, testing, and implementing ML models in population health? (2) What are the priority areas for further research?

We used the GRADE (Grading of Recommendations Assessment, Development and Evaluation) [14], the National Institute for Health and Care Excellence (NICE) [15] approaches to guideline development, and other guidelines specific to epidemiology and health economics modeling [16,17]. We also drew insights from participatory frameworks for policy development governing ML [18] and from documentation on the governance of community data trusts, which provide data for many of the ML models we studied [19]. In addition, we considered international guidelines on AI ethics, such as the Montreal Declaration for Responsible Development of AI [20] and recommendations from the European Commission High-Level Expert Group on AI [21], along with the World Health Organization guidance on *Ethics & Governance of Artificial Intelligence for Health* [22].

Guideline Panel Composition and Management of Competing Interests

To identify experts for the Delphi process, we consulted with leading researchers and practitioners in the fields of ML, public health, and ethics. We also searched online databases and professional networks to identify potential experts. We aimed to include experts from diverse backgrounds, including

XSL•FO
RenderX

academia, industry, and government, with 17 chosen to be a part of the guideline panel (Multimedia Appendix 1). Our guideline panel includes academics in computer science, statistical modeling, epidemiology (clinical epidemiology, social epidemiology, infectious disease, and population health), health economics, ethics, sociology, primary care, public health, and the social determinants of health. Each member has contributed their disciplinary expertise and perspective regarding the social constructions influencing data, bias, and bias mitigation (Multimedia Appendix 1). Our panel members also bring diverse experiential knowledge, aligning with our guidelines' emphasis on recognizing the importance of lived experience in equitable policy development. Panel members did not report any direct conflicts of interest. To ensure transparency, members also agreed to disclose any less direct or potential competing interests, but no such conflicts were found.

Review of the Literature

We conducted a series of literature searches to retrieve existing guidelines related to population and public health, focusing on their intersections with equity, technical aspects, and knowledge mobilization. We searched a range of sources, including original research, reviews, commentaries, editorials, and gray literature (eg, government reports, policy documents, and organizational websites). In the course of this work, we drew on common elements found in other guidelines addressing bias in ML models [10,18,23,24]. These included practices such as engaging with communities impacted by biased models, prioritizing diversity in the teams developing and implementing models, considering which groups considered marginalized could benefit most from involvement in population and public health ML model development, ensuring robustness in the identification of groups considered vulnerable in data, systematically evaluating and reporting on bias, and conducting post-implementation evaluations to continue mitigating bias. In parallel, we conducted and reported three scoping reviews on ML applications in population and public health, specifically examining their use in addressing risk factors, NCDs, and communicable diseases. Two of these reviews have been published, providing an empirical foundation for our guidelines[25,26]. The first review found that bias mitigation was rarely addressed in ML studies focused on population health, particularly in the context of NCDs, with most efforts limited to addressing sex-related bias [25]. The second review, which examined ML applications for addressing risk factors for NCDs, found that although nine of the 20 studies mentioned algorithmic bias, these discussions were generally superficial and limited to traditional biases such as recall or misclassification [26]. To date, few systematic reviews have examined bias in ML applications for public health. Our findings are supported by another systematic review on the use of AI and ML in disaster response and public health emergencies, which similarly noted a lack of bias mitigation strategies despite the growing use of ML in these settings [27]. Our guidelines address this gap by offering operational recommendations that emphasize transparency, stakeholder engagement, and context-specific risk assessment [25]. Finally, we shared our evidence synthesis with the guideline committee alongside our draft recommendations.

Topic Selection and Development of Recommendations

We used a modified Delphi approach to develop our recommendations, consisting of two iterative rounds. An initial list of relevant topics for ML applications in population and public health was compiled by SD and SB, based on a review of gray literature, academic publications, current practice reports, and consultations with the study team.

In round 1, this list was refined during three virtual workshops held on November 24, 2022, December 9, 2022, and December 13, 2022. These sessions focused on ethics and equity, technical considerations, and knowledge mobilization. During the workshops, participants assessed draft recommendations using a modified Likert scale and provided written feedback. SB and SD analyzed the quantitative scores and qualitative input to identify consensus and areas of divergence.

In round 2, we circulated the revised draft recommendations to the panel in advance of a follow-up virtual meeting. Panel members discussed the content and submitted additional written feedback. We incorporated these inputs to finalize the recommendations, drawing on frameworks such as GRADE and other relevant guideline development methodologies.

The final recommendations were organized into five thematic categories: (1) equity, diversity, and inclusion; (2) public health emergencies, deidentified population data use, and consent; (3) due diligence during model conceptualization and early development; (4) technical transparency, consistency, and data management; and (5) knowledge mobilization to the public, ML experts, and public health professionals.

Recommendations

Recommendation 1: Prioritize Partnerships and Interventions That Support Communities That Are Disadvantaged by Social and Economic Policies

This includes activities such as algorithmic bias mitigation, capacity building, and fostering equitable representation. Partnerships should not only engage diverse collaborators with expertise in ethical AI and public health but also invest in building local capacity to support sustainable and responsible ML deployment in diverse settings.

ML models may be prone to various types of bias, which can significantly impact the health and well-being of communities made vulnerable by social and economic policies. ML approaches that rely on data from internet searches or social media may lack representativeness, tending to exhibit a bias toward processing data from individuals with higher socioeconomic status, from certain age groups, or those living in urban areas rather than remote or rural areas [6]. Similarly, ML models used in population health often encounter missing or nonrepresentative data when relying on electronic medical records or public health data, which may not fully capture the diversity of the communities they aim to serve [28,29].

XSL•FO
RenderX

Members of diverse community groups, including communities disadvantaged by social and economic policies, bring a variety of perspectives and lived experiences to the table. These perspectives and insights must be actively prioritized in decision-making to identify and mitigate algorithm-related harms effectively [30]. Such experiences are crucial for meaningful research and transformative change within institutions. Expert consultation, while valuable, should not replace the direct involvement of people with lived experience; instead, it should complement it [31]. Unfortunately, those who stand to benefit most from fair and responsible ML applications are also those most at risk of algorithmic harm due to systemic biases and exclusion [32].

Prioritizing equity in ML requires balancing ethical considerations with technical feasibility and real-world implementation challenges. While transparency is critical for trust and accountability, full transparency can be resource intensive and difficult to achieve in low- and middle-income countries (LMICs), where data infrastructure and regulatory oversight may be limited. Similarly, while equity-driven approaches aim to reduce algorithmic harms, they require sustained investment in local expertise, which may not always be immediately available. Feasibility must therefore be considered at each stage, ensuring that solutions are both ethically sound and realistically implementable in diverse public health settings.

In LMICs, where these guidelines are particularly relevant, implementing ML partnerships and equity-focused interventions is often constrained by financial limitations, workforce shortages, and fragmented health data systems. Ensuring that ML applications promote equity while remaining feasible requires balancing ethical considerations with practical constraints. Many public health institutions in LMICs operate with competing priorities, making it challenging to allocate resources solely toward algorithmic transparency, bias mitigation, or extensive auditing processes. Policymakers, health care organizations, and ML developers in these settings must adopt scalable, context-aware approaches that allow for phased implementation. Resource-limited settings can start with standard approaches to data definition and extraction, streamlined documentation, internal monitoring, and bias assessments targeted at high-risk applications where disparities are most pronounced. Furthermore, the literature from LMICs emphasizes the need for tailored implementation approaches. In Africa, for example, ongoing discussions have identified key priorities such as strengthening electricity and internet infrastructure [33], expanding the data science workforce through increased educational opportunities [33], leveraging smartphone-based AI apps [33], and developing AI frameworks that reflect regional needs [34]. In addition, fostering multisectoral partnerships and policy initiatives has been recommended as a way to incentivize and support responsible AI adoption [35].

The trade-offs between transparency, equity, and operational feasibility must also be carefully managed. While transparency fosters trust and accountability, excessive documentation requirements or mandatory external reviews may slow the deployment of ML-driven health interventions, particularly in rapidly evolving crises such as infectious disease outbreaks. In such cases, prioritizing community engagement, establishing advisory panels with representatives from populations considered marginalized, and implementing practical bias mitigation strategies such as integrating socioeconomic variables into model adjustments can ensure ethical safeguards while maintaining efficiency. Flexible regulatory frameworks that accommodate local resource constraints can allow LMICs to adopt ML responsibly without overwhelming already burdened health care infrastructures.

Partnering directly with communities can help address these gaps. This includes building trust, capacity building, and advancing representation [32]. Bias in ML models can stem from various sources, including data collection, label selection, and feature inclusion. Stakeholders from communities considered disadvantaged should be engaged not only to address data biases but also to guide decisions on selecting fair labels and features. For example, using health care expenditure as a proxy for need can introduce bias if spending patterns differ across communities due to economic disparities. Direct involvement of community members can also help identify potential biases in data sources and variables, as well as develop more equitable models. For instance, in the development of predictive models for health care access, community insights can reveal overlooked barriers, such as transport challenges or financial constraints. To mitigate this, ML users should prioritize diverse and representative datasets, monitor error rates and performance levels across different patient groups, and consider the downstream implications (eg, potential impacts on health care access and quality of public health interventions) [32].

True partnership goes beyond consultation; it requires ongoing collaboration and investment in local expertise. Many LMICs and resource-constrained settings lack appropriate safeguards, technical expertise, and infrastructure to implement ML tools effectively. Addressing these gaps requires more than just ethical guidelines. It demands direct investment in skills, resources, and institutional support. Practical strategies to foster capacity building include mentorship programs that connect ML experts in high-income countries with local researchers and policymakers to support training and facilitate knowledge exchange. For example, codeveloping open-access educational resources tailored to public health professionals can help increase AI literacy. Sharing technical resources, such as code and cloud-based computing capacity, can support implementation, provided these efforts are led by LMIC stakeholders. Additional strategies include investing in affordable and scalable ML tools designed for LMICs to ensure usability even with limited infrastructure and fostering partnerships between public health institutions, universities, and community organizations to bridge knowledge gaps. By prioritizing these efforts, ML tools can be developed not only with but also by the communities they aim to serve.

Ultimately, capacity building is a long-term commitment that requires sustained funding, institutional support, and local leadership. While external collaborations provide valuable expertise, true sustainability depends on empowering local communities to take ownership of ML initiatives. This ensures that ML applications in public health are not only effective and

XSL•FO
RenderX

transparent but also grounded in the realities and needs of the populations they serve [36].

Recommendation 2: Use ML in Public Health Emergencies and Other Dynamic, Fast-Paced Situations by Collecting, Analyzing, and Using Population-Wide Deidentified Data

ML can be useful in public health emergencies and other dynamic, fast-paced situations by collecting, analyzing, and using population-wide deidentified data. This process of information gathering and manipulation of deidentified data can be carried out without consent, provided that ethical safeguards are in place and risks related to privacy, misuse, and transparency are actively mitigated.

ML plays a crucial role in gathering, reporting, and analyzing information rapidly, which is vital for mitigating further health damage in dynamic, fast-paced situations such as public health emergencies. According to the United Nations' Sendai framework, reducing disaster risk involves understanding situational risk, strengthening governance, improving preparedness for an effective response, and allocating resources toward measures that can enhance resilience [37]. Prediction models and protocols, such as evacuation planning, have been used to alleviate the adverse effects of such emergencies. ML has greatly enhanced the ability to monitor information and make timely decisions during emergencies. This has enabled disease outbreak prediction, improved evacuation planning, and optimized the distribution of resources to areas in need [27].

During a public health emergency, the rapid collection of deidentified data without consent may be necessary to ensure timely responses. However, this urgency must be balanced with the potential risks of data misuse, privacy breaches, and lack of accountability, particularly in regions with weaker institutional safeguards. In LMICs and other resource-constrained settings, insufficient regulatory oversight may increase the risk of unauthorized access, data exploitation, or reidentification of individuals.

To minimize these risks while maintaining the efficiency of ML-driven public health responses, organizations and governments should adopt structured ethical frameworks that ensure transparency, accountability, and proportionality in data use. Principles such as FAIR (Findable, Accessible, Interoperable, and Reusable) and CARE (Collective Benefit, Authority to Control, Responsibility, and Ethics) offer structured guidelines for ethical data collection and governance and thus can be used in contexts where regulatory oversight is limited. The FAIR principles focus on making health data widely accessible and reusable, which is essential for rapid public health responses while maintaining data integrity and security. The CARE principles, on the other hand, ensure that data collection respects collective benefit and community authority, particularly in Indigenous communities and those considered marginalized, preventing exploitative data use [38]. In addition to regulatory measures, capacity-building efforts should prioritize the establishment of independent data governance bodies within LMICs to oversee ethical ML implementation. Encouraging multistakeholder collaborations, including engagement with civil society organizations and the communities affected, can further enhance accountability. By embedding these safeguards, public health responses can remain rapid and effective without compromising ethical considerations, even in regions with limited regulatory infrastructure.

Similarly, determining whether individuals or populations would be willing to disclose certain information may be complex. Most people and organizations recognize that some degree of data collection without consultation may be necessary. During the COVID-19 pandemic, researchers effectively used deidentified census data to identify high-risk neighborhoods without individual consent [39]. This approach can serve as a model for using public health data during emergencies while adhering to ethical standards. Ethical frameworks related to consent, privacy of information, and their implications for population and public health, as well as crisis management, can help evaluate the ethical feasibility of proposed solutions, even if they do not address all aspects of the current situation. In their development of an ethical data access framework, Lusignan et al [40] outline that structuring collective as well as organizational thinking and decision-making regarding what is and is not appropriate within a crisis early on makes for improved trust between the data providers and recipients, as expectations may be collaboratively set, negotiated, and ideally fulfilled or exceeded. To accelerate the use of deidentified data in public health responses, ethical frameworks should allow faster-access pathways for researchers who can demonstrate secure data handling and infrastructure. This could involve streamlined approvals for projects with proven privacy measures.

Ideally, this process should occur during the interpandemic phase, using inclusive structures and governance models with oversight powers. This process should determine whether the benefits to society, such as reducing long-term loss of life and health, outweigh the trade-offs involving public interest, privacy breaches, and ethical considerations. To ensure the enforcement of these guidelines in real-world scenarios, particularly where regulatory oversight is lacking, we propose several mechanisms. One approach is to integrate these guidelines into existing public health governance structures, ensuring alignment with established ethical and legal frameworks [41]. In addition, public health institutions and regulatory bodies could establish independent review panels to assess compliance with these ML guidelines [42]. Another enforcement mechanism could be the development of accreditation or certification programs for ML applications in public health, which would require adherence to ethical and transparency standards [43].

Recommendation 3: Ensure Fairness Across Populations and Mitigate Bias

The level of bias mitigation should be proportional to the context and potential impact of the model, ensuring that even low-risk applications maintain essential fairness safeguards. All aspects of the model's implementation should be assessed, including inherent, external, or incompletely known factors that could contribute to bias.

Risk assessment is central to any innovation, but it is especially important for ML, which is prone to certain liabilities [44]. The use of algorithms in health care can perpetuate racial biases due

XSL•FO
RenderX

to existing disparities in health care delivery. When designing algorithms to predict health outcomes based on genetic findings, bias may arise if there is limited or no research conducted in certain populations. For instance, using data from the Framingham Heart Study to predict cardiovascular risk in non-White populations has led to biased results, overestimating or underestimating the risk [45].

To clarify how risk relates to bias mitigation, risk should be defined based on the potential for harm or inequity, particularly to populations considered vulnerable, rather than solely on model complexity or scope. Risk assessment should consider the model's intended use, the sensitivity of the outcome (eg, health care access or resource allocation), and the potential for systemic harm if biases are present. Importantly, a lower risk designation should never justify a lax approach to bias mitigation. Instead, risk levels should guide the *type* of mitigation strategies deployed, with simpler models undergoing appropriate fairness checks and more complex, high-impact models requiring comprehensive audits and subgroup analyses.

Given the wide range of ML models, conducting situation-specific risk assessments, especially for populations that may be vulnerable due to social or economic policies, is essential. We need to develop protocols to ensure fairness across diverse populations, using metrics such as subgroup performance, false-positive or false-negative rates, and bias-specific checks (eg, checking for overrepresentation or underrepresentation of particular groups). Transparency should extend to data sources, model methodologies, and decisions made during development. Providing accessible documentation, including technical reports and simplified explanations, can help both technical and nontechnical stakeholders understand potential biases and their mitigation [32]. Transparency should highlight how different populations are represented in training data and how model outputs vary among them. For example, models predicting health care access should clearly show performance disparities between urban and rural populations.

Transparency, explainability, and interpretability of ML models are critical for stakeholder trust and decision-making. Transparency refers to how openly the model's design, data sources, and decision-making processes are shared, helping stakeholders understand how the model operates. Efforts should be made to improve the transparency of models, such as through clear explanations of how inputs influence outputs, visual aids, and plain language summaries. Explainability focuses on making specific predictions understandable, clarifying why a model produced a particular output through methods such as feature importance analysis or decision trees. Interpretability relates to how easily a human can understand the model's internal logic or decision-making process, which is often linked to model simplicity or the use of interpretable techniques such as linear regression or rule-based systems. Altogether, these concepts ensure that ML models are accessible, trustworthy, and accountable to both technical and nontechnical stakeholders.

For example, using interpretable models in clinical settings can help physicians understand and validate AI recommendations, enhancing adoption and reliability. ML is sometimes portrayed as a technology requiring advanced training to understand, leading it to both hopeful expectations and suspicion. It is important to clearly communicate the inherent and associated risks of the model and define what is meant by ML in its context [32]. When ML-related technologies and their risks are explained in plain language, public distrust tends to decrease [46].

Recommendation 4: Ensure Public Availability of Data Sources, Model Methodologies, and Technical Details, Along With Bias Mitigation Strategies, Used in the Contexts of Models to Promote Transparency, Reproducibility, and Trustworthiness Across ML Studies

Providing accessible information about the technical aspects of an ML study or solution, such as its data sources, population, characteristics, and model variables, along with detailed descriptions of its methodology and the deidentified datasets used, supports reproducibility, bias mitigation, and trustworthiness [32]. However, ensuring public availability of data must be balanced with the sensitivity of health data, privacy regulations, and proprietary constraints. To promote meaningful transparency, a structured approach is necessary, one that goes beyond simply sharing code and considers regulatory, ethical, and contextual limitations. Drawing on European Union legislation and literature in computer science, Kiselva and De Hert [47] suggest that transparency must be seen as a fundamental "way of thinking" and an all-encompassing concept that characterizes the process of developing and using AI.

Achieving transparency requires balancing openness with the risks of reidentification, legal restrictions, and proprietary interests. While transparency enhances trust in ML models, full public disclosure of health data is not always feasible due to privacy laws such as the Health Insurance Portability and Accountability Act (HIPAA) and General Data Protection Regulation (GDPR), institutional data-sharing policies, and concerns over commercial confidentiality.

In public health contexts, transparency should function as a system of accountability rather than unrestricted access to all datasets. ML documentation should be structured to ensure usability while maintaining compliance with privacy and proprietary safeguards. This includes providing methodological details and bias mitigation strategies, ensuring that plain language summaries are available for nontechnical stakeholders, and adopting tiered-access models where sensitive data can be reviewed under controlled conditions rather than being made fully public. The need for transparency should also be weighed against the practical barriers to data sharing. Health data often originate from multiple institutions with varying governance policies, making harmonization difficult. In addition, proprietary models developed by industry partners may involve intellectual property protections that restrict full disclosure of methodologies. Addressing these challenges requires the development of standardized documentation and data governance agreements that balance the need for public trust with confidentiality concerns.

To enhance data sharing, transparency, and bias mitigation, dataset development protocols should align with existing

XSL•FO
RenderX

frameworks to integrate new and prior information. Data used for model training, validation, or implementation should be of high quality (eg, completeness, source consistency, and linkage potential) and consistently accessible and updated, especially data related to employment, education, occupation, other socioeconomic status factors, and health inequalities [48]. In applications of linked data and ML in the health sciences (eg, to estimate population-level health indicators), bias can arise from nonstandard data collection methodologies. Developing standardized protocols for all data sources used in each project and including variance assessment and context-appropriate handling (eg, oversampling, imputation) in bias mitigation strategies are essential. For example, in response to bias concerns during the COVID-19 pandemic, ML models were adjusted to incorporate sociodemographic data to improve accuracy in predicting infection spread among populations considered marginalized [49]. Another successful example includes the use of algorithmic audits in health care AI applications, where independent researchers identified and mitigated racial biases in predictive models used for hospital readmission rates [50]. Transparency should include public documentation of these bias mitigation strategies while ensuring that sensitive details remain protected.

Assessing bias and performance across subpopulations is another essential element of responsible transparency. For public health surveillance, sensitivity may be prioritized to avoid missing cases, whereas models used for treatment decisions may emphasize specificity to minimize unnecessary interventions. Metrics such as area under the curve, positive predictive value, and user satisfaction should be evaluated across different subpopulations to detect and correct bias. It is equally important to identify variance in datasets, as high variance can exacerbate bias in ML models. Underfitting, which occurs when a model fails to capture important patterns, and overfitting, where a model becomes hypersensitive to minor fluctuations in data, should be addressed through continuous model tuning and hyperparameter optimization.

In addition to predeployment fairness checks, postdeployment monitoring should include regular performance evaluations across diverse subpopulations to detect bias drift, which can emerge as population characteristics change. Bias drift occurs when the model's predictive performance deteriorates or produces skewed results over time, often reflecting shifts in population demographics or health care access patterns. We also highlight the importance of model update protocols incorporating community feedback loops, participatory audits, and transparent reporting of adjustments to ensure that updates are responsive and equitable.

We recommend that organizations implement structured, iterative audit cycles to support these processes. These cycles should include predeployment fairness checks using simulated population data and postdeployment ethical audits conducted at regular intervals or following significant model updates. In addition, establishing rapid-response mechanisms to address emerging ethical concerns during deployment can help maintain accountability. Incorporating stakeholder feedback from impacted communities through participatory reviews ensures that evaluations remain inclusive and socially responsive.

Recommendation 5: Facilitate Regular, Multidisciplinary Discussions Involving ML Developers, Public Health Professionals, Ethicists, and Community Representatives to Identify Biases, Ensure Fair Implementation, and Increase Transparency

Provide plain language summaries and guidelines that are consistent in terminology to raise awareness among both the public and experts about ML-related bias and debiasing.

Efforts to raise public awareness about ML and its benefits should be balanced with accurate information about potential harms that may be associated with its implementation. In a study by Musbahi et al [51], the views of patients and the public about AI in health care were analyzed. The top 5 concerns included decreased human interaction, data security, obtaining consent for data use, errors in AI systems, and the potential irrelevance of AI in health care. Despite factors promoting the adoption of technology in health care settings, achieving sustainable implementation remains a challenge. Providing information to address individual concerns about the safety and effectiveness of ML models is essential. Public disclosure and scientific interrogation of potentially harmful occurrences or risks associated with ML, including unintentional biases, build trust with the public. Efforts to raise awareness should use accessible language and incorporate research best practices (eg, consistent terminology, structured abstracts, and established reporting guidelines) to make technical concepts easier to understand for a wider audience [46]. This approach not only raises awareness but also fosters trust among nontechnical stakeholders, such as community members and health care practitioners. Past multidisciplinary engagements have proven valuable in addressing bias and transparency concerns in ML applications. For instance, the World Health Organization convened multistakeholder panels to assess AI-based disease surveillance tools, leading to refined ethical guidelines [52]. Similarly, the Canadian AI for Public Health initiative facilitated workshops bringing together data scientists, epidemiologists, and policymakers to discuss bias mitigation strategies in ML-based public health interventions [53]. A structured approach to future engagements could include regular stakeholder summits, interdisciplinary task forces, and community-centered consultations.

Summary

ML is rapidly advancing and holds potential for uses to improve the health of individuals and communities. However, these efforts must prioritize equity. Model developers, statisticians, epidemiologists, public health professionals, policymakers, and funders must collaborate to ensure that ML implementations avoid prejudice and discrimination while also enhancing human capabilities, connections, and knowledge in health and disease contexts. This approach aligns with the ethical integration of AI in health [54].

Our recommendations align with existing frameworks. In the United States, our guidelines support the principles outlined in the Executive Order on Safe, Secure, and Trustworthy AI, which emphasizes the importance of equity, privacy safeguards, and

XSL•FO
RenderX

risk mitigation in health-related AI applications [55]. Similarly, our focus on transparency and bias mitigation aligns with the European Union's AI Act and GDPR, which collectively promote ethical AI deployment, data protection, and algorithmic accountability [56,57]. Our recommendations complement the UK AI Regulatory Principles, which emphasize fairness, accountability, and transparency, particularly in public sector applications [58]. Finally, our guidelines build upon principles from the Pan-Canadian Artificial Intelligence Strategy [59], which highlights equity, interdisciplinarity, and inclusivity as core pillars of responsible AI adoption in public health. These country-specific frameworks emphasize the importance of adapting ethical ML guidelines to regional regulatory and social contexts, while ensuring global alignment on core principles such as equity, transparency, and data privacy. Our recommendations add to these discussions by offering a public health–specific lens, focusing on bias mitigation in population-level models, fostering community partnerships, and emphasizing the impact of social determinants of health in ML implementation.

We had a diverse range of disciplines and approaches represented in our team, including AI, ML, computer science, population health, epidemiology, ethics, and AI applications in health. A limitation of this work was that we have adapted methodologies initially designed for developing clinical practice guidelines, as there is no clear guidance for developing ML applications in population and public health. In LMICs, there might be limited resources available for adequately monitoring and documenting public health interventions that use ML. While our recommendations aim to promote equity and enhance the integration of ML models in LMICs for population and public health purposes, they may not cover all possible use cases. Implementing these guidelines in diverse settings presents several challenges, including variations in data quality, resource availability, and stakeholder engagement. Addressing these challenges is essential to ensure that ML models enhance public health outcomes equitably.

Limitations

Some key limitations include difficulties in engaging communities considered disadvantaged, ensuring data representativeness, and maintaining transparency with limited resources. Operationalizing these recommendations will require adaptable protocols, increased local capacity, and collaborative efforts. For example, developing simplified, context-specific inclusivity checklists and leveraging international partnerships can help overcome resource gaps. Ultimately, ongoing evaluation and stakeholder input are crucial for refining these guidelines and ensuring their effectiveness across varied public health contexts.

Conclusions

Without adequate bias prevention and mitigation during ML model development and implementation, ML applications in population and public health contexts could worsen existing health disparities or even contribute to new ones. Similar to the development of health policy aimed at promoting equity, it is crucial to carefully assess ML innovations before, during, and after their development and deployment. This ensures that model design and delivery are equitable and based on data representing all groups. Achieving equity requires adhering to ethical principles of equity, transparency, and engagement, as well as multidisciplinary efforts involving both model developers and population health practitioners committed to bias prevention and mitigation standards. Monitoring the outcomes of such adherence, including the guidelines proposed here, can promote less biased use of ML to inform policy. Future work should include piloting these guidelines in a range of public health settings, including LMICs, and developing practical tools to assess their effectiveness. Evaluation efforts could involve tracking the diversity of stakeholders involved in model development and testing, measuring improvements in model accuracy for underrepresented groups, and assessing whether decisions based on these models contribute to more equitable health outcomes. Ongoing assessment and adaptation of these guidelines will be crucial for ensuring responsible and fair use of ML in public health. ML is not just a rapidly evolving technology but also a tool that can promote equity in population and public health if a commitment to mitigating bias is maintained by all stakeholders involved in its design and delivery.

Abstract

The US Department of Defense (DoD) is establishing its wastewater surveillance capacities to support national security objectives and promote the public health and medical readiness of US service members. Wastewater surveillance is an emerging technology that has traditionally been leveraged for detecting infectious diseases. However, its potential future applications could yield a vast and unpredictable amount of information that could be used for a wide variety of both health- and nonhealth-related purposes. The US military also serves an inimitable role for the country and its citizens, and exercises significant levels of control over its service members compared to civilian organizations. Further, its present and potential wastewater surveillance activities may reach far beyond just military installations. These factors raise unique ethical considerations that must be accounted for by leaders and policymakers to ensure the DoD implements a wastewater surveillance network in a manner that is both impactful in supporting public health and appropriate to the scope and population under surveillance. This paper explores important ethical features in conducting wastewater surveillance that are both specific to the DoD experience and applicable to wider public health initiatives.

Introduction

Wastewater represents a promising source for obtaining valuable public health data to inform decision-making and response efforts [1]. Wastewater testing includes the tools and technologies used for various activities (eg, research, law enforcement, public health), while wastewater surveillance (WWS) is the activity of assessing biological, chemical, and analyte signatures for determining population-level trends to inform public health decision-making [2-5]. Traditionally, WWS has been leveraged to monitor for select infectious disease pathogens, such as poliovirus and more recently, SARS-CoV-2 during the COVID-19 pandemic [2-4,6]. However, wastewater testing has been used in recent years to detect numerous other targets, ranging from dietary patterns to the genetic makeup of communities [2,3,6-10]. Wastewater surveillance is an appealing public health instrument due to its scalability, cost-effectiveness compared to clinical monitoring, and the ability to detect surges in infectious disease cases, days before they become clinically relevant [11,12]. Recognizing the potential utility and value of WWS, the Centers for Disease Control and Prevention led the development of the National Wastewater Surveillance System. This system allows environmental scientists and public health departments across the country to track specific pathogens, including SARS-CoV-2, influenza A, respiratory syncytial virus, and mpox and report data into the National Wastewater Surveillance System to inform public health decision-making [13]. This system currently collects data from over 1000 sites across the United States, representing 35% of the US population, and it continues to add collaborating sites and other pathogens of public health concern to its surveillance list [13]. There are also plans by researchers and private corporations to further expand the detection capabilities of wastewater testing technologies to include illicit drug use, noncommunicable diseases, genetic information, and other targets. There are meaningful differences in the ethical considerations between wastewater testing and WWS, partly because wastewater testing has broader applications, such as research, law enforcement, and espionage [14,15]. However, this paper focuses on WWS, addressing wastewater testing only as it pertains to WWS as a public health activity.

XSL•FO
RenderX

Recently, the Department of Defense (DoD) has started prioritizing wastewater testing and surveillance, as highlighted in the emerging capabilities and technologies section of the 2023 Biodefense Posture Review [16]. It currently oversees multiple individual WWS projects within the United States and overseas, partners with other government agencies and private industries to explore and expand its wastewater testing technologies, and is building the capacity to develop and manage a DoD WWS network. It has already invested tens of millions of dollars toward advancing its WWS efforts. The DoD plays a distinctive role in ensuring social security and maintains a unique relationship with its ervice members (SM). A DoD WWS network has a potentially vast global scope, covering diverse civilian and military populations [17]. Given (1) the DoD's unique population and security considerations, (2) the rapid evolution and promising applications of wastewater testing technologies, and (3) the significant unknowns regarding the potential future uses of these technologies, there is an urgent need to address the ethical considerations inherent to implementing a WWS network for the DoD. These efforts are imperative to ensure it is executed appropriately and has suitable policies in place for management.

It is critical that environmental scientists, policymakers, and those engaged in WWS must be aware of the current and potential ethical issues related to wastewater testing and surveillance. Policy development, particularly for emerging technologies, must be focused on ethical implications and should aim to provide appropriate guidance and boundaries. This paper explores the ethical features of WWS and offers recommendations to address these concerns— that are important for any group planning to implement a WWS system. While many ethical considerations discussed in this paper are universal to any WWS system, their application within the DoD (whether in identity, scope, or importance) compared to other contexts is unique and deserves particular attention.

Targets of Wastewater Surveillance

The scientific evidence and methodology for wastewater sampling and testing must be established for each pathogen or target under consideration for surveillance. Pursuing large-scale sampling without a sufficient understanding of the target would be both ineffective and an unethical use of resources. For infectious diseases, this might involve pathogen-specific knowledge of (1) sampling and detection methods; (2) laboratory testing, genomic sequencing, and analysis; (3) relationship between detection levels in wastewater and clinical detection in humans; and (4) methods to mitigate the spread of the disease. A key component of conducting ethical public health activities includes ensuring the surveillance and responses to the surveillance findings are done in effective, scientifically sound, and evidence-based ways. The negative opportunity costs of inefficiently utilizing public health funds could harm other health areas where funds could have otherwise been allocated. Addressing this concern should include pilot testing of new pathogen targets or wastewater testing technologies as well as cost-effectiveness analyses prior to full integration into a WWS system [18]. For example, if a pilot project discovered that a new potential feature of the WWS system only marginally reduced infectious disease transmission at a significant cost, then those funds might be better directed to more effective public health activities.

Kass [19] describes an ethical framework for the assessment of public health programs and emphasizes that one of the key aspects of an ethically conducted program includes its effectiveness in achieving the stated goals. Relatedly, monitoring and program evaluation should be incorporated into the workflow of a public health program to ensure alignment with its goals [20]. For WWS, this could involve monitoring to determine whether WWS programs are effective at limiting infectious disease transmission among communities where they are being implemented, compared to those without such programs. Additionally, as WWS technologies and methodologies are developed and refined, efforts should be made to assess for concordance between WWS findings and clinical or on-ground surveillance data. Thus, an ethical WWS program must employ scientifically sound sampling and analysis methods and demonstrate effectiveness in achieving its goals, supported by clinical and epidemiologic evidence.

Currently, most WWS programs are focused on infectious diseases. However, there are other potential targets that have been explored beyond infectious pathogens (eg, noncommunicable diseases such as cardiovascular disease and cancer). While it is difficult to predict what technologies will become available in the future to assess WWS [21,22], many of the core ethical issues at present will remain relevant regardless of the future technological capability. The DoD leadership should be cognizant of preventing excessive mission creep (ie, broadening of the original objective) [23,24]. Using WWS for purposes beyond promoting and preserving health can be dangerous and cause ethically fraught scenarios. For example, while opioids and other substances of abuse (eg, methamphetamines, cocaine, nicotine) could be monitored via WWS, it raises equity concerns and risks of overpolicing [25]. Although the DoD already implements randomized drug screening for its SMs, WWS could introduce additional equity concerns. For instance, many higher-ranking personnel and officers typically live off-base, but the DoD would more accessibly conduct WWS in on-base areas where lower-ranking personnel primarily reside. This disparity might result in military leadership focusing punitive actions on lower-ranking enlisted personnel in an inequitable, unjustified manner, despite the possibility that higher-ranking individuals living off-base might use illicit substances in equal measures but remain undetected. This inequity would be particularly problematic considering that WWS captures all individuals using the sanitation system, including SMs, families, civilian employees, contractors, and visitors. In the future, WWS could also be used to detect medication-related metabolites (eg, reproductive health medications), human genetic content (eg, racial or ethnic composition of communities), and other potentially sensitive or politically contentious targets. It is important to thoughtfully consider what may become possible for WWS capabilities and to ensure that DoD leaders and policymakers remain vigilant in keeping its focus on appropriate health targets and public health–promoting outcomes.

XSL•FO
RenderX

Populations and Areas of Wastewater Surveillance

Where should the DoD focus its wastewater surveillance efforts? This question is practically, legally, and ethically important because there are few areas where WWS could be conducted with only DoD SMs present. Understanding the size and vulnerability of the populations targeted by WWS can influence the interpretation of and responses to the data produced by it [26]. Thus, exploring where the DoD should conduct WWS naturally leads to the question: on whom should the DoD focus its WWS efforts?

On-base DoD locations and DoD transport vessels are obvious areas to focus WWS efforts. Four primary location types can be considered for on-base WWS: (1) facilities, (2) clinics and hospitals, (3) recruit and trainee sites, and (4) housing. On-base DoD locations refer to areas both within the United States and abroad, including permanent international installations and temporary bases established during conflicts. On-base facilities (both medical and nonmedical) and recruit and trainee sites are the least ethically problematic locations, as these areas typically constitute force health protection–relevant activities and have the highest concentration of SMs. While DoD civilian and contractor personnel also work in these areas, conducting WWS at these locations is fully within the DoD's responsibility and legal jurisdiction to support and promote the health of DoD SMs as well as civilian and contractor personnel. Military transport vessels (eg, large aircraft and naval ships) may prove to be particularly important catchment points for sentinel surveillance, especially for tracking the transmission of infectious diseases [27-29].

On-base housing is another force health protection–relevant area, as these are locations where SMs and those closest to them spend most of their off-duty time. An SM's family often lives on-base with them, and the family's health can directly impact the health of SMs and their units. Further, infectious diseases present among SM families are also present among SMs; therefore, conducting surveillance of beneficiaries can better inform the epidemiologic picture of infectious disease prevalence and transmission within military units. Thus, there is a high probability of detecting pathogens of DoD significance in these areas. Moreover, the DoD has a precedent of assuming some fiduciary responsibility for promoting the health and well-being of SM families, through a variety of clinical and social support systems (eg, Tricare health care coverage, paternity/maternity leave policy, education options, free counseling services, housing support, wellness centers). It is also impossible to extricate on-base housing WWS sampling of SMs from family members who live with them. Therefore, it is within the DoD's purview to promote SM families' health, and if the WWS is conducted in a minimally invasive, deidentified, and ethically sound manner, WWS could be a valuable way to further support these health objectives.

The DoD also has a vested interest in WWS abroad; these international locations can be grouped into three categories: (1) joint military exercises, (2) ally military installations, and (3) foreign areas of mutual interest with the host nation. There should be two key underlying requirements for all international locations (beyond DoD installations located abroad): (1) the DoD must obtain the permission of the host nation in which they are guests to conduct WWS and (2) the WWS should provide some benefit to that host nation. Ensuring these criteria are fulfilled will promote an equitable relationship between nations and help avoid exploitative or colonialist interpretations of mutually beneficial public health activities. Another critical consideration for the DoD in conducting international WWS is that the host nation should be empowered to exercise as much sovereign control over the public health activities occurring in its own territory as it sees fit. The DoD and the host nation may both have interests in conducting WWS in certain locations in that country; however, the host nation should decide if and how WWS should proceed. The DoD's role should be supportive, which can manifest in a variety of ways depending on the context and needs of the host nation, including leading the WWS project, funding host nation researchers, providing methodologic input and subject matter expertise, or developing technical and analytical capabilities. Challenges may arise if an ally nation requests WWS support that the DoD is not positioned to support, either on principle or due to resource constraints. International scientific collaborations require agreement from all involved parties. If the DoD does not want to engage, then they are not required to do so, particularly if the DoD has ethical reservations regarding an expansion of the ally nation's surveillance activities to include controversial targets or populations. If the DoD is supportive of the request but is resource constrained, then it can offer support in other ways (eg, technical consultation, references to other potential collaborators). If the foreign nation's request involves surveillance targets that are of importance to them but not of interest to the DoD, then the DoD can consider offering low-cost support (eg, information, consultation) in the spirit of preserving and strengthening the relationship. Generally, approaching host nations from the perspective of support, providing the host nation opportunities to lead decision-making, and emphasizing the mutually beneficial aspects of the collaboration will support an equitable partnership.

Joint military exercises serve as collaborative training opportunities for two or more militaries to build cohesiveness, promote mission readiness, and grow camaraderie among allies. In such scenarios, it is acceptable for either the DoD or other militaries to lead WWS efforts, provided all the participating militaries whose wastewater is sampled endorse their permission for WWS to be conducted during the exercise, and for the data to be shared with the sampled parties that participated, if requested. This practice supports the participating military's autonomy by providing an opportunity for group informed consent, whereby a nation's military can provide permission or denial for participation of its SMs. For WWS at ally military health care facilities and installations, it is appropriate for the ally nation's military to lead, with the DoD providing support these efforts as defined by what is agreed upon between the two militaries. The flow of data should be bidirectional and beneficial for both parties for the endeavor to be equitable. For international civilian settings, such as health care facilities, the ally nation's relevant health organizations (eg, ministries of health, health research institutes) should serve as key partners,

XSL•FO
RenderX

and the DoD should support and coordinate with them in the conduct of the surveillance and sharing of data. The host nation's organization should make efforts to ensure awareness of WWS efforts within the communities involved, especially in specific locations such as health care facilities, and that the facility's leadership is aware, and approves of the WWS.

Management of Wastewater Surveillance Data

Once the WWS has been conducted, how should data be managed? The DoD faces important ethical considerations regarding the type of data to be collected and its management. A balance must be struck between allowing beneficial data access and ensuring data protection. WWS can generate a variety of data, including molecular and biological signatures, health and disease markers, biochemical indicators of illicit activities, and associated identifiable demographic metadata [17]. While possessing large amounts of data is typically beneficial for determining appropriate responses, course of actions, and preventive planning, protecting these data is crucial, especially as the DoD arguably experiences more frequent and powerful attacks on its information security infrastructure compared to other organizations. Therefore, managing the focus on which data to protect (eg, personally identifiable information vs aggregate data) and how to protect it (eg, cloud or servers vs hardline firewalls) will be crucial for ensuring minimized risk of data weaponization or leakage. Wastewater surveillance can produce highly granular data that can be used by public health researchers and officials for improving the quality of the communities they serve; however, this level of detail is not always essential when communicating with end users. Establishment of well-defined data-sharing agreements which incorporate ethical guidelines and treat WWS data with the same scrutiny as Controlled Unclassified Information or Classified determinations, wherein raw information sharing is conducted only as needed, will aid in reducing improper use of WWS information. Data security can be handled in a similar manner by escalating access and storage restrictions corresponding to data aggregation and specificity. For instance, aggregated, community-level detection data of public health targets could be stored on shared drives with minimal restrictions; however, individual molecular and genetic data could be stored behind hardline firewalls on dedicated IT systems. Anonymization and the use of beacons are additional potential methods that could help in ensuring individual human subjects cannot be identified by WWS; however, both methods have their inherent limitations [30]. Nonetheless, it is likely that data security approaches will not lend to one size fits all solutions and will be dictated by the surveillance effort, parties involved, and required outcomes. The DoD must take strong measures to ensure only authorized personnel access appropriate levels of WWS data.

As WWS data becomes more granular and specific, the ethical responsibility to ensure data security and appropriate use and access increases proportionally. This escalation of responsibility in proportion to the level of granularity of the data is derived from the increasing probability of it being personalized and potentially damaging to individuals or small groups. For example, depending on where the wastewater is sampled, it could be possible to pinpoint illicit drug use or the location of an individual to a specific household. In fact, analyzing local sewage for genetic markers was one of the methods potentially used by the United States to confirm Osama bin Laden's location prior to him being killed in 2011 [15]. It may also become possible in the future to obtain personal genetic information through WWS and to associate it with personally identifiable information; the DoD must be prepared to either dispose or strongly protect this data. There are significant risks if foreign adversaries gain access to this level of data, as well as real concerns regarding how this information could be misused domestically in politically motivated ways. One way to combat these concerns is to establish clear sampling strategies with requirements to destroy unused sample portions once the appropriate predetermined targets have been tested or detected.

There are also important considerations regarding the sharing of WWS data when it has broader implications beyond the DoD, and is relevant to other public health entities, such as US government groups (eg, local health departments, the Centers for Disease Control and Prevention), ally nations, or nongovernmental organizations (eg, the Bill and Melinda Gates Foundation). There are certain ethical responsibilities in the sharing of appropriate levels of data when it can also be of benefit to others, and the DoD should take steps to collaborate with these groups to promote health security. Thus, taking all these considerations into account, one overarching goal for a DoD WWS network is to ensure the data is maintained at an aggregate level as much as possible for monitoring of community and population-level trends rather than specific information on individuals or small groups.

Utilization and Response to Wastewater Surveillance Data

Public health surveillance data should not be collected unless there is a potential for a meaningful and actionable response. If surveillance findings are not translated to public health action or policy changes, the benefits accrued from the surveillance efforts are minimal [31]. Collecting data only for the sake of collection is an inappropriate use of resources; therefore, there should be focused and organized plans in place for using the WWS systems and information derived from them prior to their implementation. Additionally, there should be rigorous discussions about how military leaders and public health officials respond to such information as it becomes available to them. There are innumerable ways in which the leadership could respond to WWS data when it is received in near real-time. While this information offers an opportunity to ethically use that data, there is a risk of inappropriate response to it [32]. Notably, military commanders make the final decisions regarding public health actions or interventions, particularly those of consequence. It is likely that a medical or public health professional will not be making the decision, and the military commander may have no background in science, medicine, or public health. While making the intervention decisions in response to WWS data, these commanders and

XSL•FO
RenderX

their leadership teams should lean heavily upon the expert advice of medical and public health professionals to inform their decisions to help ensure they take the most appropriate actions. The key consideration here is that the responses—whether determined by military command or leadership from preventive medicine, public health, or clinical groups—should be appropriate, proportional, and context- and community-specific based on the information received through the WWS system.

General Ethical Considerations

Finally, there are unique ethical considerations for the DoD that civilian organizations do not necessarily face to the same extent. The military has substantial authority, control, and access over the lives of its SMs. It can dictate aspects ranging from what to wear, where to live, how to behave, and nearly every aspect of SMs' lives. Given the extent of this control and its durability and depth, the DoD has an elevated ethical responsibility toward the health and well-being of its SMs [33]. Further, there is a public health ethics principle, which argues that a public health program should use the least invasive or minimally burdensome (to the population being targeted by the program) methods to accomplish its goals [16,34]. Service members already forgo significant autonomy afforded to civilians; therefore, any public health program that might additionally strip away their autonomy must be seriously deliberated before implementation. Although WWS may not directly interfere with the lives of SMs while the data is collected, the actions related to WWS (eg, how leadership responds to the information, what data is collected, and how the data is managed) could infringe upon their privacy and autonomy. However, if conducted appropriately, the potential health benefits for the SMs would likely outweigh minor privacy or autonomy concerns. Additionally, the implications extend beyond military populations when considering the health of SMs. The mission of the DoD and SMs is to protect US citizens, interests, and national security. If SMs are unwell, experience disease outbreaks, or are targeted using bioweapons, it places the country at risk, as they will be less able to support their security objectives by failing to achieve optimal operational capabilities and mission readiness. Furthermore, SMs and military installations do not exist in isolation. If an infectious disease emerges among a military population in a certain area, it is likely there is a similar problem in the surrounding civilian community, or at least presents a risk to them. Therefore, these considerations add to the elevated responsibility of the DoD to support and promote the health of its SMs.

There are also several broad ethical considerations for how the DoD conducts WWS. There is a tension underlying many public health actions, between preserving personal freedom and autonomy of individuals and maximizing the public health benefits for the group. This tension is manifested in several ways, including the amount and types of data to be collected, proportionality and appropriateness of response to the data, level of invasiveness of the surveillance, populations, and areas selected for surveillance [35,36]. DoD leadership should balance protecting the freedom and autonomy of its SMs while also prioritizing the health of the force from a population perspective [33]. Additional resources providing ethical guidance for the operation of public health surveillance systems that are applicable for WWS are available from the American Public Health Association's Public Health Code of Ethics and the World Health Organization's Guidelines on Ethical Issues in Public Health Surveillance [34,37].

Justice is another key ethical concept, and when appraising a DoD WWS program, two relevant perspectives must be considered: (1) distributive justice and (2) procedural justice. Distributive justice is an ethical principle concerned with the fair distribution of benefits and burdens. In the DoD WWS context, it involves ensuring that the distribution of resources, outcomes, and interventions based on the surveillance findings is done in an equitable way (eg, distributing vaccines based on WWS findings of acute elevations in vaccine-preventable diseases). It also includes the fair distribution of resources for conducting WWS throughout the United States and international installations. Procedural justice is an ethical principle concerned with fair processes and methods. It includes features such as inclusion, transparency, neutrality, respect, and trust [38]. For DoD WWS, it might involve transparent communications and decision-making, community considerations, stakeholder participation, access to relevant data for the surveilled communities, among others.

There are a variety of other general ethical considerations that are applicable to WWS, which are briefly mentioned here and should be explored further. First, there are differences between conducting public health surveillance versus research and the varying regulatory, oversight, and ethical requirements. Second, there may be differences in what actions are permissible when considering baseline surveillance versus those needed during public health emergencies. Finally, there are inevitable future possibilities beyond our current capabilities or knowledge regarding what might become possible through conducting WWS. What might WWS be capable of in the future, and how do we anticipate and plan for that? Although there are myriad ethical considerations for the appropriate conduct of WWS by the DoD both currently and in the future, it is undoubtedly a burgeoning area of public health that the DoD should pursue and be engaged in a substantial, effective, and meaningful manner, as there are innumerable potential benefits to a DoD WWS network.

Conclusions

Wastewater surveillance offers tremendous promise and opportunities to advance public health by enhancing disease surveillance, informing public health and clinical decision-making, and improving public health response times to mitigate negative health impacts to populations [39,40]. The DoD should adopt WWS and position itself to take advantage of the current and potential future benefits. It should also recognize the practical and ethical differences between using wastewater testing for public health surveillance, research, or other potential military purposes. With over 1.3 million active-duty SMs, 1.1 million National Guard and Reserve members, and 700,000 civilian personnel, the DoD is the largest organization in the United States, and has responsibilities to their health and readiness [41]. Further, the Military Health

XSL•FO
RenderX

System serves a total of approximately 9.5 million beneficiaries, which includes both SMs and their families [42]. WWS has the potential to benefit not only these populations, but others in the United States and overseas as well. However, these opportunities also present a potential for misuse, which could be detrimental to those being surveilled, raising important ethical questions about how and why WWS should be conducted. The DoD also has elevated ethical obligations to the well-being of its SMs due to the breadth and depth of control it exercises over them. Although ethical issues may arise related to WWS, these issues can and should be addressed through proper deliberation and policy implementation, as the potential public health benefits could be substantial. The DoD has responsibilities to protecting the national security of its citizens broadly, which implies a crucial role in infectious disease surveillance for outbreaks as well as bioengineered and emerging pathogen threats. Therefore, the DoD should pursue wastewater surveillance in an ethically appropriate, scientifically robust, and thoughtfully planned and executed manner to guide public health decision-making, protect the well-being of its SMs, and support US government health security objectives.

Abstract

The COVID-19 pandemic proved how sharing of genomic sequences in a timely manner, as well as early detection and surveillance of variants and characterization of their clinical impacts, helped to inform public health responses. However, the area of (re)emerging infectious diseases and our global connectivity require interdisciplinary collaborations to happen at local, national and international levels and connecting data to understand the linkages between all factors involved. Here, we describe experiences and lessons learned from a COVID-19 pilot study aimed at developing a model for storage and sharing linked laboratory data and clinical-epidemiological data using European open science infrastructure. We provide insights into the barriers and complexities of internationally sharing linked, complex cohort datasets from opportunistic studies for connected data analyses. An analytical timeline of events, describing key actions and delays in the execution of the pilot, and a critical path, defining steps in the process of internationally sharing a linked cohort dataset are included. The pilot showed how building on existing infrastructure that had previously been developed within the European Nucleotide Archive at the European Molecular Biology Laboratory-European Bioinformatics Institute for pathogen genomics data sharing, allowed the rapid development of connected “data hubs.” These data hubs were required to link human clinical-epidemiological data under controlled access with open high dimensional laboratory data, under FAIR (Findable, Accessible, Interoperable, Reusable) principles. Based on our own experiences, we call for action and make recommendations to support and to improve data sharing for outbreak preparedness and response.

data sharing; data management; open science; COVID-19; emerging infectious disease; global health

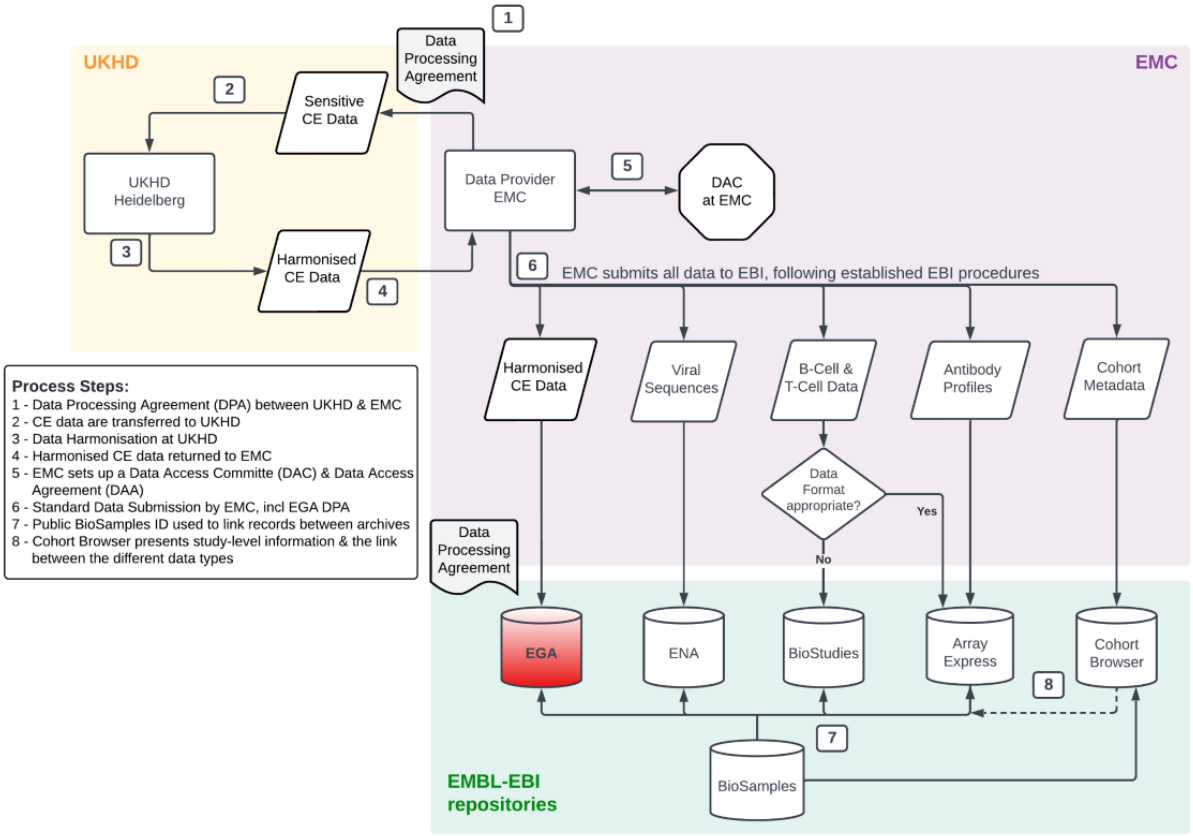
Introduction

The COVID-19 pandemic proved in a real-case scenario how rapid FAIR (Findable, Accessible, Interoperable, Reusable) [1] sequence data sharing was used to inform public health response policies [2]. An international collaboration, the Reconciliation of Cohort data in Infectious Diseases (ReCoDID) [3], a 4-year project that began in January 2019, was funded by the European Commission’s Horizon 2020 programme with a focus on the global response to emerging pathogens. Building on existing infrastructures and partnerships, the consortium was funded to develop a sustainable model for the storage, curation, and analyses of complex datasets collected from infectious disease related cohorts to facilitate and speed up outbreak research. In 2020, a pilot study was developed within this project using COVID-19 data from Erasmus Medical Center (Erasmus MC) as a use-case. The incentive was that in an ongoing global COVID-19 pandemic, linking data for connected data analysis with the potential to better understand the disease would be of public interest and of public health importance. The aim of the pilot was to test the potential for sharing linked laboratory data and clinical-epidemiological (CE) data in the evolving European infrastructure for open science in a centralized model. The centralized model, as opposed to a decentralized or federated data sharing model, was chosen for this pilot because we wanted to build on existing infrastructure [4,5]. The model has the

XSL•FO
RenderX

potential of hosting and curation of large datasets, the benefit of standardized data input and output leading to interoperability, easing re-analysis by others necessary for improved prediction and preparedness on global, EU and national level, as was needed for a newly emerged outbreak. A decentralized or federated data sharing model has the benefit of not needing to move the data, but the consequences often manifest themselves in no sharing or limited sharing and linking of datasets, difficulty to apply federated data analyses across a wide range of data formats and sources, with predictions and preparedness happening more at local or regional level. Given the diversity of datasets and the complexity of sharing data from clinical research and in line with the rapidly evolving situation during the COVID-19 pandemic, we wanted to learn what it would take to release linked data from opportunistic studies, rather than pre-approved cohort data.

Here, we describe experiences and lessons learned from this pilot, providing insights into the complexities of internationally sharing linked, cohort datasets for connected data analyses.



Pilot Set Up

The following sections have references to the timeline (Multimedia Appendix 1) in which the steps taken to set up and complete a pilot with a small but complex, linked dataset from opportunistic COVID-19 clinical and laboratory research studies as done in (academic) hospital settings are shown. We divided these steps into the following categories: data identification and acquisition, ethics and legal requirements (data protection), data harmonization, and data storage and delivery. Starting in November 2020, meetings took place with basic researchers and clinical scientists who had generated COVID-19 data as part of pandemic related research [6,7]. The drafted data map illustrated how complex the seemingly “simple” datasets (clinical, genomic, pathogen genomic, and high-dimensional laboratory) were. Different data sharing rules and governance for different parts of the datasets existed, and different identifiers and platforms for data capture and storage had been used. It became apparent that these procedures were not unique to COVID-19 pandemic and were common practice at the hospital. Finally, after a further meeting with the involved scientists to discuss datasets that could be linked in a pilot, a small cohort of 151 patients (intensive care unit and non–intensive care unit) who had tested SARS-CoV-2 positive (reverse transcription polymerase chain reaction) between May 2020 and May 2021 was selected for inclusion in the pilot, for whom several data types were partially available, including SARS-CoV-2 viral whole genomes, protein-microarray serological readouts, T- and B-cell data as well as CE data (data identification and acquisition).

Due to the extensive legal discussions around data sharing (ethics and legal requirements), the implementation of the long-term model of the ReCoDID data workflow was brought to a standstill (see “Enablers and Barriers Affecting the Execution of the Pilot”). Therefore, a slightly deviated dataflow model for the pilot was agreed on. The deviation was solely focused on CE data and meant that instead of Heidelberg University Hospital (UKHD) transferring harmonized CE data directly to the European Genome-Phenome Archive (European Molecular Biology Laboratory-European Bioinformatics Institute [EMBL-EBI]), the harmonized CE data were transferred back from UKHD to Erasmus MC, and Erasmus MC carried out the CE data submission to the European Genome-Phenome Archive, including a further data processing agreement (Figure 1). This change was necessary to circumvent one of the barriers (”Adherence to GDPR, and differences in its interpretation” in Table 1) and to move forward with the pilot and to facilitate the development of the connected datasets platform. Furthermore, the Erasmus MC’s legal and privacy offices and the institute’s COVID-19 clinical database team (established in June 2020) were contacted to discuss the aim of the pilot, the access procedures to the CE data, as well as all other steps and legal requirements for sharing the CE data internationally. For this purpose, a Data Protection Impact Assessment was carried out. A data access request for CE data though the Erasmus MC’s COVID-19 clinical database was also required (ethics and legal requirements).

Figure 1. Overview of Erasmus Medical Center (EMC)'s pilot dataflow, linkage and presentation for EMC's connected dataset pilot. The roles of the participating institutes within this pilot were as follows. EMC: mobilization and consolidation of the datasets (data identification and acquisition) by the EMC team at the source within EMC, participant-level and derived BioSample record registration to include metadata about biological samples, linking and submission of all data to repositories within the European Molecular Biology Laboratory-European Bioinformatics Institute (EMBL-EBI) infrastructure including deposition of clinical-epidemiological (CE) data under controlled access at European Genome-Phenome (EGA), depositions of viral sequences at the European Nucleotide Archive (ENA), B-cell and T-cell data, as well as antibody profiles at BioStudies and ArrayExpress repositories, respectively, and setting up a data access committee (DAC) and data access agreement (DAA) (data storage and delivery); University Hospital Heidelberg (UKHD): harmonization of the CE data and data dictionary at UKHD according to international standards (data harmonization); EMBL-EBI: provided the process for data linking on a participant level, including linking of the CE data to omics data types, using the hierarchical BioSamples database model and presentation of EMC's cohort study in the Reconciliation of Cohort data in Infectious Diseases Cohort Browser (data storage and delivery). All steps taken in this process (numbered arrows) are also numbered in the key entitled "Process Steps."

Table . Enablers and barriers that affected the Erasmus Medical Center (Erasmus MC) pilot's execution.

Description of enablers and barriers	Stakeholders	Category of actions
Enabler Description		
Active support from legal advisors or GDPR[a] specialists. Navigating the complexity of regulations governing data sharing, such as the GDPR, and to apply these accordingly, requires expert privacy and legal knowledge. The active support from legal or GDPR specialists was therefore pivotal in defining the process of dataflow within ReCoDID[b].	Academic hospitals or institutes	Ethics and legal requirements
Building forward on existing infrastructure for sharing (biomedical) data, allowed the rapid development of the connected data hubs to include controlled access sensitive data for/in this pilot.	Researchers; European Union and national funding agencies	Data storage and delivery
Building forward on existing collaborations, as developed in ReCoDID and COMPARE (Collaborative Management Platform for Detection and Analyses of (Re)emerging and Foodborne Outbreaks in Europe) [8], facilitated the steps in the pilot and helped to further build trust necessary for data sharing between participants. The collaboration between the data provider or controller (Erasmus MC) and the respective EMBL-EBI[c] repositories, as well as between the EMBL-EBI repositories, was needed in this pilot to drive further developments and to extend the existing infrastructures to host and present connected datasets.	Researchers; European Union and national funding agencies	All
Dedicated data scientist championing the pilot. Acquiring data from different sources and systems and collected by various specialist teams, linking such data, and ensuring the (legal) requirements are fulfilled before sharing such data, is cumbersome and time-consuming. A dedicated data scientist, supported by encouragement and advocacy of the principal investigator for data sharing amongst researchers, ensured the pilot kept moving ahead.	Academic hospitals or institutes	All
Barrier Description		
Adhering to GDPR, and differences in its interpretation. The data workflow gave rise to legal issues in the context of the GDPR, with regards to GDPR roles (eg, controller vs processor), potential liabilities, different interpretations of Article 49 (d) (Derogations for specific situations, important reasons of public interest), also in regard to the transfer of data to international organizations (here: EMBL-EBI), and resulted in long-lasting legal discussions to define the process of dataflow within ReCoDID.	European Union and national governments; supervisory authorities[d]	Ethics and legal requirements

XSL•FO
RenderX

Description of enablers and barriers	Stakeholders	Category of actions
Insufficient FAIRification[e] and sharing of initial data. Lack of both mandatory FAIRification and sharing rules and specialized staff in inter-pandemic times led to a situation during the pandemic, when time and resources were naturally scarce, often differently prioritized and competing priorities existed, where FAIRification and data sharing was not the main priority. This also led to a situation where harmonization of CE[f] data according to international standards (WHO-ISARIC[g] format) [9] was delayed or not completed.	Academic hospitals or institutes; researchers; European Union and national funding agencies	Data identification and acquisition; data storage and delivery
Insufficient interoperability of the data. Establishing linkages between CE data and corresponding high-dimensional lab data was challenging, and the availability of overlapping data types was limited. Various identifiers were used for CE data and derived high-dimensional laboratory data, and metadata was not fully harmonized, making it difficult to establish linkages. Furthermore, as high-dimensional data types were generated in separately funded projects, a limited amount of overlap in high-dimensional data types existed for the patients.	Academic hospitals or institutes; researchers; European Union and national funding agencies	Data identification and acquisition
Issues contributing to difficulty in CE data acquisition		

XSL•FO
RenderX

Description of enablers and barriers	Stakeholders	Category of actions
• Competing priorities: there was a plethora of clinical studies to be entered into the institute's COVID-19 clinical database. Consequently, there were difficulties in getting approval for prioritization of data entry and data access for this project. Finally, over time there was a reduced interest with decreasing burden of COVID-19 in completing the data entry of CE data. • Time consuming and resource intensive handling and storage of CE data: CE data was stored at different specialized hospital health record systems, that allowed only partial automation of data entry into the institute's COVID-19 clinical database, and records needed to be administered individually. During a time when clinical services were overburdened with COVID-19 cases this resulted in a backlog of CE data that needed to be entered into the institute's database. • Discontinued institutional funding and support for its COVID-19 clinical database: after one year (in 2021), the database was discontinued and subsequently placed under different management. This delay also meant that additional requirements, eg, related to data protection and ethics, had to be met before CE data could be accessed and shared.	Academic hospitals or institutes	Data identification and acquisition

[a]GDPR: General Data Protection Regulation.

[b]ReCoDID: Reconciliation of Cohort data in Infectious Diseases.

[c]EMBL-EBI: European Molecular Biology Laboratory-European Bioinformatics Institute.

[d]The supervisory authorities (barrier "Adhering to GDPR, and difference in its interpretation") refer to the independent public authorities in each Member State responsible for monitoring the application of the GDPR.

[e]FAIR: Findable, Accessible, Interoperable, Reusable.

[f]CE: clinical-epidemiological.

[g]WHO-ISARIC: World Health Organization-International Severe Acute Respiratory and emerging Infection Consortium.

Linking of Different Data Types

At the time of conducting this pilot, submission of SARS-CoV-2 viral genomes to repositories such as EMBL-EBI's European Nucleotide Archive (for raw sequences) and GISAID [10] (for consensus sequences) was done routinely, other laboratory datasets (protein-microarrays, T- and B-cell data) were not shared. To link SARS-CoV-2 genomes to the other datasets a check was done to verify whether viral genomes had been submitted from the 151 individuals. This exercise required iterative rounds of mapping 4 different identifiers. The internal mapping exercise further revealed the partiality of all other datasets for the individuals included in this cohort. Serum antibody profiles generated using protein-microarrays were available for 40 patients, T-cell phenotype and reactivity data for 28 patients and clonal antibody cross-reactivity data using B-cell profiling for 17 patients out of 151 selected patients in the cohort. For 7 patients out of 151 all data types were available.

Configuration of Data Infrastructure and Data Delivery

With the exception of the viral genomes that were routinely submitted to known repositories (refer to "Linking of different data types" section), for storage and linkage of the dataset it was needed to identify suitable respositories for all other laboratory datasets. This meant establishing where new pilot data types could be hosted, and how the EMBL-EBI system could be leveraged to link all pilot datasets within the EMBL-EBI system, so that the datasets could be eventually also "presented" through a Cohort browser [11]. Although the EMBL-EBI repositories were not fully designed to host one of our data types (T-cell) it was possible to submit the outputs with some adjustments to the format as proof of concept. This leaves room for discussion between the respective researchers and the EMBL-EBI to allow for a more routine application.

The upload of the last Erasmus MC pilot datasets was completed in November 2022. To link all datasets EMBL-EBI's BioSample database [12] was used with a hierarchical model allowing

XSL•FO
RenderX

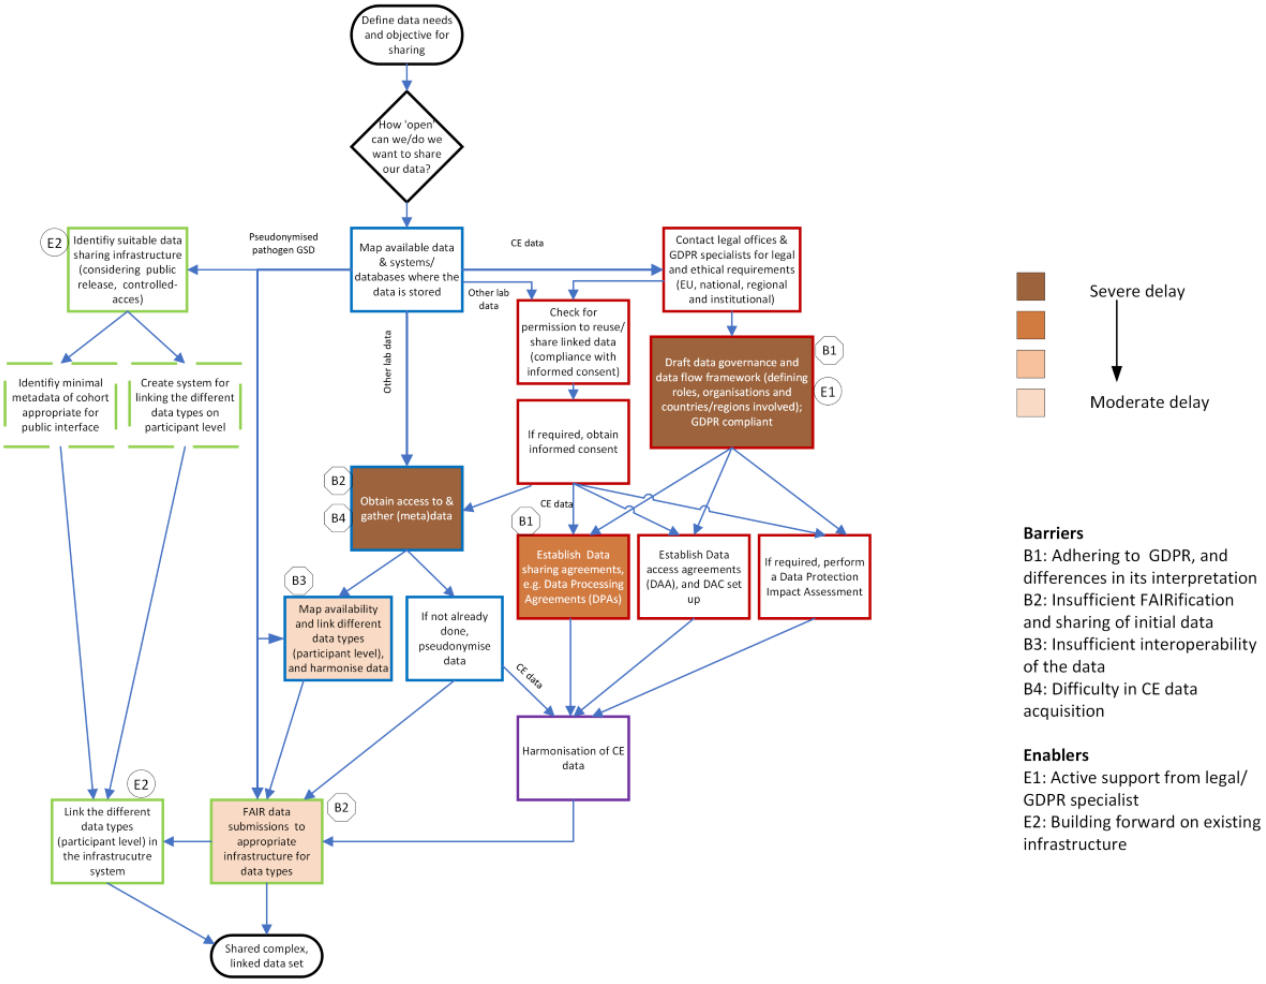
linkage between individuals and their derived samples. With the completion of linking all data types on participant level and presentation of all datasets through the Cohort browser, the pilot was considered as completed (data storage and delivery) in December 2022 [13]. Study level metadata and links to the datasets in the corresponding repositories can be accessed through the Cohort browser and the BioSamples browser at EMBL-EBI [14].

Enablers and Barriers Affecting the Execution of the Pilot

Several enablers and barriers were identified that either facilitated or hampered the execution of this pilot, respectively (Table 1). The main category of actions affected by these barriers and enablers was also identified, as well as the main stakeholder(s) to influence the enablers and barriers.

Several barriers significantly delayed the sharing of a linked dataset in this pilot. The barriers associated with complying with ethics and legal requirements, and with data identification and acquisition, caused the most evidential delays. Some of these barriers tended to reinforce each other, particularly due to shared underlying issues, such as the siloed nature of clinical and complex laboratory data collection and storage. At the start of the pilot, CE data was in different hospital systems, and not yet integrated into the (newly established) institute's database for COVID-19 patient related CE data ("Issues contributing to difficulty in CE data acquisition" in Table 1). Derived high dimensional laboratory data was stored in different systems, separate from patient and diagnostic databases ("Insufficient FAIRification and sharing of initial data"). This was a result of data being gathered by multiple different specialist teams, often for separately funded projects, as well as the lack of linked data infrastructures capturing both patient and (raw) laboratory data, which is typical for hospital systems. Furthermore, the COVID-19 pandemic was characterized by a fragmented funding landscape. Many projects were funded, often focusing on a specific research question or field, thereby reinforcing the siloed nature of specialist teams' work. In addition, for each of these projects, patient sample materials were needed (eg, swabs, blood, and serum). Consequently, high-dimensional lab data were generated for only a subset of patients, based on availability of sample material and requirements of the specific research topic ("Insufficient interoperability of the data").

Interestingly, the newly established institute's COVID-19 clinical database could have in principle worked as an enabler for data sharing. It was designed with the aim for CE data to be collected, stored and retrieved from one central database, and potentially address the issue of CE data being siloed in different existing hospital IT systems and databases and improve the FAIR aspects of such data. Yet, a variety of issues, described in Table 1, caused significant delays in CE data acquisition and sharing.



Several factors contributed to or facilitated the sharing of a linked dataset in this pilot, which showed the willingness of the involved teams to overcome the barriers in the sharing of a complex, linked dataset.

Critical Path for Sharing a Complex, Linked Dataset

The critical path analysis (Figure 2) defined the steps in the process of sharing a complex, linked cohort dataset, showing the necessary order of steps or tasks to complete the submission and sharing of such datasets through an appropriate infrastructure, based on our pilot experiences. These steps were classified into the same 4 categories of actions introduced above, data identification and acquisition (4 steps), ethics and legal requirements (7 steps), external data harmonization (1 step), and data storage and delivery (5 steps). Most of the steps in this process could be worked on concurrently, depending on the availability of resources (eg, time of legal staff; availability of appropriate, and standardized templates). As shown in Figure 2, pathogen genetic sequence data (GSD) required a minimum number of steps (1 step), followed by other laboratory data (6 steps), whereas CE data required at least 10 steps. This also corresponds to the time for completion of all steps for each data type in our pilot, with the least amount of time for pathogen GSD. Figure 2 also shows how the identified barriers and enablers affected the process for this pilot.

XSL•FO
RenderX

Figure 2. Critical path for sharing a complex, linked dataset. Two rounded boxes mark the start and endpoint; the diamond box represents a decision. Steps were classified into 4 categories of actions (color coding corresponds to timeline): data identification and acquisition (4 steps, shown in text boxes with blue margins), ethics and legal requirements (7 steps, shown in red), external data harmonization (1 step, shown in purple), and data storage and delivery (5 steps, shown in green). Dashed green boxes represent steps that were needed for this first pilot to build the system (European Molecular Biology Laboratory-European Bioinformatics Institute). Different types of data required different steps in this process, as shown for pseudonymized pathogen genetic sequence data (GSD), other laboratory datasets (other lab data), and clinical-epidemiological (CE) data. The identified barriers and enablers are indicated at the specific steps in the process that were mainly affected for our pilot; 2 enablers are not shown as these did not affect specific steps but acted as general facilitators of this process for our pilot. DAC: data access committee; EU: European Union; FAIR: Findable, Accessible, Interoperable, Reusable; GDPR: General Data Protection Regulation;

Mission (Im)possible: A Call for Action

The pilot demonstrated that sharing a linked cohort dataset using a centralized approach can succeed, but several crucial barriers (as described in Table 1) exist that cause long delays. Although these barriers were not unique to COVID-19 pandemic and have been extensively described previously [15-17], they persist today, as currently the burden to overcome or circumvent such barriers is placed on the individual researchers, projects, or institutes. However, the root causes of these barriers are systemic in nature. To alleviate these barriers, stakeholders at institutional, national and international or EU level (eg, governments, health care, research, journals, funders, and legal) need to work jointly toward building a model that not only supports but motivates data exchange by simplifying steps in the process of data sharing, taking privacy and legal aspects into account, and to reward researchers in new ways [18]. Below we describe some immediate actions to achieve this based on our experiences.

Support With Privacy Questions and General Data Protection Regulation

We recommend creating a roadmap amongst EU countries for how to deal with common issues, to avoid (recurrent) lengthy legal discussions. Harmonization of regional and national implementation of GDPR, and alleviation of the disproportionate burden in legal compliance activities for data sharing with international organizations, needs to be achieved [19]. Finally, additional support should be provided by the European Union to their funded projects, for example, by providing legal guidance or a top up for projects to hire legal experts.

Build and maintain FAIR Data Sharing During "Interpandemics"

Mandatory FAIRification of data in funded projects with funding for personnel to build and maintain FAIR data collections and FAIR sharing, and monitoring of and consequences for noncompliance. At the same time, more data repositories submitting to evaluation-based initiatives and accreditation

XSL•FO
RenderX

processes [20-22], could help with a cultural change toward more FAIR data sharing. Furthermore, FAIRification and sharing of data should become standard practice during the education of bachelor, master, and PhD students.

Decrease Fragmented Funding Landscape

Consideration for funding interdisciplinary projects to enable combined data sharing and, continued funding support for existing data infrastructures is key to sustaining the efforts of data FAIRification and sharing, both nationally and internationally. One clear example is the COVID-19 open data portal [23], an initiative launched at the explicit wish from the European Commission. It provides access to open data from a range of areas of expertise for use across sciences (biomedical and social sciences). A second example is the newly launched World Health Organization (WHO) pandemic hub, to develop "collaborative surveillance," a new area that seeks to bring together data collected by different areas of expertise. This includes the classical epidemiological data that are the core of public health surveillance, but also data on climate parameters, and data on factors that influence disease dynamics.

Willingness and Commitment Building (Culture Change)

We call for establishment of a common policy about data sharing allowing culture change at the EU or international level and for provision of resources to do so. One way of supporting culture change can be achieved by reflecting how researchers are recognized, rewarded, or assessed beyond publishing results in a journal. On short term, acknowledging data providers when reusing their datasets, and the use of citable data Digital Object Identifiers (DOI) pointing to their data could help (eg, as used for one of the datasets used in this pilot [24]). At institutional level, common policies about data sharing should also be established, and resources provided to implement these, to improve existing sharing norms and cultures.

Standardization and Interoperability

Institutes need to prioritize standardization or reconciliation of existing databases and systems to tackle data siloes. Overarching infrastructures at University Hospitals that would allow and enhance standardization, harmonization, and linking of different data types locally and nationally could also increase interoperability at EU and international level [25].

Discussion

Without action, barriers will persist, especially for sharing CE data, which hamper FAIR data sharing for infectious disease preparedness and response. The actions described here also contribute toward the commitment from closed to open research information, as put forward in the recent Barcelona Declaration [26]. The first and uppermost question needs to be answered at institutional and national level: Do people want to share data and what are they prepared to invest in terms of a collaborative effort to do so, if there was funding, GDPR and other support, for data sharing to move away from a felt "burden" to being a seen "benefit." On the path toward more open data sharing researchers' and other stakeholders' concerns about sharing "their" data need to be addressed [15,27,28].

Meanwhile, decentralized or federated approaches are often preferred, as these circumvent barriers [16,29,30] and are less resource- and time intensive for (clinical) researchers and institutes. Federated networks, where decentralized but interconnected nodes allow data to be queried or analyzed by other nodes in the network without the data leaving its location, have been proposed as a solution and are being worked on to address the siloing of health data and current barriers to data sharing [31]. However, common obstacles to broader uptake of federated networks include the absence of data standards or limited adherence to existing standards, the complexity of designing, implementing and deploying federated solutions that preserve privacy [32]. The challenges must be addressed before federated networks can be implemented more widely, especially across national borders [31], but the question remains if full federation will ever be possible. Other concerns with federated approaches, such as the forthcoming European Health Data Space [33], are about significant delays in the authorization by national health data access bodies for reuse or secondary use of health data [34], and introduction of paywalls [35], potentially leading to inequity.

There is a need to streamline the timeliness of steps for sharing CE and other data, and to ensure no additional barriers are created in sharing a linked cohort dataset. Ongoing discussions to include digital sequence information, including pathogen GSD, under the Nagoya protocol [36], or the WHO CA+ [37], could potentially result in new barriers due to additional steps to complete legal procedures before pathogen GSD could be shared. This may considerably delay the prompt sharing and access to pathogen GSD, which has proven crucial in early detection, diagnostics, and identifying variants during the COVID-19 pandemic [2], while its impact on improving access and benefit sharing mechanisms remains uncertain [38].

The multidisciplinary nature of infectious disease research and collaborations reflects the complexity of research and public health questions which need to be understood and answered around (re-) emerging diseases. While certain answers can be found in isolation within a specific area of research and small numbers of patients, larger complex questions require a joint outlook and a combination of data sources to be examined together [39].

Conclusions

Here we have shown the complexities in sharing a small but complex, linked dataset from opportunistic COVID-19 clinical and laboratory research studies as done in (academic) hospital settings. We also provided actionable elements to shorten the timeline to go through this process. Actions that are taken now to improve data sharing for outbreak preparedness and response will improve our ability to detect and respond to emerging threats in the future. We call upon governments, funders, global and regional organizations, scientists and their institutes, journals and industries to tackle known barriers hampering data sharing for infectious disease preparedness and response.

Acknowledgments

The work described here would not have been possible without many other people within the Erasmus Medical Center (Erasmus MC) and the Reconciliation of Cohort data in Infectious Diseases (ReCoDID) consortium; we are grateful for your dedication, effort, and for supporting the performance of this study. Specifically, we would like to thank the following people. At Erasmus MC: Pieter Fraaij and Jeroen van Kampen for support with the data landscape; Divyae Prasad and Marie-Catherine Bouquieaux for SARS-CoV-2 data submissions; Mickey Haasnoot and Laurens Groenendijk for support with the legal requirements; Tamara Van Huuksloot, Viola Woeckel, Anne-Lotte Masson and Kenneth Davids for support with the institutional database. At European Molecular Biology Laboratory-European Bioinformatics Institute: Nadim Rahman and Zahra Waheed for support with the European Nucleotide Archive; Dipayan Gupta for support with BioSample; and the ArrayExpress/BioStudies and European Genome-Phenome Archive teams. At Heidelberg University Hospital (UKHD; Germany): Fruzsina Molnar-Gabor for legal support concerning the General Data Protection Regulation. At McMaster University (Canada): Priscilla Cesar and Claudia Emerson for the overall RECoDID Data Governance framework. Financial support for this work was provided by the European Union's Horizon 2020 research and innovation program (grant agreements 825746 [ReCoDID] and 874735 [VEO]). The funders had no role in any aspect pertinent to the study, nor in the decision to submit the manuscript. A preprint of this manuscript has been published by Zenodo.

Authors' Contributions

Although the datasets themselves and their connected data analysis are not the focus of this manuscript, the pilot study, to share a complex linked COVID-19 cohort dataset, would not have been possible without the respective data providers. Data providers were BBOM, RDdV, GPvN, RSS, JvB, and ECMvG. FT carried out clinical-epidemiological data harmonization. Funding acquisition was done by TJ, MPGK, MYvR, and GC. CA and GR carried out the project administration (management and coordination responsibility for the pilot planning and execution at Erasmus Medical Center and European Molecular Biology Laboratory-European Bioinformatics Institute respectively). The project was conceptualized and the manuscript conceived by MYvR, CA, and MPGK. Writing-original draft was carried out by CA and MYvR, and Writing-review and editing by all authors. Figures were designed by MYvR and GR. Visualization (preparation, creation and presentation of work at consortium meetings) was done by CA and MYvR. CA and MYvR contributed equally to this work.

Abstract

Current societal trends reflect an increased mistrust in science and a lowered civic engagement that threaten to impair research that is foundational for ensuring public health and advancing health equity. One effective countermeasure to these trends lies in community-facing citizen science applications to increase public participation in scientific research, making this field an important target for artificial intelligence (AI) exploration. We highlight potentially promising citizen science AI applications that extend beyond individual use to the community level, including conversational large language models, text-to-image generative AI tools, descriptive analytics for analyzing integrated macro- and micro-level data, and predictive analytics. The novel adaptations of AI technologies for community-engaged participatory research also bring an array of potential risks. We highlight possible negative externalities and mitigations for some of the potential ethical and societal challenges in this field.

Introduction

> *"While the future might indeed be bright for AI, it wouldn't be so by accident. We will have to earn it, together."* [Dr. Fei-Fei Li] [Founding Director, Stanford Institute for Human-Centered AI] [From The Worlds I See: Curiosity, Exploration, and Discovery at the Dawn of AI 1]

The last several decades have witnessed a growing mistrust in science among both policy makers and the public at large on an unprecedented scale [2]. The reasons for this trend appear to be many and varied, including a lack of understanding about how science actually operates, partly at least due to an absence of participatory educational opportunities and direct engagement in meaningful science activities [3]. This, in turn, has been linked with poor self-ratings of scientific literacy among school-aged adolescents and adults alike [3]. A general confusion about what the public should reasonably expect from research in terms of scientific veracity or "truth" has been an additional contributor to the public's skepticism about science. These problems have been amplified to a significant extent by social media, which has often worked, either intentionally or unintentionally, to confuse or obfuscate the truth [4]. Unfortunately, such efforts arguably have been abetted by scientific institutions themselves as well as scientific journal outlets which, in their haste to grab the day's headlines, have at times stripped scientific results of their complexity, nuance, and context; or, shockingly, filled untold numbers of journals with "fake science" [5]. Well-documented historical injustices also have contributed to a lack of trust in academic and scientific institutions, particularly among communities of color. For example, the US Public Health Service Untreated Syphilis Study at Tuskegee has generated mistrust in health care institutions and research for generations [6]. More recently, the University of Arizona was found guilty of using DNA samples from the Havasupai Tribe for research without their consent [7]. Recent controversies and public health crises (eg, the COVID-19 pandemic) also have given rise to increased questioning of public health authorities and have sown doubts regarding scientific validity and reliability, which have exacerbated feelings of mistrust.

This alarming trend of mistrust in science threatens public health efforts in multiple ways, which include the following recent examples: (1) misinformation concerning vaccines, including

XSL•FO
RenderX

outright dismissal of the extensive multigenerational evidence base supporting the development and use of vaccines to prevent a myriad of dangerous and at times fatal diseases that have threatened the public's health; (2) skepticism surrounding the wide-ranging, multidisciplinary evidence base establishing the considerable effects of climate change that threaten the health of the planet and all of its living inhabitants; and (3) the growing distrust of health care systems as well as pharmaceutical companies (ie, "big Pharma"), which has become especially acute among marginalized groups, including minoritized and under-resourced communities [8].

The mistrust of science coincides with other pernicious societal trends reflecting disconnection and skepticism in other facets of daily life. These include growing concerns in the health and mental health fields around the current levels of civic disconnectedness and community disengagement among significant sections of the population. Recent data indicate, for example, that civic participation, social engagement, and community connection among segments of today's youth and young adults are declining, with this trend having been worsened by the COVID-19 pandemic [9].

The confluence of these trends with the emergence of an often-bewildering pace of advances in the worldwide IT sector has served to exacerbate feelings of confusion and mistrust among broad segments of the population. This has included, in particular, the unexpectedly disruptive force of the current artificial intelligence (AI) revolution across all sectors, including health care, education, and research. Threats regarding the spread of misinformation, increasing systematic biases against already marginalized populations, data privacy issues, and potential job displacement are among the leading concerns of the public, in addition to other impacts that the widespread acceptance and use of AI might have on various segments of society, from individuals through governments and policy makers [10].

The above issues have led to the following questions: (1) how can science in general be made more accessible to the public in ways that can reduce confusion and mistrust and increase the meaningfulness of scientific inquiry to directly benefit individuals and their communities, and (2) how can the potential of AI be harnessed to bolster the public's engagement in public health science while mitigating the distrust and confusion about both research and AI itself?

Increasing Public Participation in Scientific Research

Public participation in science research (PPSR) is one way researchers have been addressing the increasing mistrust among decision makers and the public toward science. A growing number of studies have included PPSR methods, such as citizen science, that have utilized educational outreach efforts to increase public knowledge and awareness of scientific principles and best practices [11]. Important, systematic efforts have been employed to actively involve a greater number and variety of community members in the scientific process [12]. Such participatory research paradigms can have substantial positive impacts for increasing transparency, knowledge, and trust in scientific inquiry, particularly when they involve generating actionable data of direct relevance to those involved [13].

Within the broader umbrella of PPSR frameworks, citizen science—generally defined as involving lay persons in the research process to advance science—is an increasingly popular approach to engage community members in research activities [14]. A strength behind citizen science is its underlying principle that scientific inquiry can often benefit from including diverse members of the community from varying educational, occupational, social, and cultural backgrounds. Various forms of citizen science have occurred over several centuries and have involved diverse fields, including the life, environmental, health, social, and behavioral sciences [15]. Citizen science can directly benefit research by providing extra pairs of "helping hands" in the data collection and problem-solving aspects of science [14]. Beyond democratizing data acquisition, citizen scientists also can contribute to the fuller research process, including problem definition, data interpretation and prioritization, data-driven solution generation, and results dissemination [16-18]. This more fully participatory "by the people" form of citizen science can advance scientific inquiry as well as promote meaningful knowledge and solutions for the local communities that are involved [13,16,17].

An example of this type of citizen science in the public health arena is the technology-enabled "Our Voice" Global Citizen Science Research Initiative [19], where residents from diverse and often under-resourced communities learn how to partner with researchers and community organizations in collecting and interpreting aggregated and anonymized contextual data (eg, photos, text, and audio). These data identify features of residents' local environments that help or hinder their health [16,17]. They then learn how to effectively communicate their data to decision makers and work with them to activate health-benefiting changes in their local environments [16,17]. Over nearly a decade, the multi-generational "Our Voice" Initiative has produced demonstrable community-driven physical and social environmental impacts across 100+ projects involving over 25 countries spanning 6 continents [16,17].

Leveraging the Potential of AI to Promote More Powerful Citizen Science for Advancing Public Health

While the current focus of health-oriented AI applications has been primarily at the individual patient level, the thoughtful and strategic application of AI at the community level offers potentially powerful tools to augment participatory science activities across the fuller research process. At the same time, it is important that both researchers and participants recognize the potential risks of AI and are committed to implementing multilayered mitigation tactics aimed at addressing them (see Table 1, Figure 1, and the subsequent section focused on risk mitigation).

XSL•FO
RenderX

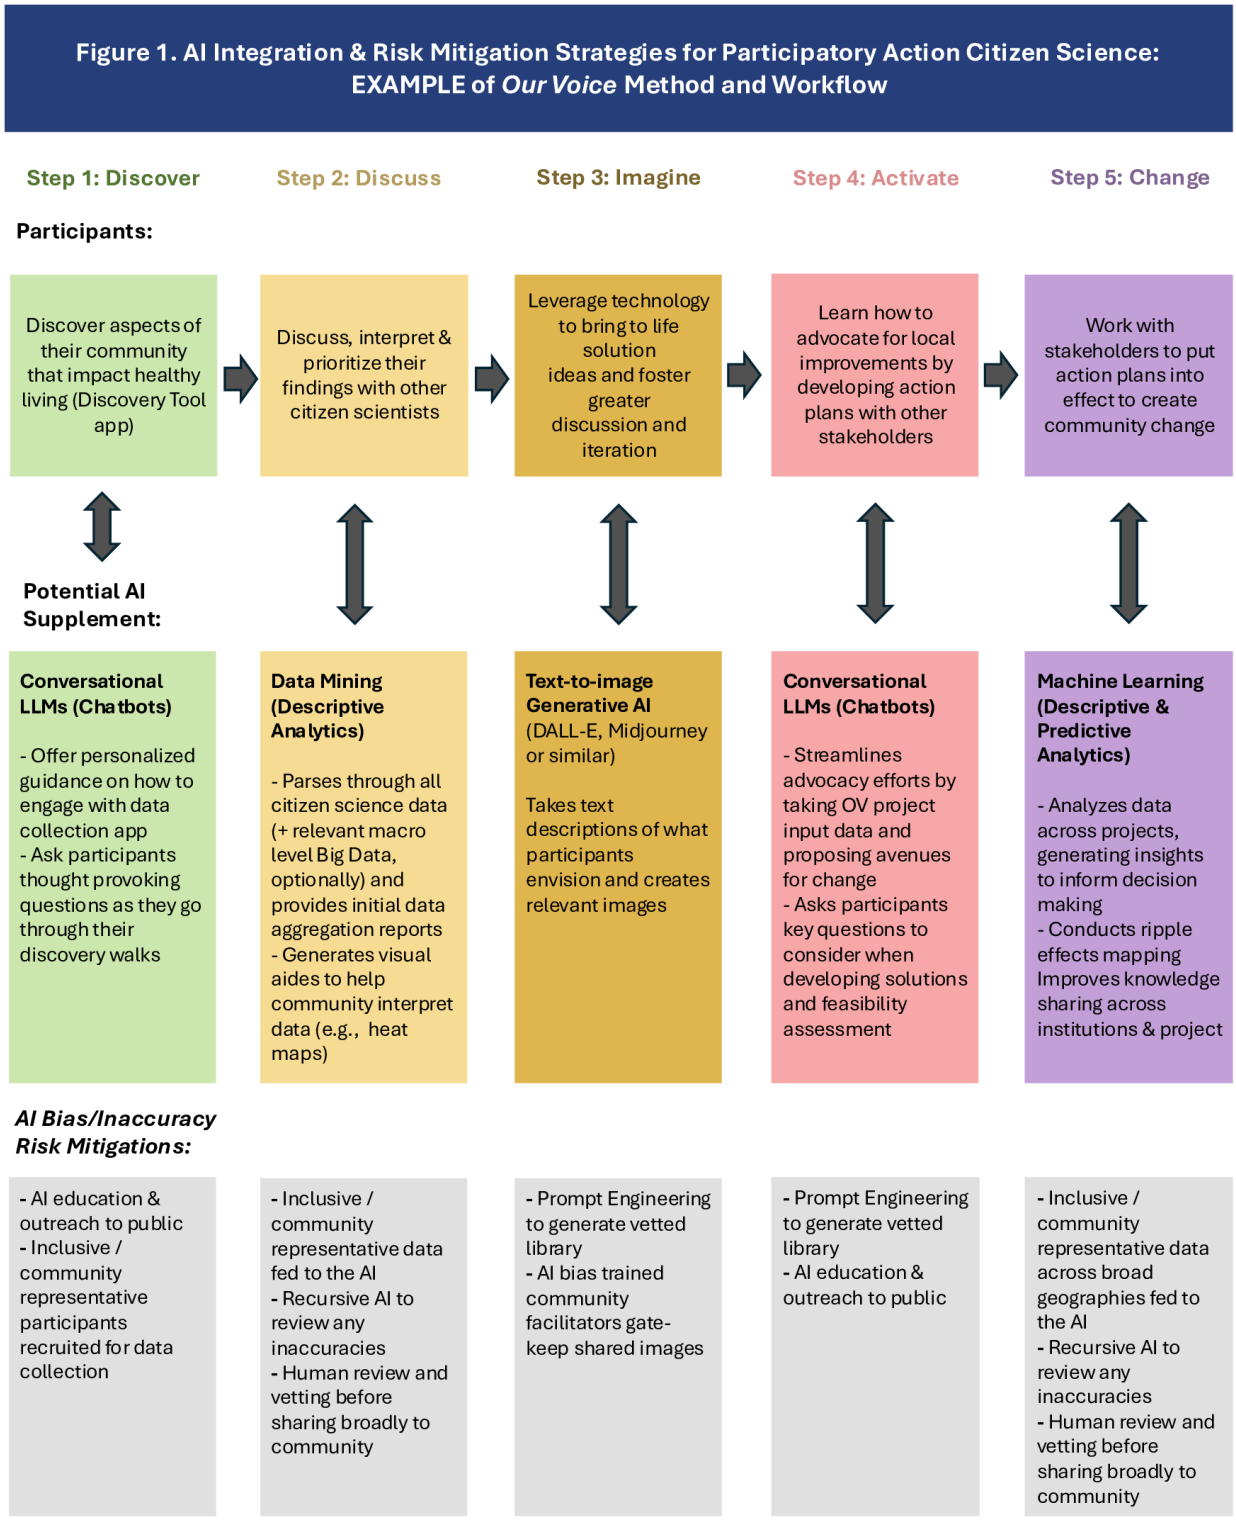

Table . Examples of potential artificial intelligence (AI) uses within community-engaged public health citizen science research, along with potential risks and risk mitigation strategies.

Potential use of AI within community-engaged research	Potential risks	Risk mitigation strategies
Conversational LLMs[a] (ChatGPT or similar) for onboarding participants, offering personalized guidance on engaging with technology, and asking thought-provoking questions	• Biased or culturally insensitive conversations emerge • AI "hallucinations" where factually inaccurate commentary is made	• Dedicated time spent in prompt engineering to determine language best used to minimize these biases in this context, and then shared as best practices to the public • Public education on AI, the training data that were used, and discussion of shortcomings
Text-to-image Generative AI tools (DALL-E, Midjourney, or similar) for helping the community visualize their data (eg, turning text descriptions into relevant images)	• Biased or culturally insensitive pictures generated and shared • Impossible or impractical to execute ideas presented	• Human (expert) review and gatekeeping before images shared broadly to the public • Prompt engineering and similar efforts aimed at community data collection are shared with participants in advance to enhance the potential relevance and feasibility of solutions
Data Mining (Descriptive Analytics) for analyzing macro- and microlevel data, generating integrated data reports, visualizations, etc.	• Inaccuracies or AI hallucinations injected into the dataset • Loss of control, research rigor, and cognitive competence by scientists who defer too much to AI	• Intentional efforts made to feed AI inclusive and community representative data • Recursive AI use: feed output back to AI to check for inaccuracies • Require scientists to review all data generated for accuracy and meet field standards for scientific literacy or competence
Data Mining (Predictive Analytics) for reviewing large datasets, providing data aggregation reports, and generating visual aids to help the community interpret data	• Data presented may result in wrong conclusions, resulting in further inequities • Loss of control, research rigor, and cognitive competence by scientists who defer too much to AI	• Human (expert) review and governance of all generated findings • Recursive AI use: feed output back to AI to check for inaccuracies • Require scientists to review all data and methods for accuracy and meet field standards for scientific literacy or competence • Empirical testing of AI to determine when it helps or hurts scientific skills and competencies

[a]LLM: large language model

XSL•FO
RenderX

Figure 1. Artificial intelligence (AI) integration and risk mitigation strategies for participatory action citizen science: example of "Our Voice" Method and workflow. LLM: large language model; OV: Our Voice.

Using the "Our Voice" multistep citizen science method as an example, potentially valuable AI applications can occur at each step (see Figure 1). The steps include resident-engaged data collection using a multilingual mobile app ("Discover" step); facilitated analysis, discussion, and prioritization of relevant local issues ("Discussion" step); leveraging of visualization technologies to bring potential solutions into clearer focus ("Imagine" step); communicating relevant community issues and brainstorming feasible solutions with local decision makers ("Activate" step); and continued partnering with stakeholders in bringing action plans to fruition ("Change" step). In addition to these integral steps, the above "Our Voice" method has been supplemented at times with an increasingly proactive and thoughtful approach to engage the community prior to

XSL•FO
RenderX

embarking on citizen science activities, as well as the thoughtful dissemination of findings and insights to researchers, decision makers, and the public (a "Share" step). The careful integration of relevant AI applications into these different citizen science processes may assist in supplementing and enriching the different step outputs, as well as helping to address at least some of the challenges with public trust, given the active role that community members play in this type of participatory science.

Some examples of potentially relevant AI tools that can be explored are given below for each step.

Discover (Data Collection) Step

A challenge to address in the discover (data collection) step is that the inclusion of AI in this step should not supersede the real, on-the-ground data collected by local citizen scientists. Any additional data presented by the AI at this step is intended to be an augmentation that goes through human review before it is included in project data capture.

Conversational large language models (LLMs) can be employed in a strategic and transparent way to personally guide the use of citizen science data collection apps such as the "Our Voice Discovery Tool" app, along with "real-time" dynamic prompts to more fully engage residents as they go through their data collection walks. In addition, utilizing computer vision, hearing, and other "real-world" perceptual sensing tools (eg, smell) may help to produce more robust and comprehensive data capture and classifications to augment the contextually focused citizen science data [20]. The goal of using such sensing tools along with LLMs would be to enrich citizen scientists' data collection activities to produce more nuanced and detailed data to analyze and combine with other relevant data sources (eg, geographic information systems and social network models).

Discuss Step

A challenge to address in the discuss step is that AI should not absolve researchers and participants from the task of ensuring analytical accuracy and rigor, nor replace efforts in interpreting the data and gleaning insights. As AI is known at times to experience "hallucinations" and commit errors when it comes to data analysis and interpretation, whatever is generated by it should be seen as a first-pass draft of something that helps researchers and community members enrich their own interpretations and iterations.

ChatGPT and similar conversational LLMs can be engaged during community meetings to support residents' group discussions during data interpretation and solution-building activities. For example, LLMs may be able to support thoughtful community-level discussion and advocacy, not as an omniscient "black box" but as an attentive community-level support system and Socratic thinking aide. Rather than attempting to "replace" community members' perspectives and lived experiences, LLMs may be employed to play the role of "devil's advocate" in a more neutral way, to help residents better understand the concerns of marginalized groups as well as policy makers. LLMs also may allow participants to better assess the feasibility of their data-driven ideas for positive change by supplementing knowledge or experience gaps that the average citizen scientist may have (eg, "Considering the financial constraints of X and timeframe to solve this issue by Y, which of these 5 solutions are the most feasible to address …..?"). In presenting participants with more detailed background information regarding the implementation of different data-driven solutions or strategies, residents can be further informed about the potential complexities that come with improving their communities. AI also could be leveraged to generate and describe multilevel insights by combining diverse sources of data, from citizen scientist–generated microscale data that capture local contexts and individual-level biosensing outputs (eg, heart rate and physiological stress responses) through macroscale population-based social determinants and health data. This, in turn, could result in the development of interactive maps from such mixed-methods data sources that arguably could foster faster insights and public health responses from policy makers. For example, the initial efforts to visually combine citizen scientist–generated microscale data describing residents' neighborhood-lived experiences with macroscale epidemiological data about their larger environmental contexts have yielded richer results than would have been obtained from either data source alone [21]. Leveraging AI in this manner to assist with combining and visualizing different forms of data could actually free up researchers and citizen scientists to engage in higher-order thinking and analysis that is required for creatively addressing some of society's most pressing issues. For instance, in California, low participation in community-supported public health initiatives that provide opportunities for affordable healthy food access is often driven by diverse factors that can vary by locale. The multifactorial issues driving low program uptake often are challenging for researchers, governmental agencies, and community-based organizations to understand sufficiently to be able to intervene effectively. It is possible that AI tools could help by aiding the visualization of how microlevel "lived experience" data vary with respect to macrolevel contextual data. Such multilevel visualizations would allow researchers and community partners to spend more of their time understanding and solving the problem, as opposed to gathering and synthesizing relevant data to describe the problem.

Imagine Step

A challenge to address in the imagine step is that AI should not have free reign in determining what the best solutions for the community are. Using culturally tailored inputs, AI's creativity can be used as a supplemental aide to the collective community's brainstorming while not superseding it.

Several AI tools may be useful in helping residents, decision makers, and researchers better imagine what scientifically generated health-enhancing changes can actually look like in their own communities and environments (eg, through generative AI text-to-image tools such as DALL-E and Midjourney). For example, Stanford's Center on Human-Centered Artificial Intelligence awarded a seed grant to "Our Voice" that will allow citizen scientists to take images collected during local "discovery walks" and transform them into reimagined futures through such generative AI tools (eg, an image of an unsafe intersection to get to school could be "morphed" into images of different solutions such as a crosswalk, pedestrian bridge, etc). The early testing of this form

XSL•FO
RenderX

of AI with school children living in the El Pozón neighborhood of Cartagena, Colombia—where the majority of inhabitants live below the poverty line and lack access to essential services—is showing how the thoughtful, culturally tailored use of text-to-image AI tools can generate meaningful and actionable solutions to local environmental problems (eg, stagnant water and uncollected garbage). These rapid visual renderings could in turn lead to enhanced and richer discussions of trade-offs and foster new ideas among community members and researchers.

Activate and Change Steps

A challenge to address in the activate and change steps is that, as noted above, an optimal goal of AI use is to supplement and enrich such conversations, as opposed to driving them. Sharing the above types of visualization tools and information with local decision makers may help to jump-start relevant solution-building efforts. Generative AI could be used to aid in the creation of presentation materials, help community members role-play conversations with local decision makers in preparation for scheduled meetings with them, and identify issues and suggest modifications to the action plan created during the community meetings.

Share Step

A challenge to address in the share step is that it is recommended that researchers avoid risking diminished scientific rigor and accuracy through outsourcing major data interpretation to AI. As noted earlier, people are in the best position to fully understand and evaluate what the data mean, including, in this case, the citizen scientists who have collected those data.

Machine learning tools also can be used to aid researchers in the aggregation of data across projects and expedite their ability to glean useful insights across different citizen science projects and research groups.

In addition to the above types of citizen science-oriented strategies, through utilizing AI-generated virtual reality simulations, citizen scientists along with other community members can experience physical, cultural, and social situations that they might not otherwise encounter in their daily lives [22]. Such AI-generated virtual reality simulations also can provide community members and decision makers with hands-on opportunities to interact with virtual characters representing differing cultural backgrounds that may lead to increased cultural sensitivity [22]. These AI-driven virtual or simulated environments can additionally allow community members to try out citizen science data gathering and similar tools before real-world use [20].

Additional Recommendations on Mitigating Potential Risks of AI

Amidst the potentially promising uses of AI for the public health and citizen science fields noted above, including its potential to expand the breadth and utility of the data being collected and interpreted, a number of ethical challenges and concerns have been raised, some of which have been touched on earlier and in other articles [23]. These include the different types of risks, as described in this paragraph. AI could diminish, distort, or replace data being collected in the field with output that is less accurate (ie, AI "hallucinations") and less representative of community member experiences and responses. AI output may be based on information and sources that are not culturally relevant or appropriate for a given community or context. Potential challenges emerge when AI is presented with contrasting ideas from citizen scientists, researchers, and other stakeholders and autonomously makes prioritization choices among them. The introduction of AI tools into the public health research process could actually serve to increase the "depersonalization" of the research process, leading to a greater rather than a lower distrust of science. Finally, major concerns have been raised that through potentially oversimplifying and directing aspects of the scientific process, LLMs and similar AI tools could significantly diminish scientists' data processing skills and cognitive competencies.

The publicly available use of ChatGPT and similar generative AI tools as "short cuts" for increasing time efficiencies at the potential expense of thought and deliberation has served to heighten many of these concerns.

In response to such threats, some potential solutions have begun to emerge (see Table 1), as described below.

Thoughtfulness and Transparency

A potential solution is being thoughtful and transparent in determining when IA (information augmentation to support human intelligence) versus AI (artificial intelligence, which is often used as a replacement for some human activities) is best suited. For example, in places where the radius for impact is large and missteps would be difficult to rectify or could cause grave harm, AI, which to date generally does not have community participation or checks for bias mitigation, ought to be used with great caution. In such instances, using technology instead to aggregate and synthesize data findings, and leaving the interpretation of those findings to people, could be wiser.

A mitigation example could be the data collection of citizen scientists' lived experiences in the context of community determinants of health that could be synthesized to share summary statistics, generate heat maps, or word clouds; however, any interpretation of their data, along with solution-building and implementation, would not be outsourced to AI without human supervision and community-level interpretations and buy-in.

Employing Explainable AI Concepts and Strategies

Another potential solution is the use of explainable AI (XAI) that involves processes and methods that allow human users to understand and better trust the results and output created by machine learning and similar algorithms. It can be used to describe an AI model, its expected uses and impacts, and potential biases (eg, based on sex or race).

A mitigation example is the use of a set of vetted chat prompts and outlined best practices that could be provided to users ("prompt engineering"), instead of assuming that the results of ChatGPT are correct and accurate. These best practices could include examples of wording to enter into ChatGPT to improve

XSL•FO
RenderX

results and ideally catch AI "hallucinations." Here is one such example: "For any and all responses, end each response with a bulleted list that includes (1) any assumptions you are making, (2) citations of any sources you have used to determine the response to my prompt, and (3) any biases or concerns you want to review if you had access to unlimited data or personnel." In addition, the responses generated by the AI system can be fed back to itself with the prompt "Check this response for any factual inaccuracies or state anything you cannot back up with reputable sources."

Launching Active Educational and Outreach Initiatives

There are growing concerns related to the potential of AI, including generative AI, to promote biased results and intensify health inequities through the lack of diverse data that are representative of different societal groups. Therefore, it is important to launch active educational and outreach initiatives to better inform the public across all walks of life about AI, its uses, ethical implications, and the precautions about which people should be aware. Educational efforts aimed specifically at diverse communities and populations may help to increase transparency concerning both the promise and limitations of this emerging field. It also may help ensure that key community norms and values are taken into account [24]. Such outreach-based multidisciplinary and community-driven educational efforts tailored to the needs of different populations may additionally help to empower currently under-represented groups to actively participate in data collection and information sharing to help mitigate such biases [24]. Involving community members in the development of AI methodologies from the beginning is important to ensure transparency and reduce mistrust among participants [24]. While such proactive educational efforts have been focused primarily on health care, they could benefit public health research and activities as well.

A mitigation example is described here. Zainab Garba-Sani and colleagues have developed the A.C.C.E.S.S. AI model, which lays a framework for involving communities in the AI-rollout process as follows: A = "Affirm your aims," C = "Consider your communities," C = "Cultivate your conversations," E = "Embrace your essentials," S = "Specify your scope," and S = "Scrutinize your spaces" [24]. Through training sessions and workshops with diverse groups, A.C.C.E.S.S. serves the dual purpose of not only educating people about AI and its potential applications but also gathering their input on how AI should be thoughtfully designed for their unique contexts. Another example of such an initiative is the nonprofit "AI4ALL" movement that aims to advance an increasingly human-centered, inclusive AI discipline [25]. Through proactive participatory approaches such as these, we can begin to demystify AI and ensure that diverse communities are brought to the table when implementing AI tools.

Increasing Efforts to Improve Data Upon Which AI is Modeled and Trained

As AI is merely holding up a mirror to the society or data upon which it is trained, the biases inherent in AI responses are likely due to the missing perspectives and incomplete data upon which it was built. Leveraging collaborations across institutions, social or civic interest groups, and diverse communities to improve the training data should help AI become more aware of differing perspectives and hopefully reduce if not completely minimize the bias. Outreach-based multidisciplinary and community-driven educational efforts as described below that are tailored to the needs of different populations may additionally help to empower currently under-represented groups to actively participate in data collection and information sharing to help mitigate such biases [24].

A mitigation example is the need for clear guidelines and incentives from scientific organizations, universities, journals, and granting organizations (eg, specific grant announcements from the NIH in this area) concerning expanding the population representativeness of the datasets upon which AI is based; this can send a clear message regarding the importance of this issue to the field as well as society at large.

Setting AI-Specific Ethical Standards and Having Expected AI-Influenced Outputs Verified by Experts

It is important to set AI-specific ethical standards across universities, other research organizations, scientific outlets, and funding sources that include the ethics review of study methods as well as have the expected AI-influenced outputs verified by experts trained in the relevant ethics fields. Publishers of scientific journals, books, and other scientific communication channels should be encouraged to provide specific guidelines related to the publication of research investigations that include AI. Demanding transparency of AI use in scientific research more generally is recommended, as a growing collection of policy makers, technology developers, and scientific organizations are currently doing. Setting up appropriate "guardrails" prior to AI use is similarly important to help ensure that flawed, offensive, or inaccurate information does not unexpectedly find its way into AI-driven conversations or other outputs.

A mitigation example is described here. As part of institutional review board policies and activities, some grant-making organizations have included, in addition to the review of a grant proposal's scientific merit, a separate ethics review involving experts in ethics and similar fields to identify areas of potential ethical concern and methods for the mitigation of such concerns. An example is the Stanford Human-Centered Artificial Intelligence Center's process of including a separate ethics review of AI grant proposals to help ensure that appropriate AI-relevant guardrails are in place prior to funding.

Regulating Transparent Data Ownership and Use

It is important to regulate transparent data ownership and use to ensure that access to citizen science data is not limited by commercial interests [20]; this helps to ensure that AI tools and resources are available to everyone, which can democratize its use and diminish public suspicion and skepticism. For example, many users of ChatGPT and similar platforms may not understand that their data currently may be sent to the parent company OpenAI to subsequently power future AI learning, and then be ultimately used by unnamed sources for a variety of undisclosed purposes.

A mitigation example is that, instead of relying on public GPTs whose data ownership and use are ambiguous, the Stanford

XSL•FO
RenderX

School of Medicine and other academic institutions have developed their own custom GPT that ensure data security, HIPAA compliance, and similar outcomes. Additional AI resources that are being developed at Stanford include a user-friendly "AI Playground" platform, built on open-source technologies, that allows the Stanford community to try out various AI models and tools as well as compare the utility of different tools in a head-to-head fashion.

Human Governance and Oversight Over AI Output

It is imperative when undertaking community-engaged forms of research that scientists work to ensure that AI-generated contributions to the research endeavor do not supersede or otherwise hamper the credibility of the contributions from community members and their representatives. While AI tools are often used to obtain meaning from large datasets, in the participatory public health research field, it is typically the residents themselves who can best provide meaning and context to the data being collected and interpreted.

A mitigation example is that the addition of community advisory experts, panels, and similar oversight bodies can help ensure that the use of AI enriches but does not overshadow either the scientific process itself or scientists and the public's participation in that process. It will be particularly valuable to include the expertise of ethicists familiar with AI who can identify potential areas of concern and help build appropriate safeguards.

Ensuring That Scientific Competencies are Enhanced Rather Than Diminished as a Consequence of the AI "Revolution"

With the rapid expansion and ease of use of ChatGPT and other LLM tools across a range of scientific and educational fields, there have been growing concerns related to the detrimental effects that the overuse of such tools can have on current and future generations of scientists and the public. These concerns include the real danger that regular substitution of LLM-generated written and oral communication in science, as well as across other facets of life, could significantly diminish cognitive competencies and the creative and innovative thinking that is the foundation of the scientific process itself. It is clear, at this early stage of generative AI use in participatory science as well as in other scientific areas, that carefully created guidelines for AI usage in all aspects of scientific education and training should be developed and put into place to ensure LLMs and other AI tools support, rather than replace, the facilitation and participation of community-engaged research endeavors.

A mitigation example is described here. A year-long deliberative process by Stanford University's Department of Epidemiology & Population Health has resulted in a clear set of early principles and guidelines for the use of generative AI tools in one of its major education programs. The guidelines have helped to diminish ambiguity among students and faculty while reinforcing the importance of human-centered educational activities in growing the cognitive competencies of vital importance to the advancement of science. In addition to clear guidelines for AI use and requirements that scientists at all levels of training and experience review their data and methods for accuracy, other suggestions include the further development of field-specific scientific standards for scientific literacy and competence independent of AI usage.

It is also important to ensure that scientific data collection and analysis activities themselves are not in some way diminished or curtailed through overdependence on AI tools. As noted earlier, the judicious use of certain AI tools in the participatory science area may help to enrich and expand the insights and impacts gained through participation by residents, decision makers, and scientists working together. However, it is critical that such AI tools undergo thorough empirical testing to determine when, how, and with whom they can enhance rather than impede scientific knowledge and insights. As one example, the "Our Voice" research team is conducting initial experiments to better determine how the use of "text-to-image" generative AI may affect the ability of citizen scientists to better visualize and understand the proposed health-promoting environmental changes drawn from their data. Among the populations for which such tools are being systematically tested are older US women and school children living in the El Pozón neighborhood of Cartagena, Colombia, which was highlighted earlier. In a second example, a recent "Our Voice" citizen science project conducted in Bogotá, Colombia has illustrated how resident-collected data that were augmented via virtual reality tools can ignite compelling discussions and solution building among participants, scientists, and local stakeholders [22].

The multidimensional mixed-methods data collection methods, sources, and analyses required by the types of participatory scientific methods described in this Viewpoint also may serve as a means for preventing the diminution of cognitive competencies. For example, we have found that the increased complexity of the multilevel, mixed-methods data acquired when microscale (eg, citizen scientists' "lived experiences") and macroscale data sources are integrated requires an increased interdisciplinary understanding of both these different forms of data and more intricate and multifaceted data analysis methods, which can serve to enhance cognitive competencies [21].

Discussion and Conclusions

Citizen science has been shown to be effective in positively engaging diverse groups of community members in meaningful, action-oriented research [17]. Such participatory methods can help to lessen both mistrust in science and civic disengagement, which are trends that threaten to impair advances in public health. Can the judicious applications of various AI tools serve to amplify the potential of participatory science for reducing these trends while broadening meaningful scientific advances in public health? Given that it is clear that the AI "genie" is out of the bottle and will likely have substantial impacts across virtually all aspects of science, it is critical that we meet the AI challenge head on. The inevitable integration of AI into participatory research methods must be thoughtfully managed in order to amplify, and not replace, the collective documentation of human lived experiences, and to ensure that the applications of such data to affect change truly reflect the priorities of local communities. We believe that the time is ripe to systematically evaluate the potential of AI beyond current individual-level applications by exploring its utility as a

XSL•FO
RenderX

community aid for advancing public health. At the same time, it is imperative that we continually keep in mind the potential risks accompanying its use, especially among underserved, under-resourced communities. We call on the research community to consider such challenges proactively and empirically over the coming years, finding innovative ways to mitigate the risks while testing the impacts of AI on trust in science, civic engagement, knowledge advancement, and community-driven change.

Acknowledgments

The authors thank Ann Banchoff, MSW, MPH and Steven Lovett, PhD for their valuable input related to this manuscript. We also thank Eduardo De La Vega Sr, PhD for his innovative early community-engaged research activities in Colombia using generative large language models, and Arjan Walia, MS for his leadership in the initial systematic evaluation of generative artificial intelligence models in community-engaged research with older US women. Dr. King received partial support from US Public Health Services grants 5R01AG07149002 (King) and 1R44AG071211 (M Fauci) from the National Institute on Aging. King, Doueiri, and Kaulberg received partial support from a seed grant provided by the Stanford Institute for Human-Centered Artificial Intelligence at Stanford University. The authors declare no potential conflicts of interest with respect to the research, authorship, or publication of this article. No copyrighted material, surveys, instruments, or tools are included in this manuscript.

Conflicts of Interest

None declared.

Abstract

Foodborne illness is a continuous public health risk. The recognition of signals indicating a cluster of foodborne illness is key to the detection, mitigation, and prevention of foodborne adverse event incidents and outbreaks. With increased internet availability and access, novel data streams (NDSs) for foodborne illness reports initiated by users outside of the traditional public health framework have emerged. These include, but are not limited to, social media websites, web-based product reviews posted to retailer websites, and private companies that host public-generated notices of foodborne illnesses. Information gathered by these platforms can help identify early signals of foodborne illness clusters or help inform ongoing public health investigations. Here we present an overview of NDSs and 3 investigations of foodborne illness incidents by the US Food and Drug Administration that included the use of NDSs at various stages. Each example demonstrates how these data were collected, integrated into traditional data sources, and used to inform the investigation. NDSs present a unique opportunity for public health agencies to identify clusters that may not have been identified otherwise, due to new or unique etiologies, as shown in the 3 examples. Clusters may also be identified earlier than they would have been through traditional sources. NDSs can further provide investigators supplemental information that may help confirm or rule out a source of illness. However, data collected from NDSs are often incomplete and lack critical details for investigators, such as product information (eg, lot numbers), clinical or medical details (eg, laboratory results of affected individuals), and contact information for report follow-up. In the future, public health agencies may wish to standardize an approach to maximize the potential of NDSs to catalyze and supplement adverse event investigations. Additionally, the collection of essential data elements by NDS platforms and data-sharing processes with public health agencies may aid in the investigation of foodborne illness clusters and inform subsequent public health and regulatory actions.

Introduction

An estimated 1 in 6 people experiences an episode of foodborne illness in the United States annually, placing an estimated US $77.7 billion burden on the US economy [1,2]. Most of these illnesses are considered sporadic; however, limitations in foodborne outbreak surveillance may hinder the detection of outbreak-associated cases. The identification and investigation of foodborne illness clusters requires a high degree of coordination across state and local jurisdictions and, in some cases, federal agencies [3].

XSL•FO
RenderX

At the federal level, outbreaks are investigated when they involve cases in multiple states, implicate imported products, or when federal support is requested. Most of these outbreaks that involve known pathogens are traditionally initiated through laboratory-based surveillance systems with the identification of illness clusters by molecular subtyping of clinical isolates or case reports from ill individuals with a common exposure and illness who seek medical care. These clusters can then be linked to a common vehicle based on supporting epidemiologic information, traceback findings, and laboratory testing results from food and environmental samples. This information is usually first received by state or local health departments (LHDs) before it is passed on to federal partners, when deemed necessary. Outbreaks that involve known pathogens may also be identified through matching the genetic similarity of historic and contemporary isolates from product or environmental samples to clinical isolates via molecular subtyping techniques, such as whole genome sequencing [4].

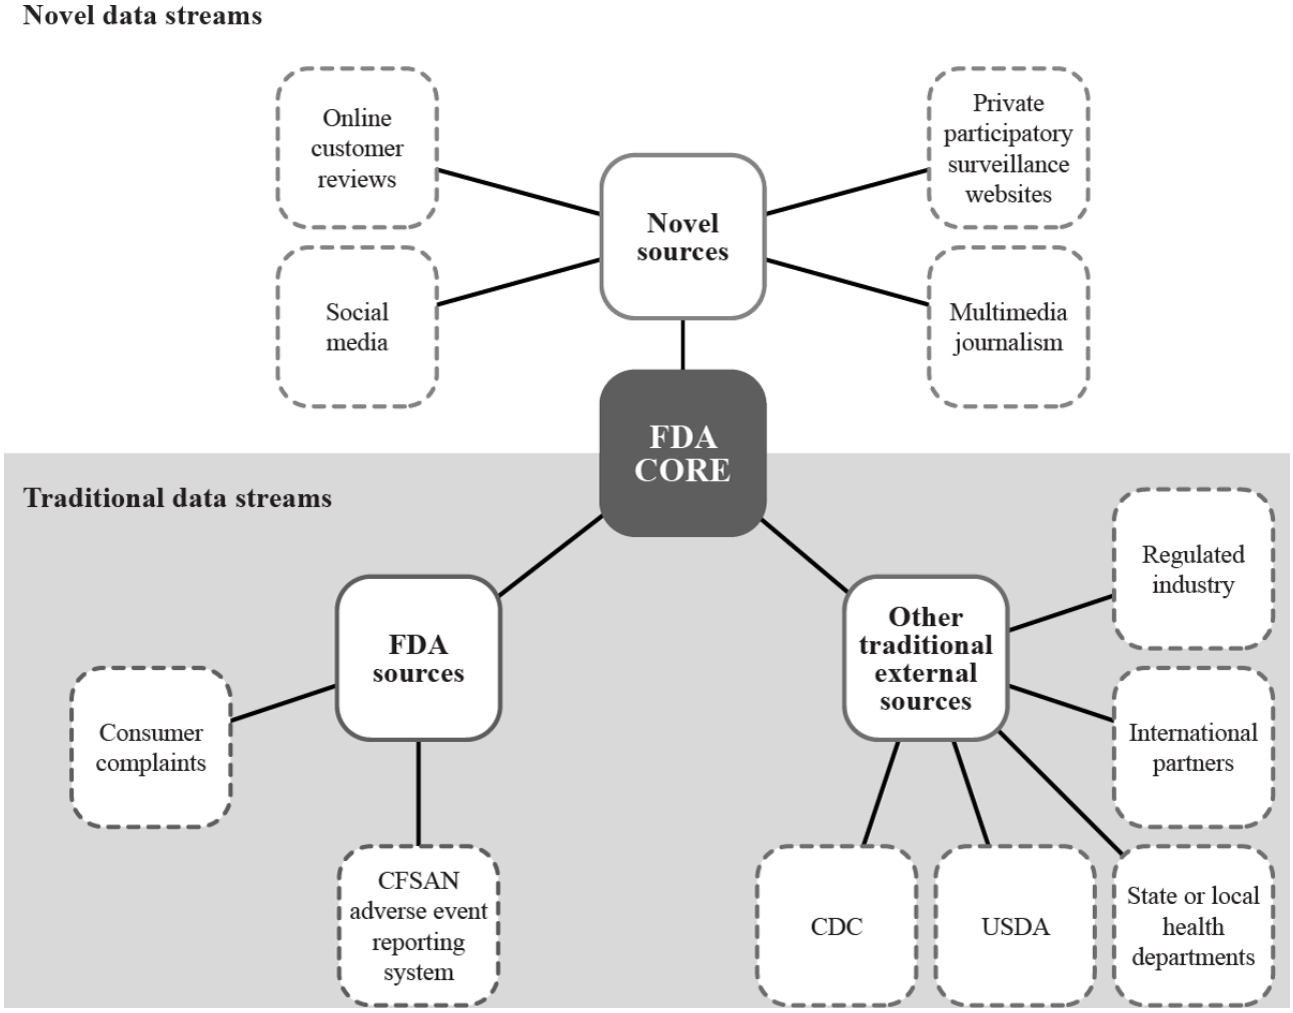
In situations where an etiology is unknown or has not yet been identified, consumer complaint systems provide a mechanism for consumers to self-report adverse health events, including foodborne illness. This allows public health entities to conduct disease surveillance to help mitigate this primary limitation of laboratory-based surveillance. Consumer complaint–based systems allow for the collection and storage of consumer reports that can be submitted in a range of formats, including in-person, phone, e-mail, and web form [5]. A survey of LHDs in the United States revealed that a majority (81%) use consumer complaint–based systems and attributed the detection of 69% of foodborne outbreaks in the past year to consumer complaints [6]. State health departments that have conducted self-assessments of their consumer-complaint systems, such as Minnesota and Rhode Island, have credited the detection of 79% and 80% of foodborne outbreaks to consumer complaints, respectively [7,8]. Of the surveyed LHDs in the United States, 75% reported the ability to receive consumer complaints via email, and 40% reported the availability of a web-based reporting form [6]. The Integrated Food Safety Centers for Excellence help states to continually improve these complaint-based surveillance systems as well [9]. In the United States, the various consumer complaint systems create a patchwork that helps to capture information on foodborne illnesses that may not be reported to medical professionals. However, holistically, this patchwork can pose challenges as data from the various consumer complaint systems are stored separately. Recognition of signals depends on a sufficient number of complaints to come to the same complaint system.

Complaint-based surveillance is also used at the federal level to identify potential clusters of foodborne illness. The US Food and Drug Administration (FDA) collects complaints or reports submitted from consumers, health care providers, industry members, public health officials, or other submitters via 2 web-based mechanisms using the MedWatch or Safety Reporting Portal as well as by phone, email, fax, and physical mail [10-13]. A complainant may submit similar reports via multiple mechanisms, and it may not be possible to distinguish if they are duplicate reports or are separate cases. A key element of identifying illness clusters via this approach is the availability of complete and reliable epidemiologic data, such as illness onset date and contact information, to link complainant reports. This information is also needed to narrow down potential etiology and food vehicle [5].

Disease surveillance and outbreak information received by the FDA from various internal and external sources, including federal, state, and local health partners, is evaluated by the FDA's Coordinated Outbreak Response & Evaluation (CORE) Network, which was established in 2011 and charged with coordinating efforts to find, stop, and prevent illnesses linked to FDA Center for Food Safety and Applied Nutrition (CFSAN) regulated products [14]. These products include all human foods not falling under the jurisdiction of the US Department of Agriculture Food Safety Inspection Service and account for 75% of the food supply in the United States [15]. Once an actionable signal has been identified, further investigational activities and public health actions (eg, product traceback, recalls, and communication) are coordinated across local, state, and federal partners, a process that has been described elsewhere [3].

Traditional investigative tools, such as laboratory-based surveillance, do face challenges including but not limited to underdiagnosis and underreporting of illnesses, varying illness reporting structures, the increased use of culture-independent diagnostic testing, and resource availability [16,17]. While some of these challenges are mitigated by public health consumer complaint systems described earlier, the increased accessibility and use of novel data streams (NDSs) provide new information that may further aid in the detection and investigation of foodborne illness clusters. NDSs include nontraditional sources of information such as social media, web-based customer reviews, multimedia news (comment sections from news stories about clusters of illnesses), and private participatory reporting platforms (PPRPs) that actively collect data on food poisoning.

The availability of crowdsourced web-based information provides an opportunity for public health entities to potentially augment existing traditional foodborne illness surveillance systems or identify clusters not detected by traditional tools. The evolution of cell phones to more readily allow users to access the internet has made these NDSs even more accessible as a tool for the submission of consumer complaints. These NDSs, in the context of foodborne illness, consist of reports of consumer information related to food products that are relayed digitally through social media, search histories, customer reviews (ie, product and restaurant reviews), and PPRPs [18]. Some PPRP sites have the express goal of collecting data on people who believe that they have gotten sick from food. Information from these sources may be shared directly with public health agencies or may be mined by agencies in response to a signal.



NDSs can be integrated with traditional public health surveillance programs to catalyze or supplement investigation, and several examples of this exist at the local and state health department level. For instance, the Chicago Department of Public Health has used social media posts generated within jurisdictional limits to address consumer complaints of food poisoning and to target health inspections [19]. The New York

XSL•FO
RenderX

City Department of Health and Mental Hygiene has similarly evaluated the use of customer-submitted restaurant reviews to detect outbreaks and target health inspections [20]. These are just a few documented examples of the use of NDSs by state and LHDs. No systematic use of these data sources has been documented at the federal level at this time.

Reports of foodborne illness clusters can come from a variety of traditional and novel data sources (Figure 1). In this review, we (1) highlight key details of 3 recent adverse event clusters that were investigated by the FDA and were catalyzed or supplemented by NDSs, (2) discuss challenges and limitations associated with the current use of NDSs by the FDA, and (3) propose opportunities for improvement and the future use of NDS applications during foodborne illness surveillance and investigational activities conducted by the FDA.

Figure 1. Examples of adverse event and illness cluster data sources evaluated by the US Food and Drug Administration Coordinated Outbreak Response & Evaluation (FDA CORE) Network. Multimedia journalism may also be considered a traditional data source in some cases. Three Case Studies

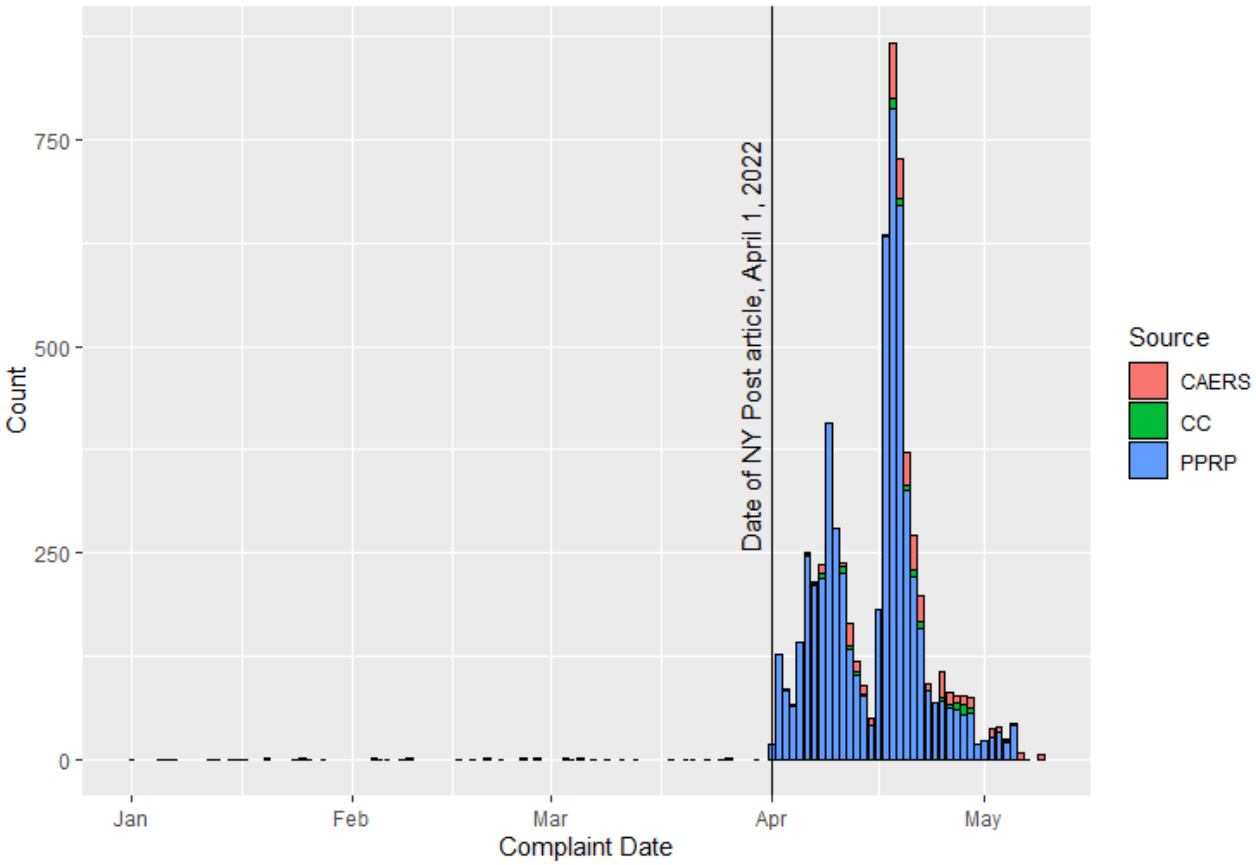
Overview

To illustrate the use of NDSs during FDA investigations of foodborne illness clusters, the following 3 case studies describe recent incidents linked to dry breakfast cereal, ketogenic shakes, and plant-based crumbles, respectively. Each of these incidents provides a unique look at how these data streams were used by the FDA to identify or supplement investigations. There may be duplicate reports included in the analyses of these case studies, as reports may have been submitted by the same complaint through multiple points in FDA and to a given PPRP or other form of NDS. The following case studies are meant to highlight examples of this use and are not meant to be comprehensive reviews of the entire incidents.

Dry Breakfast Cereal

On April 1, 2022, the New York Post published an article that highlighted an increase in illness reports mentioning a dry breakfast cereal product on a PPRP [21]. The article stated that at least 139 consumers reported vomiting and diarrhea after consuming the dry breakfast cereal of interest, which prompted an FDA investigation. After FDA CORE initiated an investigation, the PPRP shared complaint data with the FDA, which was reviewed by FDA CORE and used for an initial assessment of the incident. FDA's medical evaluation of 470 PPRP reports received from January 1, 2022, to April 5, 2022, identified symptom onset data for 349 (74%) reports, most of which (96%) suggested nonrapid symptom onset (exceeding 30 min since consumption). In some cases, due to the nature of the reporting tool, these data sometimes omitted necessary



XSL•FO
RenderX

epidemiologic information such as the date the person first reported feeling ill, food exposure date, and illness duration.

Thus, the investigation instead focused on reports directly submitted to the FDA. FDA consumer complaint reports collected between June 1, 2021, and May 10, 2022, that mentioned exposure to the dry breakfast cereal product of interest and explicit gastrointestinal (GI) symptoms were reviewed. Only one of the 120 consumer complaint reports submitted between June 1, 2021, and May 10, 2022, was received in 2021. The remaining 119 were submitted after April 1, 2022, the day the NY Post article was published. Of these 120 consumer complaints, many reported GI symptoms.

Between June 1, 2021, and May 10, 2022, there were a total of 438 Center for Food Safety and Applied Nutrition Adverse Event Reporting System (CAERS) reports associated with the dry breakfast cereal product, 437 of which were submitted after April 1, 2022 (Figure 2). The FDA conducted an analysis of 406 CAERS reports that contained suspected cases with exposure to the breakfast cereal, explicit GI symptoms, and were received prior to April 30, 2022. Of 406 CAERS reports, only 160 had information on illness onset, most of which suggested symptom onset occurred 1‐24 hours after consumption. Overall, 558 FDA adverse event reports (120 consumer complaint and 438 CAERS reports) and 6272 PPRP reports of GI illness were associated with this incident.

Figure 2. Distribution of adverse event reports received by various reporting platforms concerning dry breakfast cereal (2022). CAERS: Center for Food Safety and Applied Nutrition Adverse Event Reporting System; CC: Food and Drug Administration consumer complaints; NY: New York; PPRP: private participatory reporting platform.

In response to illness reports related to the dry breakfast cereal product, the FDA conducted preventive control inspections at 2 manufacturing facilities that produced the dry breakfast cereal of interest and at 1 product supplier in order to document manufacturing operations and identify potential deficiencies. An FDA investigation was also conducted at the corporate offices of the dry breakfast cereal brand in order to collect records pertaining to manufacturing processes, facilities, products, suppliers, quality control practices, and consumer complaint data. Concurrently, the Michigan Department of Agriculture and Rural Development initiated a preventive control inspection at another supplier to the brand. No significant observations were found during these inspections. FDA chemical and microbial analyses were completed on product and environmental samples. FDA and state partners also analyzed clinical and consumer product samples. However, no causative agent for this incident was identified. Evidence from this investigation indicated that this was, in fact, not a microbial outbreak related to dry cereal.

Ketogenic Shakes

In March 2022, a PPRP shared with the FDA an analysis of complaints they received about Brand A protein or meal replacement shakes, a generic brand produced for Retailer A. The analysis demonstrated that there was an increase in complaints associated with Brand A when compared to other protein or meal replacement shake brands starting in January 2021. The PPRP provided all complaints to the FDA for Brand A protein or meal replacement shakes submitted between

XSL•FO
RenderX

January 2021 and March 2022. A review of this information found that 28 of 32 reports specifically identified the ketogenic shake from Brand A, and the FDA initiated an investigation into this product. During the investigation, 6 additional complaints were received, culminating in a total of 34 complaints specifically identifying Brand A ketogenic shakes reported to the PPRP between January 2, 2021, and March 30, 2022. These PPRP reports were challenging to use as they lacked complete epidemiologic information, and specific product details, such as lot numbers, were not consistently available. Further, some of the data that was provided was unstructured and required manual review and extraction.

Additionally, reviews for the ketogenic shake product were extracted on March 24, 2022, from Retailer A's website. This data also required manual review and data extraction. Between January 9, 2021, and February 2, 2022, 54 reviews contained text with complaints indicating an adverse event. Finally, FDA systems were queried for complaints related to the Brand A ketogenic shake over the previous 2 years. Between June 6, 2021, and April 8, 2022, 2 consumer complaints and 4 CAERS reports were received by the FDA. Complaints from all 3 data sources (FDA, consumer reviews, and PPRP complaints) were compiled, and a total of 93 were reviewed. Symptoms were varied but included mostly GI distress, and many reported a rapid onset of symptoms (<30 min). The number of reports received for Brand A was compared to the number for Brand B ketogenic shake to ascertain whether the amount of complaints was unusual. The Brand B ketogenic shake had nearly equivalent product labeling to the Brand A ketogenic shake, but the 2 brands did not share a manufacturer. Both brands were nationally distributed in the United States. The FDA CAERS database and the PPRP were also queried for complaints that specified Brand B during the same time frame. These Brand B queries returned no complaints from the PPRP and 1 complaint from FDA CAERS.

Closed retail samples of 2 flavors of Brand A ketogenic shakes and open and closed samples from a complainant's home were collected. Chemical and sensory analyses were completed on all product samples collected by the FDA, and no unusual findings were identified. No public communications or regulatory actions resulted from this investigation. However, details of the investigation were shared with Retailer A, who had already discontinued distribution of the product based on poor web-based reviews and who further, in response to FDA notification, made the remaining product in their stores unavailable for purchase. Ultimately, laboratory testing did not detect any specific undeclared ingredients or toxins as a causative agent for these adverse events, but the investigation did highlight potential consumer intolerances to some declared ingredients used in ketogenic food products.

Plant-Based Crumble Product

In June 2022, the FDA received consumer complaints and adverse event reports referencing GI illness suggesting abnormal liver function (eg, jaundice and dark urine) that may have been attributable to the consumption of a plant-based crumble product produced by Brand C. As of June 23, 2022, 20 CAERS reports and 13 consumer complaints had been evaluated. Although some complainants reported several Brand C products, all complaints specified the plant-based crumble product. Most reported GI and liver-associated symptoms. This incident became heavily publicized as reports pertaining to the adverse events were reported digitally. Additionally, consumers reported adverse health outcomes to various other sources, such as state reporting mechanisms, a PPRP, and directly to Brand C. As of October 18, 2022, this incident included 393 (177 consumer complaints and 216 CAERS reports) adverse event reports in 39 states with 133 hospitalizations and zero deaths. Estimated illness onset dates ranged from April 19, 2022, to September 4, 2022.

Closed and open samples of Brand C plant-based crumbles product were sampled from complainants' homes. Closed and undistributed product samples were also obtained from Brand C's warehouses. Both chemical and microbiological analyses were performed, but there were no significant findings. However, in 2024, the FDA made a public posting noting that tara flour, an ingredient used in this product, did not meet the Generally Recognized as Safe standard, so it was an unapproved food additive [22]. The FDA issued a web post on the investigation and posted the company recall on the FDA recalls page [23,24]. The FDA further performed several domestic inspections related to the incident and 1 foreign inspection, though none of these actions provided evidence of contamination.

During this investigation, the FDA also reached out to the PPRP to examine any reports they had received regarding this product. The website had received 24 complaints associated with Brand C products from April 4, 2022, to October 18, 2022, 7 of which mentioned the product of interest (plant-based crumbles). Of these 7 complaints, 4 reported GI symptoms and 3 reported various liver-associated ailments. Records from the PPRP were obtained to rule out other vehicles of interest, such as other Brand C products and products from a separate company, Brand D. Although 8 other products were mentioned, none were mentioned more than twice. Further, the PPRP had only received a single complaint for Brand D, which described nausea and vomiting. Based on these reports and the data from FDA systems, other Brand C and Brand D products were excluded as not likely vehicles of illness for this incident.

Discussion

Overview

The use of NDSs to identify adverse event signals or supplement FDA investigations of foodborne illness clusters may offer opportunities such as earlier detection of clusters and vehicle confirmation as seen in the case studies described earlier. However, data collection from NDSs also presents challenges that may reduce their utility during ongoing incident investigations. The advantages and challenges associated with the use of NDS data are discussed in the following section, along with a summary of future steps to better harmonize public health efforts.

XSL•FO
RenderX

Advantages

Traditional, laboratory-based methods of foodborne disease surveillance are largely reliant on the detection of foodborne illnesses via information collected at the clinical level, such as laboratory tests and health care provider reports [25]. These signals are dependent on ill persons seeking medical care, yet some research indicates that fewer than 15% of individuals with self-suspected foodborne illness seek medical attention or report to an LHD [25]. The most recent Foodborne Disease Active Surveillance Network (FoodNet) population survey supports this, noting that only 16.9% of respondents with an acute GI illness sought medical care [26]. Further, most episodes of foodborne illness are self-limiting, and only a small percentage of illnesses in the United States are estimated to result in hospitalization [2]. Once a case of foodborne illness is detected, associated epidemiologic information is gathered by trained epidemiologists, which ensures collected information is detailed and accurate. However, national mandatory reporting of foodborne illnesses is limited to a select set of diseases [27]. While this list includes most well-established foodborne pathogens, it is not as useful for illnesses without a known etiology. Notification of the public health system to new illnesses is also slow, as lag times often range from 2 to 4 weeks or more, depending on the etiology, time of year, and laboratory testing capability. As discussed, some of these limitations are mitigated by various consumer complaint-based systems that are not limited by specific etiology and do not require a person to seek medical care. This is particularly important for localized outbreak detection.

NDSs have the potential to address gaps that exist in traditional foodborne illness surveillance methods and empower consumers. For example, data from these systems can alert public health agencies to foodborne illnesses in situations where medical care is not obtained (eg, due to financial reasons, lack of perceived necessity). NDSs may also provide early signals for foodborne illness clusters that would otherwise be slowed due to expected lag times in case reporting or unforeseen delays. Common barriers to traditional reporting, such as cost, time, access, or awareness, may also be avoided by consumers who use NDSs. In the United States, mechanisms to report an adverse event directly to a public health entity vary across the state and federal levels, while NDS companies have varying user-friendly formats for accepting consumer complaints. Therefore, the generation of an adverse event report on a PPRP or a review on a product webpage may be more intuitive, simpler, and less time-consuming for the public in some situations.

The broad reach of NDSs strengthens their ability to catalyze public health investigations. The larger number of associated complaints can also contextualize reported symptoms, which is useful in situations where the pathogen or hazard is emerging and case symptomology is unknown. One example of this is the ketogenic shake investigation, in which complainants described a rapid onset of short-lived symptoms after consuming the product, making it more unlikely for complainants to seek care under these circumstances. Despite the low volume of related complaints reported to the FDA, which typically would not rise to the level of an investigation, an FDA investigation was triggered due to the number of complaints reporting a similar product or symptomology within product reviews and PPRP reports.

A signal received via NDS of a suspected illness related to an FDA-regulated product may allow the FDA to evaluate consumer risk using investigative tools such as traceback if the incoming data includes necessary details about the product. Traceback helps ascertain if illnesses are related to a common source, which leads to further investigation and, potentially, product actions. Details within NDS reports may help to target firm inspections, product sample collection, and product testing, all of which can inform compliance actions. Retailers may also use information from NDSs as an early alert to a poor-quality product or one that may be causing adverse reactions among consumers, such as in the example provided with ketogenic shakes. This unsolicited information allows retailers to internally initiate actions to protect consumers prior to a manufacturer-initiated product recall or the attention of regulatory and public health agencies. Traceback information obtained from NDSs may also help to rule out products not linked to adverse events. Although NDS data can inform industry and regulatory investigations, the source for NDS reports may be anonymous; therefore, the veracity of the data should be considered during decision-making.

Challenges

An overarching limitation of NDSs stems from the quality of available data. Consumer complaints made to the FDA use forms that incorporate standardized epidemiologic data elements, including those identified by the Council to Improve Foodborne Outbreak Response [27]. These forms also collect details used to assess complaint trends and detect potential food safety issues. NDSs do not reliably capture key data elements essential for public health investigations such as those outlined in Table 1, which includes an expanded list of data elements in addition to those put forth by the Council to Improve Foodborne Outbreak Response. As NDSs often obtain information for other purposes, data gaps are expected and can hinder public health investigations. For example, epidemiologic information is used by investigators to identify a common etiologic agent, which is critical in the absence of clinical validation. Without epidemiologic information, the cause of a food safety issue is more challenging to identify, and the scope of product testing is significantly more resource intensive. Product and exposure information are also necessary to identify a common source of illness and inform traceback investigations. A lack of actionable data inhibits public health response, which was illustrated during the 3 investigations described here.

Another limitation associated with NDS systems is that the data are often unstructured. Information from complainants is typically in the form of free-text entry (eg, social media posts, product reviews, web-based comments), which currently require manual review to extract key data elements. This process is resource-intensive, subject to human error, and has limited feasibility for large numbers of posts or comments. Automated data review may reduce the burden of manual review in the future, but specialized tools are expensive investments for ad hoc analyses, and varying data sources may necessitate different technical approaches. Similar to traditional outbreak data

XSL•FO
RenderX

sources, NDS reports may also be duplicated across reporting platforms, as individuals may submit complaints on multiple NDS platforms, multiple complaints on one platform, and directly to the FDA (Figure 1). Some NDS platforms do minimize report duplication with requirements for users to sign into an account, to have verified purchases to leave a review, or by tracking the IP address of the user. However, evaluation of complaint uniqueness for enumeration across platforms may require manual deduplication or simply not be possible.

Table . List of key data elements for actionable public health response for collection by novel data systems, expanded and modified from the Council to Improve Foodborne Outbreak Response [27].

Data type	Data element
Epidemiologic	• Illness onset date and time • Symptoms • Duration of symptoms • Care-seeking behavior • Suspected exposure of interest • Exposure date • Other recent exposures (past 7 days)
Product	• Photo of product packaging • Brand • Best buy date or best if used by date • Lot code • Product description on label • Purchase location and purchase date • Manufacturer, distributor information
Complainant's contact information	• Name • Phone number • Email address
Affected individual's contact information (if not the same as the complainant's)	• Name • Phone number • Email address
Affected individual's demographic information	• Age • Gender • State of affected individual's residence
Method of report	• Date of complaint • Type of platform • Method of complaint

Ultimately the structure, breadth, and utility of information available in an NDS are dependent on the purpose of the platform. Certain NDSs, such as web-based reviews and social media posts, share information publicly, though not explicitly for public health goals. Due to this, food safety complaints made on these platforms usually lack critical data elements but have the potential to provide contextual information that can catalyze or supplement an investigation. PPRPs do have a public health goal, and compared to official government complaint systems, they may be easier to find and use, which makes them attractive options to complainants. However, although these sites may be easier to use, the data captured may be incomplete or of lower quality than data collected from traditional complaint systems. Public health and regulatory officials must keep these limitations in mind when considering NDSs in an investigational context.

When a signal for an adverse event is received, public health investigators review the reported symptoms, in conjunction with laboratory diagnoses, to determine an etiology and define cluster criteria (ie, develop a case definition) [27]. With NDSs, limited epidemiologic information may result in nonspecific symptomology. Alternatively, investigators may rely on medical records and laboratory documentation to accumulate evidence in search of a possible etiology, but complainant contact information is not often included in NDS reports, which prevents investigators from obtaining follow-up information. Thus, reports from NDSs must be grouped based on available epidemiologic features, which results in a broad case definition, extensive record requests, and resource-intensive review by investigators. Therefore, biological plausibility and medical review should be considered when refining a case definition and evaluating likely exposures when using NDSs.

Evidence has shown that media attention, particularly TV news coverage, can lead to an increase in adverse event reporting during a health scare [28,29]. This would also affect reporting to NDSs, which could see greater impacts given their ease of reporting, particularly if an NDS uses tools such as social media to share information on the incident. This effect was illustrated during the dry cereal incident, as complaints to both NDSs and FDA increased dramatically after newspaper reporting (Figure 2). One possible further complication of media attention is the amplification of unreliable and spurious signals that leads to

XSL•FO
RenderX

stress on public health response entities, who already have limited resources.

Many actors are involved in multistate investigations, each with unique roles and challenges. One of these challenges is identifying proper medical and epidemiologic experts to evaluate data collected from PPRP or other NDS sources. CDC, for example, has investigational programs aligned to specific pathogens, so it can be difficult to identify which group would provide expertise during an investigation involving an unknown etiology.

As NDS platforms are not managed by established public health systems, information sharing with entities that have authority to take public health action is limited. Although some public health agencies may partner with third-party NDS platforms, subscribe to their services, or survey their data, NDS data may not be automatically escalated to a public health authority, which may not always be clear to the public when submitting their report. Also, some NDS companies may require public health agencies to pay to access complaint data. In addition, NDS platforms vary in the user information they collect, which can limit the ability to conduct follow-up with ill persons. It is also important to note that these NDS systems may divert ill people away from submitting reports to established public health reporting and surveillance systems. People who report their illnesses on these NDS platforms may assume that their reports will automatically be shared with authorities, which is not the case. In addition, submitting complaints to NDS systems may give people the false expectation that the information they provide will be actionable by public health agencies.

One reason that laboratory results can be confirmed relatively quickly in traditional outbreaks is that the etiological agent is known, and multiple laboratories are often able to perform and analyze testing results. Conversely, NDS-detected outbreaks often have an unknown etiological agent, which requires broad, instead of targeted, testing and often takes longer to return results.

Similar to limitations discussed regarding epidemiologic data, information collected from consumers through NDSs may lack critical elements needed for product traceback, such as product and purchase information. Although photos can be shared of a product, photos and product descriptions obtained from consumers do not consistently provide information on lot numbers, purchase dates, or purchase locations. Using a phone to submit complaints, while convenient, may limit the amount of information that people are able to submit. This information can aid regulatory authorities to conduct traceback, as some products may have the same name or label but have been produced or grown at different locations. Purchase information may also inform traceback investigations through identification of the manufacturer; however, these details are not consistently captured from NDSs or from traditional outbreak data sources. Ultimately, the lack of consistent product and purchase information may hinder the identification of a specific implicated product for further industry or regulatory action.

Opportunities

While NDSs have been helpful at the local level in identifying establishment-based illness clusters or targeting limited resources for inspections, foodborne investigations at the federal level focus on multistate outbreaks or vehicles that enter interstate commerce [7,20,28]. In these situations, etiologic agents are generally not related to ill workers or conditions at a retail establishment, but rather issues further up the supply chain. Similar to traditional outbreak data sources, NDSs reports may be of assistance during FDA investigations to identify signals related to branded or packaged products that are easily identified by the consumer, as opposed to loose items, such as produce, with no clear or easily identifiable brand or manufacturer. NDSs are also most likely to identify incidents that involve a rapid onset of symptoms, as with the ketogenic shakes investigation, or unusual symptoms, as in the plant-based crumble product investigation.

Signal detection and data collection through NDSs will likely become more prevalent. Therefore, it is incumbent upon public health agencies to determine the best ways to use this data, integrate it into established signal detection systems, and potentially collaborate with platform hosts. There is also a need to establish a process, once a signal is detected via NDS, where ill individuals can be interviewed with a standardized questionnaire that can be used to further evaluate potential exposures and etiologies. NDS providers should consider adding the noted critical data elements (Table 1) to existing data captured by their sites or provide public health officials with contact information to follow up with complainants. CDC and state health departments or LHDs can play an important role in coordinating patient interviews and epidemiological data collection, including medical records. In the future, the further development of tools for natural language processing, website scraping, and optical character recognition technology (software to extract text from an image) may also be useful when applied to NDSs for signal detection or to supplement ongoing outbreak investigations.

Conclusions

NDSs may enable quicker signal detection in certain situations compared to traditional surveillance methods for foodborne illness clusters attributable to unknown agents. Recently, NDSs have provided supplementary data during traditional investigations and sparked investigations into previously undetected signals, which may or may not have provided enough information for an actionable public health response. While PPRPs and product reviews are the focus in this paper, future signals may come from other NDSs, such as web-based social media platforms. To effectively integrate these data into public health surveillance and response, working protocols could be developed to help agencies better collect, surveil, and assess this data. NDSs with a focus on public health should also do their best to collect critical epidemiologic, product, and clinical data, enhancing their utility as a resource for public health agencies.

Acknowledgments

The response efforts discussed in this manuscript included numerous public health officials at local and state health and regulatory departments and public health laboratories in the United States, who serve as the backbone of any multi-state foodborne illness outbreak investigation. We also appreciate the assistance provided by US Food and Drug Administration (FDA) Emergency Response Coordinators who coordinated the response between FDA and state partners. The findings and conclusions of this report are those of the authors and do not necessarily represent the official position of the FDA and the Centers for Disease Control and Prevention (CDC).

Scaling Up and Enhancing the Functionality of the Electronic Integrated Diseases Surveillance and Response System in Uganda, 2020-2022: Description of the Journey, Challenges, and Lessons Learned

Abstract

In 2017, Uganda implemented an electronic Integrated Disease Surveillance and Response System (eIDSR) to improve data completeness and reporting timelines. However, the eIDSR system had limited functionality and was implemented on a small scale. The Ministry of Health, with support from the Infectious Disease Institute, Makerere University, and Health Information Systems Program Uganda, upgraded the system functionality and scaled up its implementation. This study describes the process and impact of upgrading eIDSR functionality and expanding its implementation across additional districts. The Ministry of Health, through its Integrated Epidemiology, Surveillance & Public Health Emergency Department, coordinated the implementation of the eIDSR. User requirements were identified through consultations with national surveillance stakeholders. The feedback informed the design and development of the upgraded eIDSR functionalities. The eIDSR rollout followed a consultative workshop to create awareness of the system among stakeholders. A curriculum was developed, and a national training of trainers was conducted. These trainers cascaded the training to the district health teams, who later cascaded the training to health workers. The training adopted an on-site training approach, where a group of national or district trainers would train new users at their desks. The eIDSR system was upgraded to the District Health Information Software 2 (DHIS2) 2.35 platform featuring faster reading and writing tracker data, handling over 100 concurrent users and enhanced case-based surveillance features on Android and web platforms. From October 2020 to September 2022, the eIDSR was rolled out in 68% (100/146) of districts. Additionally, the system permitted prompt reporting of signals of epidemic-prone diseases. Improving the functionality and the expanded geographical scope of the eIDSR system enhanced disease surveillance. Stakeholder commitment and leveraging existing structures will be needed to scale up eIDSR.

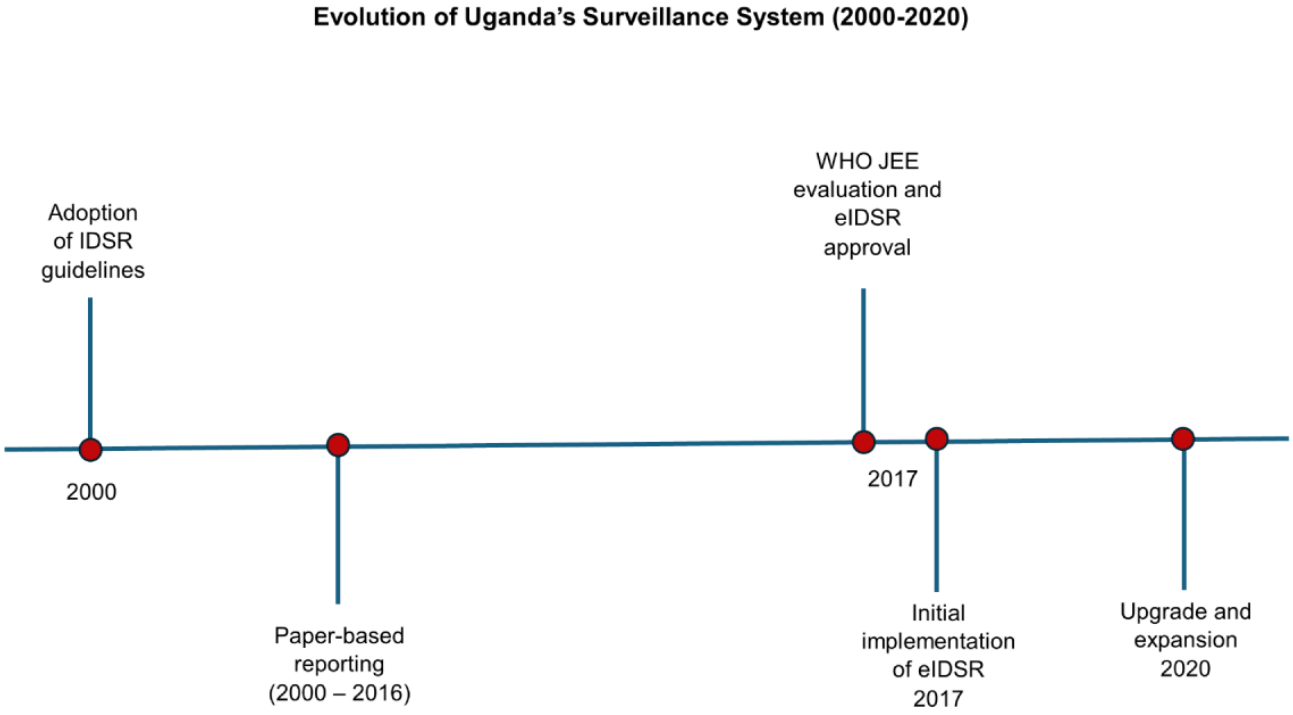
KEYWORDS

electronic Integrated Disease Surveillance and Response; eIDSR; disease surveillance; training of trainers; Uganda; digital surveillance systems; health worker; eHealth; public health; digital health

Introduction



Uganda is highly susceptible to public health emergencies due to its proximity to the ecologically diverse and biologically rich tropical Congo Basin, recurrent epidemic-prone outbreaks, and refugee inflow [1]. In the last 5 years before 2024, Uganda has faced several significant outbreaks, including Ebola and Marburg virus diseases, cholera, measles, and Crimean-Congo hemorrhagic fever, highlighting the ongoing threat of infectious diseases [2]. Before 2000, surveillance systems were not robust enough to detect outbreaks early, leading to delayed responses and exacerbated public health impacts. For instance, the 2000 Ebola outbreak in Gulu, which resulted in 224 deaths,

underscored the inadequacies in early warning and response mechanisms at the time [3].

Uganda embraced the Integrated Disease Surveillance and Response (IDSR) technical guidelines in 2000 [2]. However, the IDSR system was largely paper based. Reports from health facilities were transmitted physically to the district-by-district surveillance focal persons. The process of transporting paper-based reports often took several days to weeks, depending on the distance between the facilities and district offices, the availability of transportation, and other logistical challenges. This manual process led to delayed data transmission and response [2,4]. The World Health Organization (WHO) Joint External Evaluation conducted in 2017 highlighted the fragmentation and lack of coordination between human health, animal health, and laboratory data systems, which hindered effective surveillance of zoonotic diseases [3]. Additionally, the system faced challenges with data quality, including errors and inconsistencies due to manual data entry, as well as inadequate infrastructure, such as unreliable internet and computer systems, which further limited the effectiveness of the surveillance system [3]. In light of these findings, the Ministry of Health (MOH) approved the implementation of the electronic Integrated Disease Surveillance and Response (eIDSR) System in 2017 (Figure 1) to improve the timeliness of reporting; enhance data accuracy and quality; facilitate integration of data across human health, animal health, and laboratory sectors; and improve the capacity for data analysis and decision-making in public health interventions [5].

Figure 1. Road map of Uganda's surveillance system since 2000. eIDSR: electronic Integrated Disease Surveillance and Response; IDSR: Integrated Disease Surveillance and Response; WHO JEE: World Health Organization Joint External Evaluation.

The Electronic Integrated Disease Surveillance and Response System

The eIDSR system is based on the electronic application of the principles of the IDSR to facilitate early detection, investigation, and response to public health events [6]. The eIDSR was developed and customized on the District Health Information Software 2 (DHIS2) open-source software platform (version 2.35; Health Information Systems Program [HISP], University of Oslo) [7]. Unlike the conventional paper-based system used in health facilities, which requires data to be recaptured electronically at the district level, the eIDSR facilitates the instantaneous reporting of notifiable diseases through its SMS, Android, and web platforms [8]. The Android platform had an offline data entry functionality that allowed case-based notification and registration. The SMS platform facilitated immediate notification through a toll-free code currently used by the Uganda MOH. The application could also save data offline and automatically submit it as soon as an internet connection was available [9]. While improving paper-based reporting, the eIDSR system still faced challenges in ensuring that the data collected were complete and accurate. The eIDSR system facilitated case reporting through electronic case investigation forms for 9 out of 33 priority diseases and conditions. Inconsistencies in data entry and gaps in reporting affected the reliability of the information, which in turn impacted decision-making. The interface was not sufficiently user-friendly, which sometimes led to errors in data entry and delays in reporting. Moreover, the need for advanced data visualization tools made it difficult for public health officials to quickly interpret data trends and make informed decisions.

The enhancements and upgrades to the eIDSR system were therefore justified by the need to address these specific challenges. These upgrades included the addition of electronic case investigation forms for other priority diseases and advanced reporting tools to improve data timeliness and quality by streamlining the data entry process. New data visualization features were also added to enable public health officials to

XSL•FO
RenderX

quickly interpret complex data through charts, graphs, and heat maps, facilitating more informed and timely public health actions. Additionally, enhancements were made to ensure better interoperability with other health information systems, thereby reducing data fragmentation and improving the overall efficiency of the surveillance system. The user interface was also redesigned to be more intuitive and user-friendly, reducing the likelihood of errors and encouraging more consistent use of the system by health care workers.

In October 2020, the Infectious Diseases Institute, Makerere University, in collaboration with the Uganda MOH and the HISP Uganda, upgraded the functionalities and scaled the eIDSR to 100 out of 146 districts. This study describes the process and impact of upgrading eIDSR functionality and expanding its implementation across additional districts.

Methods

Overview

A coordinated approach was used to systematically design the enhancement of functionalities and scale-up of the eIDSR. The process began with gathering user requirements from surveillance stakeholders. These requirements were then translated into technical upgrades. The MOH Integrated Epidemiology, Surveillance, and Public Health Emergencies (IES&PHE) Department led coordination. A cascade training model was then conducted to equip health care workers with the necessary skills.

Coordination

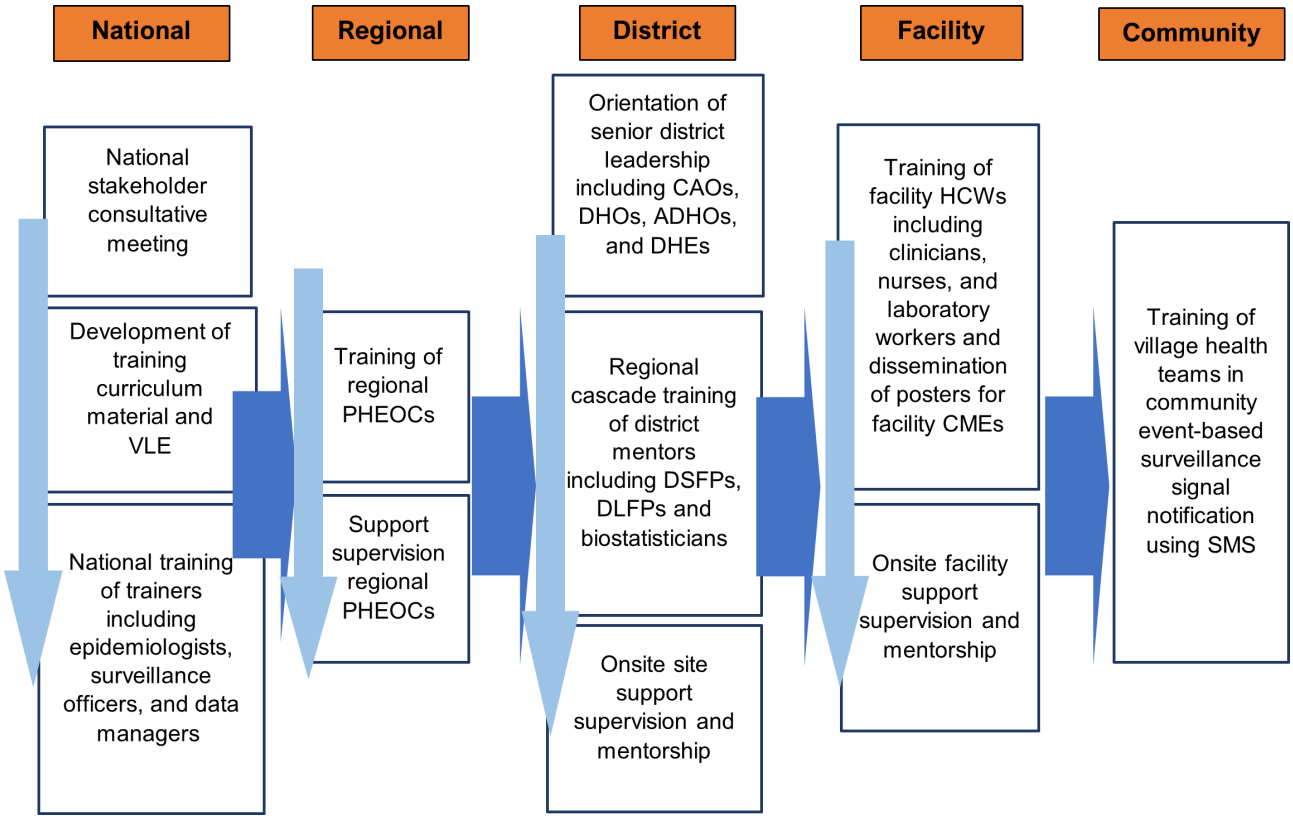
The MOH, through its IES&PHE Department, coordinated the implementation of the eIDSR. The IES&PHE Department provided leadership and oversight throughout the implementation process. By coordinating the efforts of various stakeholders, the department ensured that the system was aligned with the country's health priorities. The MOH coordinated the collection of user requirements to ensure that the eIDSR system addressed the specific needs of end-users, such as surveillance officers and health workers. Additionally, the MOH was responsible for convening national surveillance stakeholder meetings.

User Requirements Gathering

User requirements were identified through consultations with national surveillance stakeholders, including the Ministry of Agriculture, Animal Industry, and Fisheries (MAAIF), implementing partners, as well as regional and district surveillance officers. The requirements were gathered on several aspects: system functionality, such as its ability to capture and transmit data in real-time; data quality, accuracy, completeness, and timeliness of reporting; user adoption; and operational challenges, such as technical issues and resource constraints. The feedback gathered was instrumental in informing the design and development of the upgraded eIDSR functionalities, which aimed to address gaps in the existing system.

System Development and Enhancement

The technical team from the HISP Uganda then translated these requirements into operational enhancements. The eIDSR system was upgraded to the DHIS2 2.35 platform, featuring faster reading and writing tracker data and enhanced case-based surveillance features on Android and web platforms. Key changes included the integration of advanced reporting tools, real-time data visualization features, and enhanced interoperability with other health information systems, such as laboratory and animal health data systems. These upgrades were intended to streamline data collection allowing more concurrent users, improve accuracy, and enable more timely responses to public health threats (Figure 1).



National surveillance stakeholder engagement meetings were regularly convened to obtain user feedback and ensure ongoing coordination and harmonization of the eIDSR rollout. These meetings brought together representatives from the MOH, MAAIF, and other stakeholders to review system performance, address challenges, and plan the expansion of eIDSR to additional districts.

Training

An eIDSR curriculum was developed through a collaborative process involving key stakeholders from the MOH, implementing partners, and subject matter experts in epidemiology, surveillance, and health information systems. The development process began with a needs assessment to identify the specific skills and knowledge gaps among health workers at various levels of the surveillance system. The curriculum was further refined through a series of consultative workshops, where feedback was gathered from national and regional trainers, district health teams, and other stakeholders. This iterative process ensured that the training content was relevant, practical, and aligned with the MOH's surveillance goals. Additionally, the curriculum incorporated IDSR best practices in disease surveillance and reporting, while being tailored to the local context of Uganda. Real-time simulations, case studies, and interactive sessions were added to make the training more engaging and to reinforce learning outcomes. The curriculum focused on alert notification, case notification, registration, and reporting using SMS, Android, and web platforms. The training curriculum also covered the fundamentals of surveillance, such as event-based surveillance and indicator-based surveillance, as well as priority diseases and events for immediate reporting. The rollout model adopted the MOH-recommended approach, where training was cascaded from the national to lower levels (Figure 2).

XSL•FO
RenderX

Figure 2. The electronic Integrated Disease Surveillance and Response (eIDSR) implementation approach in Uganda, 2020-2022. ADHO: assistant district health officer; CAO: chief administrative officer; CME: continuing medical education; DHE: district health educator; DHO: district health officer; DLFP: district laboratory focal person; DSFP: district surveillance focal person; HCW: health care worker; PHEOC: Public Health Emergency Operations Center; VLE: virtual learning environment.

At the national level, national training of trainers was conducted to establish a cohort of national trainers to cascade training to the regional level. This training targeted epidemiologists; health information analysts; laboratory, clinical, monitoring, and evaluation specialists from the MOH; and implementing partners. At the regional level, the national trainers oriented the district health teams on the eIDSR. The district health team comprised of biostatisticians and the Health Management Information System focal persons, district surveillance focal persons, district laboratory focal persons, district veterinary officers, and health subdistrict surveillance focal persons.

At the district level, regional trainers trained clinicians, nurses, laboratory and health information assistants, and facility- and community-based health workers (ie, village health teams) at the facilities. Health workers were selected from high-volume facilities; regional and district hospitals; level 3 health centers that provide a broader range of services including outpatient and inpatient care, basic laboratory services, maternity services, and minor surgeries; and level 4 health centers that provide comprehensive care to larger areas with emergency obstetric care, basic surgeries, laboratory services, and treatment for common diseases. District surveillance focal persons that were trained were given tablets, monthly airtime, and internet data to support case registration and reporting of priority diseases. The trainers subsequently provided post-training mentorship and support supervision to subnational health teams through mentorship to ensure that skills gained during the training were sustained.

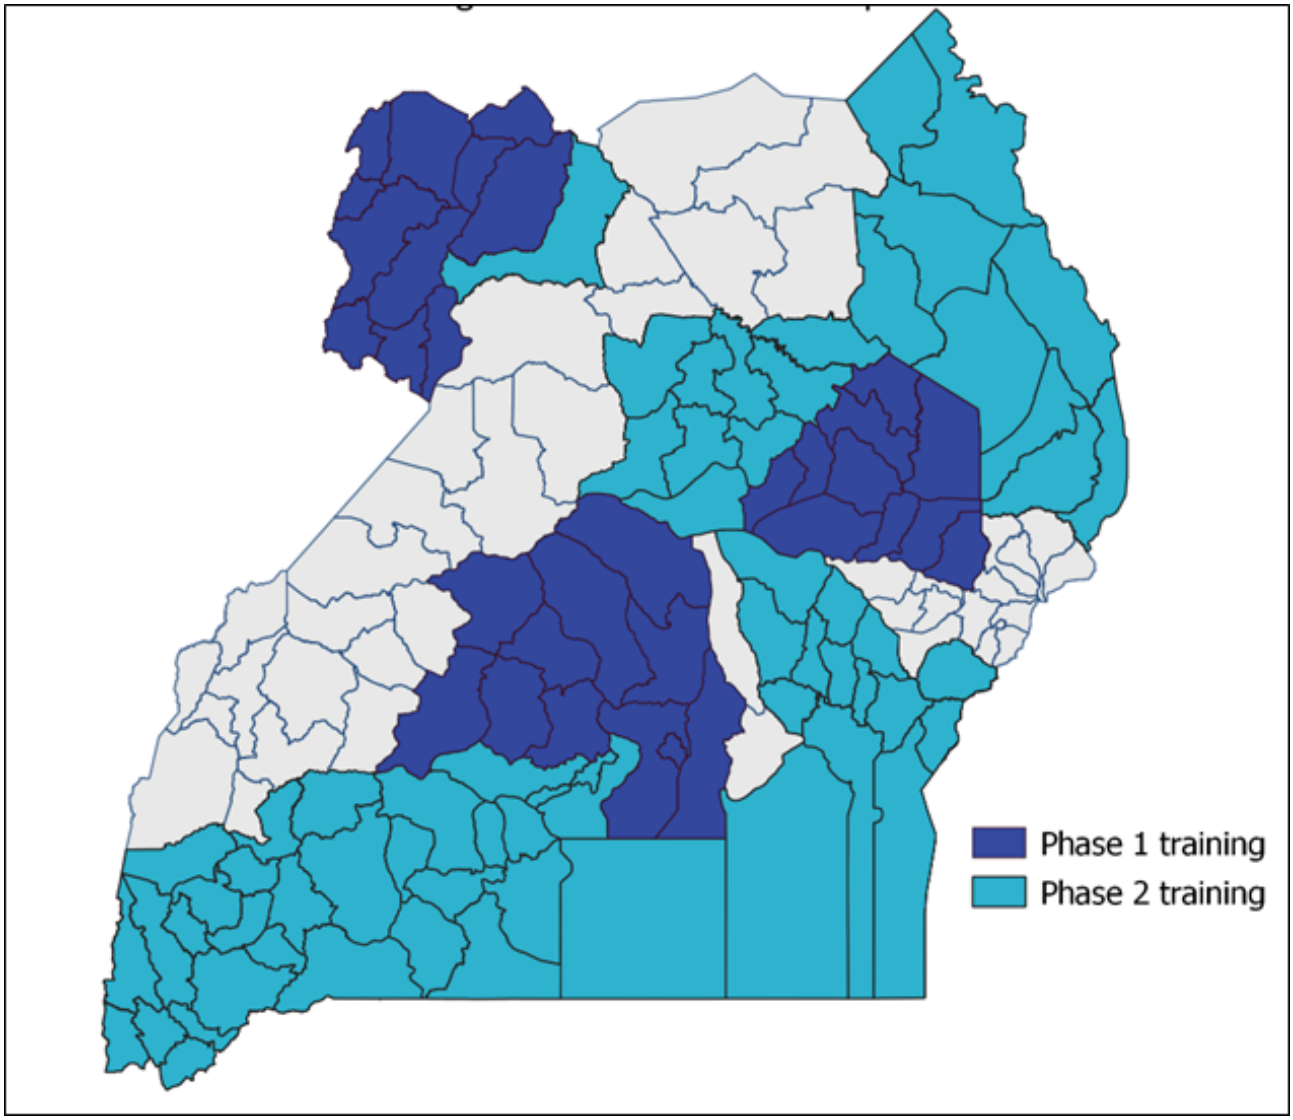
System Upgrade and Stakeholder Engagement for eIDSR Enhancement

In 2020, the HISP Uganda developers improved the eIDSR system to the DHIS2 2.35 platform version following the user requirements gathering process. Improvements included the development of an additional 19 electronic case investigation forms for priority diseases, including rabies, anthrax, severe acute respiratory illnesses or influenza-like illnesses like COVID-19, and cholera. These diseases were identified due to their potential for outbreaks, high burden, and emerging threats. The existing eIDSR system lacked comprehensive tools to capture detailed case investigation data. The new forms were developed to address this gap by including essential variables such as exposure history, symptoms, and hospitalization details to enable effective disease tracking of case investigation details, exposure and travel history, symptoms, underlying conditions, and hospitalization.

The laboratory requests and results module were improved to capture laboratory requests for tests to be conducted on the specimen collected for each case. Variables captured include the identification, place, and time (date) of sample collection and the reference and final laboratory results. The improvements in the case outcome module also enabled more accurate tracking of health outcomes and final investigation results. The specimen tracking module was developed to link an existing system that facilitated tracking specimens across the laboratory hubs and laboratories until the completion of the case investigation. The module was developed to send an automated notification via

XSL•FO
RenderX

email and SMS to the reference laboratory and the national disease surveillance team.



Additional upgrades to the system included enhanced data management and analytics capabilities that included the design of highly customizable forms to track individual-level data to facilitate case-based surveillance with data validation functionality for data quality assurance. Data analysis upgrades included robust charting capabilities to include epidemic curves to facilitate epidemiological data analysis. The upgrade included geographic information systems analysis using thematic mapping, allowing overlay of population, climate, and other layers using the Maps app and supporting geolocation of individual cases. In a bid to enhance situational awareness, a smart web-enabled television at the national level was procured to facilitate access to international news outlets and facilitate data visualization from the eIDSR.

The eIDSR System Adoption and Use

During the 2 years of implementation (October 2020 and September 2021), the eIDSR was scaled up to 68% (100/146) of districts and cities (Figure 3). Thirty national trainers and 191 of the targeted 200 district-level mentors were trained. The district mentors subsequently trained and mentored 2409 of 3295 targeted facility-level health care workers from 536 health facilities. The project also trained another cohort of national-level surveillance officers and field epidemiologists from the Public Health Emergency Operations Center on system navigation, data extraction, analysis, and use for action.

Since its rollout, the eIDSR has continued to be an essential data source for disease surveillance to facilitate the detection and reporting of public health events countrywide. Several events were detected through the eIDSR from SMS messages sent from the community between 2020 and 2022 (Table 1).

Figure 3. Coverage of the electronic Integrated Disease Surveillance and Response (eIDSR) phase 1 and phase 2 training in Uganda, 2020-2022.

Table . Outbreaks detected by the electronic Integrated Disease Surveillance and Response (eIDSR) in Uganda, 2020 - 2022.

Disease outbreak or event	Districts that notified through the eIDSR	Date (year)
Anthrax	Madi-Okollo	2022
Undiagnosed deaths	Kyotera	2021
Rift Valley fever	Kagadi	2020
Anthrax	Bududa and Manafwa	2022
Crimean-Congo hemorrhagic fever	Kagadi	2020
Undiagnosed illness (skin rash)	Pakwach	2020
Rabies	West Nile region: Arua, Adjumani, Moyo, and Yumbe	2020 - 2021
Suspected viral hemorrhagic fever: Rift Valley fever	Moyo, Obongi, Terego, Madi Okollo, and Yumbe	2020 - 2021
Anthrax	Arua and Madi-Okollo	2021 - 2022

Challenges in Implementing the eIDSR

The eIDSR system in Uganda faces several challenges that could threaten the system's sustainability. Data from system logs and user feedback indicate that insufficient technology infrastructure, including reliable internet connectivity and computer hardware, has led to delays in data submission from health care facilities.

Uganda faces significant challenges in its information and communication technology (ICT) infrastructure, impeding the successful implementation of the eIDSR in terms of real-time reporting. Inconsistent internet connectivity and limited access to computer hardware in some rural districts hindered the ability to report cases in real time similarly seen in other countries [10,11]. This was particularly problematic during peak times of disease outbreaks when timely data transmission was crucial for an effective response. It is challenging to operate ICT equipment due to limited access to broadband connectivity and electricity in some rural areas [12]. Another ICT-related challenge was the lack of smartphones among some district surveillance focal persons to register cases in the eIDSR mobile app. The lesson learned is that, for real-time reporting to be successful, ongoing investment in infrastructure, such as reliable internet and adequate hardware, is essential. Additionally, the importance of continuous monitoring and support to maintain data accuracy cannot be overstated.

Health care worker turnover and transfers have significantly impacted the successful implementation of the eIDSR. When trained staff leave, this creates skill shortages and disrupts continuity, causing a knowledge gap similarly seen in the first DHIS2 implementation [4]. This, coupled with the limited ICT skills among health care workers, especially in peripheral facilities, limits the adoption and effective use of the eIDSR. Continuous education and training of users is key to ensuring skill retention, and it is imperative to train many focal persons in each facility.

The inclusion of additional data variables for case investigations presented both an opportunity and a challenge. While the more detailed forms allowed for comprehensive data collection, health care workers found the increased data entry requirements burdensome, particularly in high-volume settings. This sometimes led to incomplete case investigations and delays in submitting reports. To address this, additional training and on-the-job support were provided, emphasizing the importance of thorough and timely data entry. The lesson learned is that there is a need to balance data comprehensiveness with the workload of health care workers to ensure that the system remains user-friendly and efficient.

Opportunities

Despite these challenges, the upgrades to the eIDSR system have provided several opportunities for enhancing disease surveillance and response. The improved system functionality, combined with the lessons learned from the challenges faced, have paved the way for future improvements. For instance, the introduction of mobile data collection tools and offline data entry options could further enhance real-time reporting capabilities, especially in remote areas. Additionally, increased stakeholder engagement and continuous feedback from users will be critical in refining the system and ensuring its long-term sustainability. The pivotal role played by the MOH throughout the implementation process, coupled with the active involvement of district health team trainers, creates a strong possibility of the government taking ownership of eIDSR implementation, independent of external project support.

Discussion

We successfully upgraded eIDSR system functionality and scaled up to more than half of the districts in the country within 2 years of implementation. We also established a cohort of surveillance staff at national and subnational levels who could train health workers across all levels of health care. The implementation of eIDSR was one of the key priority actions in real-time surveillance to address gaps that were recommended from the last WHO Joint External Evaluation conducted in 2017.

The WHO IDSR framework, which strongly emphasizes the necessity for electronic surveillance tools to allow a wide range of crucial surveillance functions, served as a guide for improving the functionality of the eIDSR system [6]. These functions encompass alert notification, case investigation and registration, data quality assurance, real-time reporting, and monitoring and evaluation [9]. The expanded goal of enhancing the national

XSL•FO
RenderX

electronic surveillance system has the potential to benefit significantly from the enhanced functionality of the eIDSR. This broader system intends to seamlessly integrate laboratory tests, notification processes, emergency responses, and reporting mechanisms with indicator-based surveillance, event-based surveillance, and case-based surveillance data across the human health sector. Notably, the eIDSR adheres to open standards and was carefully created on the DHIS2 platform, enabling smooth interchange and connectivity with other software applications and data sources [12]. This strategic alignment puts Uganda on a trajectory for developing interoperability with numerous electronic surveillance systems across multiple industries, in addition to laboratory systems.

A crucial element of the successful rollout of the eIDSR system was the establishment of the curriculum and training of health personnel. Learning is improved by creating a thorough curriculum that incorporates on-site mentoring improvement [13,14]. It was crucial to have onsite supervision and experienced national trainers with knowledge of the eIDSR, public health, and disease monitoring. Maintaining competency requires regular monitoring and evaluation, which includes refresher training. Documenting training records maintains accountability. Sustainability is promoted by incorporating eIDSR training into already-existing health care training programs, and community involvement increases understanding of the system's significance and the responsibilities that health care professionals play in disease monitoring, ultimately improving public health outcomes.

The commitment of the MOH and existing administrative structures provided an opportunity to implement the eIDSR. For example, the division of health information in the MOH is mandated to coordinate initiatives to digitize the health infrastructure [15]. The IES&PHE Department coordinates surveillance and response to public health emergencies. However, several factors documented by unpublished support supervision reports could threaten the sustainability of the system even after enhancement of the system; these include workforce challenges, such as weak ICT infrastructure at the district and health facility level and insufficient funding at the district to conduct surveillance activities. Additionally, Uganda does not have in place interoperable and interconnected electronic reporting for animal health [3]. Data use is lacking as we wait for outbreaks to act rather than use available data to predict specific disease outbreaks, and analysis also remains a challenge.

There are potential limitations to this project. First, the analysis was not intended to be a formal review of the eIDSR platform; we did not assess how the system performed. Thus, additional research is needed to examine to what extent the intervention contributed to improved reporting rates. Secondly, this project did not train village health teams due to inadequate funding. Our project did not give phones or tablets to facility health workers; therefore, we cannot make definitive claims about the effect of implementing the eIDSR on improving case reporting rates.

Conclusions

Improving the functionality and expanding the eIDSR system's geographical scope improved the efficiency of disease surveillance. The system's enhanced features, such as advanced reporting tools, improved data timeliness by streamlining the data entry process, and visualization features enabled quick interpretation of complex data, facilitating decision-making.

The wider geographical reach signifies a successful initial scale-up. To ensure the sustained success and scale of the eIDSR system, future programs should facilitate stakeholder commitment and leverage existing structures. Engaging internal and external stakeholders is crucial for securing long-term support, commitment, and endorsement at the national and subnational levels.

Acknowledgments

We acknowledge the US Centers for Disease Control and Prevention and the Infectious Diseases Institute, Makerere University for funding. Special appreciation is also extended to Health Information Systems Program Uganda for their invaluable technical assistance. Their expertise played a crucial role in the successful implementation and customization of the system. We acknowledge Uganda's Ministry of Health for its leadership and guidance throughout this project. Finally, we would like to express our gratitude to all individuals and organizations who contributed to this endeavor, directly or indirectly.

Abstract

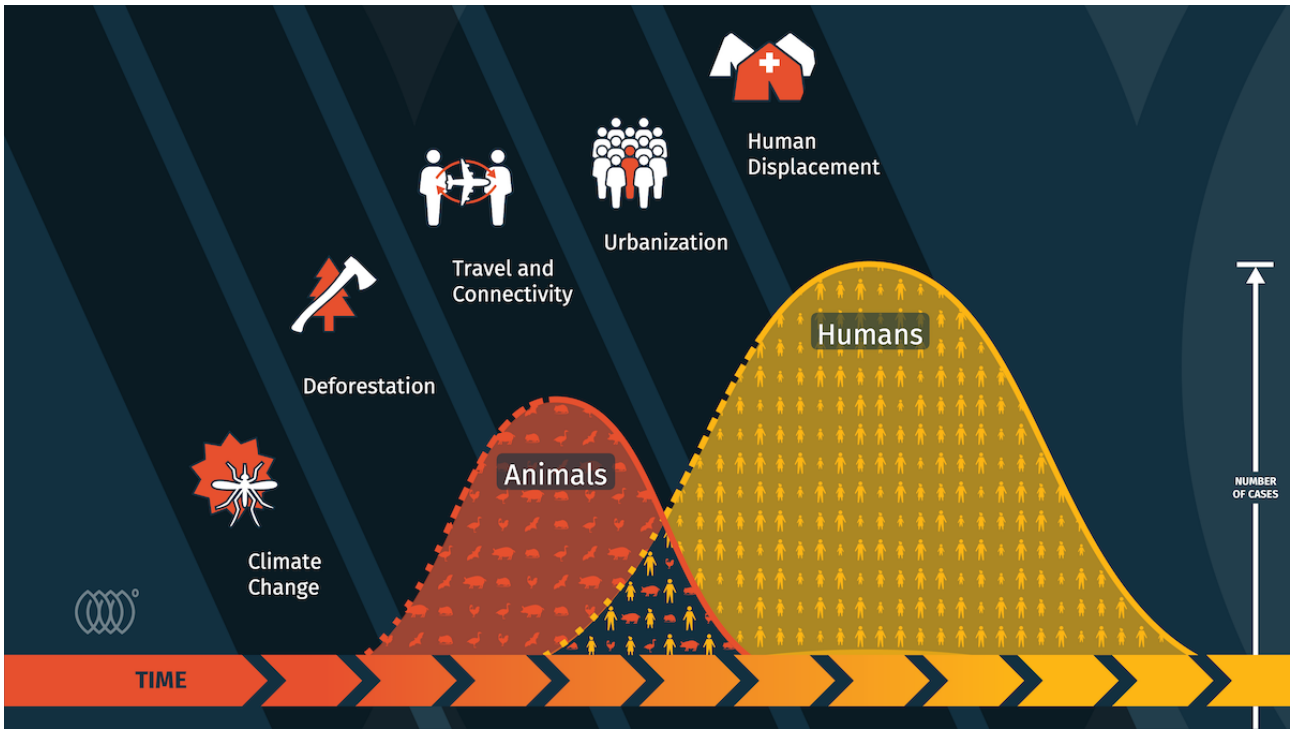
Early detection of a newly emerging or reemerging infectious disease is crucial to minimize the impact of such a threat on lives and livelihoods. With three of four pathogens capable of causing epidemics or pandemics arising first in animals and spreading to humans as zoonosis, a One Health approach to early detection is paramount. One Health participatory surveillance, defined as the bidirectional receiving and transmitting of data for action through direct engagement of the target population, is an effective form of collaborative surveillance to enhance global health security. Participatory surveillance systems can vary greatly when developed for a specific purpose or to meet a particular community's needs. Different geographies, languages, customs, beliefs, and practices often influence the breadth and depth of the data collected within each system. Imagine, however, if each of these varied systems could "speak" to each other, sharing their aggregated, deidentified data to create a comprehensive, real-time view of planetary health. The key is to collect the same information from users in each system, or at least a minimum set of key data parameters, to generate One Health surveillance greater than that of any individual system. To enable this vision, we propose a minimum set of key data parameters for One Health participatory surveillance that could be collected in any system through self-reporting by the public. This real-time collaborative surveillance could be the earliest indicator of a human, animal, or environmental health threat as it does not require interaction with a health care facility or provider where most disease surveillance traditionally occurs. One Health participatory surveillance that can detect major syndromes of potential emerging or reemerging pathogens through self-reporting on human, animal, or environmental health is a practical, scalable solution to identify and respond to rapidly spreading contagions.

(JMIR Public Health Surveill 2025;11:e77448) doi:10.2196/77448

KEYWORDS

One Health; participatory surveillance; collaborative surveillance; data parameters; pandemics; epidemics; global health security

Introduction



Of infectious diseases with epidemic or pandemic potential, 75% are zoonoses, meaning they spread to humans from wildlife or domestic animals [1,2]. Oftentimes, insect vectors such as mosquitoes, ticks, or fleas play a pivotal role in spreading disease from animals to humans [3,4]. Other times, infections spread from an infected animal to humans by way of direct contact with skin or saliva, or via the respiratory route [5]. In the case of hantavirus, for example, the inhalation of virus-contaminated particles when sweeping floors covered with dried urine and feces from deer mice led to acute respiratory infections in humans [6-8]. Regardless of the method of spillover, once a pathogen is established within the human population, numerous factors such as attitudes, behaviors, demographics, and politics can often exacerbate the further spread among humans [9,10].

Various additional dynamics lead to the emergence and spread of infectious diseases, including the speed and extent of international travel and trade, land use, climate change, lack of public health infrastructure, and access to health care, to name

XSL•FO
RenderX

just a few (Figure 1) [9,11]. Although not all drivers of disease emergence can be eliminated, cooperation and collaboration across public and private sectors, scientific disciplines, and geographic borders can significantly improve early detection and trigger an effective and timely response. An integrated approach to disease surveillance across species is paramount for the early detection and prompt response to emerging infections [12]. Prioritizing surveillance in planetary hot spots, those areas with the greatest likelihood of zoonotic outbreaks, is a compelling approach to reducing collective risk [13].

Figure 1. A One Health approach. Of every newly emerging infectious disease, 75% arise in animals and spread to humans. Animal outbreaks (shown in red) can quickly lead to human outbreaks (shown in yellow) when people are in close contact with livestock or wildlife. If we prioritize our efforts to find outbreaks faster in animals, it is possible to prevent human infection. Factors like climate change, urbanization, and increased travel and trade can exacerbate the spread and must also be considered.

One Health Participatory Surveillance

Directly engaging communities to report on the health of their family, themselves, and their animals, and any concerns regarding air or water quality, or other environmental health hazards is how we can safeguard the world from epidemics and pandemics. Nobody understands that something is “not quite right” better than the person who lives, works, or frequently spends time where these observations are occurring, and of course, nobody understands something is not right in how a person feels better than the individual themself.

Imagine if each of us took a couple of minutes each day, or even just once per week, to report on our health status and our family’s, or concerns within our immediate environmental surroundings. This could be done through email prompts, smartphone apps, brief SMS text messages, social media posts, or an interactive voice response system, or even seamlessly via passive data already captured by our phones, wearable devices, or other smart technologies. Ideally, if the majority of the community were doing the same, this form of collaborative surveillance [12] could detect the earliest signs of an emerging health threat. Everyone’s report would anonymously be connected on a visual platform to “see” that something is not right in a particular geographical region or simultaneously in several regions at a given point in time. This real-time collaborative surveillance could be the earliest indicator of a human, animal, or environmental health threat, as it does not require an interaction with a health care facility or provider, where most disease surveillance traditionally occurs.

Speed of detection is crucial. The faster a threat is identified and verified as true, the faster prompt actions can ensue to minimize its impact. Faster action saves lives and preserves livelihoods [14,15]. Once a threat gets a foothold in society, its impact grows exponentially in most cases. This is especially true for infectious disease threats once they enter the human population.

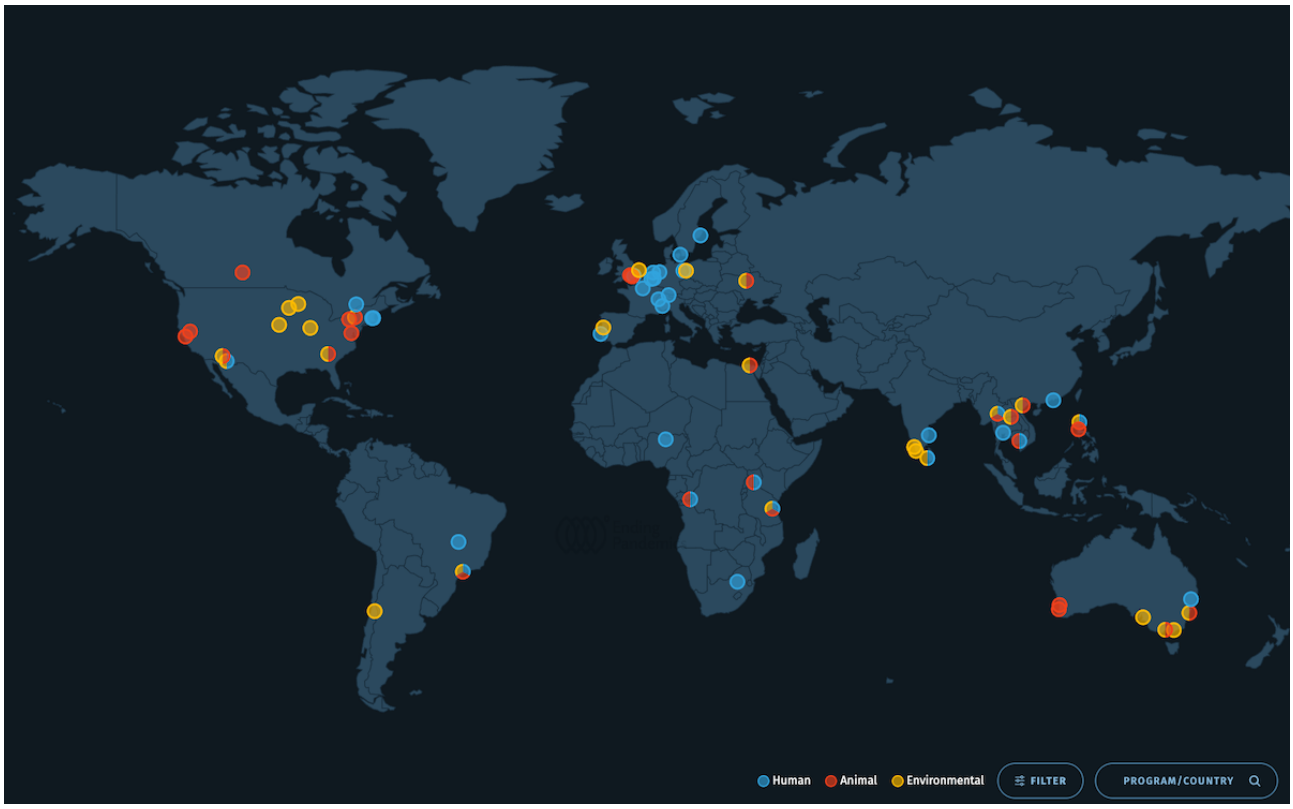
Collaborative surveillance can be achieved through participatory surveillance, defined as the process of receiving and transmitting data for action through direct engagement of the target population [16,17]. Participatory surveillance is the most efficient, cost-effective, and inclusive method to detect threats in real time—anywhere and everywhere across the world [18-21]. Each participatory surveillance system can be designed in any language, engaging users through local customs, practices, and beliefs, and adding features such as gamification to attract certain age groups or specific cohorts. Recruiting and retaining users is a significant obstacle that can be overcome with user-centric design principles and other nonfinancial incentives [22,23]. The more users that are engaged with the system, the more useful it becomes for early detection. The 2-way communication enabled through this approach can also

XSL•FO
RenderX

be instrumental in mounting a rapid and effective response. Numerous COVID-19–specific self-reporting systems were developed during the pandemic, validating the utility of participatory surveillance for the early detection and monitoring of emerging infections [24-26]. As more ecosystem dynamics and environmental data are integrated with human and animal disease surveillance efforts, the likelihood of accurately predicting and preventing zoonotic disease outbreaks will increase.

The most effective disease surveillance requires communities to harmoniously apply the best science, technology, and practices regarding human, animal, and environmental health in planetary hot spots for emerging infections and beyond. For the past decade, Ending Pandemics, a US-based nonprofit, has provided technical guidance and catalytic funding to support participatory surveillance in partnership with low- and middle-income countries on five continents [27]. A stellar example of One Health participatory surveillance was created in 2014 in Chiang Mai, Thailand, where community health volunteers are trained to report suspected illness in domestic livestock and poultry through submission of photos and simple data forms on mobile phones. Today, the system is receiving reports on food safety, contaminated water, and counterfeit drug sales in addition to reports of human or animal illness. In 2025, the system added wastewater surveillance as another mechanism for the early detection of an emerging zoonosis [28]. This One Health participatory approach was replicated in Tanzania in 2016, where village health volunteers report on human and animal illnesses among the pastoral herding communities whose livestock often comingle with the wildlife in the Serengeti region. Participatory surveillance has also been successfully used during mass gatherings in Brazil with the 2014 World Cup and 2016 Olympic Games [19]. The most successful participatory surveillance systems are those that are collaboratively developed, locally owned and resourced, and established as deep partnerships with the government from the time of inception.

Expanding Collaborative Surveillance



Although individual participatory surveillance systems exist, imagine if each of these varied systems could “speak” to each other, sharing their aggregated, deidentified data to expand the global view of the planet’s health. Each of these systems can be designed to engage specific population groups, churches, schools, workplaces, or any other social network. The key is to collect the same information from users in each system, or at least a minimum set of key data parameters, to generate One Health surveillance greater than that of any individual system.

Perhaps an analogy would be useful. If each surveillance system represents a spoke on a wheel, then each system has a pivotal role in holding the wheel’s rim in place and distributing pressure evenly. For the wheel to turn smoothly and bear weight without collapsing, every spoke must be made of the right material, cut to the correct length, and fastened securely. If even one spoke is too weak, too short, or poorly connected, the integrity of the entire wheel is compromised. The more spokes you have, the stronger and more resilient the wheel becomes. This redundancy adds durability and performance, allowing the wheel to handle greater challenges without faltering. If the wheel itself represents global disease surveillance, then each spoke signifies a vital part of this global system by capturing key information at the local, national, or regional levels.

To get a better idea of progress toward creating this global disease surveillance “wheel,” in 2022, Ending Pandemics conducted a systematic literature review and surveys to map the participatory surveillance “spokes” monitoring the health of animals, humans, or the environment across the world (Figure 2) [17,29]. The resulting map illustrates that the approach of directly engaging communities in self-reporting the health status of their members, animals, or environment is rapidly increasing in all areas of the world. Users of this map can learn key details about each system, including the number of reporters, the focus area of the system, and key contacts for the creators of the system. Although every system on the map represents bidirectional information sharing, some are sector specific and limit their reach to wildlife, livestock, the environment, or human health monitoring. Several systems, however, have achieved the One Health monitoring goal of incorporating data parameters that span all sectors. One Health participatory surveillance is the key to quickly finding and responding to emerging health threats and, in some cases, is contributing to the prediction and prevention of potential diseases with epidemic or pandemic potential. The ultimate success of One Health participatory surveillance will be realized when all systems can share data as mutual key data parameters are collected among the various systems.

Figure 2. One Health participatory surveillance interactive landscape map. This interactive map highlights participatory surveillance systems in people, animals, and ecosystems for detecting and responding to potential disease outbreaks. The systems' colors indicate the sector they focus on, with red indicating animal health, blue indicating human health, and yellow indicating environmental health.

One Health Participatory Surveillance Data Parameters Compendium

Every participatory surveillance system collects information as a set of data parameters. Ending Pandemics compiled a compendium of data parameters from participatory surveillance systems that operate in one or more of the One Health sectors: humans, animals, and the environment. Through a series of virtual workshops in 2021-2022 with experts from each sector, including health experts from the World Health Organization, the Food and Agriculture Organization of the United Nations, and the World Organization for Animal Health, a set of data parameters within each sector was compiled that were geared toward the public. Data parameters that seemed too "specialized" for public participation were excluded from the final set. Where available, information was gathered on how different parameters are collected within the individual systems.

The One Health Participatory Surveillance Data Parameters Compendium [30] is a snapshot into the world of participatory surveillance systems collecting data on human, animal, and environmental health. The compendium illustrates the breadth and depth of what is being used in participatory surveillance systems operating across the world. The compendium can serve the needs of those who may be contemplating the development of a participatory surveillance system, looking to expand a current system to include additional health sectors, or adapting data parameters to match other systems to foster collaborations and data sharing.

Establishing a Minimum Set of Key Data Parameters

Participatory surveillance systems are generally designed to collect information relevant to the community it is monitoring with a specific intent or purpose. Hence, some systems are focused directly on the public's health, and others might be tailored more to wildlife health or conservation, with the "reporter" having special training or expanded knowledge relative to the system's intent, such as a park ranger or veterinarian. Imagine, however, if we could collect a minimum set of key data parameters that monitor One Health across every participatory surveillance system, not necessarily all the parameters in each system, but a minimum set of key data parameters that can detect an emerging health threat of zoonotic origin by monitoring the health of animals, humans, and the environment.

Ending Pandemics used the compendium of data parameters collected across the known participatory surveillance systems and reduced this fairly massive set of data parameters to approximately 100 data parameters for consideration in a system designed for use by any member of a community (ie, the public). In 2022, the Fourth International Workshop on Participatory Surveillance (IWOPS) convened human, animal, and environmental health experts from 28 countries to further refine this set of 100 parameters into a potential minimum set of key data parameters for inclusion in any system [31]. The main goal of this intensive consultation process was the ability of this minimum set of key data parameters to detect any emerging

XSL•FO
RenderX

zoonosis, with the ultimate goal of potentially detecting environmental, wildlife, and domestic livestock and poultry threats before any human illness. If not detected before spillover, this minimum set of key data parameters can provide a fuller picture of an emerging infectious disease threat as the earliest human cases are identified through self-reporting. Our proposed minimum set of key data parameters consists of 42 data parameters across human, animal, and environmental health, along with 10 general data parameters to collect information on demographics, location, and timing of reports. We have also included the potential for photographs, diagnostic tests or laboratory confirmation, and digital biomarkers (eg, automated wearables, contactless physiological sensing, or other smart technologies) to be added by system designers where relevant and available (Figure 3). The addition of these latter data elements can add specificity to the system and help validate the self-reported syndromic data.

Figure 3. Minimal set of key data parameters for One Health participatory surveillance. This set of 42 parameters across human, animal, and environmental health, along with 10 general parameters and additional auxiliary parameters, can be incorporated into participatory systems to enable One Health surveillance to detect any emerging zoonosis.

The Value of a Minimum Set of Key Data Parameters

As stated earlier, the faster an emerging infection is detected, the quicker an effective response can ensue to limit loss of life and preserve livelihoods. Several major epidemics and pandemics throughout history were the result of a previously unrecognized pathogen [32]. Hence, relying on diagnostics or laboratory tests would not be useful at the earliest stages of such outbreaks. In fact, with the lack of readily available, widely dispersed diagnostics for even known pathogens, the clustering of similar symptoms in time and space is often the only means to detect an emerging disease. Syndromic surveillance, therefore, is often relied upon for the early detection of a newly emerging or reemerging infectious disease [33]. Participatory surveillance that can detect major syndromes of potential emerging or reemerging pathogens through self-reporting of illness is a practical way to help identify a rapidly spreading contagion.

In general, the minimum set of key data parameters should identify a newly emerging or reemerging pathogen based on the frequency of reports and the geographical location of such reports. We believe that respiratory diseases have the highest likelihood of wide-scale epidemics or pandemics, and the minimum set of key data parameters should pick up such a threat. Cough and shortness of breath, plus or minus sore throat, can be effective at identifying influenza, severe acute respiratory syndrome, Middle East respiratory syndrome, or a yet unknown respiratory pathogen. When combined with fever, malaise, body aches or pains, a cluster of such reports heightens concerns of a serious respiratory threat. It may even be possible to specify

XSL•FO
RenderX

a potential diagnosis with additional symptoms being reported. Likewise, data parameters on health-seeking behavior and absenteeism from school or work can provide further evidence of illness severity.

Additional self-reported symptoms can also identify other potential pathogens by collecting syndromic information on rash illness, diarrheal illness, or hemorrhagic fever. Key data parameters on exposure to domestic animals, wildlife (including rodents), and insect vectors like mosquitoes, ticks, and fleas can lead to a plethora of other zoonotic threats to be considered as the cause of an outbreak. Furthermore, several of the key data parameters in the minimum set can provide valuable information on sickness or die off in domestic animals or wildlife, or environmental concerns like flooding or water safety that might spur further investigation, leading to the prediction and prevention of human illness from zoonosis.

The minimum set of key data parameters was analyzed by expert human curation to validate that most emerging infectious disease threats with epidemic or pandemic potential could be identified through various combinations of terms. For example, the minimum set of key data parameters should be able to identify most emerging infections capable of causing epidemic or pandemic disease. The World Health Organization updated its list of priority pathogens capable of causing epidemic and pandemic diseases in 2024 [34] by convening over 300 scientists to consider the evidence on virus families and bacteria, as well as "Disease X." Disease X is included to indicate an unknown pathogen that could cause a serious epidemic or pandemic. With major syndromes being reported regularly, it is more than likely that Disease X would also be detected through One Health participatory surveillance.

The Value of Collecting Similar Data Parameters: Case of Global Flu View

Participatory surveillance systems for influenza-like illness have been well established in numerous countries, many operating for over a decade [35]. Ending Pandemics convened the developers of each of these systems at the Second IWOPS in 2013 [36]. The IWOPS community established a minimum set of data parameters among systems collecting self-reported information to monitor the annual risk of influenza. As a result, deidentified and aggregated data are shared on a digital platform, Global Flu View (GFV), to improve situational awareness and increase our understanding of how influenza emerges across the world [37].

GFV is a system orchestrator platform that converges and combines influenza-related data from 11 countries, harmonizing the way information is captured and reported by ensuring that datasets from different systems and regions remain consistent, comparable, and accurate. As a part of the platform's approach, GVF offers a ready-to-use tool kit for institutions interested in deploying or enhancing their own participatory surveillance systems. The tool kit significantly lowers the barriers to entry by providing a clear and concise guide on the key data parameters that have already been vetted across multiple regions. At the same time, GFV maintains a high degree of flexibility to accommodate local realities and linguistic nuances, allowing the naming and coding of parameters to be adapted into more culturally and contextually appropriate terms. Ultimately, this approach amplifies the quality and timeliness of influenza-like illness data worldwide, helping health authorities spot potential outbreaks sooner and collaborate more effectively in responding to public health threats.

GFV represents one example of what is possible when participatory surveillance systems can "speak" to each other regarding influenza-like illness data parameters. Embracing the entire minimum set of key data parameters encompassing One Health will expand the value of participatory surveillance for all epidemic and pandemic threats.

Limitations

This minimum set of key data parameters is not without limitations. The parameters are based on syndromic surveillance, with the goal of being highly sensitive to enable early detection of any potential health threat to the community. A primary goal of participatory surveillance is speed of detection; hence, the system may produce false positives. The occurrence of false positives, however, is offset by the potential to quickly uncover a rapidly spreading infection within the population. Measuring sensitivity generally requires comparison with "gold standard" surveillance data to determine the true frequency of the disease in the population [38]. To capture the sensitivity of a particular participatory surveillance system, a gold standard for early detection will need to match the purpose of this system. While the broad range of parameters in this minimum dataset provides high sensitivity, the parameters lack specificity. This reduced specificity may be overcome as participatory surveillance systems allow users to include diagnostic or laboratory tests, digital biomarkers, or other data derived from future advances in technology like wearables and environmental sensors. Furthermore, as the field of rapid diagnostics continues to expand in all areas of the world, especially the availability of home test kits, greater specificity in diagnosing the threat among the population reporting into the system will be possible. Further work is needed to determine the sensitivity and specificity of the minimum set of key data parameters for One Health participatory surveillance.

The minimum set of key data parameters is intended to rapidly detect any emerging zoonosis, whether signs and symptoms appear first in animals or humans. As such, the minimum set of key data parameters may not detect some endemic diseases or subclinical infections in humans and animals, nor are they intended to monitor the general health of the population. Participatory surveillance is intended to complement other surveillance efforts such as severe acute respiratory infection, sentinel sero-surveillance, sequential biologic sampling in high-risk communities, or health care–based surveillance systems. Integrating participatory surveillance among populations that are also part of the severe acute respiratory infection or other targeted surveillance systems can serve to expand the reach of monitoring within a given population.

RenderX

Conclusion

Early detection is paramount when it comes to any emerging infectious disease. Participatory surveillance is an effective method of collaborative surveillance that allows anyone to participate in monitoring the health of their communities to detect the earliest signs of an emerging infectious disease threat. Furthermore, participatory surveillance allows for monitoring factors in the environment along with wildlife and domestic livestock surveillance for detecting zoonotic diseases. A minimum set of key data parameters for One Health participatory surveillance can enable an individual system anywhere in the world to connect to share information with other systems collecting similar data. This, of course, requires standardization of data collection or analysis to permit true comparisons among systems. As more systems become integrated into regional or global surveillance efforts, the greater the chances of detecting zoonotic diseases of epidemic or pandemic potential at their earliest stages of emergence. Persons or organizations using the minimum set of key data parameters to create a new participatory surveillance system or to expand a system currently in use can adapt these parameters to fit the needs of their specific community. For example, they can survey users within their system to help ascertain the applicability and clarity of the specific parameters and the potential need for revisions or additional terms. With further advances in environmental and animal health monitoring, it may be possible to predict and prevent human infections from occurring at all. When this potential is realized, the resulting greatly enhanced global health security will allow the prevention of major epidemics and pandemics.

Acknowledgments

We gratefully acknowledge the valuable contributions of all participants of the first to fourth International Workshops on Participatory Surveillance in advancing this work on participatory surveillance. We also wish to recognize the authors of the One Health Participatory Surveillance Data Parameters Compendium, whose work played a critical role in informing the development of the minimum set of key data parameters for One Health participatory surveillance. The collective efforts of these groups were instrumental in advancing this effort.

Abstract

Background: The Brazilian project, launched in 2021, aims to establish a nationwide injury registry that systematically collects detailed information on incidents and individuals across the country, regardless of injury severity. The registry integrates information from prehospital and hospital care, various health systems lacking interoperability, and data from sectors such as firefighters and police. Its primary aim is to enhance health surveillance by providing timely, high-quality information that guides prevention strategies and informs policymaking. In addition, the project seeks to reduce morbidity and mortality associated with injuries.

Objective: This study aimed to investigate the effects of injury registry data on policymaking, hospitalization rates or duration, and mortality.

Methods: The systematic review followed PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines, with a protocol registered in PROSPERO (International Prospective Register of Systematic Reviews, CRD42023481528). A total of 5 databases were searched in November 2023, with an update conducted in March 2024, incorporating reference lists from the studies included. Two reviewers independently screened records, extracted data, and assessed methodological quality using the Newcastle-Ottawa Scale, resolving disagreements with a third reviewer. Studies were eligible if they reported results related to the implementation and use of injury or trauma registry data for at least one outcome of interest, while those based on other sources were excluded. Synthesis of findings was presented in tables, and the observed results were reported as number or percentage differences.

Results: Out of 9100 studies retrieved, 3951 were excluded due to duplication, leaving 5149 for selection, with 15 full texts reviewed. Only 5 studies met the inclusion criteria, highlighting a notable scarcity of research on the effects or results of registry data on injury outcomes. It is important to note that the studies included reflect correlations rather than causalities, and there are currently no publications on impact. The findings suggest that injury and trauma registries have the potential to inform policymaking, which can lead to enhanced health outcomes. One study noted a 3-day reduction in intensive care unit stay (from 16 to 13 days; $P<.05$) and a 4% reduction in expected hospital mortality (from 17.5% to 21.5%) for patients with an Injury Severity Score ≥16, while another showed a 42% annual decrease in traffic injury hospital admissions (from 45 to 16). Significant methodological heterogeneity and the small number of studies limited the feasibility of a meta-analysis.

Conclusions: Establishing an injury registry in Brazil presents a significant opportunity to enhance health outcomes through informed policymaking. While it is crucial to set appropriate expectations regarding its effects on morbidity and mortality, particularly concerning the causality and transportability of the findings to the Brazilian context, its role in facilitating preventive measures and improving surveillance capabilities remains valuable.

Introduction

Injuries resulting from various incidents, such as accidents, falls, drownings, burns, poisonings, and acts of violence directed at oneself or others, represent a global concern. Annually, approximately 4.4 million deaths are attributed to injuries, constituting nearly 8% of all deaths. Unintentional causes account for 3.16 million fatalities, while acts of violence result in 1.25 million deaths. According to the World Health Organization, among individuals aged 5 - 29 years old, 3 of the top 5 causes of death are injury-related: road traffic injuries, homicide, and suicide. In addition, falls lead to over 684,000 deaths each year, highlighting a growing and often overlooked public health issue [1].

In Brazil, injuries and violence have frequently ranked as the fourth leading cause of death. In 2022, the country recorded 152,945 fatalities attributed to injuries, which corresponds to approximately 75 deaths per 100,000 inhabitants, constituting nearly 10% of all deaths. Most of these fatalities were due to accidents (46.9%), with traffic accidents accounting for 22.8% and falls for 11.8%. Homicides represented 29.0% of the deaths, while suicides accounted for 10.8%. Studies highlight the significant impact of injuries on premature mortality and disability, particularly among young individuals aged 20 - 39 years old and males, emphasizing the urgent need to prioritize this issue in the country [2,3].

Conversely, nonfatal injuries also pose a significant public health challenge. Every year, millions of people worldwide experience nonfatal injuries, resulting in visits to emergency departments or hospitalizations [1]. In Brazil, in 2022, the number of hospitalizations due to injuries was nearly 8.8 times higher than the number of deaths, totaling 1,351,021 hospitalizations, which translates to over 600 injury-related hospitalizations per 100,000 Brazilians. Falls were the most prevalent cause of these hospitalizations, accounting for 34.4%, followed by traffic accidents at 17.9% [4].

The National Policy for the Reduction of Morbidity and Mortality from Accidents and Violence was established in response to the challenge posed by injuries as a public health issue in Brazil [5]. This policy has led to several key initiatives, including the launch of the National Policy for Emergency Care in 2003 [6] and the proposal for creating the National Network for the Prevention of Violence and Health Promotion in 2004 [7]. Two years later, in 2006, the Violence and Accident Surveillance System in Sentinel Services was implemented [8]. In 2010, the Life in Traffic Project was initiated, emphasizing intersectoral coordination and data integration for traffic accident surveillance and intervention across 54 Brazilian municipalities [9,10]. Furthermore, beginning in 2011, interpersonal and self-inflicted violence were included in the list of diseases and conditions subject to compulsory notification in public and private health services in the country [11].

An injury registry is a systematic and standardized database that records detailed information about events and individuals who have sustained injuries, regardless of their severity or whether they result from accidents, falls, violence, or other causes. These databases can encompass a wide range of injuries, from minor ones that may not require hospitalization to more serious injuries that do. Traumatic injuries that require acute care delivered to hospitalized patients, typically resulting from high-impact events such as car accidents, severe falls, or gunshot wounds, are usually included in trauma registries. Both types of registries play important roles in injury prevention, research, and health care management. The primary distinction lies in the scope and severity of injuries each type of registry deals with. They allow policy makers to efficiently target resources and implement evidence-based interventions [12-15].

Recently, in 2021, a project was initiated under the Institutional Development Support Program of the Unified Health System (Programa de Apoio ao Desenvolvimento Institucional do Sistema Único de Saúde [PROADI-SUS]), a strategy of the Brazilian Ministry of Health, executed by the Hospital Israelita Albert Einstein, to establish a national injury registry. The primary aim of this initiative is to enhance health surveillance capacity by providing timely, high-quality information to guide the development and evaluation of prevention strategies and policymaking related to accidents and violence. To achieve this, the project focuses on improving data integration and quality from prehospital and hospital care, as well as from various existing health information systems that currently lack interoperability. In addition, it seeks to incorporate data from multiple sectors involved in injuries and violence, including firefighters and police. The objective is to consolidate information from diverse systems into an integrated database that will be centrally accessible to health managers and researchers throughout Brazil by 2026. Ultimately, these efforts are designed to reduce morbidity and mortality associated with injuries [16,17].

The success of trauma systems has been reported in various localities, with their effectiveness well-established [14,18-20]. Estimates indicate a 15% reduction in the odds of mortality [21,22]. Furthermore, the implementation of trauma registries has been well-documented, and these registries are consistently recognized as essential tools for improving trauma systems and policymaking [13,23]. However, a significant knowledge gap remains regarding the effects of injury registries that encompass all injuries, regardless of their severity or whether hospitalization is required [23].

Considering the current efforts to implement an injury registry in Brazil, there is an urgent need to establish an evidence base in this context. Therefore, this systematic review aimed to investigate the effects and results of injury registries on policymaking and injury outcomes, particularly in terms of reducing hospitalizations and mortality. Hence, the research question guiding this review is as follows: “What is the effect of implementing an injury registry on policymaking, hospitalization rates or duration, and mortality due to injuries?”.

Methods

Protocol

The development of this study followed the recommendations of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement, ensuring adherence to

XSL•FO
RenderX

best practices in systematic review methodology [24,25]. The PRISMA 2020 checklist for a systematic review report is completed and provided in Checklist 1, while the checklist for the abstract is provided in Checklist 2. A protocol for this systematic review was registered in the PROSPERO (International Prospective Register of Systematic Reviews) database under registration number CRD42023481528. A comprehensive version of the protocol has been published [26].

Eligibility Criteria

The eligibility criteria for this systematic review were formulated according to the PICOS structure (Population, Intervention, Comparison, Outcomes, and Study), as shown in Table 1. A search was conducted for articles reporting results or effects related to the implementation and use of data from injury registries, including trauma registries, for at least one of the outcomes described in Table 1. These registries were established within cities, states, provinces, countries, hospitals, or other well-defined administrative boundaries. Nonrandomized intervention studies were considered for inclusion, which involve those that cannot use randomization to allocate individuals or clusters of individuals into intervention groups, including quasi-experimental studies. Analytical observational studies, such as cohort studies and before-and-after studies, were also considered for inclusion. Only nonrandomized intervention studies and analytical observational studies could adequately address the research question that guided this systematic review, as a randomized controlled trial would not be feasible in this context.

Table . Eligibility criteria presented in the population, intervention, comparison, outcomes, and study structure.

Acronym	Description	Criteria
P	Population	Cities, states, provinces, countries, hospitals, or other well-defined administrative boundaries.[a]
I	Intervention	Implementation and use of injury registries, including trauma registries.
C	Comparison	No restrictions on comparators
O	Outcomes	Policymaking (changes and design, including preventive measures, health care improvements, surveillance actions, among others), hospitalization rates or duration, and mortality.
S	Study	Nonrandomized intervention studies or observational studies

[a]The population consists of the locations where injury registries have been implemented, with no restrictions on the patients served by health services regarding age, gender, or other attributes.

Studies were excluded if they were based on sources other than an injury or trauma registry. Articles without full-text availability were also excluded after attempts to contact the corresponding authors to request the full text. In addition, opinion articles, editorials, letters to the editor, conference abstracts, systematic or literature reviews, and any other studies that lacked empirical research regarding the effects of injury registries. The studies excluded were documented in an attached table within the systematic review. There were no restrictions on publication date, country, or language.

Information Sources, Search, and Selection Process

The search was conducted in the MEDLINE databases via PubMed, Embase, Lilacs via the Virtual Health Library, Scopus, and Web of Science. To ensure comprehensive literature coverage, the reference lists of studies included and relevant systematic or literature reviews identified through the search were also reviewed. The bibliographic search was performed in November 2023, with an update in March 2024.

The implemented search strategies are presented in Multimedia Appendix 1. The search terms were defined based on the population, intervention, and outcomes, following the PICOS structure. These terms include controlled vocabulary specific to each database, as well as uncontrolled vocabulary terms, synonyms, natural language, related terms, expressions, and truncations, all aimed at broadening the scope of the search. The strategies were developed in collaboration with a librarian experienced in conducting systematic review searches. Initially, the MEDLINE strategy was created with input from the research team and subsequently reviewed by a specialist with expertise in the research topic. Once the MEDLINE strategy was finalized, it was adapted to the syntax and subject headings of the other databases.

The literature search results were uploaded to Rayyan, where duplicates were eliminated, and an initial screening of abstracts and titles was conducted to identify potential studies for inclusion. Finally, the full texts of these potential studies were assessed to determine their eligibility. Adhering to PRISMA recommendations, both steps were performed independently by 2 reviewers [ACMS and LESL]. Any disagreements not resolved through discussion between the reviewers were arbitrated by a third reviewer [BZO]. The complete list of articles excluded during the full-text assessment is detailed in Multimedia Appendix 2, along with the documented reasons for study exclusions.

Data Collection Process and Data Items

Studies that passed the eligibility stage proceeded to data extraction, which was performed using a predefined Excel spreadsheet by the same independent reviewers [ACMS and LESL]. The following information was extracted from each study: title, year of publication, authors, corresponding author

XSL•FO
RenderX

contact, language, abstract, objectives, population (inclusion criteria, size, and characteristics), methods (type of study, time horizon, study site, comparators, and statistical significance), outcome measures (policies implemented, including health care improvements and preventive measures, hospitalization rates or duration, and mortality), funding, and conflicts of interest. Regarding the registries, the information collected included the type of registry (whether it was an injury or trauma registry), registry age, and specific focus of the registry. When disagreements arose, the full-text articles were reviewed again by the reviewers.

Data Synthesis

Summaries of study characteristics were presented in a table, and data synthesis was explored based on outcomes. The policy changes and designs, including preventive measures for injuries, health care improvements, surveillance actions, stakeholder partnerships, among others, were also synthesized in a table. For each hospitalization rate or duration, and for mortality, the intervention results were reported through number or percentage differences. A meta-analysis could not be conducted due to considerable methodological heterogeneity among the included studies and the small number of studies reporting the same outcome; consequently, publication bias could also not be assessed.

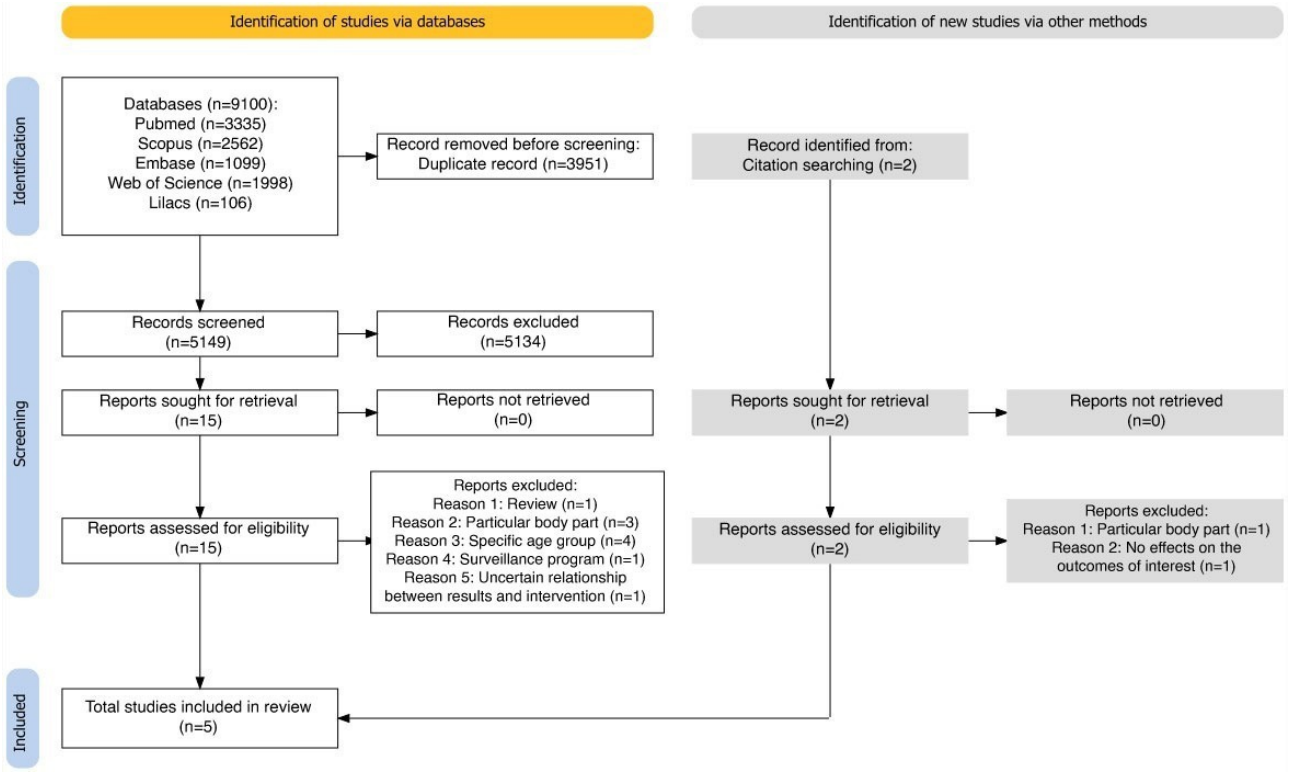
Quality Assessment

Two reviewers [ACMS and LESL] independently assessed the methodological quality of studies using the Newcastle-Ottawa Scale (NOS) [27] for cohort studies and an adaptation of this tool for cross-sectional studies [28]. This tool was deemed the most appropriate considering the study designs of interest in this review. According to the instructions of the NOS tool, the assessment was conducted considering the study as a whole, regardless of the specific outcomes analyzed in this systematic review.

The NOS is organized around 3 main dimensions of observational studies: participant selection, comparability between groups, and outcome evaluation. Quality assessment in NOS uses a star system. For cohort studies, up to 9 stars can be awarded across the 3 domains: selection (up to 4 stars), comparability (up to 2 stars), and outcome (up to 3 stars) [27]. For the adapted tool for cross-sectional studies, up to 10 stars can be awarded across 3 domains: selection (up to 5 stars), comparability (up to 2 stars), and outcome (up to 3 stars) [28].

To standardize study evaluation, specific criteria were defined for all studies. In the selection dimension, the item "Representativeness of the exposed cohort" considered the country of the registry to assess population representativeness. For the item "Was follow-up long enough for outcomes to occur" in the outcome dimension, studies were awarded a star if they had a minimum follow-up period of 3 years. The bias assessment involved independent evaluation by pairs (ACM-d-S and LESL), with discrepancies resolved by a third reviewer (TFGdSB).

Results



Study Selection

The database searches yielded 9100 potentially relevant records. After removing duplicates, 5149 unique records underwent screening based on their titles and abstracts. Subsequently, 15 full-text documents were examined, resulting in the inclusion of 5 papers [29-33]. In addition, a search was conducted in the references of the initial studies included. However, no additional articles meeting the inclusion criteria were identified through these searches (Figure 1).

A total of 12 studies were excluded from our review [34-45], with reasons for exclusion listed in Checklist 2. Among these exclusions, 1 study was disregarded due to its nature as a literature review [34]. In addition, 8 focused exclusively on a particular body part [38-41] or age group [36,42-44]. In one of them, the relationship between the reported results and the registry was not clear [35]. Another showed no associations on the outcomes of interest for this review [37]. Finally, 1 study presented results that appeared to extend beyond the implementation and use of data from registries; it reported findings from its surveillance program [45].

XSL•FO
RenderX

Figure 1. Flow diagram of the search and selection process of the studies included in the review.

Study Characteristics

The characteristics of each study included are provided in Tables 2 and 3. Of the 5 studies, 3 conducted in Germany involved data from trauma registries, with publication years ranging from 2004 to 2013 [29-31]. The remaining 2, one conducted in Cardiff, Wales, published in 2004 [32], and another in Harstad and Trondheim, Norway, published in 1995 [33], used data from injury registries.

Among the studies included, 4 used an observational cohort design, using a before-and-after approach [29-32]. One of these included a corresponding comparison group [29], while 2 others compared the obtained results with expected values as well [30,31]. Notably, 1 adopted a mixed design, incorporating a cross-sectional assessment involving hospitals to evaluate their efforts to improve care quality [31]. The fifth study classified itself as quasi-experimental; however, the outcome of interest for this review was assessed using a cohort [33].

Four of the studies described policymaking outcomes. Two, focusing on trauma registries, detailed health care improvements [29,31]. Meanwhile, 2 other centered on injury registries presented results on diverse approaches to injury management, including preventive measures against assault [32] and traffic injuries [33]. In addition, 2 studies reported associations of these policies on hospitalization [31,33], and 4 described the mortality outcomes [29-31,33].

Table . Details of studies included.

First author, year (country)	Study details				
	Study type	Time horizon	Population	Comparator	Funding
Helm M, 2013 (Germany) [29]	Observational (cohort)	Almost 10 years, divided into 4 periods: January 1998-December 1998; January 1999-December 2000; January 2001-December 2005; January 2006-March 2007.	Patients admitted via emergency rooms at a Level I trauma center (all patients: n=2239, and ISS[a] ≥16: n=1174)	First observed period and TR-DGU[b] hospitals data (ISS ≥16, national trauma centers from Germany)	Not explicitly indicated in the study
Ruchholtz S, 2008 (Germany) [30]	Observational (cohort)	7 years, from 1999 to 2005	Patients with ISS ≥16 admitted to 105 hospitals of the TR-DGU (n=11,013)	First observed period and values expected	not explicitly indicated in the study
Ruchholtz S, 2004 (Germany) [31]	Observational (cross-sectional+ cohort)	3 years, from 1999 to 2001	Hospitals transmitting data for ≥100 patients to TR-DGU (n=21) and patients with ISS ≥16, directly transferred from the accident site (n=2702)	First observed period and values expected	German Research Foundation and German Society for Trauma Surgery
Warburton AL, 2004 (Wales) [32]	Observational (cohort)	7 years, from April 1, 1995, to March 31, 2002, encompassing each annual period from April 1 to March 31.	All assault patients treated at the Cardiff Accident and Emergency (A&E) department	No comparator	Wales Office of Research and Development (WORD).
Ytterstad B, 1995 (Norway) [33]	Quasi-experimental+ cohort	7 years, from July 1, 1985, to June 30, 1993, was divided into three periods of 30 months each.	Individuals treated for traffic accident injuries in hospitals in two Norwegian cities, Harstad (n=22,970) and Trondheim (n=158,911).	Trondheim and first observed period	Norwegian Research Council for Science and the Humanities (NAVF) and Norwegian Directorate of Health/The Royal Norwegian Ministry of Social Affairs

[a]ISS: Injury Severity Score.

[b]TR-DGU: Trauma Register of the German Society of Trauma Surgery.

Outcomes

Policymaking

In total, 4 of the 5 studies included demonstrated the use of injury or trauma registry data as a policymaking tool. The key policies identified, including health care improvements and preventive measures, are synthesized in Table 4.

Two studies conducted in Germany involved data from trauma registries and demonstrated their use in continuously improving the care of hospitalized patients. One of these [29] shows the evolution of emergency room management in a national trauma center over a decade, marked by significant improvements across four distinct phases. These improvements resulted from ongoing monitoring of hospital data and comparisons with the Trauma Register of the German Society of Trauma Surgery (TR-DGU) to identify areas needing enhancement. Interventions included incorporating diagnostic exams and imaging procedures in the emergency room, refining personnel training protocols, and implementing time-efficient treatment algorithms. The other study [31] involved interviews with 21 hospitals regarding their efforts to improve care quality based on trauma registry data feedback. Optimization measures were introduced in the emergency room, surgical care, and intensive care. In the emergency room, changes included the installation of digital X-ray systems and spiral CT scanners. Organizational improvements focused on enhancing interdisciplinary coordination through quality circles and guidelines, as well as training and documentation. In surgical and intensive care, optimization targeted therapy areas, although specific details were not provided.

The 2 studies that described policymaking results related to injury registries presented preventive initiatives against assault and traffic injuries. For violence prevention, 1 study [32] detailed efforts by a multisector steering group, including assault awareness campaigns, targeted policing initiatives, and night transport management strategies. The use of data to guide judicial decisions, particularly for alcohol and entertainment license applications, was also highlighted. The authors concluded that using injury data from assault patients attending A&E departments in Cardiff, Wales, effectively targeted police

XSL•FO
RenderX

and local resources to reduce city-wide violence. The other study [33] also focused on traffic injury prevention through a multisector group's efforts. It described education initiatives targeting high-risk groups, traffic safety measures like installing stoplights and constructing separate pedestrian and cyclist roads, and enhanced traffic enforcement such as vehicle checks and speed limit enforcement. Legislative changes included assigning local health authorities the responsibility for accident prevention. The study emphasized using data to inform various stakeholders about traffic injury risks and prevention strategies. Conducted in Harstad, Norway, the data were actively used in a community-based injury prevention program.

Table . Key policies identified in studies.[a]

Policies	Studies
Trauma registry	
Continuous quality management in health care	3 [29,31]
Changes in emergency room management	2 [29,31]
Introducing exams and imaging diagnosis in the emergency room	2 [29,31]
Adjusting training and documentation	2 [29,31]
Other measures (eg, introducing therapy in the emergency room)	2 [29,31]
Changes in intensive care (organization, diagnosis, and therapeutic measures)	1 [31]
Changes in surgical care (organization, diagnosis, and therapeutic measures)	1 [31]
Injury registry	
Violence prevention by multiple sectors group	1 [32]
Assault awareness campaigns (eg, in schools and public libraries, and for bar and club managers)	1 [32]
Targeted policing initiatives (eg, a task force to hotspot areas, and targeting alcohol-related street crime)	1 [32]
Night transport management (eg, meetings to identify barriers and opportunities for education and staff protection)	1 [32]
Use of data to guide judicial decisions (eg, alcohol and entertainment license applications)	1 [32]
Traffic injury prevention by multiple sectors group	1 [33]
Traffic injury education initiatives and campaigns to high-risk groups (eg, in schools and driving schools, at health fairs and shopping centers, for parents of small children, for police and automobile societies, and through media campaigns)	1 [33]
Traffic safety measures (eg, installation of additional stoplights, constructing separate pedestrian and cyclist roads, planning safe pathways for children going to school, and loaning safety chairs for small children)	1 [33]
Enhanced traffic enforcement (eg, checks on vehicles, speed limit enforcement, and curfews for serving alcohol in bars and restaurants)	1 [33]
Legislative change (eg, a national law assigning local community health authorities' responsibility for accident injury prevention)	1 [33]
Use of data to inform educational institutions, city planners, private and public organizations, and the community	1 [33]

[a]Including health care improvements and preventive measures, among others.

Hospitalization

Although a meta-analysis for hospitalization results was planned, it could not be conducted due to the considerable methodological heterogeneity among the studies included and the small number of studies reporting this outcome (n=2). Since quantitative synthesis is not appropriate, the results observed by the authors are presented in narrative form below. Relevant findings identified in the studies can be found in Table 5.

XSL•FO
RenderX

Table . Hospitalization and mortality results identified in studies.

Outcome or studies	Follow-up	Results
Hospitalization		
Ruchholtz S, 2004 (Germany) [31]	1999 - 2001	• 3 days in the average length of stay in the ICU[a] among patients with an ISS[b] ≥16 (from 16 to 13 days, *P*<.05)
Ytterstad B, 1995 (Norway) [33]	1987 - 1992	• 42% per year reduction in admissions from traffic injuries (from 45 to 16 admissions)
Mortality		
Helm M, 2013 (Germany) [29]	1998 - 2007	• 6.0%[c] in mortality among all patients (from 10.8% to 4.8%, *P*<.05) • 20.1%[c] in mortality among patients with an ISS ≥16 (from 33.3% to 13.2%, *P*<.05) • 11.3%[c] greater reduction in mortality among ISS ≥16 patients compared with TR-DGU hospitals (−20.1% vs −8.8%)
Ruchholtz S, 2008 (Germany) [30]	1999 - 2005	• 4.1%[c] in observed mortality among patients with an ISS ≥16 (from 22.8% to 18.7%) • 3.4%[c] in expected mortality among patients with an ISS ≥16 (18.7% vs 22.1%)
Ruchholtz S, 2004 (Germany) [31]	1999 - 2001	• 4.0% in expected mortality among patients with an ISS ≥16 (17.5% vs 21.5%)
Ytterstad B, 1995 (Norway) [33]	1985 - 1993	• 66.7%[c] reduction in traffic-related deaths (from 6 to 2, *P*<.12)

[a]ICU: intensive care unit.

[b]ISS: Injury Severity Score.

[c]Values calculated by the systematic review authors based on study data.

Two studies described hospitalization results: 1 presented findings related to the implementation and use of a trauma registry, and the other presented results related to an injury registry. The first study [31], conducted in Germany, used continuous monitoring of hospital data to introduce optimization measures in the emergency room, surgical care, and intensive care. It compared the change in average values for the length of stay in the intensive care unit and total hospital stay over 3 years (1999 - 2001), involving data from 2702 patients with an Injury Severity Score (ISS)≥16 who were directly transferred from the accident site. The authors found no significant reduction in the total average length of hospital stay for patients (from 29 to 28 days). However, there was a significant reduction of 3 days in the average length of stay in the intensive care unit (from 16 to 13 days, *P*<.05).

In the second study [33], the injury registry was actively used in a community-based traffic injury prevention program conducted in Norway. The authors observed hospitalization results by comparing the 1987 sample of all admissions from traffic accidents at Harstad Hospital with the mean annual admissions during 1990 - 1992. As a result, a 42% per year reduction in admissions from traffic injuries was observed, decreasing from an average of 45 admissions per year to 26.

Mortality

The planned meta-analysis for the mortality could also not be conducted due to the considerable heterogeneity in terms of design and methods among the studies included that reported this outcome (n=4). Therefore, a quantitative synthesis was deemed inappropriate, and the findings from the studies are summarized in the text below. Relevant results identified in the studies can be found in Table 5.

Regarding the studies that focused on trauma registries, all were conducted in Germany and observed results on mortality. One study [29] implemented various interventions in the emergency room of a national trauma center through continuous monitoring of hospital data, including the refinement of personnel training protocols and the incorporation of diagnostic exams and imaging procedures. This study observed a significant reduction in hospital mortality among all patients, decreasing from 10.8% to 4.8% (−6.0%, *P*<.05), and specifically among patients with an ISS ≥16, decreasing from 33.3% to 13.2% (−20.1%, *P*<.05). The total observation period covered almost 10 years (January 1998 to March 2007), during which a total of 2239 trauma patients were admitted via the emergency room, including 1174 patients with ISS ≥16. Similar reductions were observed in hospitals part of the TR-DGU, where mortality rates among patients with an ISS ≥16 decreased by 8.8%, from 24.9% to

XSL•FO
RenderX

16.1%. However, the reduction in the studied hospital was notably more substantial, with an 11.3% greater decrease (−20.1% vs −8.8%).

Another study [30] evaluated patient data starting from 1999, which marked the beginning of receiving annual feedback in the form of reports comparing hospital data with TR-DGU results to identify areas for improvement and support continuous quality management. This study demonstrated that consistent feedback of treatment data to hospitals is associated with positive changes in survival prognosis. During the observation period (1999 to 2005), data from a total of 11,013 severely injured patients (ISS ≥16) in 105 hospitals were documented. Mortality significantly decreased by 4.1%, from 22.8% in 1999 to 18.7% in 2005, compared with an expected rate of 22.1% for that year, which represents a 3.4% reduction in expected mortality. The same author [31] had already noted that the observed mortality rate was lower than the expected rate (−4.0%, 17.5% vs 21.5%) after the introduction of optimization measures in the emergency room, surgical care, and intensive care in 21 hospitals that transmitted data to TR-DGU between 1999 and 2001. Despite reporting potential limitations due to the expected mortality calculation method being based on United States data and finding no significant change in overall mortality rates (16.6% vs 17.5%).

The Norway study [33] aimed to test the feasibility of an injury registry and evaluate its results within a community-based traffic injury prevention program over a follow-up period of 7.5 years, from July 1, 1985, to June 30, 1993, divided into 3 periods of 30 months each. The study observed a decrease in the number of traffic-related fatalities in Harstad, with a total of 10 resident deaths: 6 in period 1, 2 in period 2, and 2 in period 3 (P<.12). This represents a 66.7% reduction in traffic-related deaths from period 1 to period 3.

Quality Assessment

Among the 5 studies included in this review, 4 were rated as good quality [29-31,33], while only 1 study was assessed as fair quality [32]. The quality assessment results for the cohort studies are summarized in Multimedia Appendix 3, and the results for the cross-sectional studies are presented in Multimedia Appendix 4.

The only study classified as fair received just 2 stars in the assessment of the dimension of selection for exposed and unexposed cohorts. It was deemed not representative of the general population, specifically the country where the registry is located, as outlined in the methodology of this review. In addition, it lacked comparability of results with an unexposed cohort. While the NOS assigns higher scores to cohort studies that include nonexposed groups, similar to the other 2 studies in this review [30,31], this study did not aim to compare its results with a nonexposed cohort, as it was designed as a before-and-after study.

The analysis of evidence certainty using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) tool was not conducted due to the designs and objectives of the studies. The diverse methodologies used, along with their focus on practical implications rather than outcomes as such, limited the applicability of GRADE.

Discussion

Principal Findings

The findings of this review suggest that injury and trauma registries have the potential to inform policymaking, including preventive measures, health care improvements, and surveillance actions, which can lead to enhanced health outcomes. The studies indicate that trauma registries are primarily designed to provide information that can enhance the efficiency and quality of care for hospitalized patients, with findings including reductions in intensive care unit stay duration and the number of deaths [29-31]. Meanwhile, injury registries are used in community-based injury prevention to identify at-risk populations and health needs, as well as to plan and implement prevention policies that address local priorities [32,33]. One of the 2 studies on injury registries demonstrated reductions in traffic-related hospital admissions and deaths [33]. The other, while not reporting a decrease in these outcomes, noted a reduction in the overall number of assault cases attending the emergency room in the sixth and seventh years of the registry [32]. These studies also emphasized the importance of involving multiple sectors, beyond just health, in injury prevention efforts. All studies highlighted the value of registries for scientific research.

However, it is important to note that the vast majority of studies retrieved from our search used registry data to generate scientific knowledge rather than to assess the impact or effects of the registry itself. For instance, 1 study aimed to identify predictors of prehospital versus hospital mortality due to road traffic injuries in an Iranian population, using data from an integrated road traffic injury registry [46]. Another study examined the epidemiology of occupational injury hospitalizations in the United Arab Emirates using a trauma registry [47]. While some studies evaluated the results of implemented policies and measures, such as one that presented significant trends and developments in acute trauma care over 20 years [35], they did not intend or did not establish causality related to the implementation and use of registry data. Consequently, despite the large number of studies identified in our search, only a few advanced to the full reading phase, as many were excluded during the screening stage after reviewing their titles and abstracts.

An important observation from this review is the notable scarcity of studies dedicated to exploring the effects or results of the use of registry data on injury outcomes. In addition, a crucial point to highlight when interpreting the results is that even the few studies included in the review reflect correlations rather than causalities. This is particularly important as the studies did not adopt designs that allowed for the control of external factors, making it impossible to conclude that the observed results can be attributed solely to the implementation and use of injury or trauma registry data. Currently, there are no impact publications.

RenderX

Limitations

The limitations of our review include the cautious search strategy, which may have excluded studies assessing surveillance information systems or other types that capture injury data, or that collected data solely for that specific research project. We were particularly careful not to subjectively define which studies originated from injury registries. Therefore, we focused on studies that explicitly identified their data sources as such. Our conservative approach focused on the terms "injury registry" and "trauma registry" to ensure the inclusion of studies containing structured registry data with direct relevance to our research question. For example, a study evaluating the impact of the Life in Traffic Project—implemented in 2010 across various Brazilian capitals to reduce traffic-related deaths and serious injuries, which is based on an integrated analysis of data from multiple sectors involved in road traffic injury issues—was not included in our systematic review [48]. The study used interrupted time series models to compare mortality rates before and after the project's implementation, revealing positive outcomes in some cities but concerning increases in others. It highlights the necessity of ongoing evaluations through data registries to enhance public policy analysis and monitoring. Despite its relevance, the tool implemented by this project did not function as an injury or trauma registry. This limitation has prompted the Brazilian Ministry of Health to organize a workshop aimed at establishing a national concept for accident and violence registries, which took place in October 2024.

Although the NOS was considered the most appropriate tool for analyzing the methodological quality of the studies included in this review, we still identified limitations in its application. Most of the studies included did not aim to compare their results with a nonexposed cohort, as they were designed as before-and-after studies. This led to one of them being classified as "fair" because the NOS assigns higher scores to cohort studies that include nonexposed groups. In addition, we had to use an adapted version of the tool for cross-sectional studies, and an analysis of evidence certainty using the GRADE tool was not conducted due to the designs and objectives of the studies. Furthermore, it is crucial to acknowledge the potential influence of publication bias, where studies yielding positive outcomes are more likely to be published, thereby shaping the landscape of the literature.

The studies included collectively provided insights into the results of trauma and injury registries on reducing hospitalizations and mortality; however, variations in methodology and context limited the ability to draw synthesized results through meta-analysis.

Comparison With Previous Work

To our knowledge, this is the first systematic review aimed at mapping the effects and results related to registry data, including those that encompass all types of injuries, regardless of their severity. Previous research has predominantly focused on this relationship with trauma systems, as evidenced by a meta-analysis that demonstrated a 15% reduction in mortality in favor of the presence of a trauma system [22], as well as by another systematic review that sought to identify which components contributed to its effectiveness [21]. In addition, we can mention a study that exclusively addressed the most common functions of trauma registry data in the formulation of health policies but did not examine its effects [13].

Conclusions

This study is especially timely, given the current efforts to develop an injury registry in Brazil. It addressed the existing knowledge gap related to the results of injury and trauma registries on policymaking and injury outcomes. Highlighting our acknowledgment that the registry alone does not directly influence morbidity and mortality; rather, these outcomes are indirect results of evidence-based policies and preventive measures implemented [13,34,49]. Besides, we emphasize that the findings of the studies included represent associations, making it essential to temper expectations regarding the causalities of their effects, as well as to exercise caution in the transportability of results from European studies to the Brazilian context.

Factors such as distinct social, economic, and cultural characteristics, access to health care, trauma burden, practices related to injury management and policies, along with the handling and use of data from the implemented injury registry, may influence the outcomes observed in studies conducted in Europe. Public health decision-makers should consider the differences in the distribution of potential effect modifiers when interpreting the results and their applicability in Brazil. Some studies discuss limitations and adjustments that can be applied through the combination of assumptions and statistical approaches to ensure the unbiased transfer of results obtained from different populations [50,51].

Furthermore, the tool being developed is expected to be low-cost, primarily based on the unification and sharing of existing information systems that currently lack interoperability. This approach represents one of the solutions identified in a study published in 2018 to address the challenges of implementing trauma registries in low- and middle-income countries [49]. Another study highlighted that trauma registries are rarely found in mid to low-income countries due to the lack of digital resources needed to maintain a costly registry. According to the author, until 2017, many countries with a significant trauma burden—including India, South Africa, Spain, China, and Brazil—had yet to develop nationwide trauma registries [52]. The national injury registry currently in development for Brazil aims not only to reduce costs but also to enhance the quality of data and analysis. The main objective is to strengthen epidemiological surveillance to support policies and preventive measures against accidents and violence.

In conclusion, the establishment of an injury registry in Brazil presents a significant opportunity to improve health outcomes through informed policymaking. While it is crucial to set appropriate expectations regarding its effects on morbidity and mortality, its role in facilitating preventive measures and enhancing surveillance capabilities remains valuable.

Future reviews should aim to broaden the scope of inquiry to include studies derived from other data sources, even if they were not explicitly identified as injury or trauma registries, but which still align with the concept of accident and violence

XSL•FO
RenderX

registries defined by Brazil after our study. In addition, it would be beneficial to conduct primary studies that examine the effects of these registries on the quality of surveillance. Without neglecting to mention that it is essential to apply methodologies that allow for the evaluation of the causal impact on health outcomes, particularly in the Brazilian context.

Acknowledgments

The authors express their sincere gratitude to Edna Terezinha Rother, the librarian responsible for developing the search strategies for the databases. This project was supported by Hospital Israelita Albert Einstein through the Programa de Apoio ao Desenvolvimento Institucional do Sistema Único de Saúde (PROADI-SUS 25000.159100/2023-77)[53], a strategy of the Brazilian Ministry of Health. The funding covered costs associated with the development and publication of this manuscript.

Authors' Contributions

ACMdS, LRC, and BZdO contributed to the conception of the study. ACMdS, TFGdSB, and LESL defined the design of the systematic review and the methods for data analysis. ACMdS and LESL drafted the manuscript, while BZdO, LRC, NNBdS, and TFGdSB provided feedback and revised the final version.

Conflicts of Interest

The authors are involved in PROADI-SUS TRAUMA, the project discussed in this article, which has the objective of establishing an injury registry for Brazil.

Abstract

Background: Content creators (CCs), like any other worker, are exposed to various occupational hazards that can affect their physical, mental, and social well-being, with psychosocial and ergonomic risks being particularly relevant. The combination of prolonged work hours, sedentary lifestyles, excessive public scrutiny, and often job insecurity and unpredictability (manifested as continuous connectivity and anticipation of sporadic tasks) presents a significant risk for the development of health issues.

Objective: This study reviews the scientific literature to identify the potential pathological processes affecting CCs on social media.

Methods: The scoping review method was used. Data were obtained from the following bibliographic databases: MEDLINE (via PubMed), Embase, Cochrane Library, PsycINFO, Scopus, Web of Science, and Virtual Health Library. The terms used as descriptors and in the title and abstract fields were “Content Creator” and “Pathologic Processes.” The search was conducted in May 2024. Agreement between authors for paper selection was measured using the Cohen κ coefficient. The documentary quality of the papers was assessed using the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) questionnaire, and the level of evidence and recommendation grade were determined according to the Scottish Intercollegiate Guidelines Network recommendations. Bias was evaluated using the Risk of Bias in Non-randomized Studies of Exposures (ROBINS-E) tool.

Results: Of the 1522 references retrieved, 6 papers were selected based on the inclusion and exclusion criteria. Of the 6 studies reviewed, 3 were exclusively focused on a single gender. The agreement on the relevance of the selected studies, calculated using the κ index, was 84.9% (P<.01). The study population ranged from a minimum of 6 to a maximum of 1544 participants. The STROBE scores ranged from 81.3% to 96.8%, with a median of 14.9% (IQR 2.1). According to the Scottish Intercollegiate Guidelines Network criteria, this review provided evidence level 2++ with a recommendation grade of B. ROBINS-E highlighted a higher number of biases in Domains 5, 6, and 7. All interventions were based on interviews, either conducted online or via email. Participant activities, as documented in the respective studies, comprised influencer roles (n=2), blogging (n=2), YouTube content creation (n=1), and live streaming (n=1). The design of the reviewed works comprised 4 qualitative studies and 2 mixed methods (qualitative and quantitative) studies. The reported health impacts were diverse, comprising burnout (n=2), anxiety (n=1), co-occurring anxiety and depression (n=1), eating disorder (n=1), chronic pain (n=1), and unspecified mental health issues (n=1). All studies highlighted the necessity for further investigation into potential pathological processes among CCs engaged in social media activities.

Conclusions: It was found that the most affected area was mental health, as observed in nearly all the reviewed studies. Despite the extensive documentation of mental health impact, it is necessary to identify the risk factors associated with the pathological processes of CCs to prevent the signs and symptoms identified in this literature review.

Introduction

The rise of social media is primarily supported by the creation of content that appeals to the public. These social media platforms have become not only a means of social entertainment but also a commercial medium where brands offer their products and services through individuals with a significant ability to influence a broad audience.

In this framework, the role of content creation (CC) stands out as a new form of employment. The emergence of this labor role, popularly known as the "influencer," led the European Union to enact the Digital Services Act, which introduced regulations for digital platforms and CCs to combat illegal content and misinformation [1]. This regulation prompted the Spanish government to introduce specific legislation that established the rights and obligations for those engaging in this profession [2].

Moreover, Spain does not currently possess specific legislation governing the working hours of CCs, nor is there any European regulation directly addressing the working time (broadcast duration) of CCs.

Thus, the exercise of this activity, as indicated by a study from the University of Valencia [3], is based on the economic performance derived from the advertising impact it has on social media. In other words, it connects commercial brands with their target audience through their ability to influence a community. Collaboration with CCs is now part of the global strategy of brands [4]. To achieve this, CCs must devote much of their day not only to content creation but also to promoting their work and engaging with sponsoring companies.

In the context of their professional activity, like any other worker, CCs are exposed to various occupational risks that can affect their physical, mental, and social well-being [5]. Particularly relevant are psychosocial and ergonomic risks. Psychosocial risks are related to factors arising from the interaction between work, individuals, and the social context: stress, pressure to maintain a constant presence on digital platforms, or public exposure can lead to anxiety or emotional disorders. Regarding ergonomic risks, these relate to the organization and conditions of the work environment: the use of data display screens, forced postures, or repetitive movements. Identifying, evaluating, and preventing these risks must be the foundation of this labor sector to avoid future health problems in CCs.

Although the negative health implications of social media engagement are recognized, there is limited understanding regarding the precise role social media plays in the development of associated pathological conditions [6]. Thus, this cocktail of marathon workdays, sedentary behavior, public overexposure, and, in many cases, job insecurity and uncertainty (being constantly connected and awaiting tasks without predictability) results in health problems, ranging from mild to severe [7].

Similarly, CCs have been associated with components of addiction (prominence, tolerance, mood modification, relapses, withdrawal, and conflict). However, Peng and Liao [8] have critiqued the ability to differentiate between problematic and highly active CCs. Recently, a novel media phenomenon termed "pathostreaming" has gained prominence. "Pathostreaming" refers to sharing misleading or harmful content (eg, obscenity and hate speech) online, alongside the propagation of hate speech across various digital platforms. The distinct characteristics of "pathostreaming" have led to the emergence of new media entities: "pathostreamers," "pathoinfluencers," and "pathousers." A critical area of ongoing research focuses on the mental health of these individuals and their influence on their followers [9].

There is no doubt that work through digital platforms is growing in importance; however, it also presents significant challenges for the health and safety of its workers. Specifically, all the risks involved in the activities will be present (transport, cleaning, workplace adaptation, home-based work, etc), but these are exacerbated by the unique characteristics of work on platforms [10,11].

CCs are often expected to produce quality work while managing their own stress. The pressure of the creative process, combined with the challenge of meeting deadlines, can lead to burnout. One of the main forms of digital content creation is the live streaming of video games. The study noted that video game players and those engaged in electronic sports were at a higher risk of developing numerous chronic diseases and experiencing increased mortality, highlighting a concerning reality in this research [12].

At the same time, participation on this Web 2.0 platform, with prolonged exposure as an idealized image, was correlated with depressive symptoms, self-esteem problems, anxiety, and body dissatisfaction [13]. Furthermore, this overexposure may occasionally result in the reception of hate speech. The experience of being targeted by hate speech is distressing for content creators (CCs); this sense of attack can diminish their self-perception and self-esteem, thereby compromising their well-being [14]. In this line, Fung et al [15] conducted a systematic review that highlighted the importance of social media in public health issues. They emphasized how the generated content influenced both the well-being of creators and viewers.

All of the above justifies the need for this review. In recent years, social media has experienced a remarkable surge, giving rise to new forms of employment. Among these, CCs stand out as a rapidly growing and increasingly influential group across various sectors. This professional field has evolved and diversified, attracting a significant portion of the active workforce, particularly among younger generations.

Therefore, the central aim of this study is to critically analyze the available scientific bibliography, seeking to understand the potential pathological processes derived from CC within the realm of social networks and the interventions undertaken, with the ultimate aim of establishing the nature of their causal link.

RenderX

Methods

Design

This is a descriptive cross-sectional study and a critical analysis of studies retrieved through a systematic technique. The structure of this review followed the guidelines of the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) [16] and the methodological framework proposed by Arksey and O'Malley [17] for scoping reviews.

Protocol Registration

The protocol of this review was registered in the institutional repository REPISALUD of the Instituto de Salud Carlos III.

Study Population

In this review, a CC was defined as an individual responsible for generating and distributing diverse forms of material (including text, video, audio, and images) across digital platforms. Their primary aims include entertaining, informing, educating, or fostering a connection with an audience. This creative work can be performed on any web-based social media platform.

Data Collection Source

Data were obtained via direct consultation of the following bibliographic databases in the field of health sciences: MEDLINE (via PubMed), Embase, Cochrane Library, PsycINFO, Scopus, Web of Science, and Virtual Health Library.

Information Processing

To define the search terms, the Thesaurus of Descriptores de Ciencias de la Salud, developed by the Latin American and Caribbean Center on Health Sciences Information, was consulted along with its equivalence to Medical Subject Headings from the US National Library of Medicine.

From the hierarchical study of both thesauri and their indexing sheets (entry terms), the following search equations were deemed appropriate:

Equation 1: CCs on social media (Web 2.0).

"Content Creator*"[Title/Abstract] OR "Influencer*"[Title/Abstract] OR "Streamer*"[Title/Abstract] OR "Gamer*"[Title/Abstract] OR "Youtuber*"[Title/Abstract] OR "TikToker*"[Title/Abstract] OR "Instagramer*"[Title/Abstract] OR "Twitcher*"[Title/Abstract] OR "Blogger*"[Title/Abstract] OR "Vloggers*"[Title/Abstract] OR "Podcaster*"[Title/Abstract] OR "Content Strategist"[Title/Abstract]

Equation 2: pathological processes—abnormal forms and mechanisms involved in dysfunctions of tissues and organs.

"Pathologic Processes"[Mesh] OR "Pathologic Processes"[Title/Abstract] OR "Pathological Process"[Title/Abstract] OR "Disease*"[Title/Abstract] OR "Syndrome*"[Title/Abstract] OR "Symptom*"[Title/Abstract] OR "Illness"[Title/Abstract]

The final search equation was developed for MEDLINE (via PubMed) by combining the two proposed equations using Boolean logic (Equation 1 and Equation 2).

This strategy was then adapted to the characteristics of each of the other consulted databases, and the search was conducted from the earliest available date up to May 2024. In addition, a complementary search strategy was implemented to minimize the possibility of publication bias by manually searching the bibliographies of the papers selected for the review. Furthermore, experts in the study topic were contacted to determine the potential existence of gray literature (materials and research produced by organizations outside of traditional commercial or academic publications and disseminated through alternative channels). These experts were not involved in the delineation of the research scope, the refinement of the research question, the selection of studies, or the interpretation of the findings.

Final Selection of Papers

The selection of papers for review and critical analysis was informed by the criteria outlined in Textbox 1.

Textbox 1. Inclusion and exclusion criteria adopted for the review.

Inclusion criteria:

- Original paper published in a peer-reviewed journal.
- The language must be English, Spanish, or Portuguese.
- The complete paper is available for review.
- Participants aged 13 years and older (minimum legal age for engagement in the activity).

Exclusion criteria:

- Studies that do not address the objectives of the review (eg, content creator [CC] and pathological processes).
- Studies conducted exclusively with participants under 13 years [2].

The selection of relevant papers was performed by two authors of this review (SMA and JSV). To validate the inclusion of papers, the agreement rating between the authors had to be above 0.60 [18]. Any disagreements were resolved through consensus among all authors of the review.

Document Quality, Evidence Level, and Recommendation Grade

The structural validity of the papers was evaluated using the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines [19], which contain a list of 22

XSL•FO
RenderX

essential aspects that must be described in each paper. For each selected paper, one point was assigned for each item present. If an item contained several subcategories, these were independently evaluated, with the same value given to each subcategory, and then an average was calculated (this average was the result for that item), ensuring that the total score for each item did not exceed one point.

To determine the level of evidence and its recommendation grade, the recommendations of the Scottish Intercollegiate Guidelines Network (SIGN) Grading Review Group [20] were used.

Bias Study

The risk of bias in exposure effect studies was assessed using the Risk of Bias in Non-randomized Studies of Exposures (ROBINS-E) tool [21]. This tool classifies biases into 7 dimensions, rating each one on four possible interpretations: low risk (little or no concern about bias); some concerns (there is some concern about bias in this domain, though it is unclear whether a risk exists); high (the study has some significant issues in this domain, leading to a high risk of bias); and very high (the study is highly problematic in this domain. The study's characteristics lead to a very high risk of bias.

Data Extraction

Data accuracy control was performed using double-entry tables that allowed for the detection of deviations and their correction through reconsulting the original data. Duplicate records were excluded using the cross-platform ZOTERO program (George Mason University), a reference management tool developed by the Center for History and New Media at George Mason University.

Variables Under Study

The papers were grouped based on the variables under study to systematize and facilitate the understanding of the results. The following data were extracted: first author, year of publication, design, population (CC activity and age), disease, platform or location, time frame, instrument, and health issue.

Data Analysis

The data related to information retrieval were presented in terms of frequency and percentage. The agreement for paper selection by the two authors was measured using Cohen κ coefficient, with an agreement considered adequate when the value was above 60% (good or very good agreement strength).

To determine the currency or obsolescence of the selected papers, the Burton-Kebler (BK) semiperiod was calculated—defined as the median age based on the temporal range analyzed—and the Price Index (PI), which represents the percentage of papers published within the past 5 years.

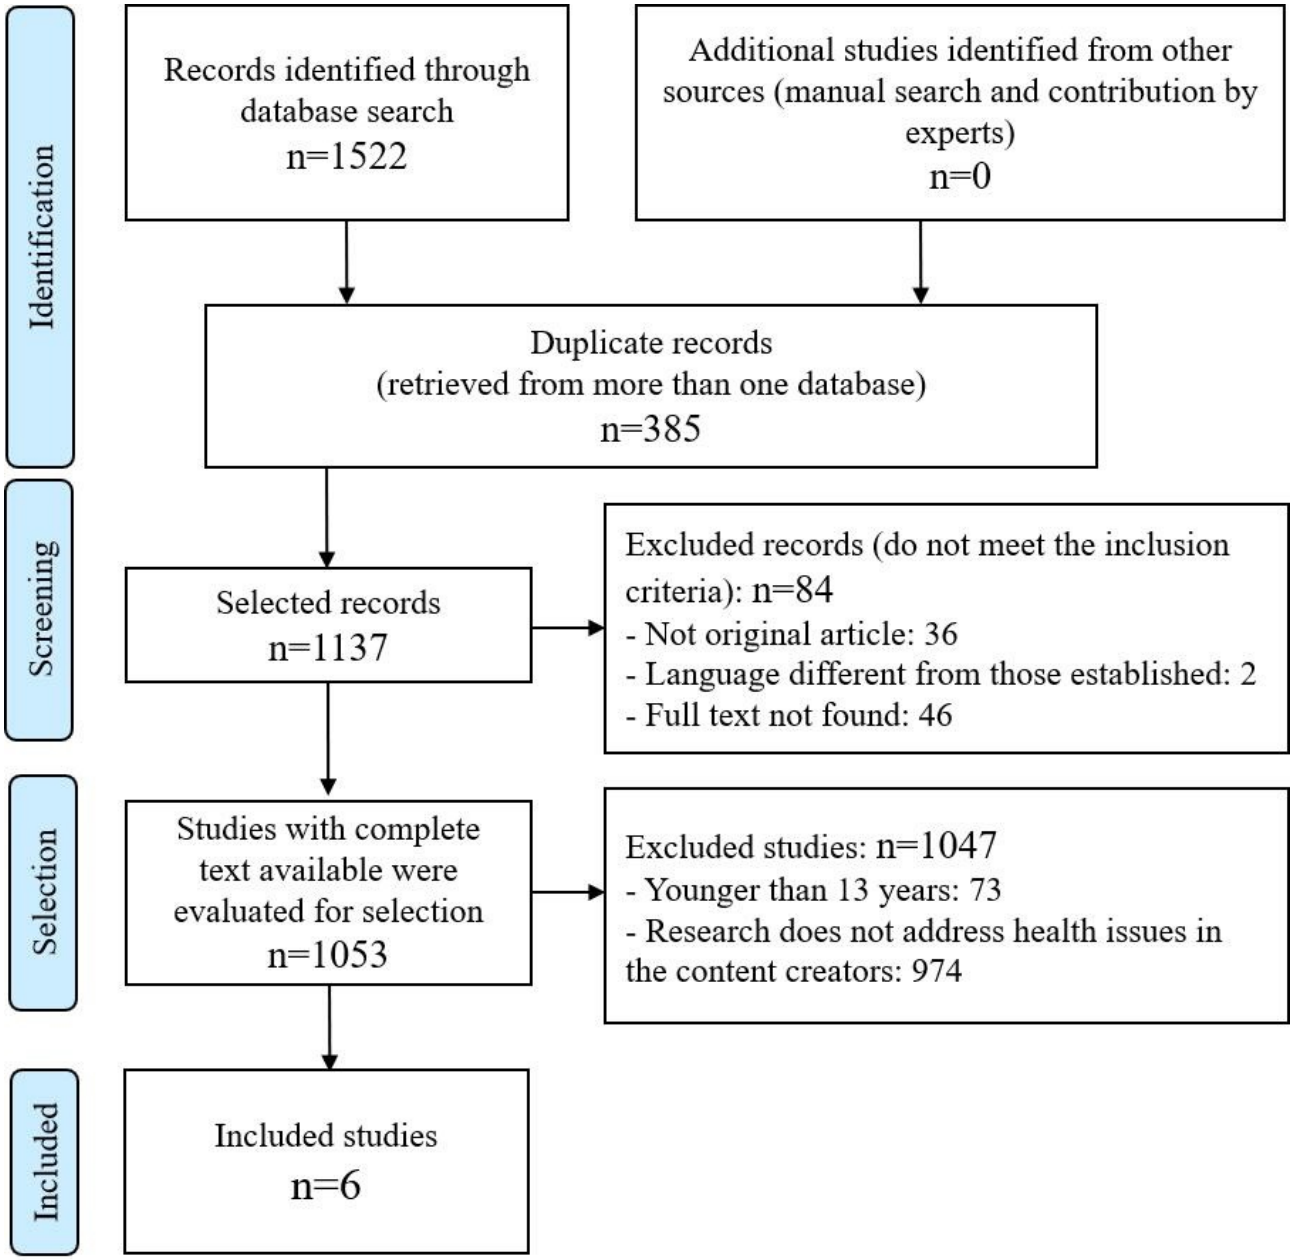
STROBE questionnaire scores were analyzed using the median, maximum, and minimum. The evolution of these scores, in relation to the years of publication, was obtained through regression analysis (R^2).

For statistical analyses, SPSS (version 29; IBM Corp) for Windows was used. The level of significance used was α=.05.

Ethical Considerations

All data were obtained from papers accepted for review. Therefore, in accordance with Law 14/2007 on biomedical research, ethical committee approval was not required due to the use of secondary data [22].

Results



Overview

By applying the search criteria, a total of 1522 references were retrieved: 200 (13.1%) from MEDLINE (via PubMed), 61 (4.0%) from Embase, 148 (9.7%) from Cochrane Library, 95 (6.2%) from PsycINFO, 519 (34.1%) from Scopus, 344 (22.6%) from Web of Science, and 155 (10.2%) from Virtual Health Library. The consultation of bibliographies of selected papers and expert consultation did not yield any new documents. The entire paper selection process can be referenced.

After eliminating 385 duplicate records and applying the inclusion and exclusion criteria (Figure 1), 6 documents [23-28] were selected for review and critical analysis; refer to Table 1.

[b]DSM-5: *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition.*

The agreement on the relevance of the selected studies between the evaluators, calculated using the κ index, was 84.9% (P<.01).

The total retrieved papers showed an obsolescence rate, according to the BK semiperiod, of 3 years, with a PI of 71.40% (7/10 papers were published in the last 4 years). Meanwhile, the papers selected for review showed a BK semiperiod of 3.5 years, with a PI of 66.7%.

When evaluating the document correction of the reviewed papers using the STROBE questionnaire, the scores ranged from a minimum of 13.0 (81.3% compliance) to a maximum of 15.5 (96.8% compliance), with a median of 14.9 (Table 2). A very low, nonsignificant direct linear trend over time was observed (R^2=0.02; P=.80).

Table . Analysis of the methodological quality of the studies according to the 22 evaluation points of the Strengthening the Reporting of Observational Studies in Epidemiology guidelines.

Paper	Score of the points in the questionnaire[a]																						
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	Value, n (%[b])
Zsila et al [23]	1	1	1	1	1	1	1	1	N/A	1	N/A	N/A	1	0.5	N/A	N/A	N/A	1	1	1	1	0.5	15.0 (93.8)
Nadler et al [24]	0.5	1	1	1	1	1	1	0	N/A	1	N/A	N/A	1	1	N/A	N/A	N/A	1	1	1	1	1	14.5 (90.6)
Gandhi et al [25]	1	1	1	1	1	1	1	1	N/A	1	N/A	N/A	1	1	N/A	N/A	N/A	1	1	1	1	0.5	15.5 (96.8)
Tran et al [26]	0.5	1	1	1	1	1	1	1	N/A	1	N/A	N/A	0.3	1	N/A	N/A	N/A	1	1	1	1	1	14.8 (92.5)
Yehuda Katz et al [27]	0.5	1	1	0	1	1	1	1	N/A	1	N/A	N/A	0.5	1	N/A	N/A	N/A	1	1	1	1	0	13.0 (81.3)
Reshef et al [28]	0.5	1	1	1	1	1	1	1	N/A	1	N/A	N/A	1	1	N/A	N/A	N/A	1	1	1	1	1	15.5 (96.8)

[a]0: does not meet the item or any of its parts; 1: fully meets the item; 0 to 1: partially meets the item; and NA: does not apply.

[b]Percentage of compliance for the total items, excluding those that do not apply (N/A).

According to SIGN criteria, this review presented an evidence level of 2++ (systematic reviews with a high probability of a causal relationship) with a recommendation grade of B (a body of evidence including studies directly applicable to the target population and showing overall consistency of results).

The risk of bias in the analyzed studies and the evaluation of the domains included in the ROBINS-E tool are summarized in Table 3, where a higher number of biases were observed in older papers, particularly in Domains 5, 6, and 7. This indicates that these studies have difficulty in appropriately measuring the results.

XSL•FO
RenderX

Table . Evaluation of the reviewed papers according to the bias domains included in the Risk of Bias in Non-randomized Studies of Exposures tool.

Domain	Zsila et al [23]	Niederauer et al [24]	Gandhi et al [25]	Tran et al [26]	Yeshua-Katz et al [27]	Ressler et al [28]
Domain 1[a]	Some concerns	Low	Low	Low	Low	Low
Domain 2[b]	Low	Low	Some concerns	Some concerns	Low	Some concerns
Domain 3[c]	Low	Low	Low	Low	Some concerns	Low
Domain 4[d]	N/A[e]	N/A	N/A	N/A	N/A	N/A
Domain 5[f]	Some concerns	Very high	High	Very high	High	Some concerns
Domain 6[g]	High	High	High	Very high	High	High
Domain 7[h]	High	High	High	High	High	High

[a]Domain 1: due to confounding.

[b]Domain 2: arising from exposure measurement.

[c]Domain 3: participant selection in the study.

[d]Domain 4: due to interventions after exposure.

[e]N/A: not applicable.

[f]Domain 5: due to missing data.

[g]Domain 6: arising from outcome measurement.

[h]Domain 7: due to the selection of the reported outcome.

The study population ranged from a minimum of 6 participants [24] to a maximum of 1544 participants [23]. Three of the 6 studies focused on a single gender: Niederauer and Maggi [24] included only men, while Tran et al [26] and Yeshua-Katz and Martins [27] included only women. Gandhi et al [25] was the only study that identified gender differences. Two studies noted that the population initially presented eating disorders [27] and chronic pain [28], while the other studies did not report any specific pathology in the studied population.

The activities performed by the individuals included in the various studies were: influencers [23,26], YouTubers [24], streamers [25], and bloggers [27,28].

Although this review focused on adults, as it investigated CC as a professional activity, two studies included minors: the studies by Zsila et al [23] and Yeshua-Katz et al [27]. Only the study by Ressler et al [28] included individuals older than 65 years.

Tools Used

All tools were shared either online or via email. The study by Zsila et al [23] was mixed (qualitative-quantitative). It analyzed qualitative aspects and established quantitative scales or values through 3 sections. It examined the problematic gaming behavior pattern, characterized by an increasing priority given to gaming over other activities, to the point where gaming takes precedence over daily interests and activities (gaming disorder). It also assessed the sense of trust, intimacy, and acceptance within a group, whether family, friends, or work (Need for Belonging Scale), and considered the potential financial support based on the second point.

Niederauer and Maggi [24] conducted an exploratory qualitative study using semistructured interviews. The methodology involved content analysis of participants' responses to identify patterns and generate thematic categories.

Gandhi et al [25] used a qualitative methodology with semistructured interviews to explore how CCs address mental health topics.

Tran et al [26] conducted a qualitative study using an ad hoc interview to analyze guilt feelings related to potential inconsistent work, using the Jacobsen Framework (a theoretical model for studying aesthetics psychology) to understand the effects of intrinsic and extrinsic motivation on CC self-esteem.

Yeshua-Katz and Martins [27] also used a qualitative methodology with a focus on personal narratives and the meanings individuals assign to their experiences with illness. In addition, content analysis based on grounded theory was used to identify emerging themes.

Ressler et al [28] performed a mixed methods study. They conducted a quantitative part with closed-ended questions to collect data on participants' characteristics, using descriptive statistics. They also conducted a qualitative portion with open-ended questions to explore bloggers' personal experiences, motivations, and perceptions of blogging's impact on their emotional and social well-being, using grounded theory to identify recurring themes and patterns.

Main Results

The study by Zsila et al [23] revealed results indicating that the lack of group belonging, along with certain types of video games, led to the development of mental health symptoms, such as anxiety and depression, as well as disturbances in sleep.

Niederauer and Maggi [24] highlighted how the lack of satisfaction in content creation could lead to signs and symptoms of burnout. They observed that unsatisfactory CC on YouTube led to various health problems, including exhaustion, discomfort, pressure, distress, anxiety, and burnout.

XSL•FO
RenderX

In the study conducted by Gandhi et al [25], it was described that the type of video game influenced how mental health was addressed for both CCs and their audiences, without specifying concrete symptoms.

The results of the study by Tran et al [26] indicated signs or symptoms of burnout in the studied population. Feelings of guilt related to unconscious work, delayed video posts, artistic blocks, and failure to keep social media platforms up to date were observed. In addition, mood regulation, self-esteem, and anxiety were reflected.

Yeshua-Katz and Martins [27] highlighted the presence of bloggers with health concerns related to eating disorders, manifesting issues such as anorexia nervosa and anxiety.

Ressler et al [28] showed that content creation for bloggers dealing with chronic pain and illness helped reduce the feeling of isolation through online communication, presenting a therapeutic potential in the act of blogging.

Thus, both Yeshua-Katz and Martins [27] and Ressler et al [28] suggested that blogging could serve as an effective means to express a patient's clinical situation and even be considered a therapeutic activity.

All studies agreed on the need for further research into the potential pathological processes of CCs engaged in social media activities.

Discussion

Principal Findings

Considering the recommendations for the objectives of a systematic review [29], this review summarized relevant information related to the occupational health of CCs working on social media. In fact, there is a wide range of research on the effects of social media use on health, particularly in young people. However, very little is known about the health of social media CCs, who also tend to be quite young.

The reviewed papers presented low obsolescence, indicating that the topic is novel. This is further confirmed by the high percentage of papers included in this study that were published in the last 5 years, ensuring confidence in the findings being up to date.

The evaluation of the document accuracy of the studies included in this review, using the STROBE guidelines, did not reveal any temporal evolution. Usually, more recent papers show better results and are linked to the progressive implementation of quality questionnaires. In fact, older studies often did not follow these quality guidelines; for example, the first documents in STROBE date back to 2004, and their usage was gradual [30]. In light of the recent publication of the reviewed studies, it was anticipated that this circumstance would not arise and that the obtained results would be satisfactory.

The level of evidence and recommendation grade for this work, according to the SIGN criteria, were in line with expectations for reviewing observational studies. Despite aiming for a consistent relationship between intervention and outcome, it is important to remember the study designs from which the evidence is derived, acknowledging that some are more susceptible to biases than others and, therefore, justify decisions less strongly. It is well known that many health and occupational safety studies still do not rely on the highest possible level of evidence [31]. This could be due to the limitations of certain primary study designs, such as clinical trials, which are considered robust but may not be suitable for evaluating occupational health interventions, as they generally have long-term effects [32]. In this review, the pathological processes of CCs may not yet be well-studied causes.

The evaluation of the domains included in the ROBINS-E tool showed the main expected biases in the observational studies, but it should be noted that no studies with appropriate cause-and-effect relationships were available, as already indicated [21]. In fact, studies on occupational health, particularly those analyzing data from social media, have shown an uncontrolled process that leads to a biased focal point [33].

On the other hand, the population size was very small, except for the studies by Zsila et al [23] and Ressler et al [28], which could establish results directly derived from the intervention and, consequently, generalize their conclusions. This issue was mentioned in all studies, which unanimously agreed on the need for further research into the possible pathological processes of CCs engaged in social media activities.

Regarding the activity developed, it was observed over the years that there has been an evolution from blogging to the use of platforms that allow live streaming, such as YouTube or Twitch, as streamers can broadcast in real time and interact with their audience. Despite the differences each platform may present, there is a unique characteristic: the effort of CCs to attract audiences and establish parasocial relationships (ie, emotional connection with someone they do not know personally) [34]. Furthermore, people aged 15-24 years (the most active on social media) are precisely those who use platforms such as YouTube and Twitch the most [35]. These 2 platforms have contributed to the so-called "democratization of content generation," allowing the audience to have a proactive role in the process. The "Twitch Generation" values, above all, authenticity and interactivity, genuine, unfiltered content, and direct interactions with their favorite streamers [36].

The presence of minors as CCs in the study by Yeshua-Katz and Martins [27] should not come as a surprise, as most platforms allow content creation starting at the age of 13. However, we must not forget that these minors are performing adult-level work, with all the associated risks, particularly from a psychological perspective. Therefore, it is crucial to raise awareness among parents and guardians while also keeping in mind the responsibility of digital platforms in safeguarding minors' rights.

In this regard, the study by Gómez et al [37] examined how "kidfluencers" (minor CCs) created content and integrated "branded content" (content linked to a brand that connects the brand with the consumer) into their creations. Martínez Pastor et al [38] demonstrated that, despite the existence of advertising regulations in all the countries studied, compliance was minimal when it came to identifying advertising content as such. In this vein, Tur-Viñes et al [39] assumed that content creation by

XSL•FO
RenderX

minor CCs is carried out with the support of parents, and in some cases, parents even open their own channels to support the transmedia strategy initiated by their children.

While the study by Ressler et al [28] included a population up to 75 years old, no specific results were found for the 65 - 75 age range. However, other studies showed that the content production of senior CCs was characterized by a pronounced digital marketing strategy, highlighting professional routines such as regularity in posting frequency, post quality, and creativity, and a close relationship with followers [40].

Traditionally associated with a more passive role as content consumers, some older adults have been developing their digital skills and are now active CCs on social media. In some cases, they have even created a vast audience and a wide range of engaged, interested, and committed followers [41]. However, there is little evidence concerning these older digital CCs, and even less regarding the pathologies associated with this activity, as these individuals are often considered excluded from the labor market.

Methodological Considerations

Conducting interviews online or via email are methods commonly used for data collection, as they are extremely cost-effective and can be sent to a large audience simultaneously. However, the reliability of the data can sometimes be questioned, as the responses received may not always be authentic. Therefore, a method should be established to support the results that might be obtained. Nevertheless, there are studies that have considered online or email interviews as an effective and convenient method [42].

In studies with quantitative methodology [23,28], a validated tool should have been used, or the homogeneity, reliability, internal consistency, and validity should have been reported [43]. In addition, in studies with qualitative techniques, the trustworthiness—credibility, transferability, dependability, and confirmability—should have been discussed [44].

The need for validation of results is fundamental in web-based studies. Collecting high-quality datasets from social media users is problematic, not only due to the biases associated with data collection methods but also with respect to consent management and the selection of appropriate analytical techniques [45].

Health Impacts and Preventive Measures

As observed in this review, the impact on mental health was one of the primary issues resulting from the activities of CCs. This is due to the constant pressure, whether imposed externally or self-imposed, that these workers face in their daily activities to meet targets.

At the same time, they must contend with the need to please their viewers, often unable to fully express their emotions or feelings, either to their audience or, even less so, to their sponsors. This situation leads to the manifestation of symptoms that affect the mental health of CCs, such as disturbances in sleep, anxiety, emotional lability, excessive worry, irritability, loss of interest, obsessions, and fatigue. This set of symptoms creates the ideal breeding ground for the development of psychiatric illnesses such as generalized anxiety disorder, dysthymia, or depressive episodes. In the most extreme cases, these can even lead to the suicide of a CC [46,47].

In addition to the extreme burnout associated with these conditions, CCs may also experience physical exhaustion and a sense of depersonalization, resulting in burnout syndrome, as indicated in the studies by Niederauer and Maggi [24] and Tran et al [26].

However, as demonstrated in this review, it would be a mistake to think that the health consequences for CCs are limited solely to mental health disorders. The prolonged use of data display screens, visual fatigue, persistent forced postures, repetitive upper limb movements, and a sedentary lifestyle can lead to musculoskeletal disorders and systemic issues. These risks associated with the occupational activity of CCs are critical to understanding the various impacts that this professional activity can have on the health of these workers.

It is essential to address these consequences at their source through preventive actions to avert health problems. To prevent these health issues, CCs should be educated and informed about the potential consequences of their work activity, emphasizing the importance of a balance between work and rest. Promoting periodic digital disconnection and avoiding marathon workdays that hinder recovery or rest is key. In this regard, it is important to identify whether CCs, or certain profiles within this group, are exposed to shift work in their activities and, if so, to apply the corresponding preventive measures. To ensure the health of workers, periodic evaluations of their well-being are essential and should be conducted regularly to identify and prevent potential health issues.

Regarding the consequences of sedentary behavior in CCs' activities, workers must be made aware of the importance of taking regular breaks during their workday, alternating between sitting and standing, to reduce the negative effects of prolonged sedentary behavior.

To mitigate the risks associated with the use of data display screens, persistent forced postures, and repetitive upper limb movements, it is crucial for CCs to ensure adequate ergonomic conditions in their work environment that promote a healthy and appropriate setting for carrying out their activities.

Critical Reflection by Authors

It is essential to consider the importance of conducting research that analyzes the impact on the health of CCs from multiple perspectives, including age, the type of Web 2.0 platform used for content creation, the target audience, the social impact generated, and the consequences for health in each of these areas. This multidimensional approach would allow for a comprehensive and detailed understanding of the occupational risks associated with this activity for the health of those engaged in it. The foundation of occupational risk prevention lies in addressing the problem at its origin. Furthermore, appropriate corrective and preventive measures must be established to minimize the risk. In this regard, there is a noticeable gap in proposals related to such measures. As long as the active population continues their work without regular medical supervision and appropriate follow-up, health problems will

XSL•FO
RenderX

persist or develop, which, if left uncorrected, could lead to severe and irreversible damage to the CCs.

Limitations

A primary limitation of this review could be the low number of studies selected, as it concerns an emerging area of knowledge. It has been stated that systematic reviews should be based on studies with designs and selections that ensure greater scientific rigor. However, this analysis included all relevant studies retrieved on the topic under investigation.

The significant difference between the papers retrieved and the final selection is primarily due to the bibliographic databases Scopus and Web of Science. Although some studies were retrieved from other databases, the majority were irrelevant, which could be attributed to their lack of proper indexing (the search was conducted in text format, consulting titles, abstracts, and keywords) and the inability to limit the search by paper type. This high "documentary noise" has been previously observed in other reviews.

According to the United States Agency for Healthcare Research and Quality, the epidemiological designs of the studies selected in this review do not guarantee the full validity and reliability of the observations obtained [48]. However, the available evidence is likely the best given the difficulties of studying this area of research and based on the observations obtained in the various interventions.

Although the real limitations are due to the characteristics of each study, important lessons can be drawn from them to formulate appropriate actions for the development, implementation, and evaluation of future Web 2.0 applications. As Drucker et al [49] rightly stated, understanding these sources of bias is crucial for both authors and consumers of scientific literature as they conduct and read systematic reviews and incorporate their findings into clinical practice and policy formulation.

Conclusions

The studies revealed that the most observed area was mental health. Although the impact on mental health has been extensively documented, it is evident that there is a need to address other aspects of this occupational activity, such as physical health and its social impact, in future studies.

Content creation, therefore, is an emerging activity that is not without health issues, especially in the realm of mental health. It is crucial to continue conducting research that addresses these problems at their origin and determines preventive measures to mitigate their effects. Thus, more detailed studies from an occupational health perspective are necessary.

Acknowledgments

No artificial intelligence tools were used in the conduct of this review.

Data Availability

Data sharing is not applicable to this paper as no datasets were generated or analyzed during this study.

Authors' Contributions

SMA and JSV were responsible for conceptualization, methodology, formal analysis, supervision, project administration, writing (original draft), and writing (review and editing). ERP was responsible for methodology, formal analysis, data curation, and writing (review and editing).

Abstract

Background: The Olympic Games are an example of a mass gathering that involves a complex and large crowd composition, with a large number of illnesses and injuries occurring at previous Olympic Games, and the Olympic Games also becoming a target for terrorist attacks.

Objective: With the help of mass-gathering medicine as a guide, this study aims to critically summarize and analyze the state of illness, injury, and terrorism during the Olympic Games in order to reduce the incidence of illnesses and injuries in crowds and to offer lessons for the organization of major international sporting events such as the Olympics.

Methods: The procedure for this scoping review followed the 5-step methodological framework of Arksey and O'Malley. We searched electronic databases such as PubMed, Web of Science, and Scopus. We extracted, summarized, and categorized general information on each study, game characteristics, illness and injury profiles, terrorism characteristics, preventive measures, and surveillance paradigms.

Results: We conducted a database search and retrieved a total of 9587 studies on 2 occasions. After removing duplicates and screening, we included 120 studies. Only 12 studies on the Summer, Winter, and Paralympic Games published before 2000, and 108 studies from 2000 onward, comprise the 120 studies, marking an unprecedented number of studies in this field of research, particularly in recent times. Of the 120 studies, 80 were illness-related, 81 were injury-related, and 2 were terrorism-related. Nine studies explicitly assessed body parts, including shoulders, feet, and dentistry; 26 studies specifically investigated certain illnesses and injuries, such as COVID-19 disease, heat-related illnesses, and concussions. Of the 120 research studies, 18 specifically analyzed sports such as gymnastics and weight lifting, with 11 studies focusing especially on COVID-19 disease. The most studied games were the Tokyo 2021 Olympic or Paralympic Games, the London 2012 Olympic or Paralympic Games, and the Rio 2016 Olympic or Paralympic Games. The system of injury and illness surveillance in the Olympic Games goes through 3 stages of development: the first trial of information technology, the construction of networks, and the enhancement of intelligence.

Conclusions: A critical summary of studies of illness, injury, and terrorist attacks at previous Olympic Games is important for injury and terrorism prevention at major sporting events such as the Olympic Games. Surveillance methods require improvements in surveillance technology, data sharing, and privacy protection.

(JMIR Public Health Surveill 2025;11:e66829) doi:10.2196/66829

KEYWORDS

Olympic Games; illness; injury; terrorism; surveillance; PRISMA

Introduction

According to the World Health Organization definition, a mass gathering is "any organized or spontaneous event that attracts a sufficient number of people to strain the planning and response resources of the community, city, or country hosting the event." [1]. Mass gatherings include World Youth Day, the Olympic Games, and political rallies [2]. The Olympic Games are the world's largest and most influential sporting event, with a particularly large and complex population that involves many stakeholders. Since the XXVI Olympic Games in Atlanta in 1996, hundreds of thousands of athletes, volunteers, spectators, and other stakeholders have consistently participated in each Olympic Game. Such large-scale crowd gatherings can pose significant public health concerns for the well-being and safety of participants, host country inhabitants, and even the worldwide human population [1].

XSL•FO
RenderX

Previous studies of major health and safety issues at the Olympic Games have focused sporadically on illness, injury, and terrorist attacks [3,4]. The studies focused on groups of tens of thousands of people, such as athletes and Olympic personnel, and found that the most common illnesses were respiratory, gastrointestinal, and heat-related illnesses [5-7]. Meanwhile, numerous studies have explored the sites, types, mechanisms, and incidence of injuries in athletes from previous Olympic Games, as well as the competitions with the highest risk. In recent years, traditional high-risk and emerging uncertain infectious illnesses such as the global epidemic and variation of COVID-19 disease, the active global cholera epidemic [8], and the unknown future of mankind's Illness X [9] have posed a significant threat to major international sporting events such as the Olympic Games. Furthermore, terrorism concerns have historically drawn attention to previous Olympic Games as a security issue. Simultaneously, bioterrorism has the characteristics of easy transport, low cost, hidden dissemination, and wide influence [10], and it takes advantage of the global influence of the Olympic Games, which makes it very easy to become a potential high-risk threat.

Protecting the health of athletes is an important task for the International Olympic Committee (IOC) [11]. The IOC and host nations, among other stakeholders, implement several strategies to mitigate and manage infections, injuries, and acts of terrorism. Regarding illness and injury prevention, host countries implement immunization programs, enhance publicity and education, prioritize personal hygiene, devote attention to medical personnel training, and modify the competition rules [12-14]. Furthermore, surveillance systems such as the Web-based Injury and Illness Surveillance System and Event-based Surveillance are adopted for monitoring [15,16]. Regarding counterterrorism responses, actions encompass organizing drills, providing funding, and strengthening security. Examples include the deployment of a disaster medical assistance team and a highly sophisticated chemical-biological incident response unit during the 1997 Atlanta Olympic Games. [17,18]. Meanwhile, mass-gathering medicine is a specialized discipline [19] that focuses on the provision of medical care and health protection during large crowd gatherings, providing some guidelines for the prevention of illnesses, injuries, and terrorism arising from the Olympic Games.

Extensive studies have demonstrated the prevalence of illnesses and injuries during the Olympic Games, along with multiple instances of terrorism, posing a significant risk to the physical and emotional well-being and security of athletes and individuals participating in the Games. However, systematic studies on the prevention and control of illness, injury, and terrorism in the Olympic Games are rare, and analytical studies of the evidence on the factors contributing to these health and safety impacts are still very sporadic. To fill this gap, the objective of this scoping review is to provide an overview and critical summary of the available evidence on risk factors, preventive measures, and surveillance approaches to illness, injury, and terrorism at the Olympic Games, with a view to providing counterstrategies to help major national and international sporting events in the future reduce health and safety risks.

Methods

Design and Search Strategy

The procedure for the scoping review followed Arksey and O'Malley's 5-step methodological framework, including (1) identification of the study problem, (2) identification of relevant studies, (3) study selection, (4) extraction and graphing of data, and (5) collation, summarization, and reporting of results [20]. Results were presented in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) recommendations [21].

On April 1, 2024, we conducted a systematic search of electronic databases (PubMed, Web of Science, and Scopus). The search strategy was divided into two parts: (1) the sports event, such as "Olympic," "Paralympic," or "Winter Olympic Games"; and (2) terms that covered topics such as "injury," "illness," "infectious diseases," or "terrorism" (see Multimedia Appendix 1 for the detailed search strategy [22-87]).

Inclusion and Exclusion Criteria

The inclusion and exclusion criteria applied in this study are detailed in Textbox 1.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Studies explicitly addressing the Olympic Games context.
- Study populations involving Olympic athletes or stakeholders (eg, spectators, volunteers, and officials).
- Focus on health risks (eg, illness and injury) or safety risks (eg, terrorism).
- All publication types with accessible full text.
- Papers written in English.

Exclusion criteria

- Studies not related to the Olympic Games.
- Case reports or studies on individual athletes without group-level analysis.
- Studies unrelated to illness, injury, and terrorism, or imaging detection studies.
- Publications with unavailable full text.
- Paper not written in English.

Data Extraction

General information was extracted (ie, year of publication and type of study). Data related to the characteristics of the Summer Paralympic Games, the Winter Paralympic Games (ie, date, location, type of study group, illnessnesses, injury, or terrorism studied, etc), was extracted, along with the key findings of each study, including the occurrence of illnesses, injuries, terrorist attacks, and so forth, as well as preventive measures (Multimedia Appendix 1).

Classification of Illnesses

The classification of illnesses in this study will be the IOC consensus statement: methods for recording and reporting of epidemiological data on injury and illness in Sport 2020 (including STROBE [STrengthening the Reporting of OBservational studies in Epidemiology] Extension for Sport Injury and Illness Surveillance) [88] were combined with the *International Classification of Diseases* [89], which was processed and fused to form an innovative classification of illnesses applicable to this review and eventually divided into 18 organ or system classifications (Multimedia Appendix 1).

Results

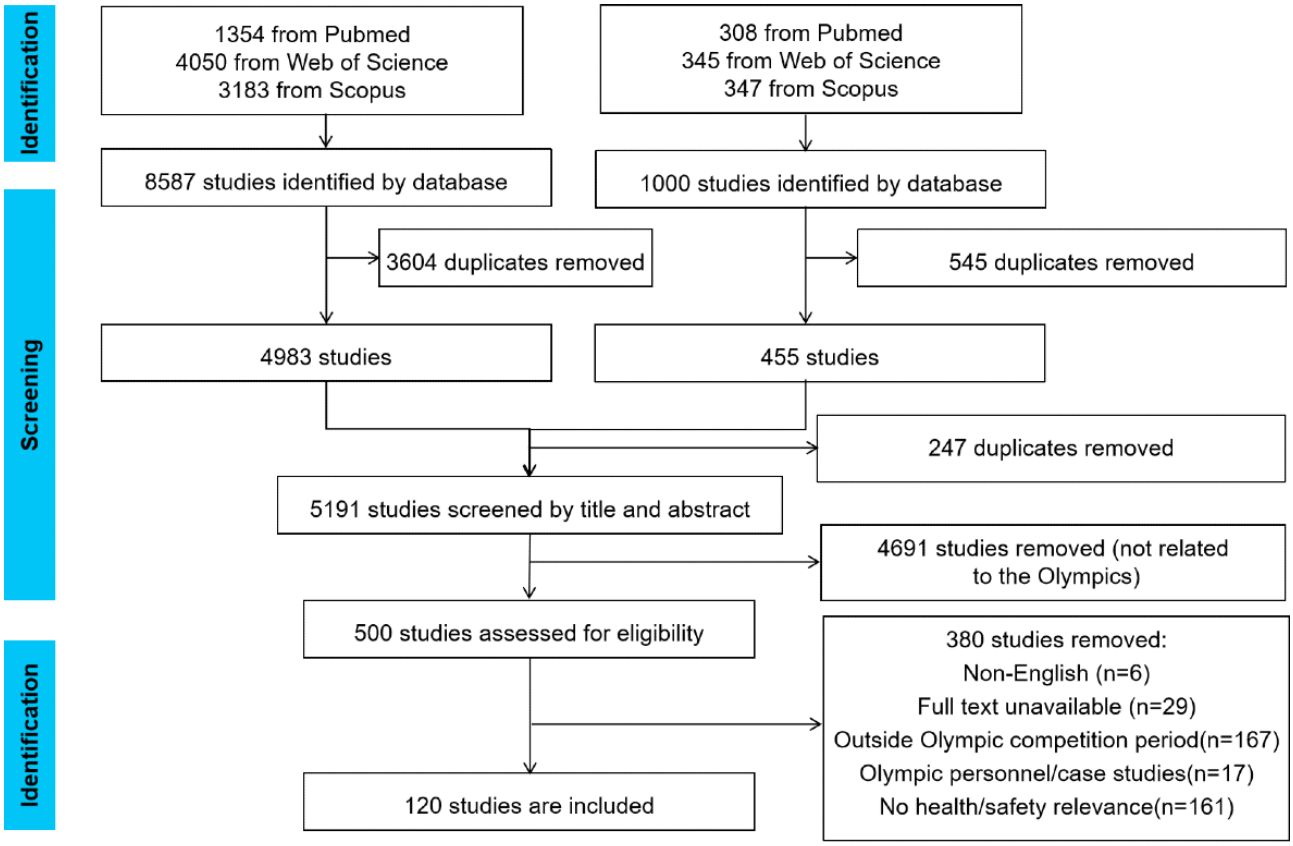
General Characteristics of Included Studies

We searched the database, and the first search included 8587 studies, which were supplemented for the Olympic infectious illness studies, and 1000 were searched again, and 120 studies were contained after removing duplicates and screening (Figure 1).

Only 12 of the 120 studies on the Summer, Winter, and Paralympic Games were published before 2000, while 108 appeared from 2000 onward, reflecting an unprecedented surge in this field of research, particularly in recent years. Eighty-one of the 120 studies focused on illness, 81 on injury, and 2 on terrorism. Of the 120 studies, 18 analyzed events such as weight lifting and gymnastics; 9 analyzed bodily parts including shoulders, feet, and dentistry; and 26 analyzed particular illnesses or injuries such as COVID-19 disease, heat-related illnesses, and concussions, including 11 on COVID-19 disease. Out of all the studies conducted, 79 focused on the Summer Games, 48 on the Winter Games, and 50 on the Paralympic Games. Tokyo 2021, London 2012, and Rio 2016 were the top 3 most studied games (Figure 2). Across all illness studies, the most common organ or system illness for each study based on illness organ or system classification was respiratory system illness (n=35), the second most common organ or system illnesses for each study were gastrointestinal system illness (n=17) and skin system illness (n=8), respectively, and the third most common organ or system illnesses for each study were gastrointestinal system illness (n=10) and skin system illness (n=7). Additionally, the 120 publications included 3 reviews on injuries in Paralympic sports, 1 review on injuries in Winter Paralympic sports, 1 review on injuries in Winter Olympic Games, and 1 review on terrorist attacks.

XSL•FO
RenderX

Figure 1. Screening process for studies eligible for inclusion. The first search yielded 8587 studies, and the supplementary search yielded 1000 studies.



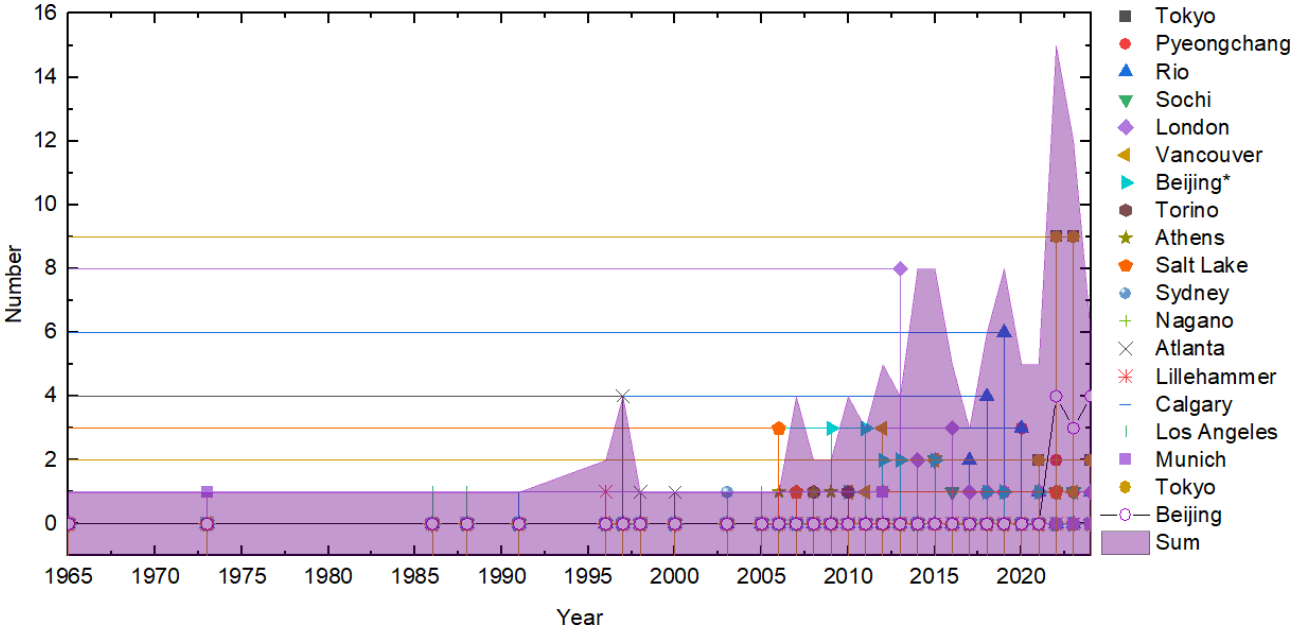


Figure 2. Trends in the number of studies per Olympics and the number of publications per year in the literature (shaded). Beijing refers to the 2022 Beijing Winter Olympics, and Beijing* refers to the 2008 Beijing Olympics.

Health and Safety Risks and Influencing Factors

Risk and Influencing Factors of Illnesses

Respiratory System Illness

Respiratory illnesses have been the most common illnesses at all Olympic Games, and the IOC Medical and Scientific Committee has noted that acute respiratory illnesses are often the most common reason for athletes to seek medical assistance at major sporting events [90]. The number of respiratory infections during the 1996 Summer Olympics in Atlanta [91] and the overall number of respiratory illnesses at the 2008 Beijing Olympics [92] reached a peak of 922 and 3944 cases, respectively. The system most affected by illness during the London 2012 Paralympic Games was the respiratory system [15]. COVID-19 disease has also caused some spread in events such as the Olympics. For example, the Tokyo Olympic Committee recorded 430 cases of infections related to the

XSL•FO
RenderX

Olympic Games [93]. The total number of positive cases monitored under closed-loop management during the Beijing Winter Olympics and Paralympics was 212 [94].

The primary determinants of respiratory illnesses are infection, allergies, environment, and various other related factors. Viruses and bacteria, such as measles, chicken pox, and influenza, primarily cause infections and widely affect the respiratory system. For example, respiratory illnesses were mostly caused by infections in the London 2012 Paralympics [95], Sochi 2014 Winter Olympics [96], Rio 2016 Olympic Games [97], and Pyongyang 2018 Winter Olympics [98]. The main risk factors for allergy and the environment are the mechanical and dehydrating pressures generated in the airways and the levels of air pollutants, irritants, and allergens inhaled by athletes during hyperventilated exercise conditions [99]. Symptoms of pollen allergy, such as worsening rhinoconjunctivitis and asthma, can be destructive to athletes expecting their best performance [100]. Prolonged exposure to mixed exhaust aerosols during exercise may result in reduced lung function and may promote vascular dysfunction [101]. During the Winter Olympics, physical activity in cold and dry air conditions causes inflammation and damage to the airways, possibly leading to a higher incidence of hyperresponsiveness to airways and asthma [102]. The long period of preparation and hard work during the 2008 Beijing Olympic and Paralympic Games led to the prevalence of other factors, such as fatigue, in staff respiratory illnesses [92].

Gastrointestinal System Illness

Illnesses of the gastrointestinal system are widely affecting athletes and those associated with the Olympic Games. Some studies have found that competitions, such as running, are the most demanding type of exercise for the gastrointestinal tract. More than 80% of athletes encounter gastrointestinal issues while exercising [103]. There were 120 cases of illnesses in the gastrointestinal system during the 2012 Summer Olympics in London, which accounted for 16% of all illnesses [104]. There were 131 cases of gastrointestinal system illnesses at the Rio 2016 Olympics [7]. At the 2018 PyeongChang Winter Olympics, 168 staff members were diagnosed with norovirus at the team's accommodation near PyeongChang, and 4 athletes were also detected with the virus [105].

The primary determinants of gastrointestinal system disorders encompass infection, food, environment, and other related factors. In terms of infection, about 90% of viral gastroenteritis outbreaks are caused by norovirus [106]. The majority of virus transmission occurrences happen through person-to-person contact, contact with infected surfaces or environments, ingestion of food, or ingestion of water [107]. Allergies, environmental pollutants, and vigorous physical activity also contribute to the development of gastrointestinal illnesses [95,108]. Between 30% and 50% of people who play power endurance sports may have 1 or more problems with their stomachs, such as diarrhea, nausea, vomiting, and heartburn [108]. It has also been shown that variables such as gastrointestinal symptoms at rest, age, gender, diet, and years of training are associated with gastrointestinal discomfort during exercise [109].

Skin System Illness

Olympic athletes are susceptible to traumatic, environmental, and infectious skin disorders [110]. At the 1996 Atlanta Olympic Village polyclinic, 261 cases of dermatological conditions were documented, including rashes, infections, and other skin-related issues [111]. During the Tokyo 2020 Paralympic Games, there were 73 cases of skin illnesses, accounting for 26.1% (73/280) of all illnesses [112]. Skin and subcutaneous tissue illnesses occurred in 91 cases during the London 2012 Paralympic Games and are the second most common illnesses [113]. During the PyeongChang 2018 Paralympic Winter Games, skin system disorders such as limb or prosthetic interface lesions, residual limb or skin subcutaneous pain, rashes, skin breakdown, and abscesses were observed [114]. Skin system illnesses were the third most common system illness during the Beijing 2022 Paralympic and Paralympic Winter Games [5,14].

The main influences on skin system illnesses are infections, high-intensity physical activity, and specific competitions [115]. Skin system illnesses are particularly common among Paralympic athletes. Causes of skin infections in athletes with spinal cord injuries, amputations or limb deficiencies, and so forth, include loss of sensation and prolonged exposure to pressure in wheelchair-bound athletes, high forces at the residual limb-socket interface, hot or humid environments, sweating during exercise, and possible bacterial contamination in the exercise environment [95]. Skin and subcutaneous tissue are the most commonly affected systems in wheelchair basketball, weight lifting, and seated volleyball [113]. Certain sports are particularly prone to frictional stresses caused by repetitive movements, such as jogging, racquetball, baseball, golf, or any sport that entails frequent contact with equipment [115].

Heat-Related Illness

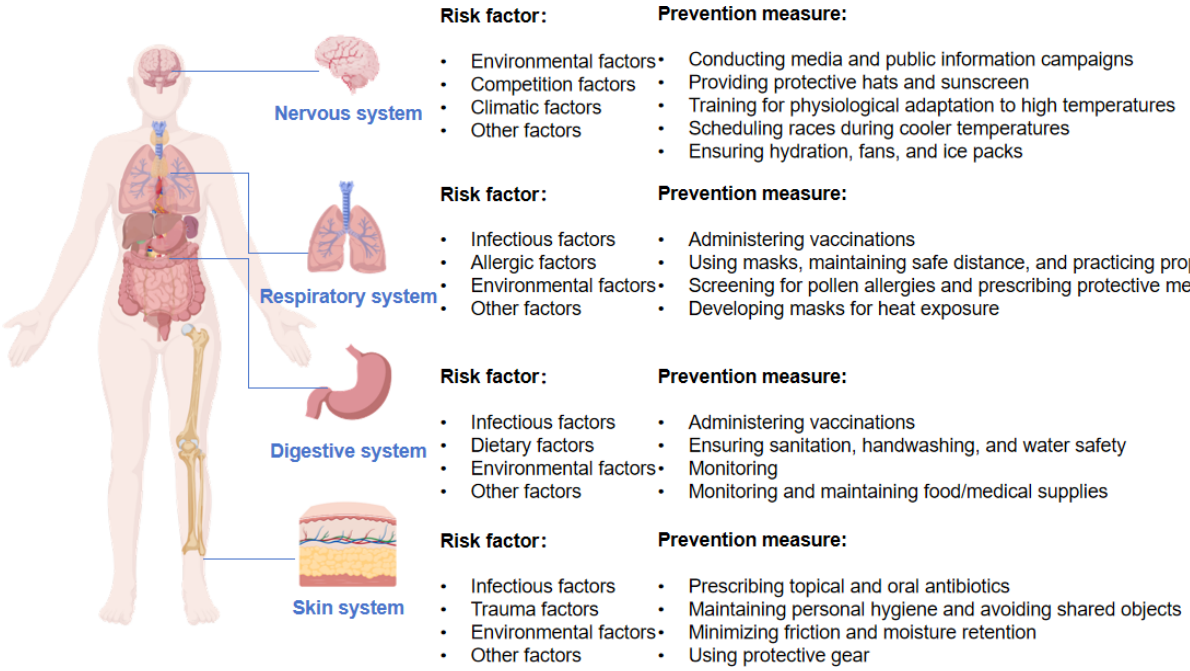
Heat-related illnesses affect a significant number of athletes and Olympic professionals at the Summer Olympic Games. A total of 213 heat-related illnesses were reported at the 1984 Los Angeles Olympics [116]; 372 people were treated for heat-related illnesses at the 1996 Atlanta Olympics, with symptoms including heat cramps, dehydration, heat syncope, and heatstroke [117]; at the 2008 Beijing Olympics, during the opening ceremony alone, there were up to 381 cases of heat-related illnesses [118]; and 225 cases of heatstroke occurred during the 2021 Tokyo Olympics, of which 100 were treated in athlete clinics and 125 in spectator clinics [119]. Therefore, it is evident that a rise in temperatures and other environmental factors during the Summer Olympic Games will result in heat-related illnesses among a significant number of people.

Factors contributing to mass heat-related illnesses are the environment, the specific competition, and the climate of the host country, with climate being the dominant factor. Spectators in hot outdoor environments, among others, account for the majority of heat-related illness visits (939/1056, 88.9%), while members of the Olympic family are largely indoors in cooler temperatures, where heat-related illnesses are rare [91]. A study pointed out that marathon, race walking, cycling, and competitive swimming are the Olympic sports with the highest frequency of heatstroke illnesses [120]. The climate of Atlanta, which is expected to pose a significant risk for heat-related

XSL•FO
RenderX

illnesses [120], is consistent with this study, showing that the climate of the host country of an event plays a determining role in the occurrence of heat-related illnesses. As an example, Tokyo experiences a tropical monsoon climate, Beijing experiences a temperate monsoon climate, and Los Angeles experiences a Mediterranean climate (Figure 3). The shared features of the Olympic Games held in these countries are high temperatures, which directly contribute to the prevalence of heat-related illnesses.

Figure 3. Geospatial location of the Olympic host cities included in the study.



Other Organ or System Illness

Furthermore, there was a higher prevalence of neurological illnesses, genitourinary illnesses, and circulation illnesses. A total of 38 neurological illnesses were recorded at the 2016 Rio Olympics, representing 6% of all illnesses [7]. At the opening ceremony of the 2008 Beijing Olympics, a total of 25 instances of urinary tract illnesses were observed [118]. The 2008 Beijing Olympics and Paralympics reported a total of 49 instances of cardiac illness and 34 instances of vascular illnesses [121]. In addition to this, psychological issues such as competition stress and mental illness in the Olympic Games, especially the Paralympic Games, should also be given attention [111,122]. Special consideration should be given to illnesses associated with colds in susceptible populations participating in the Winter Olympic and Paralympic Games [123]. There have been numerous fatalities at the Olympic Games, with 1 athlete in each of the snowboarding events in 1964 and 2010 losing their life [124,125], a cameraman dying of cardiac arrest during the 1996 Olympic Games [91], a doctor from the Alpine Ski Team accidentally colliding with a tracked snowmobile and dying instantly in 2012 [123], and an athlete at the 2016 Summer Paralympic Games in Rio who experienced a head injury during the competition (Figure 4) [126].

XSL•FO
RenderX

Figure 4. Factors affecting high-risk illness and preventive measures in the Olympic Games. Figure 4 is an original image created by the authors; however, the organ images were sourced from BioGDP [127].

Risk and Influencing Factors of Injuries

Information on injuries related to the Summer and Winter Olympic Games is given in Table 1. Alpine skiing, Nordic skiing, and sledge hockey are the 3 key sports in the Winter Paralympics, and their associated sports injuries are more prominent [122]. Compared with recreational sports, the Olympics are faster, higher, and more competitive, with athletes having greater difficulty completing competitions and often neglecting minor injuries for the sake of winning honors, which can lead to more serious injuries [128,129]. The most common areas of sports injuries in the Summer Olympics are focused on the lower limbs and lower back, which may be related to the fact that the lower limbs and lower back need to bear the weight and impact of the human body in high-speed running, change of direction, and jumping, as well as high confrontation and high-load states, and are prone to injuries [130]. The most common types of injuries in Winter Olympic Games may be related to the movements executed in these sports, many of which involve high-speed twisting and shear forces [128]. For instance, ice hockey, a sport included in the Winter Olympics, is a sport marked by fast movements and intense body contact, resulting in contusions and sprains in vulnerable anatomical regions such as the hands [131]. Paralympic athletes experience a higher frequency of injuries to their upper extremities, namely, the shoulder, wrist, and elbow. This is because wheelchair athletes heavily depend on their shoulders for all their activities. Additionally, the nature of the injuries experienced by some of these athletes results in a smaller number of athletes participating in competitions with fully functioning lower extremities compared with their upper extremities [132]. The effect of competition difficulty, protective equipment, and assistive devices on injury has been noted in Winter Paralympic injury research [122]. Compared with summer sports, winter sports have a higher incidence of contusions, fractures, and concussions due to impact and speed [133]. Additionally, the Olympic Games have introduced new sports, posing challenges to precompetition and in-competition prevention and treatment efforts [129].

Table . Information on injuries related to the Summer and Winter Olympic Games.

Games	Highest risk competitions	Most common areas of injury	Most common types of injuries
Summer Olympics [130]	BMX, taekwondo, football, rugby, mountain biking, boxing, handball, hockey, weight lifting, etc	Knee, thigh, ankle, lumbar spine, calf, and foot	Joint sprains or ligament ruptures, muscle strains, contusions or hematomas, skin lacerations, and tendinopathies
Winter Olympics [131]	Freestyle skiing, snowboarding, alpine skiing, bobsledding, and ice hockey	Knees, chest/waist/back, and wrists/hands/fingers	Contusions, hematomas, and bruises, followed by strains (including muscle breaks, tears, or tendon ruptures) and sprains (including dislocations, subluxations, and ligament ruptures)

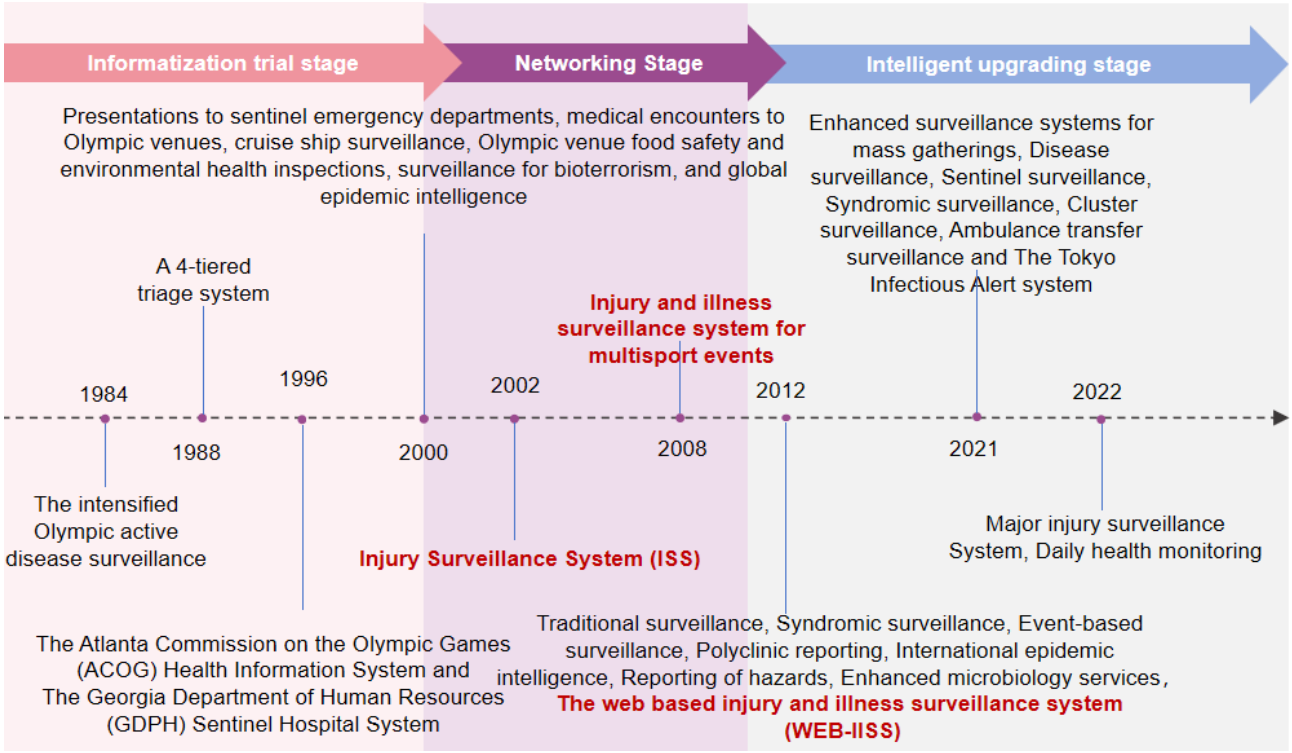
XSL•FO
RenderX

Risk and Influencing Factors of Terrorist Attacks

The Olympic Games are highly susceptible to terrorist groups due to their prominent presence, the magnitude of the events, and the significant number of spectators. On September 5, 1972, a group of 11 Israeli athletes and coaches were abducted and subsequently murdered by members of the Black September organization at the Athletes' Village [18], and during the 1996 Olympics in Atlanta, the 100-year anniversary of the Olympic Park bombing killed 2 people and sent 111 victims to city hospitals [17]. Besides terrorist acts that took place immediately during the Olympic Games, there have been other terrorist occurrences that are either directly or indirectly associated with the Olympic Games or other significant athletic events. Following the news of London's successful attempt to host the 2012 Olympic Games on July 7, 2005, 4 terrorist assaults occurred in the city within 24 hours, resulting in the loss of 52 lives. On the eve of the 2010 World Cup final, an al-Qaeda spokesman declared on a North African jihadist website that the tournament would be targeted by suicide bombers using "undetectable explosives" [18]. In a study that noted at least 74 terrorist attacks against stadiums in the last 50 years, there have been 4 or more attacks in each subsequent year since 2011, with a peak of 11 in 2015 [134]. In recent years, although there have been no terrorist attacks at Olympic Games events, the Games may face other emergencies, such as demonstrations, bombings, and so forth, including bioterrorist attacks.

Illness, Injury, and Terrorism Risk Surveillance System

Injury and illness surveillance at major sporting events prior to the 1990s relied primarily on traditional paper records and manual counting [135]. Actually, this appears to be the situation with the monitoring of the Olympic Games. With the rise of the internet and information technology, injury surveillance systems have gone through the following 3 phases.



The stage of information technology attempts was roughly from the 1980s to the early 2000s. With the rise of computer and internet technology, the Olympic Games began to experiment with the application of information technology to injury and illness surveillance, recording athletes' health status through a preliminary surveillance network system or an electronic medical record system, and using databases for data storage and management. For example, the active illness surveillance system during the 1984 Summer Olympics in Los Angeles included a network of 46 hospitals, 90 doctors' offices, and so forth [136]. Two complementary public health surveillance systems, the Georgia Department of Human Resources Sentinel Hospital System and the Atlanta Commission for the Olympic Games Health Information System, were established for the 1996 Summer Olympic Games in Atlanta [117]. Early surveillance methods still do not have convenient and efficient features. They are achieved through the employment of workers and fixed weekly calls with the match venue to achieve the purpose of surveillance, such as 4 levels of detection of injury classification scale, in order for the researchers of the charts to be retrospectively reviewed in order to understand the patient's body-related situation [136,137] .

The networking phase was roughly from the beginning of the 21st century to around 2010. With the spread and development of internet technology, the Olympics began to establish a web-based injury and illness surveillance system. These technologies provide instantaneous transmission and exchange of data to enhance the effectiveness and precision of surveillance mechanisms. For the Sydney 2000 Olympic Games, public health planning covering disaster response planning, environmental hazard monitoring, and food safety strategies was developed, as well as surveillance systems covering both domestic and international parts of the country, including enhanced infectious illness surveillance, bioterrorism monitoring, global outbreak intelligence, and so forth [138,139]. The 2002 Salt Lake Winter Olympics developed a new public health surveillance system based on electronic medical records, with the goal of identifying unusual patterns of symptoms that could represent clusters of illness, with the hope of identifying these events of significance in a timely manner so as to allow an adequate public health response and management [140]. The International Paralympic Committee implemented the injury surveillance system and continued to do so at all subsequent Winter Paralympic Games [141]. The Athens 2004 Olympic Games used a team sports injury-reporting system, which reported information such as the injured player's jersey number, time of game, site of injury, and type of injury [142]. The 2008 Beijing Olympics used a medical intake system to record unusual patterns of illness or injury that required further investigation [92].

The intelligent enhancement stage is mainly from 2010 to the present. With the rapid development of big data, artificial intelligence, and other technologies, the Olympic Games' web-based injury and illness surveillance system has been continuously upgraded and improved, and the system is able to use data analysis technology to dig out the rules and trends behind the data, providing a scientific basis for the formulation of prevention and control measures (Figure 5). London 2012 Olympic and Paralympic Games used traditional monitoring, integrated monitoring, event-based surveillance, integrated clinic reporting, and so forth [16], with escalating scientific and technological methods. The IOC's injury and illness surveillance system for multisport events was used in the Olympic Games in Beijing 2008, London 2012, Sochi 2014, Rio 2016, and Pyeongchang 2018 [96-98,143]. The intelligence drive led to the first adoption of the Web-based Injury and Illness Surveillance System at the London 2012 Paralympic Games, and since then, the WEB-IISS has been adopted and continually improved and enhanced at the Sochi, Rio, PyeongChang, Tokyo, and other Paralympic Games [112,114,132,144,145]. Surveillance for the Tokyo 2021 Olympic Games also involves multiagency and multifaceted aspects, including Japan's Extreme Emergency and Post-Disaster Surveillance, Open-Source Epidemic Intelligence, and Multi-Surveillance System [119,146,147]. Injury surveillance for the Beijing 2022 Winter Olympic Games remains an integral part of the IOC's initiative to protect the health of athletes and record injuries and illnesses in a web-based tabular format, as well as data from the local organizing committee's medical (polyclinic) facilities and on-site medical support [14,119].

XSL•FO
RenderX

Figure 5. Main surveillance systems for injury and illness at previous Olympic Games.

Discussion

General Characteristics

There were only 12 studies on the Summer Olympics, Winter Olympics, and Paralympics before 2000, and a total of 108 studies published in 2000 and beyond, particularly in recent years when the amount of literature in this area of research reached an unprecedented level, reflecting the fact that in recent years the importance attached to health and safety issues at the Olympic Games has reached an unprecedented level. Furthermore, the 3 most extensively studied games also demonstrate the growing emphasis on health and safety in the games in recent years. The 120 studies involving comprehensive papers on injury and disease, single competitions, body parts, and single injuries or illnesses show that in addition to holistic studies of illness and injury, scholars are also focusing on high-risk competitions and major injury areas. It is noteworthy that only 2 studies were conducted on terrorism, reflecting, on the one hand, the theme of peace and development and the near absence of terrorism in recent years and, on the other hand, the lack of ability to think in peace and insufficient research on new types of bioterrorist attacks.

Related Health Risks

Illness is the most common risk factor in Olympic events. Illnesses of the respiratory system, the gastrointestinal system, and the skin system should pay particular attention to the infectious factors, which can be prevented and controlled in terms of the sources of infection, the route of transmission, and the susceptible population. In controlling the source of infection, attention is paid to screening for incoming illnesses, early diagnosis and isolation, and tracking, surveillance, and, if necessary, isolation and observation of close contacts of patients [16,148]. Emphasis should also be placed on dynamic surveillance and early detection of global illnesses, such as open-source epidemiological intelligence and multisource surveillance systems for infectious diseases [146,147]. In terms of cutting off the routes of transmission, it is advocated to wash hands frequently, wear masks, and avoid touching the mouth, nose, and eyes with hands, and so forth, so as to reduce the chances of pathogens spreading through hand-to-hand contact [6]. Maintaining cleanliness and hygiene in living and competition environments, with regular disinfection and ventilation, thereby reduces the survival time of pathogens in the environment and decreases pathogen concentrations in enclosed spaces [14]. Pay special attention to food and drinking water hygiene, avoiding food sold by street vendors, following water safety recommendations, and so forth [149]. With regard to the protection of susceptible groups, timely inoculation of appropriate vaccines and popularization of knowledge on the prevention and treatment of infectious illnesses, special attention is paid to the older adults, children, pregnant women, and other vulnerable and highly sensitive groups, and the necessary protective measures are taken, such as reducing the number of outings and avoiding crowded places [150].

Furthermore, illnesses affecting the respiratory and gastrointestinal systems, among others, can be attributed to a range of potential influencing factors such as environmental conditions (temperature, humidity, altitude, pollution, and pollen), diet, and exposure to diverse cultures, populations, and pathogens [151]. Particular attention should therefore be paid to environmental challenges related to heat, air quality, and water quality [152]. The management of respiratory system illnesses resulting from high altitude or cold conditions, air pollution, and pollen allergies includes the use of heat and moisture exchange respiratory device masks, allergy screening,

XSL•FO
RenderX

and the administration of preventive drugs for illness prevention and control [100,102]. Dietary and nutraceutical approaches to regulate the microbial, together with the avoidance of nonsteroidal anti-inflammatory medicines and high fructose meals, can effectively treat gastrointestinal system issues induced by intense aerobic activity [103,153]. For illnesses of the skin system, especially moisture, sweat, friction [110], UV exposure [154] of body parts of specific competition events, and (people with disabilities) special populations should be considered. As heat-related illnesses can cause a medical surge, athletes and spectators (especially children, older adults, and vulnerable groups with underlying medical conditions) should be cooled, protected from the sun, hydrated, and avoided from competing in the heat [155]. Attention is also drawn to the recommendations of the World Economic Forum's Global Commission on Biodiversity Cities on urban greening and the installation of white reflective roofs and continuously shaded pavements [156]. Furthermore, apart from preventing the aforementioned illnesses, our upcoming studies should also prioritize the mental health of professional athletes [122,128,157]. The issue of cardiac arrest should be taken seriously as deaths have occurred in previous competitions and reference can be made to the Resuscitation Council of Great Britain's best practice guidelines on cardiac arrest [158]. Vigilance against traditional high-risk [159] and emerging unpredictable infectious illnesses should also be an important measure in illness prevention.

The IOC strongly encourages National Olympic Committees and International Federations to protect the health of athletes and actively focus on injury prevention [160]. It has been suggested that changes in the incidence of injuries may be the result of changes in the composition of the Olympic program, changes in environmental factors (eg, venue or track design, rules of the game, or other factors), changes in the awareness of athletes and their medical staff of the importance of recognizing and reporting minor incidents, and the availability of training in the recording of injuries and illnesses [96,98]. For example, encouraging taekwondo athletes to use more head kicks and removing helmet protection for boxers have led to a high incidence of injuries in combat sports, with the removal of protective helmet protection tripling the overall risk of injuries [143]. Injuries are common in the Olympic Games, and risk factors for injury mechanisms in high-risk events, video analysis, and precise biomechanics factors for movement techniques are essential for better direct injury prevention strategies [128,160]. Difficult and high-speed races are highly prone to injuries, and among the measures to prevent injuries are changing the rules of the competition, strengthening protective measures, and optimizing the track. For example, at the Sochi and PyeongChang Winter Olympics, modifiable injury risk factors were identified: redesigning the track, increasing the number of training sessions, changing the start time of the competition, and so forth [161]. Meanwhile, in the training of medical personnel, emphasis should be placed on clarifying common types of injuries and emergency procedures, with targeted training on contusions, muscle breaks, and sprains, including those to the knee, thoracic spine, lumbar spine, back, and other parts of the body [131]. Some studies, however, have also found an inverse relationship between the size of the National Olympic Committee (NOC) and the risk of health problems, noting that athletes from the smallest NOCs have significantly higher prevalence rates than athletes from the largest NOCs [98]. This is because larger delegations, often from countries with well-developed exercise physiology and sports medicine communities, can provide more comprehensive medical care and closer medical follow-up during the Olympic flag period, and therefore the IOC and host countries should consider the allocation of medical resources as a whole, with the inclusion of multilingual triage nurses and doctors as a noteworthy area of concern in the allocation of medical resources [162].

The problem of terrorist attacks at the Olympic Games has a long history, but in recent years, strong initiatives such as huge investments, high-tech equipment for monitoring, and armed military forces for security have hardly been associated with rumors of terrorist attacks at the Olympic Games [98]. Medical staff instructed on bomb blast injuries, pharmacies stocked with therapeutic drugs, and prepared to hose down contaminated facilities prior to the Atlanta Olympics Games [111]. The Sydney Olympics also established a bioterrorism-monitoring system [139]. The Tokyo Olympics also organized a number of training events to prepare for possible mass casualties, such as terrorist attacks [163]. It appears that plans have been formed for acts of terrorism. The world's unprecedented changes are accelerating, international political disputes and military conflicts are erupting at various points, religious and ethnic conflicts still exist, and the global development and security situation is intricate and complex, which also poses certain risks to the security of the Olympic Games. Emerging biotechnology has also increased the cost, difficulty, and impact of bioterrorism attacks, with a particular focus on physical and mental health. Because of the Olympic Games' widespread global influence, bioterrorism is a prime target, so it is critical to increase surveillance and take preventative measures beforehand.

Illness and Injury Surveillance System

Surveillance systems in the Olympic Games have progressed from traditional paper records and manual statistics to information technology, networking, and intelligence, which can better facilitate the IOC's discovery of injury and illness prevalence, but there are still shortcomings such as lagging surveillance technology, limitations in the scope of surveillance (eg, lack of epidemiological data on athletes' mental health [164] and little attention to female athletes in the epidemiological data on injuries and illnesses [165]), data standards lack of uniformity, unequal distribution of monitoring resources in delegations, equipment safety, and radiation risks. In the future, technological innovation will integrate cutting-edge information technologies such as Internet of Things and blockchain to enhance monitoring intelligence and automation, enabling real-time surveillance and rapid response. Concurrently, data sharing and utilization efforts will strengthen cross-departmental and interinstitutional collaboration to dismantle information silos while promoting open data sharing and effective utilization. In privacy protection, reasonable data use will be advanced while ensuring data security through reinforced measures including encryption and access controls, guaranteeing safety throughout data transmission, storage, and usage. Finally, monitoring effectiveness will adopt an integrated

XSL•FO
RenderX

ecosystem approach to assess population-level infectious disease risks, forging synergies among medical and laboratory systems, validated tools, and essential human and financial resources [166].

Limitations of the Study

There are 3 key limitations to this study. First, most current illness classifications are by body system, which then makes it difficult to explore the causes and influences that trigger illness when analyzing the literature. Second, the study is also constrained in comparing different competitions as many papers have used different approaches to illness and injury data collection and research reporting. Third, this study does not include papers written in languages other than English, and information on Olympic-related illnesses, injuries, and terrorism may be published in the host country's native language.

Conclusions

From the perspective of mass-gathering medicine, this study investigates the occurrence of illnesses, injuries, and terrorism in the Olympic Games, analyzes the real reasons behind them, and then proposes targeted preventive measures. Through this study, we found that respiratory system illnesses, gastrointestinal system illnesses, skin system illnesses, and so on, are more common, and at the same time, heat-related illnesses also affect the Olympic personnel involved in a larger way; fighting, cycling, and ball and snow sports are prone to crowd casualties, and injuries are mainly in the knee, thigh, ankle, chest, waist, back, and so on, and the common types of injuries are contusions, strains, and so on; and the advancement of biotechnology and the volatile international situation have made bioterrorism attacks possible. In terms of health and safety risk prevention, the focus should be on vaccine-preventable illnesses, while health education should be strengthened, and so on; the rules of the competition should be revised, protective equipment should be upgraded, medical resources should be rationally allocated, and so on; and bioterrorist attacks should also be given high attention. In addition, injury and illness surveillance systems should pay attention to technological innovation, resource sharing, and information confidentiality.

Acknowledgments

The authors declare that they received financial support for the research, authorship, and publication of this paper. The National Key Research and Development Program of China (2021YFC2600504) and the National Natural Science Foundation of China (72474152) supported this research, which relied on the China National Key Research and Development Program's Research on Bioterrorism Prevention and Control Technology in Important Public Places and Research on the Elastic Control Mechanism of Biological Triage Process Based on BPR Theory.

Authors' Contributions

ST, SX, and YZ designed the study; ST, ZC, and BS were involved in study selection and data extraction; ST, TT, and YZ contributed to the writing of the manuscript. All authors reviewed and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The association between indoor temperature level and mental health is becoming increasingly important as climate change leads to extreme temperature fluctuations. Older adults are particularly vulnerable to indoor temperature changes because of their diminished ability to regulate body temperature and extended time spent indoors.

Objective: This study aims to examine the association between indoor temperature levels and mental health outcomes among community-dwelling older adults, aiming to provide essential evidence to support the development of interventions and policy strategies to improve their mental health.

Methods: In this systematic review, we conducted a comprehensive search of 7 electronic databases (MEDLINE, Embase, Cochrane Library, CINAHL, PsycINFO, Google Scholar, and ProQuest) on April 4, 2024, without restrictions on language or publication date. The National Institutes of Health quality assessment tool for observational cohorts and cross-sectional studies was used to evaluate the methodological quality of the included literature.

Results: Of the 2328 studies identified, 15 met the inclusion criteria. The majority (8/15, 53%) were conducted in Asia, followed by Europe (4/15, 27%) and 1 study each in Australia (7%), Egypt (7%), and the United States (7%). Mental health outcomes associated with indoor temperature exposure were categorized into four groups: (1) sleep problems, including insomnia; (2) emotional problems, such as emotional distress and negative mood; (3) social interaction problems, such as social exclusion and low social participation; and (4) other mental health issues, including anxiety, agitation, and annoyance. Sleep problems were the most frequently reported mental health outcome related to indoor temperature levels (9/15, 60%). Older adults living in substandard housing conditions, facing economic difficulties, and residing in urban areas were vulnerable to exposure to uncomfortable indoor temperatures because of housing-related risks, such as low energy efficiency, inadequate heating or cooling, and limited access to green spaces.

Conclusions: The findings highlight the need to develop evidence-based guidelines to improve mental health by managing indoor temperature levels in the community. Improving housing conditions through policy support could enhance the mental health of community-dwelling older adults.

KEYWORDS

emotional; housing; climate change; sleep-wake disorder; social participation

Introduction

Global temperature is rapidly increasing as a result of climate change [1]. The Lancet Countdown, an international collaboration monitoring the health impacts of climate change, warns that the unequal health impacts of climate change will worsen without immediate intervention [2,3]. As climate change leads to more frequent and intense extreme temperatures [1], interest is growing in studies on health outcomes associated

XSL•FO
RenderX

with temperature level [4]. To better adapt to environmental changes caused by climate change, communities need to understand how to protect themselves from exposure to uncomfortable temperatures [5].

Temperature is closely linked to mental health, with growing evidence demonstrating that exposure to extreme temperatures is associated with increased hospital admissions and emergency department visits related to adverse mental health outcomes such as affective disorders, insomnia, anxiety, depressive disorders, schizophrenia, and organic mental disorders [6-8]. Indoor temperature may be evaluated by both objective measurements and subjective perceptions of indoor comfort [9], which is crucial given that recent studies have found that exposures measured by a single approach are significantly associated with negative mental health outcomes.

Determining an appropriate indoor temperature is complex as it depends not only on environmental and structural factors, such as regional climate and housing conditions [10,11], but also on individual response to temperature levels. Aging further complicates this issue, as older adults experience a diminished ability to perceive and regulate body temperature, increasing their vulnerability to the adverse effects of exposure to both high and low temperatures [12]. In addition, older adults are more susceptible to inappropriate indoor temperature exposure, because they tend to spend more time indoors than do younger populations [9,13]. A recent study found that community-dwelling older adults spend up to 85% of their time indoors, whether at home or in other settings [14]. Accordingly, a growing number of studies have examined the association between indoor temperature levels and mental health in older adults [15-17]. However, without synthesizing this fragmented evidence, it remains difficult to determine which mental health outcomes are most frequently reported in association with indoor temperature or to identify which subgroups of older adults are most vulnerable. A systematic review can integrate these findings to enhance our understanding of the associations between indoor temperature, individual vulnerabilities, and mental health outcomes, essential for informing targeted interventions and policy development in the context of aging populations and climate change.

In this systematic review, we aim to investigate the association between indoor temperature levels and mental health—encompassing both clinical disorders and nonclinical outcomes—in community-dwelling older adults, addressing the following questions:

1. What characteristics of indoor temperature exposure are related to mental health outcomes in older adults?
2. Which mental health outcomes are related to indoor temperature levels in older adults?
3. What factors make older adults vulnerable to indoor temperature levels?

Methods

Design

This study is a systematic review. The reporting of this review follows the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 guidelines (Checklist 1) [18]. The protocol was registered in the International Prospective Register of Systematic Reviews (protocol: CRD42024536215). Owing to the use of previously published studies and publicly available anonymized data, ethical approval was not required.

Search Strategy

A systematic search was conducted on 7 electronic databases with the assistance of experienced medical librarians: MEDLINE, Embase, Cochrane Library, CINAHL, PsycINFO, Google Scholar, and ProQuest. In addition, the bibliographies of the screened studies were manually searched. Three categories of concepts were used individually and in combination: (1) population (older adults), (2) exposure (indoor temperature), and (3) outcome (mental health). The database literature search was conducted on April 4, 2024, with no restrictions on publication dates or language. Non-English studies were screened using machine translation tools and cross-checked among the reviewers. The detailed search strategy for each database is provided in Table S1 in Multimedia Appendix 1.

Eligibility Criteria

The inclusion and exclusion criteria are presented in Textbox 1.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria for study selection.

Inclusion criteria

- Population: older adults aged ≥60 years.
- Exposure: indoor temperature measurement
- Outcome: mental health outcomes related to indoor temperature [19,20], including *Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition (DSM-5)-defined mental illnesses (eg, insomnia, mood disorders, and delirium) and nonclinical states (eg, annoyance, social isolation, and loneliness).
- Setting: community settings including homes and nonhospital residential environments (eg, geriatric and nursing homes).
- Study design: quantitative research, including cross-sectional and longitudinal studies.
- Language: no restrictions

Exclusion criteria

- Population: Studies not reporting separate results for older adults.
- Exposure: studies combining indoor and outdoor temperature without separate indoor effects.
- Outcome: studies without mental health–related outcomes.
- Setting: Hospital settings or nonresidential environments.
- Study design: protocol papers without data and studies lacking methodological reporting (eg, editorials and commentaries).
- Language: not applicable.

Study Selection

The results of the literature search were exported from the databases into EndNote 20 reference management software (Clarivate Analytics) for organization and duplicate removal. The titles and abstracts of the retrieved articles were independently screened by 5 authors (MKP, DH, SY, YK, and MK), with all studies undergoing independent double review. For potentially relevant articles, 3 authors (MKP, DH, and SY) conducted full-text assessments independently in a double-review format. At each stage of the review process, any disagreements or discrepancies were resolved through discussion among the 3 authors until consensus was achieved.

Data Extraction and Synthesis

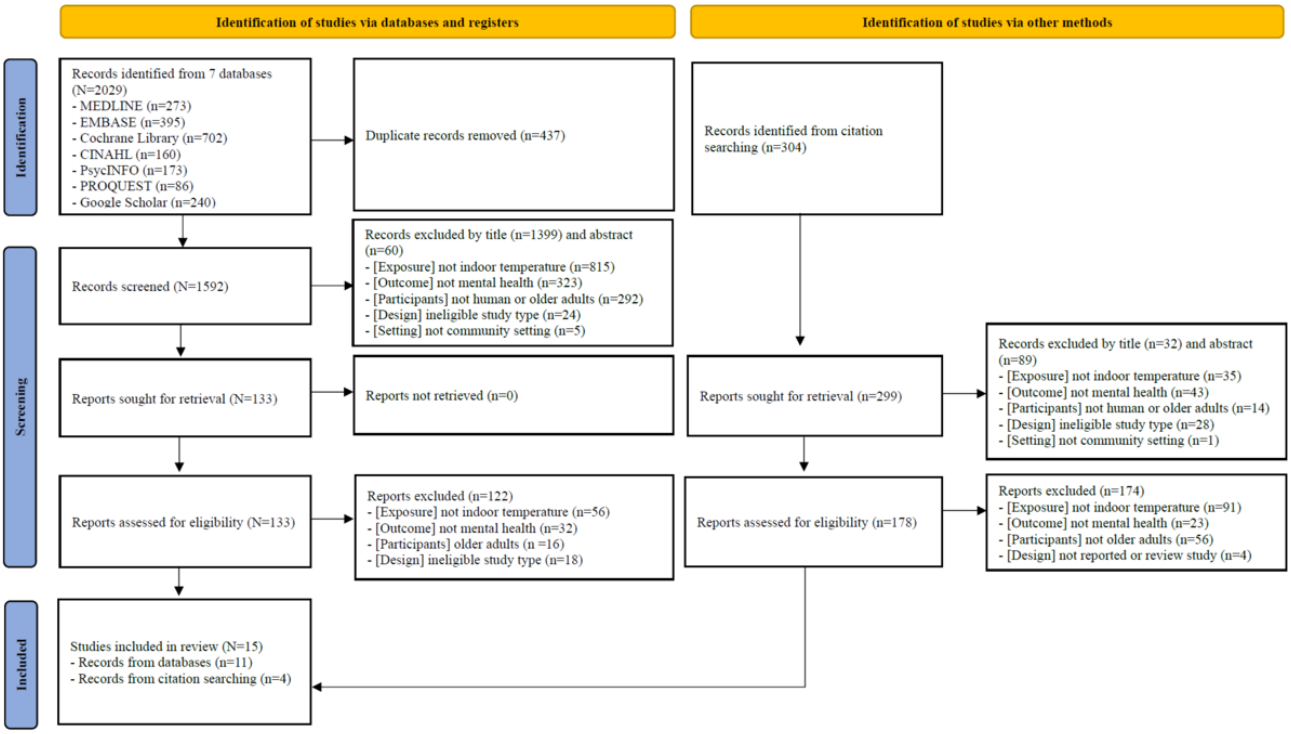
Relevant data from eligible studies were extracted into a Microsoft Excel spreadsheet. The same 5 authors extracted data from the selected studies for analysis. One reviewer (MKP) extracted information from all 15 articles, and the remaining 4 reviewers (DH, SY, YK, and MK) independently extracted information from 3 to 4 articles per person. Discrepancies were reviewed by five authors and resolved in discussion with the sixth author (BK) after re-examining the data to ensure accuracy. The extracted data included the characteristics of the studies (country, design, setting, sample size, participant characteristics, vulnerability factors, and quality assessment), exposure (target season, temperature, and measure), and outcome (mental health outcome and measurement).

Predefined research questions guided the synthesis. We conducted a structured narrative synthesis organized around: (1) characteristics of indoor temperature exposure related to mental health outcomes in older adults, (2) mental health outcomes in older adults related to indoor temperature levels, and (3) factors associated with indoor temperature exposure at varying levels in older adults. Given the heterogeneity in study designs, exposure data formats, and mental health outcome measures, pooling of effect sizes was not possible; therefore, a meta-analysis was not conducted. Instead, we summarized the direction and consistency of associations for each study-outcome pair. To enhance clarity and comparability for the heterogeneous studies, we organized the findings by outcome domain (sleep problems, emotional problems, social interaction problems, and other mental health issues) and further by exposure type (hot vs cold indoor temperature). When studies reported both objective and subjective measurements, results were presented separately, and any discrepancies were noted to highlight methodological variability.

Quality Assessment in Individual Studies

The National Institutes of Health quality assessment tool for observational cohort and cross-sectional studies [21] was used for quality assessment. This tool evaluates the internal validity of a study by asking 14 questions. The quality of the studies was categorized based on the number of criteria they met: good (>9), fair (5–9), and poor (<5) [22]. Studies were independently scored by three authors (MKP, DH, and SY) using Microsoft Excel. Any discrepancies regarding quality appraisal were resolved in discussion with the fourth author (BK).

Results



Study Selection

Figure 1 presents the screening and selection process in accordance with PRISMA 2020 guidelines, detailing the number of records included and excluded at each stage, as well as the specific reasons for exclusion during the eligibility assessment. A total of 2328 records were identified through electronic database searches (n=2029) and citation searching (n=299). After removing 437 duplicates, 1891 articles remained. A total of 1580 articles were excluded after title (n=1431) and abstract

XSL•FO
RenderX

(n=149) screening for the following reasons—ineligible exposure (not indoor temperature), ineligible outcome (not mental health), ineligible population (not human or not older adults), ineligible study design (eg, editorial or review), and noncommunity setting (eg, hospital)— leaving 311 articles for full-text assessment. Following a detailed eligibility assessment, 296 articles were excluded owing to ineligible exposure, outcome, population, or study design. Ultimately, 15 studies met the inclusion criteria and were included for the final synthesis.

Figure 1. Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow diagram.

Characteristics of Included Studies

Table 1 presents the characteristics of the included studies. Of the 15 included studies, all except 1 (7%) study [23] were published after 2010, with 10 published within the last 10 years. The majority of the studies (8/15, 53%) were conducted in Asia; the remainder were conducted in Europe (4/15, 27%) and Australia, Egypt, and the United States (1/15, 7% each). As shown in Figure 2, according to the World Bank classification [24], most studies (12/15, 80%) were conducted in high-income countries. From the 15 studies, 7 (47%) used a longitudinal design, whereas the remaining 8 (53%) used a cross-sectional design. Eleven (73%) studies focused on older adults residing at home, and the remaining 4 targeted older adults residing in nursing homes (2/15, 13%), geriatric homes (1/15, 7%), and sheltered facilities (1/15, 7%). The sample sizes ranged from 19 to 29,380. Three (20%) studies included participants with a mean age in the 60s, and 7 (47%) and 2 (13%) studies involved participants with a mean age in the 70s and 80s, respectively. The remaining 3 (20%) studies did not report mean age. Regarding participant characteristics, 3 (20%) studies examined healthy older adults [17,23,25] where 2 (13%) focused on older adults with dementia [26,27], and 1 (7%) examined low-income older adults [28].

Figure 2. Target season and mental health outcomes by region.

Quality Assessment in Individual Studies

The risk of bias assessment for the 15 studies is summarized in Table 1. The quality of the included studies varied. Six (40%) studies were rated as having "good quality." Seven (47%) studies were categorized as "fair quality" and 2 (13%) as "poor quality." Bias was primarily due to the unclear participation rate of eligible persons, a lack of justification for the sample size, and the inability to blind the exposure. Detailed results from the quality assessment of each study are available in Table S2 in Multimedia Appendix 2.

Characteristics of Indoor Temperature Exposure

The seasonal background of the studies was predominantly hot (9/15, %), with 3 (20%) targeting the cold season and 3 (20%) including both hot and cold seasons. The characteristics of indoor temperatures to which older adults were exposed are shown in Table 2. The results for indoor temperatures were presented as means in 10 studies, of which 3 (20%) also reported maximum and minimum temperatures. One (7%) study provided the set air conditioning temperature, while 5 (33%) studies did not specify the exact temperatures. The average indoor temperature during the hot season ranged from 22.7 °C to 30.5

XSL•FO
RenderX

°C, whereas the average temperature during the cold season ranged from 9.5 °C to 17.1 °C.

The methods used to measure exposure to indoor temperatures varied significantly across the studies. From the 15 studies, 10 (67%) objectively assessed indoor temperature exposure using devices such as data loggers, while 4 (27%) studies used only self-report questionnaires for subjective evaluation. Among the studies conducted during the cold season, only 1 (7%) [30] objectively assessed indoor temperature exposure. The location of indoor temperature measurements also differed, with bedrooms being the most frequently measured area (8/15, 53%), followed by living rooms (5/15, 33%). Regarding the duration and frequency of temperature measurements, 10 (67%) studies provided this information. The duration of exposure measurements across the studies varied from a few days to several months. Continuous measurements at intervals of 1 to 30 minutes were conducted in 7 (47%) studies, twice a day in 2 (13%) studies, and every 4 weeks in 1 (7%) study.

Mental Health Outcomes Related to Indoor Temperature Exposure

Table 3 shows that mental health outcomes related to indoor temperature exposure were disproportionately represented by sleep-related outcomes, with 9 of the 15 (60%) included studies focusing on this domain. Sleep problems, including short sleep duration, sleep disturbances, sleep disorders, and insomnia, were negatively associated with both hot and cold indoor temperature exposure. This predominance of sleep-related findings underscores existing gaps in the literature, as relatively few studies have examined other mental health outcomes such as mood, cognition, or social-emotional well-being in relation to indoor temperature. Of the 15 total studies, only 4 (27%) used objective methods to focus exclusively on sleep problems [17,23,25,30], whereas the remaining 11 (73%) studies measured outcomes using subjective methods. In the study by Okamoto-Mizuno and Tsuzuki [25], the association between hot indoor temperature exposure and objective sleep disturbance was statistically significant—wake episode (r=0.46; P<.05), sleep efficiency index (r=−0.47; P<.05), and wake after sleep onset (r=0.49; P<.01)—whereas the association with subjective sleep disturbance was not (P<.05). This highlights the differences between subjective and objective outcomes. The findings regarding the association between hot or cold indoor temperature exposure and emotional problems were inconsistent. In the studies by Ahrentzen et al [28] and Kanno et al [16], significant differences in emotional distress (t=−2.085; P<.05) and psychological distress (P<.001) scores were observed based on indoor temperature exposure. By contrast, Garre-Olmo et al [26] did not find indoor temperature exposure to be a significant influence on signs of negative affective mood (β=−.10 - .20; P>.05).

[b]Results comparing bedroom temperature in summer and other seasons (fall and winter).

[c]Results for setting temperature <24 °C.

Similarly, the 3 (20%) studies showed inconsistent findings regarding the association between indoor temperature exposure and social interaction problems. In the study by Lindemann et al [33], exposure to hot indoor temperatures significantly reduced social life participation (β=−4.53; *P*<.05) and hindered older adults' participation in social activities, as reflected in their dissatisfaction with opportunities related to general activity, time management, the amount of activity, and participation in the community. By contrast, Garre-Olmo et al [26] found that indoor temperature was not a significant factor affecting the amount of social interaction. Cotter et al [29] identified a significant link between living in a cold home and social exclusion (21.4% in cold homes vs 17.4% in the total sample). In addition, significant associations were found between exposure to hot or cold indoor temperature and other mental health issues (5/15, 33%), including agitation (*t*=3.09; *P*=.002) [27], loneliness (26.4% in cold homes vs 12% in the total sample) [29], and annoyance (β=1.28 - 1.33; *P*<.001) [31].

XSL•FO

Factors Associated With Vulnerability to Inappropriate Indoor Temperature Exposure

Five (33%) studies reported characteristics related to vulnerability to exposure to inappropriate indoor temperature. Residents living in poorly conditioned houses, particularly those without energy-efficiency upgrades, were found to be vulnerable to indoor temperature exposure, which can exacerbate health issues, particularly during hot weather [28]. Older adults living in cities or city centers experienced a greater increase in higher indoor temperature exposure than those living in garden cities or suburbs owing to lower access to green spaces [33]. Factors identified as increasing vulnerability to cold indoor temperature exposure included poorer health conditions (eg, disability, arthritis, and fall in the previous 6 months), poorer quality housing (eg, mold, damp, and draughts in the home; no central heating system), difficulty in paying for heating, and social exclusion (eg, feeling lonely and low social activities or hobbies) [29]. In addition, lower gait speed [33], younger age [16,23], and being female [16] were associated with greater exposure to hot or cold indoor temperatures.

Discussion

Principal Findings

To the best of our knowledge, this is the first systematic literature review investigating the association between exposure to varying indoor temperature levels and mental health among older adults. We found that exposure to both high and low indoor temperatures is associated with mental health problems in older adults. Specifically, sleep, emotional, and social interaction problems are frequently reported in association with indoor temperature levels.

Indoor Temperature Levels and Mental Health

Sleep disturbances were the most consistently reported mental health issue related to indoor temperature levels. Several studies suggested that both hot and cold indoor environments were associated with poorer sleep quality, including short sleep duration [28], insomnia [6], sleep disturbances [32], sleep disorders [34], and longer sleep-onset latency [30]. This finding is consistent with recent reviews, which have confirmed the negative association between extreme outdoor temperature exposure and sleep [35,36]. Van Loenhout et al [31] reported that more than 40% of older adults experienced severe sleep disturbances when indoor temperatures exceeded 25 °C, even during short heatwaves. The optimal indoor temperature for sleep is influenced by several factors, including regional climate and housing conditions [10,11], ventilation method used [10], and the type of bedding and sleepwear [11]. Therefore, it is important not only to maintain an appropriate bedroom temperature range but also to create a comfortable sleeping environment through adaptation strategies, such as appropriate bedding, sleepwear, and ventilation, to promote sleep health in older adults.

Indoor temperature levels were also reported to be associated with emotional problems, reduced social interaction, and symptoms such as agitation, loneliness, and annoyance in older adults. Regarding emotional problems, evaluations of housing coldness or warmth are significantly related to psychological distress [16]. In terms of social interactions, significant relationships have been identified between living in a cold home, social exclusion, and loneliness [29]. In addition, participation in social life decreases with increasing indoor temperatures [33]. Furthermore, the cumulative exposure to both hot and cold temperatures has been shown to correlate linearly with agitation [27], and increasing indoor temperatures are associated with heightened annoyance due to heat [31]. These findings are consistent with recent studies on outdoor temperature exposure, which have reported that high temperatures are associated with mood disturbances, reduced social participation due to decreased motivation, aggravation of preexisting mental health conditions, and reduced patience and tolerance [37]. However, in this analysis of indoor temperature exposure, the number of studies on outcomes other than sleep problems was three or fewer, and the methods of reporting results and statistical significance varied among studies, limiting the conclusions that can be drawn about the impact.

Meanwhile, we determined that there is a lack of studies investigating the impact of indoor temperature levels on depression, suicide, and anxiety, which have been highlighted as highly associated with outdoor temperatures [38,39]. To address these limitations, there is a need for longitudinal cohort studies and randomized intervention trials that can more robustly evaluate the causal relationships between indoor temperature exposure and a wider range of mental health outcomes in older adults.

Vulnerable Groups' Exposure to Inappropriate Indoor Temperature

Most of the characteristics related to inadequate indoor temperature exposure identified in this study were vulnerability-modifying factors that either amplified or mitigated the association between exposure and mental health outcomes. For example, this review demonstrates how poor housing and low economic status affect the mental health of older adults through indoor temperature exposures. Older adults living in affordable housing with low energy efficiency [28] or facing economic difficulties such as constraints in paying heating bills [29] are exposed to hotter indoor environments in summer and colder ones in winter. This exposure is related to various mental health outcomes such as emotional distress, reduced sleep length and quality, loneliness, and social exclusion. Older adults are considered the group most affected by poor housing conditions and are also the age group most likely to reside in such conditions [40]. Managing residential environments can be an effective strategy for improving the health outcomes of vulnerable populations by enhancing thermal comfort [41].

In addition, older adults living in cities or city centers with lower access to green spaces were more vulnerable to changes in social participation due to rising temperatures than those living in garden cities or suburban areas [33]. This might have been owing to the urban heat island effect. The urban heat island effect associated with urbanization can cause temperatures within cities to be significantly higher than those in surrounding rural areas, which is exacerbated when there is a lack of green spaces [42]. Previous studies have also emphasized that older

XSL•FO
RenderX

adults living in urban areas are at the greatest risk during heatwaves [43]. As the aging population increasingly moves to cities for health care access [44], addressing the challenges of urban heat by improving infrastructure and integrating green spaces will be essential to protecting the well-being of older adults.

On the contrary, certain preexisting conditions, such as disabilities or psychological distress, may act as potential confounders that influence both indoor temperature exposure and mental health outcomes. Previous studies have shown that people with disabilities experience mental distress 4.6 times more often than do adults without disabilities [45]. At the same time, people with disabilities have a higher risk of heat exposure-related emergency department admissions, particularly for mental disorders, compared with those without disabilities [46]. Therefore, future research should distinguish between vulnerability modifiers and potential confounders for accurate interpretation of the association between indoor temperature and mental health. This distinction will strengthen causal inference and support more precise identification of at-risk groups and intervention priorities.

Policy responses addressing the impact of inadequate indoor temperature exposure on vulnerable groups are limited. Although the World Health Organization's 2018 Housing and Health Guidelines [47] outline the importance of managing indoor temperatures for mental well-being, few policies focus directly on this issue. For example, while the US Department of Health and Human Services provides heating and cooling assistance for low-income households, these programs lack specific guidelines on optimal indoor temperatures for mental health [48]. Similarly, South Korea's Health Plan 2030 includes initiatives for creating age-friendly environments but does not focus on indoor temperature management [49]. Therefore, future policies should integrate evidence on the mental health impacts of indoor temperature exposures. From a policy perspective, legal integration could involve the incorporation of standardized indoor temperature thresholds into national building codes and long-term care facility regulations to safeguard the mental health of older adults. Embedding these standards within existing regulatory frameworks would promote compliance and sustainability, while establishing specific implementation guidelines could support nurses and facility managers in adhering to them. In community settings, incorporating indoor temperature assessments into home-visiting nursing protocols—where nurses systematically record environmental conditions alongside vital signs—could enhance surveillance of thermal environments and inform evidence-based interventions. It may be a useful strategy to prioritize older adults with poor health, those living in substandard housing, those with low economic status, and those experiencing social exclusion—identified in this review as being vulnerable to exposure to inappropriate indoor temperatures—as the target population for community home nursing services.

Measuring Indoor Temperature and Mental Health Outcomes

Objectively measuring indoor temperature exposure and identifying the appropriate temperature ranges and thresholds are the first steps to protecting older adults from extreme temperatures. Compared with younger generations, older adults are less sensitive to thermal stimuli and tend to feel less heat [50]. This means that older adults may feel thermally comfortable at temperatures that in fact could pose health risks. In our review, 6 (40%) studies [6,16,25,27,29,30] investigated sleep problems in cold environments, but only one [30] used objective temperature measurements, making it difficult to determine precise threshold values of safe temperature. The lack of objective data reduces the potential of leveraging behavioral measures to control indoor temperatures. Therefore, further research is needed to establish the optimal indoor temperature conditions for the mental health of older adults. This will enable health care providers to educate older adults on appropriate indoor temperature ranges and help them adjust their indoor temperature exposure.

This study highlights the importance of a balanced approach to using both subjective and objective measures of mental health outcomes to gain a comprehensive understanding of the influence of indoor temperature exposure. Our findings revealed that only sleep-related outcomes were objectively assessed in the literature, whereas other outcomes were measured solely using self-reported questionnaires. While subjective measures capture individual perceptions that can strongly influence behavior, they may introduce bias in older adults with mental health issues or memory limitations, potentially leading to inaccurate results when used alone. Conversely, a study conducted by Okamoto-Mizuno and Tsuzuki [25] revealed that relying solely on objective methods could result in underreporting of sleep disorders, as subjective sleep disturbances are not reflected in objective measurements. Similarly, previous studies have identified discrepancies between subjective and objective sleep assessments in older adults and recommended using both assessment methods for a more balanced evaluation [51]. Therefore, it is crucial to consider objective and standardized methods alongside subjective methods to measure mental health outcomes in older adults. Recently, methods that minimize recall bias by repeatedly measuring participants' experiences in real time using smartphones have been effectively applied to assess mental health outcomes in older adults [52,53]. Incorporating these innovative methods into research could improve the accuracy of measuring subjective mental health outcomes related to changes in indoor temperature exposure. In addition, linking mental health outcome data to corresponding indoor temperature measurements would provide more comprehensive insights.

Limitations

This study had several limitations. First, most included studies were conducted in high-income countries, with a notable number in Asia. This may limit the generalizability of the findings to other regions or lower-income settings where the impact of indoor temperature exposure on mental health might differ. Second, the heterogeneity of study designs, settings, and measurement methods in the included studies prevented the possibility of a meta-analysis. Future research using standardized methodologies is needed to establish more robust evidence. Third, the limited diversity of the outcomes in the included studies also limited our ability to fully grasp the wide-ranging

XSL•FO
RenderX

impact of indoor temperature exposure on the mental health of older adults, highlighting the need for future research that explores a broader range of mental health outcomes.

Implications

Despite the limitations, the findings of this study have significant implications for nursing care, education, research, and policy development. In nursing care, assessing indoor temperature exposure during home visits to older adults, particularly those facing economic hardships or living in substandard housing conditions, could be a valuable approach to improved recognition and mitigation of threats to mental health. Providing practical and specific guidance on maintaining optimal indoor temperatures may support the mental health of older adults.

From an educational perspective, this study highlights the importance of developing programs aimed at enhancing climate literacy among nurses and health care professionals. Such programs could help health care providers better understand the impact of indoor temperature fluctuations on the mental health of older adults within the context of climate change. In addition, these programs may improve health care providers' ability to guide older adults and their families on practical strategies for managing indoor temperatures.

In this research, the findings emphasize the value of establishing standardized study designs and measurement tools to examine the association between indoor temperature exposure and mental health. Consistent criteria for temperature measurement and mental health variables would facilitate robust meta-analyses and provide stronger evidence. In addition, future studies could benefit from adopting collaborative, multidisciplinary approaches involving environmental science, public health, and nursing. Conducting longitudinal studies that combine real-time temperature exposure monitoring with mental health assessments can provide stronger causal evidence.

Policies could focus on retrofitting older homes to enhance insulation and thermal regulation, particularly for low-income households. In addition, community-wide initiatives, such as expanding green spaces in urban areas, could mitigate heat island effects, aligning with public health objectives. Health care providers can contribute to these efforts by sharing evidence-based insights from clinical and community settings with policymakers.

Conclusion

In this systematic review, we identified an association between exposure to both hot and cold indoor temperatures and a range of mental health outcomes in community-dwelling older adults, with sleep disturbances being the most consistently reported. Evidence on other outcomes—such as depression and anxiety, which have been extensively studied in relation to outdoor temperature exposure—remains limited. Future studies using standardized and longitudinal designs are needed to establish optimal indoor temperature conditions and to inform health policies and practices that better protect the mental health of older adults.

Abstract

Background: Although the respiratory syncytial virus (RSV) membrane protein F has become one of the major target proteins for RSV vaccine development, previous studies have identified safety issues with RSV vaccines in older adults. The causes of these issues remain unclear.

Objective: We aimed to evaluate the safety and efficacy of a novel RSV preF vaccine in preventing lower respiratory tract infections (LRTIs) and RSV-associated acute respiratory illnesses (RSV-ARIs) in older adults.

Methods: We conducted a systematic review of randomized controlled trials from 5 databases—PubMed, Embase, the Cochrane Library, Web of Science, and the Cochrane Central Register of Randomized Controlled Trials—published up to July 31, 2024. For categorical variables, we used the risk ratio; for continuous variables, we used the weighted mean difference or standardized mean difference. We extracted key study characteristics and assessed their quality using the Newcastle-Ottawa Scale. Sensitivity analyses were used to evaluate the impact of individual studies on pooled effects, and publication bias was examined with Egger and Begg tests.

Results: Meta-analysis of 5 studies (101,825 older adults) showed a reduced LRTI incidence in the vaccinated group, with heterogeneity resolved after excluding 1 study. Analysis of 4 studies (99,931 participants) confirmed a lower RSV-ARI incidence with no heterogeneity. Safety analysis (14 studies, 76,695 participants) showed higher adverse events (AEs) in the vaccinated group, mainly injection-site reactions and vaccine-related AEs, but no significant difference in serious AEs. Subgroup analyses identified potential sources of AE heterogeneity, and sensitivity analyses confirmed the efficacy but suggested variability in the injection-site reactions.

Conclusions: This meta-analysis showed a statistically significant difference in the incidence of LRTI and RSV-ARI between the vaccine and placebo groups in older adults. However, no significant differences were observed in overall AEs or serious AEs.

Trial Registration: PROSPERO CRD42024525116; https://www.crd.york.ac.uk/PROSPERO/view/CRD42024525116.

KEYWORDS

respiratory syncytial virus vaccine; safety; efficacy; older population; adverse events

Introduction

Respiratory syncytial virus (RSV) is a pathogen that causes typical respiratory tract infections, with seasonal winter peaks in temperate climates [1]. Despite the relative antigenic stability of RSV and its fusion (F) protein, natural infection elicits only partial and short-lived immunity and does not consistently prevent subsequent infections [1-5]. RSV infections usually resolve without complications or sequelae in immunocompetent populations [6]. Among those at high risk, RSV may cause a potential disease burden comparable to that of influenza, including hospitalizations, intensive care unit admissions, and deaths [7-9].

In fact, in older adults aged ≥60 years, RSV can cause more serious respiratory illnesses, such as lower respiratory tract disease [10], especially in people with underlying medical conditions or those who are immunocompromised [11,12]. In older adults, RSV infections impose a significant disease burden

XSL•FO
RenderX

[13], which has been underestimated [14-16]. A recent systematic review based on data from high-income countries reported that the pooled estimates were 1.62% (95% CI 0.84 - 3.08) for the RSV-associated acute respiratory illnesses (RSV - ARI) attack rate, 0.15% (95% CI 0.09 - 0.22) for the hospitalization attack rate, and 7.13% (95% CI 5.40 - 9.36) for in - hospital case fatality rate [15]. According to 2019 global population data, the same review estimated that approximately 5 million cases of acute respiratory tract infection, 0.5 million hospitalizations, and 33,000 in-hospital deaths among older adults could be attributed to RSV in 2019 [15]. Based on the United Nations Department of Economic and Social Affairs population estimates for 2025, the number of RSV cases in older adults in high - income countries could be as high as 10.9 million, RSV hospitalizations as high as 0.8 million, and the number of deaths due to RSV as high as 74,000 [15].

The severity of RSV-associated disease in older adults has been ascribed to waning humoral and cellular immune responses (immunosenescence) that were induced by previous RSV infections [5,17-21]. Thus, vaccination approaches to overcome waning immunity could help avoid serious RSV-associated diseases in older adults [22]. An effective RSV vaccine in older adults would likely need to boost or induce potent and durable RSV-neutralizing antibody responses, as well as restore and elicit RSV-specific T-cell responses [23]. Multiple RSV vaccines targeting the prefusion F (preF) protein and administered through various platforms—including adjuvanted protein subunit, bivalent preF, adenoviral-vectored, and mRNA-based technologies—have recently been evaluated in randomized clinical trials involving older adults [24-26]. A first-in-human study in healthy adults aged 18 to 85 years has reported that the RSV preF vaccine was safe, well tolerated, and highly immunogenic [27,28]. Because immunosenescence may reduce vaccine responses in older adults, the addition of an adjuvant to vaccine formulations may enhance immune responses [29,30]. Moreover, in preclinical studies, combined regimens containing Ad26.RSV.preF and recombinant RSV preF proteins showed greater humoral and cellular immunogenicity and improved protection compared with either component alone [31].

Although the RSV membrane protein F has become one of the major target proteins for RSV vaccine development, previous studies have identified safety issues with RSV vaccines in older adults, but the causes of these issues remain unclear. We systematically evaluated safety outcomes—including overall adverse events (AEs), vaccine-related AEs, and serious AEs—using subgroup and sensitivity analyses to investigate potential heterogeneity. This review incorporates randomized controlled trials (RCTs) published up to July 31, 2024, thereby integrating the most recent large-scale evidence that was unavailable to earlier meta-analyses. In addition, we conducted a rigorous quality assessment using the Newcastle-Ottawa Scale, augmented by comprehensive sensitivity analyses and publication bias assessments, all of which strengthened the validity and reliability of our findings relative to those of prior reviews. By explicitly addressing key research gaps and synthesizing current high-quality evidence, this study provides a robust, up-to-date evaluation of the safety and efficacy of RSV vaccines in older adults, offering actionable insights for clinical practice and future research.

Methods

This meta-analysis was prospectively registered with PROSPERO (CRD42024525116) prior to commencing the study search. The analysis adhered strictly to the methodological standards established by Cochrane for intervention evaluations and is reported in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines.

Search Strategy

A comprehensive and systematic search was performed across 5 major databases (PubMed, Embase, the Cochrane Library, Web of Science, and the Cochrane Central Register of Controlled Trials) from their inception to July 31, 2024. Search terms were used both individually and in combination using the advanced search functionalities of each database. Additionally, the reference lists of relevant reviews were examined to identify additional studies.

Outcome-related terms were included only when necessary to enhance specificity and minimize the risk of omitting relevant studies. Validated study design filters were applied to target-specific methodologies (eg, RCTs or observational studies), and searches were restricted to human subjects and relevant languages, as appropriate. In addition, the reference lists of all eligible studies and pertinent systematic reviews were manually screened to identify potentially eligible studies not captured by the electronic search. Search results were exported to a reference management system (EndNote version 11; Clarivate Analytics) for deduplication and record management. The complete search strategy, including the full search string, date of execution, and retrieval yield, was documented and reported in accordance with the PRISMA guidelines.

Selection Criteria

The inclusion criteria for the meta-analysis were as follows: (1) peer-reviewed original research articles, excluding conference abstracts, gray literature, and government reports; (2) studies published in English; (3) research specifically addressing vaccination in older adult populations; (4) administration of RSV vaccines; (5) RCTs comparing RSV vaccines with placebo; and (6) studies reporting on the safety and efficacy of RSV vaccines.

The exclusion criteria for the studies were as follows: (1) non-peer-reviewed studies, including systematic reviews, meta-analyses, conference abstracts, letters, editorial comments, case reports, unpublished articles, and articles not published in English; (2) vaccination of individuals younger than 60 years; (3) studies involving animals or preliminary clinical trials; (4) non-RCTs; and (5) studies that did not report on the efficacy and safety of RSV vaccines.

Study Screening and Data Extraction

Following the application of the inclusion criteria, we imported the selected studies into EndNote for automated deduplication. Subsequently, we conducted a thorough review of the titles and

XSL•FO
RenderX

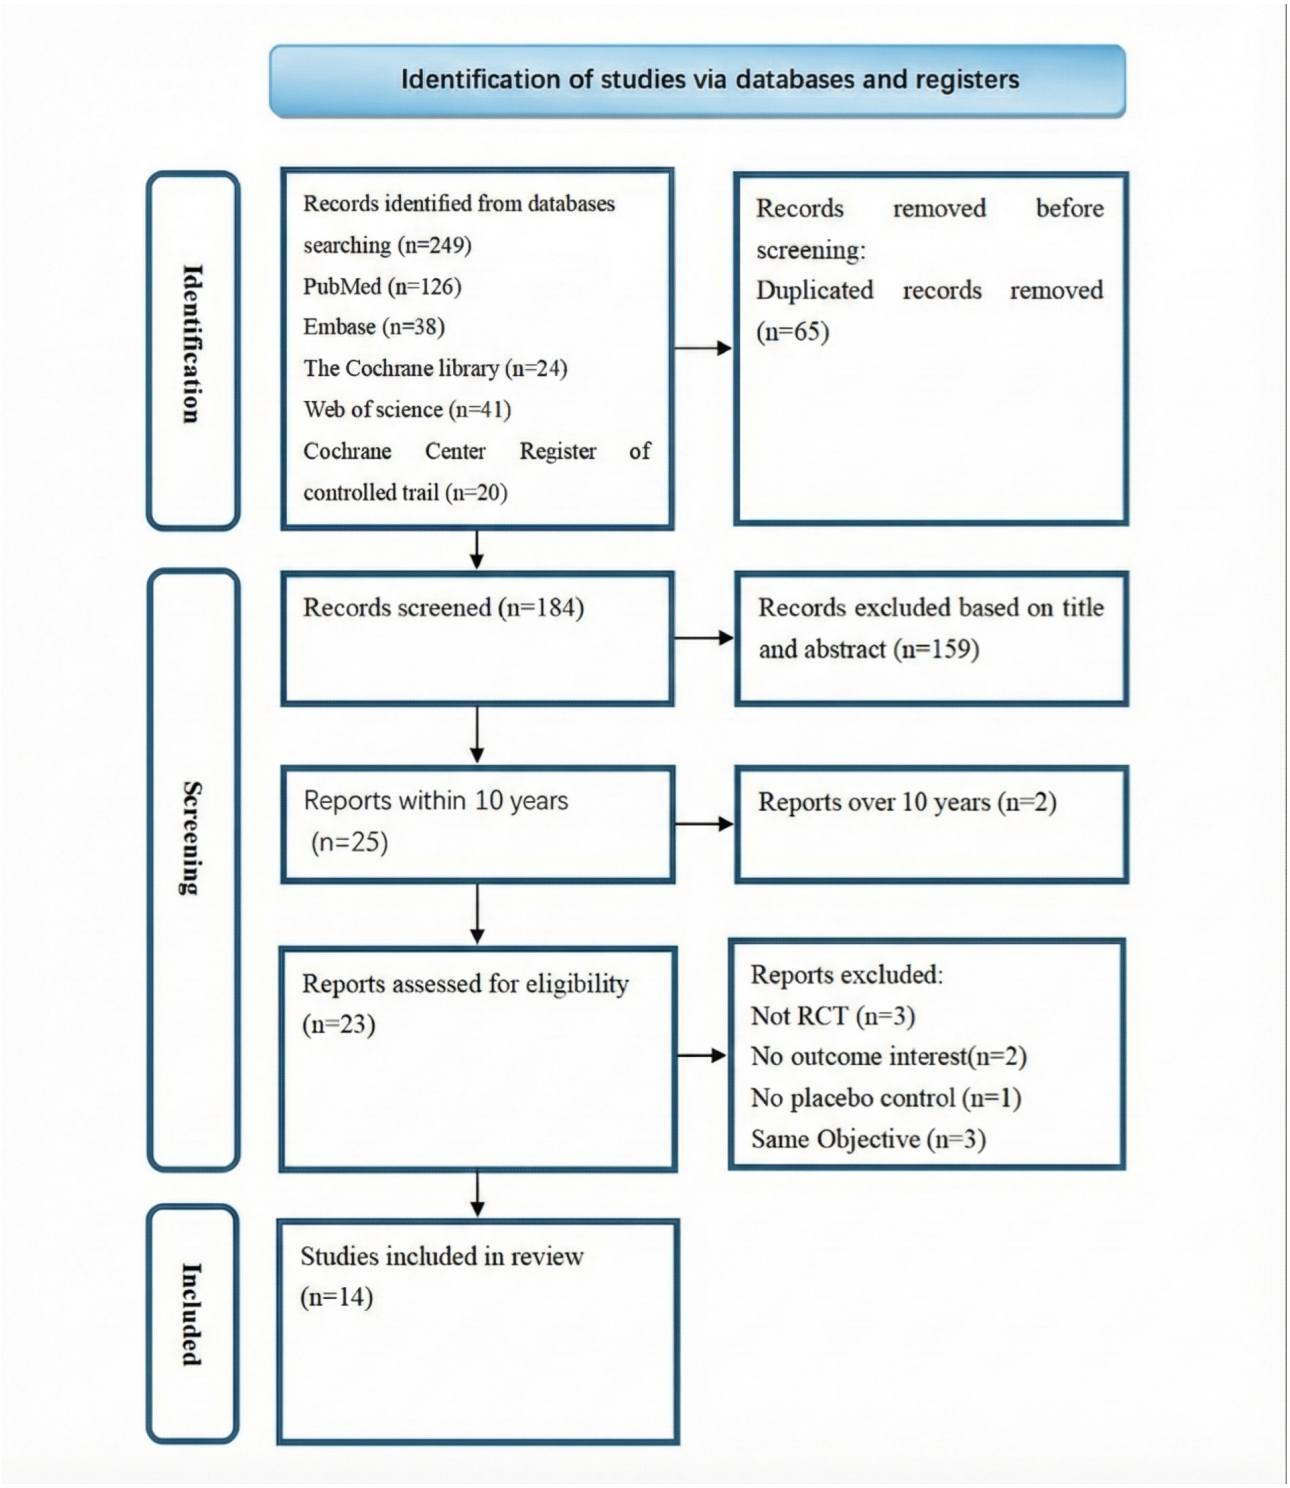
abstracts of all identified studies to determine eligibility. The methodological quality of the included studies was evaluated using the Newcastle-Ottawa Scale for cohort studies (Table S3 in Multimedia Appendix 1). The literature was independently screened by 2 reviewers (WL and QX), and any discrepancies were resolved through discussion or, if necessary, by consulting a third reviewer. The extracted data encompassed the following elements: the first author's name, year of publication, country of study, study design, risk of bias assessment for RCTs, sample size, participant grouping, baseline characteristics, interventions, and outcome measures (Table S2 in Multimedia Appendix 1). The primary outcome measures encompassed medically attended lower respiratory tract illness, RSV-associated respiratory illness in older adults, AEs, and serious AEs within this population. We conducted a comprehensive review of the included studies, original texts, and supplementary materials to ensure that the relevant data were not overlooked.

Outcome Variables

According to the studies included in the meta-analysis, the primary outcome variable commonly assessed was the number of older adults with at least one serious AE or AE, including those deemed to be related to the vaccine. Additionally, some studies have reported the number of older adults with medically confirmed RSV-associated lower respiratory tract infections (LRTIs) or lower respiratory tract diseases and the number of older adults with medically confirmed RSV-associated acute respiratory infections, providing evidence for evaluating the efficacy of RSV vaccination. Details of the outcome variables, including both primary and secondary outcomes, are provided in Tables S4-S17 in Multimedia Appendix 1.

Statistical Analysis

The meta-analysis and subgroup analyses were conducted using Stata (version 17.1; StataCorp LLC) software. For categorical variables, the risk ratio was used as the effect measure, whereas for continuous variables, the weighted mean difference or standardized mean difference was used. Each effect size was expressed with a 95% CI, and the corresponding point estimate was provided. The heterogeneity of the literature was assessed using the χ^2 test. If $P>.1$ and $I^2 \leq 50\%$, a fixed-effect model was used. If $P \leq .1$ and $I^2 > 50\%$, potential sources of heterogeneity were investigated, and after excluding any evident clinical heterogeneity, a random-effects model was used to evaluate the heterogeneity. Sensitivity analyses were conducted for both models. The significance level for the meta-analysis was set at $\alpha=.05$, unless otherwise specified. A one-way sensitivity analysis was conducted to assess the impact of individual studies on pooled outcomes with significant heterogeneity. Publication bias was evaluated using funnel plots generated by Review Manager (version 5.4.1; Cochrane Collaboration) and Egger regression test in Stata 15.1 for outcomes with three or more studies. A $P<.05$ indicated statistical significance for publication bias.



Results

Study Search and Characteristics Overview

A systematic and comprehensive literature search was conducted to identify all relevant studies pertinent to the scope of this review. Initial database queries across PubMed, Embase, the Cochrane Library, Web of Science, and the Cochrane Central Register of Controlled Trials retrieved a total of 249 records. After the removal of 65 (26.1%) duplicate entries, 184 (73.9%) unique records were screened for eligibility based on their titles and abstracts. Of these, 159 (86.4%) were excluded due to irrelevance to the research question, leaving 25 (13.6%) full-text articles for in-depth evaluation. One (4%) article was further excluded for being published more than 10 years ago, which may limit its applicability given advances in the field, resulting in 24 (96%) studies undergoing full-text eligibility assessment. Upon detailed appraisal, an additional 10 (41.7%) studies were excluded according to the predefined criteria: failure to employ an RCT design (3/10, 30%), absence of reported outcomes of interest (2/10, 20%), lack of a placebo control group (1/10, 10%), or significant overlap in the study population and objectives with another included study (3/10, 30%). Consequently, out of 24 studies, 14 (58.3%) fulfilled all prespecified inclusion criteria and were incorporated into the final qualitative synthesis. All included studies were assessed as high quality with low risk of bias (Table S2 in Multimedia Appendix 1). The systematic search and selection process is summarized in Figure 1.

Safety of Vaccination

To assess the difference in overall AEs following vaccine or placebo injections, we included 14 studies reporting AE outcomes in 76,695 older adults, including 38,459 (50.1%) vaccinated and 38,236 (49.9%) in the placebo group. The meta-analysis showed a statistically significant higher incidence of AEs in the vaccinated group, primarily injection-site reactions (eg, swelling, pain, or redness), compared with the placebo group, and significant heterogeneity was also observed (Figure 2).

XSL•FO
RenderX

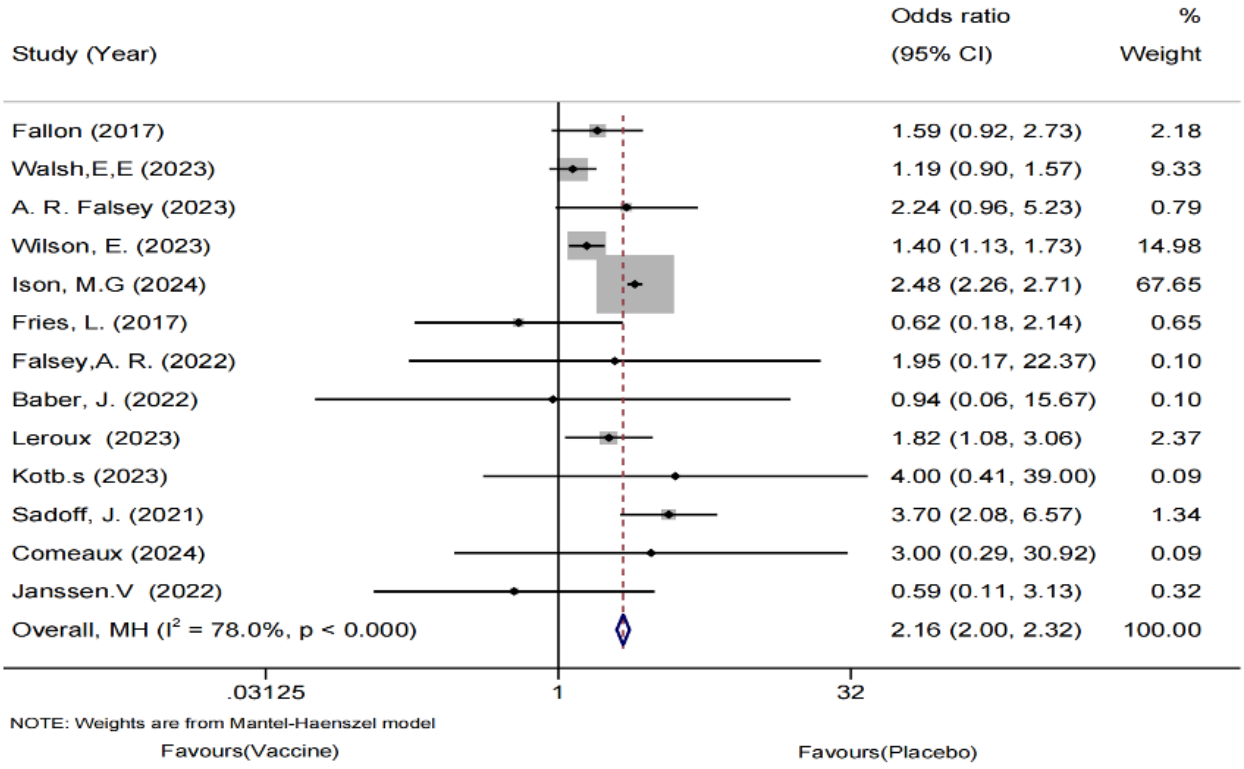

Figure 2. Forest plot of overall adverse event incidence following RSV vaccination versus placebo in older adults: 14 randomized controlled trials (n=76,695; 2017 - 2024).

Because Williams et al [32] did not report AEs, including those potentially related to vaccine components, their study was not included in the analysis in this section. A total of 13 studies (71,531 older adults) were included to analyze AEs attributable to the chemical components of the vaccine or placebo. The meta-analysis revealed a statistically significant higher incidence of AEs due to chemical components, including adjuvants and formulations containing Ad26.RSV.preF or recombinant RSV preF protein, compared with the placebo group. Significant heterogeneity was observed (Figure 3).

Figure 3. Forest plot of adverse events caused by vaccine chemical composition in older adults: 13 randomized controlled trials (n=71,531; 2017 - 2024) [26-28,33-34,35-36].

Serious AEs caused by vaccine or placebo injection were also reported in the included studies. A total of 14 studies involving a total of 76,695 older adults were included in the analysis. The meta-analysis showed no significant difference in the incidence of serious AEs between the vaccine and placebo groups (Figure 4). Moreover, no heterogeneity was detected, and publication bias was not observed based on funnel plots and Egger regression tests.

Figure 4. Forest plot of serious adverse events following respiratory syncytial virus vaccination versus placebo in older adults: 14 randomized controlled trials (n=76,695; 2017 - 2024) [26-28,32-34,35-36].

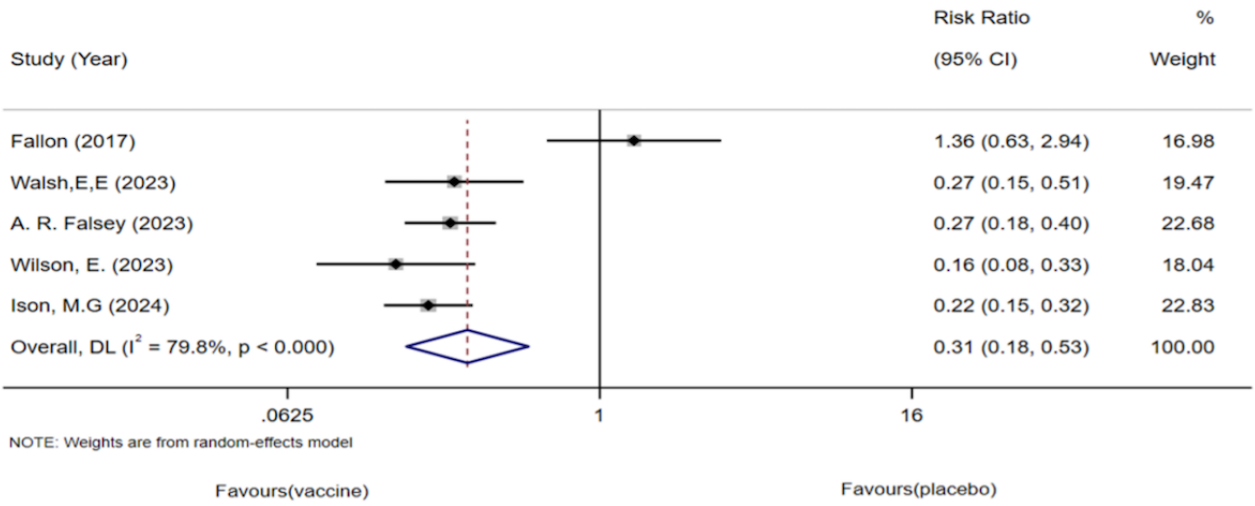
Efficacy of the RSV Vaccination

LRTI Analysis

Five studies involving 1,01,825 older adults were analyzed. The meta-analysis showed a significantly lower incidence of LRTIs in the vaccinated group (Figure 5); however, significant heterogeneity was observed. Rescreening revealed that Falloon et al's study [37] included participants with different baseline characteristics, many of whom had a history of respiratory infections. We excluded this study and re-conducted the pooled meta-analysis. The revised analysis showed a significant reduction in LRTIs in the vaccinated group compared with the placebo group (Figure 6), with significantly reduced heterogeneity. This finding suggests that the observed heterogeneity may have been influenced by the study by Falloon et al [37]. Additionally, no publication bias was detected using funnel plots or Egger regression test.

Figure 5. Forest plot of lower respiratory tract infection incidence following respiratory syncytial virus vaccination versus placebo in older adults: 5 randomized controlled trials (n=1,01,825; 2017 - 2024) [26,27,33,34,37].



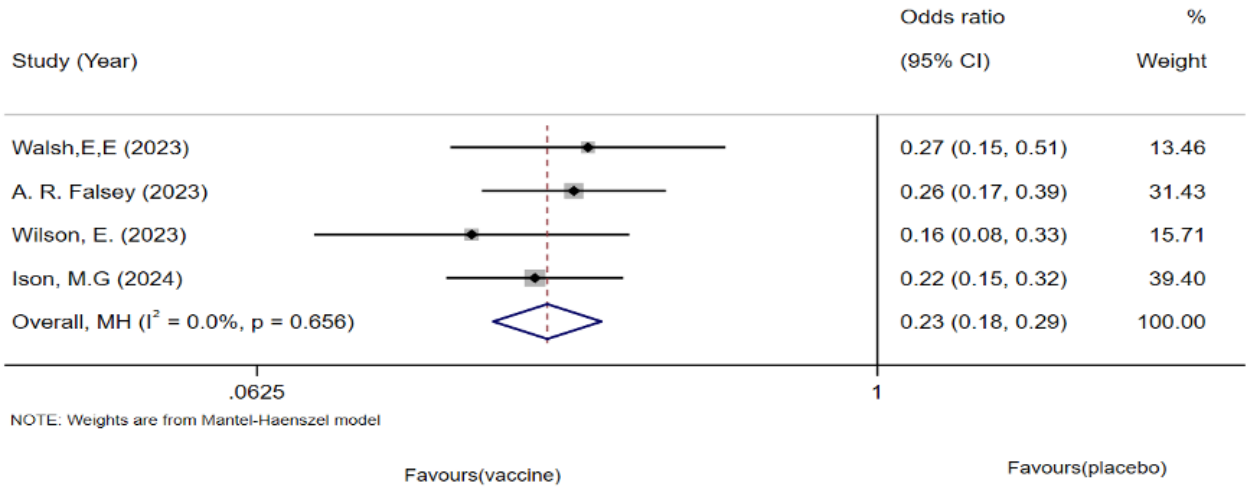


Figure 6. Forest plot of lower respiratory tract infection incidence following respiratory syncytial virus vaccination versus placebo after sensitivity analysis: 4 randomized controlled trials (n=99,931; 2023 - 2024) [26,27,33,34].

RSV-ARI Analysis

Because of the heterogeneity observed in the study by Falloon et al (Figure 7), we excluded it and analyzed 4 articles involving 99,931 older adults [37]. The pooled analysis showed a reduction in the incidence of RSV-ARI in the vaccinated group (Figure 8). No significant heterogeneity or publication bias was detected using funnel plots or Egger test.

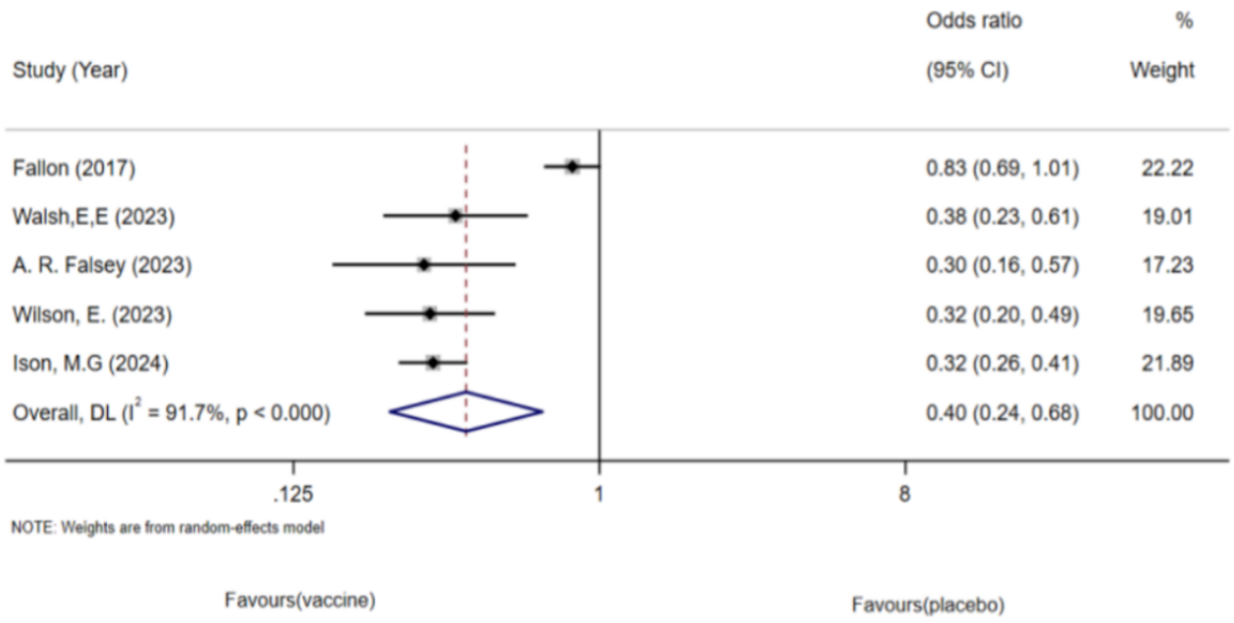

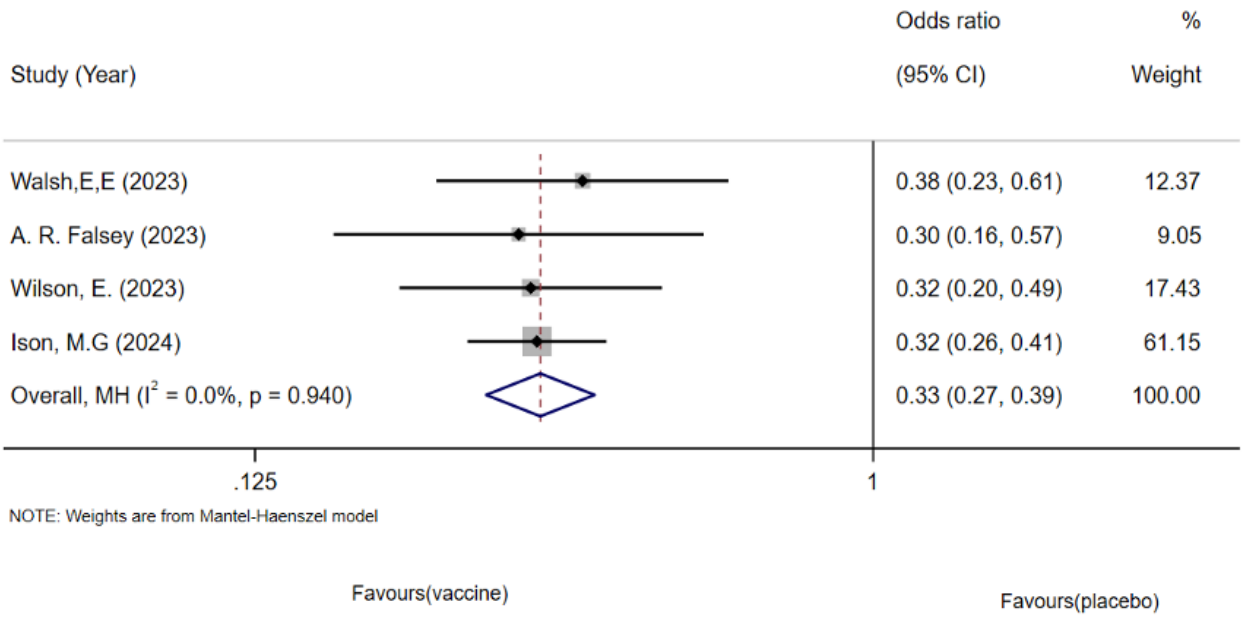

Figure 8. Forest plot of respiratory syncytial virus (RSV)-associated acute respiratory illness incidence after sensitivity analysis: 4 randomized controlled trials (n=99,931; 2023 - 2024) [26,27,33,34].

Subgroup Analysis

Overview

To investigate the cause of heterogeneity, we conducted subgroup analysis according to intervention mode, ethnic distribution, age at baseline, and the quality of studies. Stata (version 17; StataCorp LLC) was used for image rendering and analysis. The subgroup analysis in this study was only aimed at overall AEs following vaccination or placebo injection and AEs due to chemical compositions of the vaccine or placebo. Other subgroup analyses were not performed because fewer than 10 data pairs were available.

In addition, our classification of RSV vaccines was based on the target antigen rather than the manufacturing platform. mRESVIA (Moderna) encodes the RSV preF protein; although the antigen is produced in vivo through the mRNA platform, it is antigenically identical to the preF protein administered via recombinant vaccines. Therefore, mRESVIA was categorized under the preF group. Given that mRNA-based RSV vaccines only became commercially available in mid-2024, which was

XSL•FO
RenderX

beyond the primary evidence window of this review, mRESVIA was not evaluated as an independent subgroup.

Subgroup Analysis Based on Race Distribution

Given that many of the studies involved different countries, with most located in Europe or North America, we categorized the 14 included studies into 2 groups based on the percentage of White participants: those with more than 80% White participants and those with 80% or fewer. Among the studies reporting overall AE outcomes, group 1 exhibited significant heterogeneity, whereas group 2 showed a lack of heterogeneity (Figure S1 in Multimedia Appendix 2). Therefore, we conclude that racial differences may contribute to the heterogeneity observed in all 14 studies describing overall AE outcomes. However, when examining AEs due to chemical compositions, group 1 still demonstrated significant heterogeneity, whereas group 2 showed a notable improvement, with no heterogeneity (Figure S2 in Multimedia Appendix 2). These results indicate a possible association between racial composition and between-study heterogeneity. Nevertheless, given the limited number of studies in each subgroup, as well as the influence of intervention type and study quality identified through subgroup and meta-regression analyses, heterogeneity cannot be conclusively attributed to racial factors alone. Thus, race should be considered a potential, rather than a definitive, contributor to the observed heterogeneity.

Subgroup Analysis Based on Age Distribution

Despite the inclusion criteria specifying older adults aged 60 years and above, considerable age variability remained within this population. To address this, we stratified the 14 studies into 2 subgroups based on median age: those with a median age of less than 70 years and those with a median age of 70 years or more. For AEs, no significant heterogeneity was observed in either subgroup (Figure S3 in Multimedia Appendix 2). Consequently, it is difficult to ascertain whether age differences contributed to heterogeneity. However, subgroup analysis focusing on AEs attributable to chemical compositions revealed significant heterogeneity in the younger subgroup (median age <70 y), while the older subgroup (median age ≥70 y) suggested that age differences may also influence heterogeneity in AEs related to chemical compositions (Figure S4 in Multimedia Appendix 2).

Subgroup Analysis Based on Article Quality

When conducting a meta-analysis, variations in the quality of included studies can substantially influence the final pooled results. We categorized the studies based on previously conducted risk-of-bias assessments into 2 groups: high-quality studies (those with a low risk of bias) and lower-quality studies (those rated as medium or high risk of bias). For overall AE outcomes, heterogeneity was observed in the high-quality group, while no significant heterogeneity was noted in the lower-quality group (Figure S5 in Multimedia Appendix 2). This finding suggests that differences in study quality may be a contributing factor to heterogeneity among studies reporting overall AEs. Additionally, subgroup analysis of studies examining AEs related to vaccine components revealed heterogeneity in the high-quality group, whereas the lower-quality group exhibited the opposite trend (Figure S6 in Multimedia Appendix 2). These findings indicate that variations in study quality contributed to the heterogeneity observed in studies describing AEs due to chemical compositions.

Subgroup Analysis Based on Clinical Intervention Methods

In the included studies, interventions for participants were not only limited to the traditional RSV preF vaccine but also included the RSV preF vaccine with an adjuvant and the Ad26.RSV.preF vaccine. Participants were categorized into three groups based on the type of intervention: (1) RSV preF vaccine versus placebo, (2) RSV preF vaccine with adjuvant versus placebo, and (3) Ad26.RSV.preF vaccine versus placebo.

As shown in Figure S7 in Multimedia Appendix 2, significant heterogeneity was observed in the overall pooled results of the studies. Although each of the 3 groups exhibited low heterogeneity individually, meta-regression analysis revealed substantial heterogeneity between the groups. These findings suggest that the intervention method may be a potential source of the observed heterogeneity.

In the subgroup analysis of AE studies attributed to chemical compositions in vaccines (Figure S8 in Multimedia Appendix 2), significant heterogeneity was observed in the overall pooled results. Although each of the 3 groups demonstrated low within-group heterogeneity, substantial between-group heterogeneity was evident. Therefore, the intervention method can be considered a potential source of this heterogeneity.

Sensitivity Analysis

We conducted a one-way sensitivity analysis to evaluate the impact of each individual study on the risk ratio for LRTI, ARI, common AEs, and serious AEs in older adults by sequentially excluding each study (Figures S9-S13 in Multimedia Appendix 2). The sensitivity analysis revealed no statistically significant changes in LRTI, ARI, common AEs, or serious AEs among the included studies in older adults, indicating robustness of the overall results. However, in the analysis of solicited injection-site AEs, we observed that the sequential exclusion of the studies by Falsey et al [26], Walsh et al [27], and Ison et al [33] resulted in a shift from statistically significant to nonsignificant aggregated results. This finding suggests that the data on solicited injection-site AEs may lack robustness.

Discussion

This meta-analysis assessed the safety and efficacy of a novel RSV preF vaccine in preventing LRTIs and RSV-ARIs in older adults. A systematic review and meta-analysis of RCTs was conducted using 5 databases. The analysis indicated a low risk of publication bias, and the included studies exhibited high methodological quality [38]. Five studies showed a significant reduction in LRTI incidence, with low heterogeneity after removing 1 outlier. Four studies showed a significant decrease in RSV-ARI, with no heterogeneity. Safety data from 14 studies indicated more nonserious AEs in the vaccine group, mainly injection-site reactions, but no difference in serious AEs. Subgroup and sensitivity analyses supported efficacy

XSL•FO
RenderX

consistency and identified minor variability in local reactions. Overall, the RSV preF vaccine significantly reduced the risk of LRTI and RSV-ARI in older adults without increasing serious AEs. According to our findings, the administration of the RSV preF vaccine significantly reduced the risk of RSV-ARI [39].

These results align with previous findings from randomized, placebo-controlled, multicountry trials that enrolled diverse populations of adults aged ≥60 years, similar to our study participants [24,26,40]. These trials included adults with age-related medical conditions representative of those seen in the general older adult population [15,41,42]. Comparable trial designs and participant characteristics enhance the consistency of outcomes between those studies and ours. The vaccine effectively mitigated the leading causes of lower LRTIs and ARIs among older adults. Our findings indicate that the vaccine provided a significant enhanced level of protection against these infections in the target population. Furthermore, these results suggest that vaccination may be the most effective strategy for safeguarding older adults.

Our meta-analysis identified a statistically significant higher incidence of general AEs and AEs related to vaccine components in the vaccinated older adult population compared with the placebo group, with notable heterogeneity observed. Although our analysis suggests that this heterogeneity may stem from the quality of the included studies and the diverse chemical compositions among vaccine subtypes, the latter factor appears to have more significant negative implications in real-world settings. Epidemiological evidence demonstrates that older adults with chronic medical conditions are at an increased risk of developing symptomatic RSV-ARI and severe RSV disease. Additionally, these individuals are more likely to require medically attended visits and to experience progression to more severe disease [43-47]. In reality, our study did not examine the variations in health status among the enrolled older adults across the included studies owing to ambiguous family medical histories. This limitation hinders our ability to ascertain whether the statistical differences and heterogeneity in AEs are attributable to the underlying risk factors associated with subclinical or suboptimal health statuses. Despite previous studies demonstrating that one subtype of the RSV preF vaccine was well tolerated and exhibited an acceptable safety profile, the majority of solicited adverse events were transient and of mild to moderate severity [24,40]. Notwithstanding the enrollment criteria that limited participation to medically stable individuals, the overall positive benefit-risk profile of the RSV preF vaccine in older adults with comorbidities warrants further investigation [40].

On the basis of the subgroup analysis, clinical interventions were identified as a significant source of heterogeneity for both overall AEs and AEs associated with the chemical compositions in the vaccine. Previous studies have indicated that, among various types of RSV preF vaccines, subunit vaccines demonstrate significantly greater safety and a lower incidence of solicited injection-site and systemic adverse reactions [39]. To accurately characterize safety in mRNA-based RSV preF vaccines using original sources, the phase 2 or 3 randomized trial of Moderna mRNA-1345 (RSV preF mRNA) in adults aged ≥60 years reported serious AEs in 2.8% of participants in both the vaccine and placebo groups, with investigators noting no evident safety concerns and only a small number of serious AEs judged related to vaccination; thus, there was no excess of serious AEs associated with the mRNA-1345 vaccine compared with placebo [48,49]. Several solicited injection site AEs, including tenderness to touch and injection site pain, were reported more frequently in the mRNA-treated groups compared with the placebo group. However, most AEs experienced by mRNA-treated participants were transient and graded as grade 1 or 2 [50,51]. Additionally, myalgia, nausea, and chills were the most frequently reported symptoms among recipients of adenovirus-vectored vaccines. However, these symptoms were infrequently observed in our vaccination group [52]. These differences may potentially be attributed to variations in the magnitude of the immune response elicited by different vaccine platforms, a hypothesis that warrants confirmation through further immunological evaluations [53,54].

The potential for AEs among older adults could negatively influence public attitudes toward the RSV vaccine. Previous surveys have indicated that concerns about vaccine safety and side effects are the most common reasons for vaccine refusal [55]. Wang et al [55] demonstrated that older adults are more likely to have limited awareness and knowledge of RSV, which contributes to a higher propensity for vaccine refusal. Additionally, they found a negative correlation between advancing age and both vaccine confidence and vaccination rates [56,57]. This finding is consistent with the common reasons for refusing COVID-19 and monkeypox vaccines reported in previous studies [58,59]. Furthermore, administering the RSV vaccine concurrently with one or more additional vaccines during the same visit may increase the incidence of local or systemic reactogenicity [60]. Current studies have exclusively focused on the safety of the RSV preF vaccine when coadministered with various influenza vaccines in older adults. These studies have indicated that coadministration of the RSV preF vaccine with influenza vaccines results in an acceptable safety and tolerability profile [61-63]. However, data on the safety of the RSV preF vaccine in older adults when coadministered with other vaccines recommended for this age group—such as COVID-19, pneumococcal, adult tetanus, diphtheria, and pertussis vaccines, as well as the recombinant zoster vaccine—are lacking [60]. In other words, the prior vaccination history should also be considered a key factor contributing to variations within the vaccine group, necessitating more detailed clinical investigations.

Our study had several limitations. First, the number of studies included was limited, and the variations in vaccine types and doses across these studies may have led to heterogeneity in the results. This is particularly evident in the small number of experiments focusing on LRTIs and related ARIs, which prevented further subgroup analyses. Moreover, these factors may have impacted the overall study results and restricted more detailed analyses. Future large-scale studies are essential to further investigate and validate these findings. Most of the studies included in our analysis were conducted on a global scale, and the results may have been influenced by the ethnic and regional diversity inherent in these study populations. Therefore, it is necessary to conduct regional and ethnic

XSL•FO
RenderX

classification studies. Finally, it was challenging to accurately ascertain the health status of the survey participants at baseline. Any discrepancies in participant characteristics at baseline may have introduced heterogeneity into the results.

In conclusion, this meta-analysis provides strong evidence that RSV vaccination is a critical public health measure for older adults, offering substantial protection against RSV-related respiratory infections and a favorable safety profile, despite a higher frequency of mild-to-moderate AEs. The results showed that widespread RSV vaccination could significantly reduce the respiratory disease burden, lower health care use, and prevent thousands of hospitalizations and deaths annually. Consistent benefits across diverse populations and vaccine types support regulatory approval and inclusion in routine immunization programs for adults aged ≥60 years. Successful implementation will require addressing vaccine hesitancy with clear, evidence-based messaging, ensuring safe coadministration with other vaccines, and establishing surveillance systems to monitor real-world effectiveness and safety. Key research priorities include assessing long-term protection, optimal revaccination timing, evaluating performance in immunocompromised individuals, and analyzing cost-effectiveness for equitable resource use. As the global population ages and the burden of RSV increases, RSV vaccination should be considered not as an optional add-on but as an essential part of preventive care for older adults, with the potential to transform respiratory disease prevention.

Abstract

Background: Active vaccine safety surveillance (AVSS) stands as a top priority for the World Health Organization (WHO), serving as a critical indicator of the fourth maturity level for national regulatory agencies.

Objective: This review aims to define the minimal data scope for association studies in vaccine safety, providing a reference framework for implementing AVSS systems worldwide, especially in low- and middle-income countries.

Methods: The study systematically searched PubMed, Embase, and Web of Science for cohort and case-control studies related to AVSS published between January 1, 2018, and September 7, 2022. Guided by the WHO and Council for International Organizations of Medical Sciences guidelines (CIOMS), we developed a 4D framework for Minimum Data Sets (MDSs), including "Vaccine," "Outcome," "Demographic Data," and "Covariate." Variables with a frequency of at least 5% were included in the MDS.

Results: Of the 123 included studies, 102 (82.9%) were cohort studies and 98 (79.7%) originated from high-income countries, covering populations across the entire life course. The MDS for COVID-19 vaccines identified 54 variables, while the MDS for maternal populations included 96 variables. WHO guidelines were found to align better with practical applications compared to CIOMS guidelines, though both require further optimization based on the MDS findings. However, metadata for these essential variables were inadequately described across the studies.

Conclusions: The proposed MDS provides clear guidance and concise requirements for AVSS data scope. Establishing a globally standardized MDS and comprehensive metadata based on these findings is essential to enhancing the global vaccine safety ecosystem.

Trial Registration: PROSPERO CRD42023449920; https://www.crd.york.ac.uk/PROSPERO/view/CRD42023449920

vaccine safety; active surveillance; minimum data sets; metadata; association

Introduction

Vaccines are one of the most cost-effective interventions for preventing and controlling infectious diseases, and vaccination could reduce 2 - 3 million deaths annually, with an additional 1.5 million deaths that could be averted if the coverage expanded [1]. However, because vaccines are administered to healthy individuals, concerns about their safety can significantly impact public trust, leading to vaccine hesitancy. This hesitancy poses serious threats to global health, such as the resurgence of nearly eradicated diseases and challenges in achieving the Immunization Agenda 2030 (IA2030) goals [2]. To address

XSL•FO
RenderX

these challenges, robust systems for monitoring vaccine safety are essential. These systems must quickly and accurately evaluate vaccine risks and benefits while providing timely responses to safety concerns, which not only strengthens public confidence but also facilitates effective communication during vaccine rollouts [3,4]. Regulatory frameworks have increasingly recognized the importance of such measures. For instance, the US Food and Drug Administration (FDA) has mandated life-cycle safety management for vaccines since 2007, while China's Vaccine Administration Law enforces stringent safety requirements from development through postmarket surveillance [5,6]. From the perspective of evidence and monitoring approaches, the premarket clinical trials and postmarket surveillance should be essential measurements to ensure vaccine safety. While clinical trials are critical for assessing safety and efficacy before approval, proactive monitoring systems are indispensable for identifying rare or unforeseen safety issues that may not emerge during trials [7]. Active surveillance enables the timely detection of potential safety signals and provides robust evidence of vaccine benefits, complementing the limitations of passive surveillance [8].

Over the last decade, an increasing number of countries, particularly those in resource-rich regions, are attaching great importance to and accelerating the progress of active vaccine safety surveillance (AVSS) systems [9,10]. Several exemplary models were established and provided high-quality evidence for the critical decision-making of safety in immunization programs [11-16]. There are three types of data collection approaches and different functions among them. First, the Vaccine Safety Datalink (VSD) project collaborated with the Centers for Disease Control and Prevention in the United States and integrated a whole life-course cohort through data linkage, which covered 18 million individuals and included pregnant women, infants, children, and older people [17,18]. Second, the national pediatric hospital surveillance networks were established to enhance routine capacity and bridge the research gap to measure the impact and safety of vaccine programs [19]. Third, AusVaxSafety actively collects adverse events from national immunization sentinel sites through SMS text messaging or email reports [20]. In brief, these systems have gone through many years of investment and construction and now are stable, sustainable, and fast-response due to their large-scale and representative sample size.

The World Health Organization (WHO) has recently been urging and endeavoring to establish a global vaccine safety surveillance ecosystem that highlights the capacity of proactive vigilance in vaccine safety [21]. However, few studies were from low- and middle-income countries (LMICs) due to challenges in securing the necessary funding, technology, and human resources for these systems.

The use of electronic health data for AVSS requires addressing three key questions: (1) What information will researchers and policymakers need in the future for AVSS? (2) What data sources can identify this information? (3) What are the minimum data elements required? The Minimum Data Set (MDS) is a structured collection of essential data elements used for clinical and research purposes, facilitating standardized and efficient data collection. Many countries have adopted MDS frameworks to ensure data comparability, enhance public health decision-making, and support real-time safety monitoring [22]. In the context of AVSS, a well-defined MDS can help identify critical surveillance indicators, ensure data accessibility, and improve risk assessment methodologies [23]. Furthermore, metadata, which provides descriptive information about datasets—plays a key role in standardizing data classification, integration, and analysis across different surveillance systems [24]. Therefore, establishing a standardized MDS and metadata system is essential for optimizing AVSS, particularly in resource-limited settings.

Currently, 2 guidelines provide frameworks for data elements, approaches, and study designs of AVSS, but inconsistencies between these guidelines create challenges in standardizing data collection and usage [25,26]. Furthermore, no study has systematically evaluated or validated the essential data elements proposed by these frameworks, leaving their relevance and applicability uncertain. Robust AVSS systems must rely on credible and essential data to function effectively. To address this gap, our systematic review examines the data elements and metadata requirements for AVSS by synthesizing findings from association studies in vaccine safety. This review aims to define an MDS that ensures efficient AVSS implementation, particularly in resource-limited settings [27].

Methods

Search Strategy and Selection Criteria

We systematically searched 3 databases, PubMed, Embase, and Web of Science, from January 1, 2018, to September 7, 2022, to identify all the cohort studies and case-control studies of AVSS. The search strategy was registered on the PROSPERO (International Prospective Register of Systematic Reviews) database (CRD42023449920). The details are shown in Supplementary Materials (Multimedia Appendix 1).

There were two stages in the literature screening. In the first step, we selected studies with descriptions of AVSS or systems and excluded: (1) basic experiments (in vitro and animal) and basic research (pathology); (2) vaccine management and economics studies, such as policy, health economics, and sociomedical assessment, quality of life; (3) case reports, case series studies, nursing experiences, which primarily described the characteristics of individual patients or small groups; (4) vaccine effectiveness evaluation; (5) studies not in English; (6) studies belonging to other categories; and (7) uncertain studies, requiring full-text reading for clarification in the next step.

During the secondary step, we included only postmarketing association studies, such as cohort studies and case-control studies that were conducted with control groups from the same source population, regardless of whether databases were used. The following publications were excluded: (1) passive surveillance, (2) clinical trials, (3) theoretical or methodological studies for vaccine safety surveillance, (4) studies not classified as association studies, including correlational studies, signaling reports, descriptive studies, or those lacking a comparison group, (5) studies not related to vaccine intrinsic safety, (6) nonoriginal studies, such as reviews, conference abstracts, correspondence,

XSL•FO
RenderX

errata, or protocols, (7) studies not in English, or (8) studies without full text. Table 1 presents our inclusion and exclusion criteria.

Table . Inclusion or exclusion criteria.

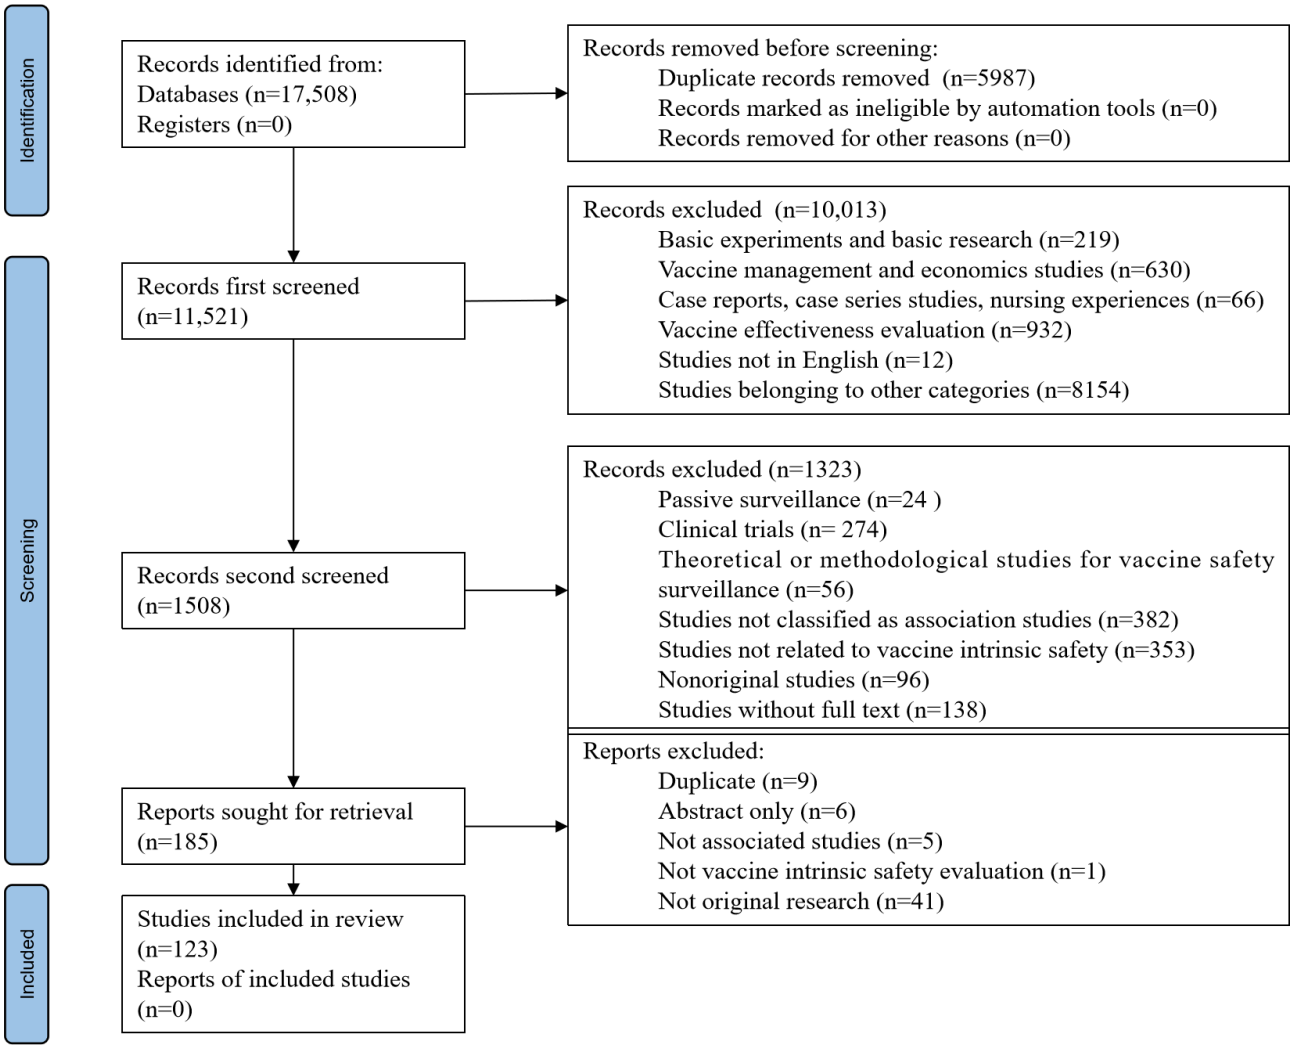
Category	Inclusion criteria	Exclusion criteria
Article type	• Active surveillance • Original studies	• Passive surveillance • Nonoriginal studies (reviews, abstracts, etc)
Study type	• Association studies (cohort and case-control studies)	• Basic experiments (in vitro and animal) and basic research (pathology) • Vaccine management and economics studies • Case reports, case series studies, and nursing experiences • Vaccine effectiveness evaluation • Clinical trials • Theoretical or methodological studies on vaccine safety surveillance • Studies not classified as association studies • Studies unrelated to vaccine intrinsic safety
Language	• English	• Non-English studies

For the above steps, 2 trained researchers independently reviewed the title and abstract of each paper, if any disagreement occurred, a senior researcher would participate in the discussion and reach a final agreement.

Data Analysis

To formulate a standard, reasonable, and validated MDS for AVSS, 3 stages were undertaken to ensure its scientific and practical validity. First, a preliminary framework for the MDS was developed by referencing relevant variables from the Council for International Organizations of Medical Sciences (CIOMS) Guide to Active Vaccine Safety Surveillance and the *COVID-19 Vaccines: Safety Surveillance Manual* [25,26]. This initial framework comprised four dimensions: “Vaccine,” “Outcome,” “Demographic Data,” and “Covariate.” In addition, metadata including data sources, encoding, quality control, and assurance were also taken into consideration. Second, to improve the rationality and feasibility of the drafted framework, experts from diverse fields including immunization, epidemiology, clinical medicine, and databases were consulted to review the framework. A total of 30 eligible studies were randomly selected to refine the framework. Third, a standardized questionnaire for information extraction was developed based on the validated framework. Relevant variables were extracted from the methodology, results, and limitations sections of each study. During this process, any overlooked elements were identified and supplemented through discussion to finalize the framework. Furthermore, basic characteristics of the included studies (authors, publication year, country or region, study design, and sample size) were also collected.

The data extraction and management were completed parallelly by 2 trained researchers using Microsoft Excel 2019, with oversight from a senior researcher responsible for quality control. Subsequently, descriptive statistical analysis was performed using R 4.3.2 (R Core Team), and data visualization was carried out using both R 4.3.2 and OriginPro (Origin Laboratories) 2021.



In the study, the key steps from study design, literature searching, framework formulation, information extraction, and analysis to interpretation have been supervised by external experts to strictly ensure high quality. Meanwhile, as for literature selection and data extraction, every participant was trained and qualified, and the information was double entry independently and parallelly, and any disagreement was ruled out by another senior researcher.

Results

Initially, 11,512 papers were identified after removing duplicated records. With 2 rounds of literature screening, 185 papers were evaluated in full text. Among them, 9 papers were excluded for duplication, 5 papers were excluded for not meeting the criteria for association studies, 1 paper was excluded due to its failure to evaluate vaccine intrinsic safety, 41 papers were excluded for not being original research, and 6 papers were excluded due to the lack of full-text availability. A total of 123 studies [14,15,17,28-147] were finally included. The inclusion and exclusion process is shown in Figure 1.

Figure 1. Preferred Reporting Items for Systematic reviews and Meta-Analyses flow diagram.

The general characteristics of eligible studies are shown in Table 2, with more specific details provided in Table S1 in Multimedia Appendix 1. Of the eligible studies, 82.9% (102/123) were cohort studies, while case-control studies accounted for 17.1% (21/123). Regarding vaccines, 39.5% (49/124) investigated the association between the COVID-19 vaccine and adverse events, while 20.2% (25/124) focused on the influenza vaccine. As for the population, 20% (25/125) focused on children or adolescents, 14.4% (18/125) on pregnant women, 10.40% (13/125) on infants, and 4.8% (6/125) on the older people. In addition, 16.0% (20/125) of studies explored vaccine safety in patients with special diseases such as cancer and inflammatory bowel disease.

[c]HPV: human papillomavirus vaccine.

[d]Patients with inflammatory bowel disease, cancer, severe influenza, juvenile idiopathic arthritis, asthma, or other diseases.

Figure 2 illustrates the utilization of the summarized MDS across 123 included studies. Among the categories, “Diagnosis” within the “Outcome” and “Covariate” dimensions appeared most frequently, with 119 occurrences (96.8%) and 102 occurrences (82.9%), respectively. In the “Demographic Data” dimension, “Geographic Information” was the most frequently reported variable, appearing in 110 studies (89.4%). Similarly, “Vaccine Name” was the most commonly used variable in the “Vaccine” dimension, with 109 occurrences (88.6%). Table 3 shows the differences between the CIOMS and WHO guidelines and the application of both in the included studies. The MDS includes almost all variables recommended in the CIOMS and WHO guidelines, along with some additional variables. These extra variables include “Birth Weight,” “Examination,” and “Mode of Delivery” under the “Outcome” category; “Geographic Information” and “Race or Ethnicity” under the “Demographic Data” category; “Technical Route” and “Adjuvant” under the “Vaccine” category; and several additional variables within the “Covariate” category. The details for MDS are shown in Table S2 in Multimedia Appendix 1.

[c]The core dataset of the WHO guidelines.

Among the 49 studies focusing on COVID-19 vaccines, a total of 95 variables were identified, of which 54 variables appeared at least 3 times (frequency >5%) and were included in the MDS for COVID-19 vaccines. These variables were distributed as follows: 14 under the "Outcome" category, 10 under "Demographic Data," 9 under "Vaccine," and 21 under "Covariate." In 18 studies targeting the pregnant population, 96 variables were identified, all of which were included in the MDS for this specific population (frequency >5%). These variables were categorized as follows: 20 under "Outcome," 11 under "Demographic Data," 11 under "Vaccine," and 54 under "Covariate." More details are shown in Tables S3 and S4 in Multimedia Appendix 1.

Figure 3 plotted the evaluation of the relationship between adverse events and vaccines. We only included diseases that appear more than five times, specifically cardiovascular disease, endocrine diseases, hemorrhagic diseases, nervous system diseases, mental illness, and immune diseases, and we consider the occurrences of outcomes to be counted twice if a publication studies two vaccines. A total of 1239 records specifying health outcomes and vaccine types were identified across 116 studies. The top 5 rare or severe adverse events, each occurring more than 20 times, were encephalopathy (n=30), birth defects (n=29), preterm birth (n=22), thrombocytopenia (n=22), and thrombosis (n=22). Adverse events with fewer than 5 (1%) occurrences were relatively concentrated in 3 groups of diseases: nervous system (n=74), cardiovascular system (n=65), and immune system (n=46). As for COVID-19 vaccines, the top 3 adverse events pairs were thrombosis (n=22), thrombocytopenia (n=19), and encephalopathy (n=17).

XSL•FO
RenderX

Figure 3. Frequency of "vaccine-outcome" pairs in included studies. 4CMenB: 4-Component group B meningococcal vaccine; BCG: Bacillus Calmette-Guerin vaccine; DTaP-IPV: Diphtheria, tetanus, acellular pertussis, and inactivated poliovirus combination vaccine; DTaP: Diphtheria, tetanus, acellular pertussis vaccine; HepA: Hepatitis A vaccine; HepB: Hepatitis B vaccine; HPV: Human papillomavirus vaccine; MCV: Measles and pertussis-containing vaccine; MMR: Measles, mumps, rubella vaccine; MMRV: Measles, mumps, rubella and varicella vaccine; PCV13: 13-Valent pneumococcal conjugate vaccine; PPSV-23: 23-Valent pneumococcal polysaccharide vaccine; RV: Rotavirus vaccine; Tdap: Diphtheria, tetanus, acellular pertussis vaccine.

A total of 17 studies were completed using the AVSS system, with 11 using the VSD project and the remaining 6 derived from various sources, including the Royal College of General Practitioners (RCGP) Research and Surveillance Centre (RSC), Pharmacoepidemiological Research in Primary Care (Base de datos para la Investigación Farmacoepidemiológica en Atención Primaria; BIFAP), Norway's emergency preparedness register for COVID-19 (Beredskapregisteret for COVID-19; Beredt C19), Post-Licensure Rapid Immunization Safety Monitoring (PRISM)–Sentinel, the Paediatric Active Enhanced Disease Surveillance network, and the Defense Medical Surveillance System. All these studies explicitly reported the standard codes for outcomes or events. Specifically, VSD used National Drug Codes and *International Classification of Diseases* (*ICD*) codes, PRISM-Sentinel used Current Procedural Terminology, BIFAP and Beredt C19 used *ICD* codes, and RCGP RSC applied 5-byte Read or Clinical Terms Version 3 codes. However, only 8 studies (9.3%) documented their quality control processes. Among these, 3 studies validated diagnoses in the database by assessing the positive predictive value, 2 confirmed data reliability by comparing original records with database entries, 2 used high-quality data that had undergone prior evaluation, and one maintained data quality through regular monitoring.

Discussion

Principal Findings

This study is the first to systematically clarify the minimum data requirements for AVSS by conducting a comprehensive review aligned with WHO and CIOMS guidelines, focusing on minimizing data range. The proposed MDS and Metadata framework for AVSS encompasses four key dimensions: "Vaccine," "Outcome," "Demographic Data," and "Covariate." Across these dimensions, 68 variables were identified: 13 in "Vaccine," 12 in "Outcome," 11 in "Demographic Data," and 32 in "Covariate." Certain variables were deemed essential for all vaccine safety association studies, including unique and anonymized individual identifiers; vaccine name and vaccination date from the "Vaccine" category; diagnosis and diagnostic date from the "Outcome" category; age and sex from the "Demographic Data" category; and history and drugs from the "Covariate" category. These aspects of data collection, quality control, and assurance must be transparently declared in AVSS protocols; however, regrettably, only a minority of studies addressed them adequately. Therefore, we strongly advocate for the establishment of a globally standardized and widely recognized MDS and Metadata framework. Such a standard would enable countries and regions, particularly LMICs, to rapidly develop AVSS systems or conduct related research. In addition to facilitating data comparability, this effort would significantly strengthen the global vaccine safety ecosystem.

The study design was carefully developed to ensure the reliability and representativeness of the findings. First, the study population covered the whole life course, and the number of studies from various groups, including the general population (43/125, 34.4%), maternal and infants (31/125, 24.8%), children (25/125, 20%), and special patients (20/125, 16%) was relatively balanced. Second, the investigated vaccines spanned a wide spectrum, comprising newly emergency-marketed COVID-19 vaccines, annually administered influenza vaccines, globally disseminated human papillomavirus vaccines, diphtheria, tetanus, acellular pertussis vaccines that often raise concerns, and more than 15 other vaccines in total. Finally, this review spanned over 23 countries and regions, with a notable proportion of 13% (n=16) of included studies from LMICs.

The 49 studies examining the safety of COVID-19 vaccines encompassed diverse populations, including the general population, infants, children and adolescents, pregnant women, and special patients. Despite this breadth, only 54 variables were used, likely reflecting the challenges of limited data availability during the rollout of an emergency vaccine. Previous studies have underscored several challenges in evaluating COVID-19 vaccine safety, including insufficient sample sizes and lower study quality [148-150]. Furthermore, misleading evidence has, at times, hindered efforts to increase vaccine coverage [151]. It is imperative for us to establish a stable AVSS system to provide reliable and sufficient data for the safety studies of emergency vaccines.

The maternal population, which includes 96 variables, reflects a broad spectrum of data, likely due to the inclusion of infant-related variables at this level. Pregnant women are frequently excluded from randomized controlled trials of drug safety because of their unique physiological characteristics [152]. Therefore, the real-world evidence from postmarketing surveillance plays a critical role in evaluating vaccine safety for this population. Furthermore, establishing continuous active surveillance systems facilitates the investigation of the long-term effects of prenatal exposure on offspring.

The standard MDS could provide precise guidance and concise extents of data requirements for the AVSS system. However, no relevant guidelines have yet been released. Although both the CIOMS and WHO guidelines briefly outline the data elements of AVSS, their contents lack consistency and empirical validation in real-world applications [153]. This study is the first to validate these concepts and develop a comprehensive framework. When compared with the common data models of established systems like the VSD and Sentinel, the MDS shares several core strengths. Like these systems, the MDS encompasses the entire lifecycle population, covers a wide array of vaccines, and accounts for a broad spectrum of events. Furthermore, the MDS in our study demonstrated the other two advantages. First, it focuses exclusively on vaccine safety surveillance, minimizing unnecessary data collection efforts and addressing the resource constraints often faced in such endeavors. Second, the MDS incorporates a wider range of data sources, including registration and survey data, which better reflect the diversity of real-world settings and enhance the representativeness of AVSS systems.

A well-defined MDS is crucial for ensuring data quality, comparability, and efficient monitoring in public health surveillance. Within an AVSS system, an effective MDS helps identify key indicators, enhances data accessibility, and strengthens risk assessment [22]. By standardizing data collection, it reduces fragmentation, ensures dataset consistency, and enables timely, automated signal detection, allowing policymakers to respond swiftly to emerging safety concerns. In resource-constrained regions, prioritizing key variables such as vaccination date, vaccine name, outcome diagnosis, and diagnosis date, among the most frequently reported in our study, ensures feasibility while maintaining surveillance effectiveness. From a public health perspective, our study aims to establish a robust AVSS that balances data accessibility and efficiency. By integrating elements from established frameworks such as CIOMS and WHO guidelines, we validate their applicability through a comprehensive literature review. Our findings offer a foundational reference for resource-limited regions, with future efforts focusing on refining MDS definitions through expert consultation and real-world application.

Metadata, which reflects data quality and applicability, is essential for ensuring that real-world data can generate real-world evidence. Unfortunately, only 14.6% of the 103 studies on databases provided Metadata information, indicating that most studies overlooked the importance of data quality control and assurance. This raises concerns about the overall quality of evidence in AVSS from previous studies. It's imperative to increase awareness and provide clear guidelines in the future. Certainly, the MDS and Metadata are essential components of the information infrastructure for scientific research on vaccine safety vigilance. Prioritizing their

XSL•FO
RenderX

importance ensures the establishment of high-quality evidence, enhances evidence transparency, and facilitates evidence translation, particularly in LMICs [154].

There were several limitations in our study. First, our review focused exclusively on association studies in vaccine safety from the past 5 years, which may only represent the latest progress in this field but not its full picture. Second, the variables mentioned in previous studies may not fully correspond to those actually used, potentially introducing some bias in the frequency description. Third, non-English studies were excluded from our analysis. However, given that AVSS studies mostly originate from high-income countries, the impact of this publication bias is likely minimal and can be disregarded. Fourth, our analysis was limited to comparative observational studies (eg, cohort studies and case-control studies) with explicit comparison groups, excluding self-controlled designs (eg, self-controlled case series, and case-crossover studies). While this exclusion represents a limitation, Self-Controlled Case Series (SCCS) studies typically require a smaller set of predefined variables, and the key variables used in SCCS designs are already encompassed within cohort and case-control studies. Therefore, although excluding SCCS studies may slightly reduce the frequency counts of certain variables, it does not affect the overall data scope of the identified MDS. Fifth, this study included variables with a frequency of ≥5% as part of the MDS. While variables with <5% frequency, although less commonly reported, may still hold significant importance, such as “place of vaccination” for detecting clustering of adverse events. For transparency and future reference, a complete list of variables identified in this study is provided in Table S5 in Multimedia Appendix 1.

Conclusion

In conclusion, following WHO and CIOMS guidance and adhering to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines (Checklist 1), this study presents an initial framework of MDS and Metadata for AVSS. This MDS can provide precise guidance and concise requirements for the data scope of the AVSS system and studies. This framework is particularly valuable for resource-limited regions, providing a foundation for implementing AVSS systems effectively and efficiently. Therefore, it is crucial to establish a standardized MDS globally based on these findings to enhance the global vaccine safety ecosystem.

Abstract

Background: It remains unclear whether the existing health care services reflect the HIV care continuum, which underscores the need for integrated care beyond viral suppression.

Objective: This study aimed to analyze the literature on health care services for people living with HIV to enhance the understanding of trends and knowledge structures.

Methods: A literature review was conducted using BERTopic, an advanced machine learning-based topic modeling technique. We searched PubMed, CINAHL, EMBASE, and Cochrane databases for English-language studies published between 2013 and 2023. Analyses were performed twice: first, to gain a broad understanding of the literature, and second, to examine the specific details of health care services described.

Results: Among the 11,269 articles screened, 204 studies met the inclusion criteria. Within the HIV care continuum, most studies focused on the treatment retention stage, while studies focusing on the long-term stage were limited. A broad literature analysis identified five key topics, with “ART adherence” emerging as the most prominent topic. A more comprehensive analysis of health care services within the literature revealed 7 topics, reflecting diverse delivery methods and content in providing health care services for people living with HIV. The predominant topic, “ART adherence and counseling,” encompassed the largest number of studies, indicating the strongest emphasis in the field. Notably, the distribution of topics exhibited a distinct pattern: while health care service diversity was the highest in the earlier stages of the HIV care continuum, it became increasingly limited in the later stages.

Conclusions: This study provides valuable insights into current HIV care services and highlights areas for future research and intervention. Despite the shift toward lifelong HIV management, existing literature remains heavily focused on medication treatment, overlooking the multifaceted health care needs of people living with HIV. Research disparities, particularly concerning vulnerable populations, underscore the need for more inclusive studies and tailored health care services. Efforts should be intensified to bridge these gaps, ensuring inclusive and equitable health care services across diverse populations and fostering interdisciplinary collaboration to meet the evolving needs of people living with HIV, thereby enhancing the HIV care continuum for all.

HIV infections; continuity of patient care; health services; review; machine learning

Introduction

Similar to other chronic illnesses, people living with HIV require a lifelong disease-specific regimen to maintain their physical, psychological, and social well-being [1]. While individuals with sustained viral suppression do not risk sexually transmitting the virus to others [2], those with poor psychological health and lower socioeconomic status—measured by factors such as income, housing, and education—are particularly vulnerable to dropping out of care. This vulnerability is exacerbated by HIV-specific barriers, including stigma, discrimination in health care settings, and individual risk factors [3-5]. To address these challenges, health care services must be scaled up to provide targeted support [3,4]. Moreover, as these barriers cannot be

XSL•FO
RenderX

immediately eliminated, a more continuous and comprehensive approach to HIV treatment and life journey is necessary.

The global response to HIV treatment has focused on retaining people living with HIV in care to ensure their healthy lives and to end AIDS [6]. In 2013, the HIV care continuum was established to outline the steps for the continuity of treatment outcomes, namely: diagnosis, linkage to care, treatment initiation, treatment retention, and the achievement and maintenance of viral suppression [7,8]. Institutions such as the World Health Organization (WHO) [9], International Association of Providers of AIDS Care [10], and US Department of Health and Human Services [11] proposed various guidelines, including health care services for people living with HIV on the care continuum at the international and national levels. These guidelines have agreed on the importance of the HIV care continuum, which requires a broader scope of integrated HIV care to achieve holistic health beyond viral suppression [12].

In the context of continuity, the WHO highlights that integrated, people-centered care expands the capacity of patients to play a more active role in long-term survival [13]. Positioned as components of the HIV care continuum, health care services such as HIV testing, medication supply, antiretroviral therapy (ART) adherence monitoring, adverse event management, immunological and virological monitoring, and follow-up for missed visits have been explored in previous studies [14-16]. However, it remains unclear whether the services being offered to people living with HIV align with lifelong continuity of care. To provide effective health care services supporting the HIV care continuum, a comprehensive data review to gain an in-depth understanding of historical trends and key perspectives on the services being provided to people living with HIV must be conducted. There are global, regional, and national differences in coverage, HIV incidence, prevalence, and mortality [17]. Low-income countries have focused on high-priority services, such as child and maternal health, due to resource constraints and immediate health care needs; whereas high-income countries possess the infrastructure, funding, and policy frameworks necessary to support more advanced health care systems. In particular, high-income countries have prioritized the development of integrated care, a prominent policy theme aimed at addressing complex and interconnected health issues, including chronic diseases and the HIV care continuum [18]. Furthermore, high-income countries often serve as benchmarks for global policy development, making their trends and outcomes particularly valuable for informing evaluation and service provision [19]. Their well-established systems, combined with consistent access to resources and comprehensive data, enable the study of integrated care systems in a way that minimizes variability and reduces potential confounding factors associated with differences in economic conditions or institutional capacities. This focus on high-income countries ensures greater comparability and facilitates the derivation of meaningful, context-specific insights. Therefore, health care services provided in high-income countries [20] need to be analyzed first to review the HIV care continuum from the long-term perspective.

As various HIV health care service studies are being conducted across treatment stages, individuals, and methods, the literature needs to be comprehensively reviewed. Traditional methods, such as manual literature reviews and qualitative content analysis, while valuable for deriving specific insights from research criteria, face significant limitations in handling large and complex datasets. These methods are time-intensive, rely heavily on human expertise, and are subjective to judgment, making them prone to inconsistency as well as bias [21,22]. Furthermore, these methods are less effective at detecting overarching trends, correlations, and topic evolution over time, particularly in diverse and extensive datasets. Manual keyword extraction and topic grouping often fail to fully capture nuanced relationships between concepts, limiting the ability to generate a comprehensive and graphical perspective of the literature. To review, summarize, classify, and detect trends more efficiently in large-scale documents, text analysis techniques offer a valuable and effective solution [23,24].

To address these challenges, this study used Bidirectional Encoder Representations from Transformers (BERT) developed by Devlin [25] in Google artificial intelligence (AI) Language. Among various text analysis technical models, BERT is recognized as one of the most recent and advanced machine learning-based approaches to topic modeling. Unlike traditional text analysis methods, techniques like BERT offer several advantages. Its ability to pretrain deep bidirectional representations enables BERT to capture the contextual meanings of words and sentences by considering both left and right contexts simultaneously [25], resulting in more accurate and nuanced topic modeling. An example of traditional methods is the Latent Dirichlet Allocation (LDA), which relies on simpler probabilistic frameworks and often fails to account for complex semantic relationships [25,26]. Studies comparing LDA and BERT have demonstrated that BERT outperforms LDA in extracting deeper and distinct topics, identifying intricate topic relationships in datasets with complex linguistic structures [27,28]. BERT is particularly effective at processing large datasets, efficiently summarizing, classifying, and detecting trends across a wide range of documents. Considering its strengths, it has been increasingly used in research, particularly literature reviews analyzing numerous studies as well as social media analyses processing numerous tweets to extract insights on health care issues [29-32]. Its scalability reduces the time and resources required for manual analysis while ensuring consistency in topic extraction and classification. In addition, BERT excels in modeling topic correlations as well as their evolution over time, providing a dynamic and graphical perspective of the data that traditional methods struggle to achieve. Its ability to handle complex linguistic structures and low-resource tasks enables the identification of meaningful patterns in diverse contexts, further enhancing its utility for analyzing comprehensive datasets [33]. While BERT offers numerous strengths, it effectively addresses the limitations of traditional approaches by ensuring objectivity, scalability, and the ability to generate insights that would otherwise require extensive human effort and expertise. These capabilities make BERT particularly well-suited for reviewing the extensive and heterogeneous body of literature on HIV health care services. This study therefore used BERT to depict the bibliographic trends and knowledge structure of publications on health care

XSL•FO
RenderX

services to improve the HIV care continuum for people living with HIV in high-income countries.

Methods

Design

This study used a quantitative content analysis using BERTopic modeling to examine the keywords and topics in the literature on health care services provided to people living with HIV. The methodological process comprised phases: (1) search strategy and selection, (2) data preprocessing, and (3) data analysis, using topic modeling with BERTopic.

Search Strategy and Selection Process

Relevant literature was searched from PubMed, CINAHL, EMBASE, and Cochrane databases. Key search terms included Medical Subject Heading (MeSH) terms, trade words, and natural language words such as "care continuum," "HIV/AIDS," and "service." The search was limited to studies published between January 2013—when the WHO first introduced comprehensive guidelines on ART for all populations across the HIV care continuum—and December 2023 [34]. The inclusion criteria were studies: (1) targeting adults diagnosed with HIV, (2) investigating or providing health care services (eg, interventions, services, or programs) to improve the HIV care continuum, and (3) any study design conducted in high-income countries. The exclusion criteria were: (1) studies targeting specific subpopulations (eg, drug users, individuals with mental illnesses, or sex workers), (2) studies targeting HIV prevention services, (3) studies for which the full text was unavailable in English, (4) studies targeting public policies, (5) literature reviews, and (6) duplicates. The exclusion of studies on specific subpopulations aimed to focus the review on general HIV care rather than focusing on tailored interventions for specific groups. While these populations face unique challenges and require specialized interventions, their exclusion was conducted to provide a broader perspective on the HIV care continuum. This approach ensures that the analysis reflects the overall capacities and integration efforts of health care systems, offering insights applicable to the wider population rather than a subset of individuals.

In total, 14,377 articles were retrieved from the databases. After removing duplicates, 11,269 articles were screened for their titles, abstracts, and full texts to determine their eligibility. Multiple studies using the same health care service were assessed through text frequency analysis to detect keyword matches. Most exhibited few keyword matches, suggesting distinct studies. Subsequently, all studies, with the exception of secondary analyses, underwent a full-text review. Three researchers (SL, MS, and LK) independently screened all the articles and selected the final list of articles for analysis after discussion. Discrepancies were discussed with the principal investigator (GK) and consensus was reached as to whether to include the article. The dataset size selected was deemed appropriate for BERT, as it demonstrated efficacy in handling modest-sized datasets with a comparable scale in previous studies, often using 100 documents [28,35]. As with many bibliometric analysis studies exploring research trends [36], a quality assessment was unnecessary. All the data, including the metadata elements of the title, abstract, authors, and year, were downloaded for analysis.

Data Preprocessing

Before data analysis, a sequence of preprocessing steps were conducted to clean and prepare the data for further analysis. Articles without abstracts were excluded to ensure a comprehensive set of textual information. Additional columns were created to classify studies by country, HIV care continuum, and health care services provided. The countries from which each study collected data and the specific stages of the HIV care continuum on which each study focused were identified to derive more meaningful interpretations of the distribution of research topics. Specific stages of the HIV care continuum, including linkage to care, treatment initiation, treatment retention, and the long-term stage [7,8], were identified. The classification was finalized following a consensus reached through discussion between 2 researchers (SL and LK), with multiple stages being investigated in one study. After incorporating studies covering multiple stages, the final corpus comprised 242 documents for analysis. To ensure a more thorough investigation of health care services, detailed descriptions of services from the methods sections of each article were extracted. This process, conducted by 2 researchers (SL and LK), enhanced the accuracy of the dataset. The usage of details regarding the health care services described in the methods section helped create a more robust text corpus, enhancing the efficacy of the subsequent topic modeling analysis.

Stop words were then excluded, and a replacement dictionary was generated. Stop words, including "a," "the," and "of," refer to common words that appear frequently in the text but do not convey insights into the specific topic of a document. All English stop words were removed using the Natural Language Toolkit library in Python. Words that barely contained significant meanings for the research purpose and degraded or hindered the interpretability of results (eg, background, method, results, and trial registration) were added to the toolkit. The extended stop words were then excluded from the data. The replacement dictionary was used to combine several words or abbreviations with the same or similar meanings and designate a single representative word (eg, people living with HIV, HIV, and AIDS). During this stage, repeated word analyses were performed with regard to abstract, and the researchers reached consensus on the words to be registered in the dictionaries through discussion.

Data Analysis

BERTopic, a Python-based package, was used to extract the primary topics from the literature. It was implemented with the all-MiniLM-L6-v2 embedding model to ensure accurate and efficient document embedding, leveraging its compact yet powerful transformer architecture to generate high-quality sentence representations for topic modeling [37,38]. The BERTopic process consists of three steps: (1) document embedding, (2) document clustering, and (3) topic representation [39,40]. Document embedding, using the all-MiniLM-L6-v2, reads sentences in both directions, pretrains them in deep representations, and then generates word embeddings (ie, representations of valued vectors transformed from words to

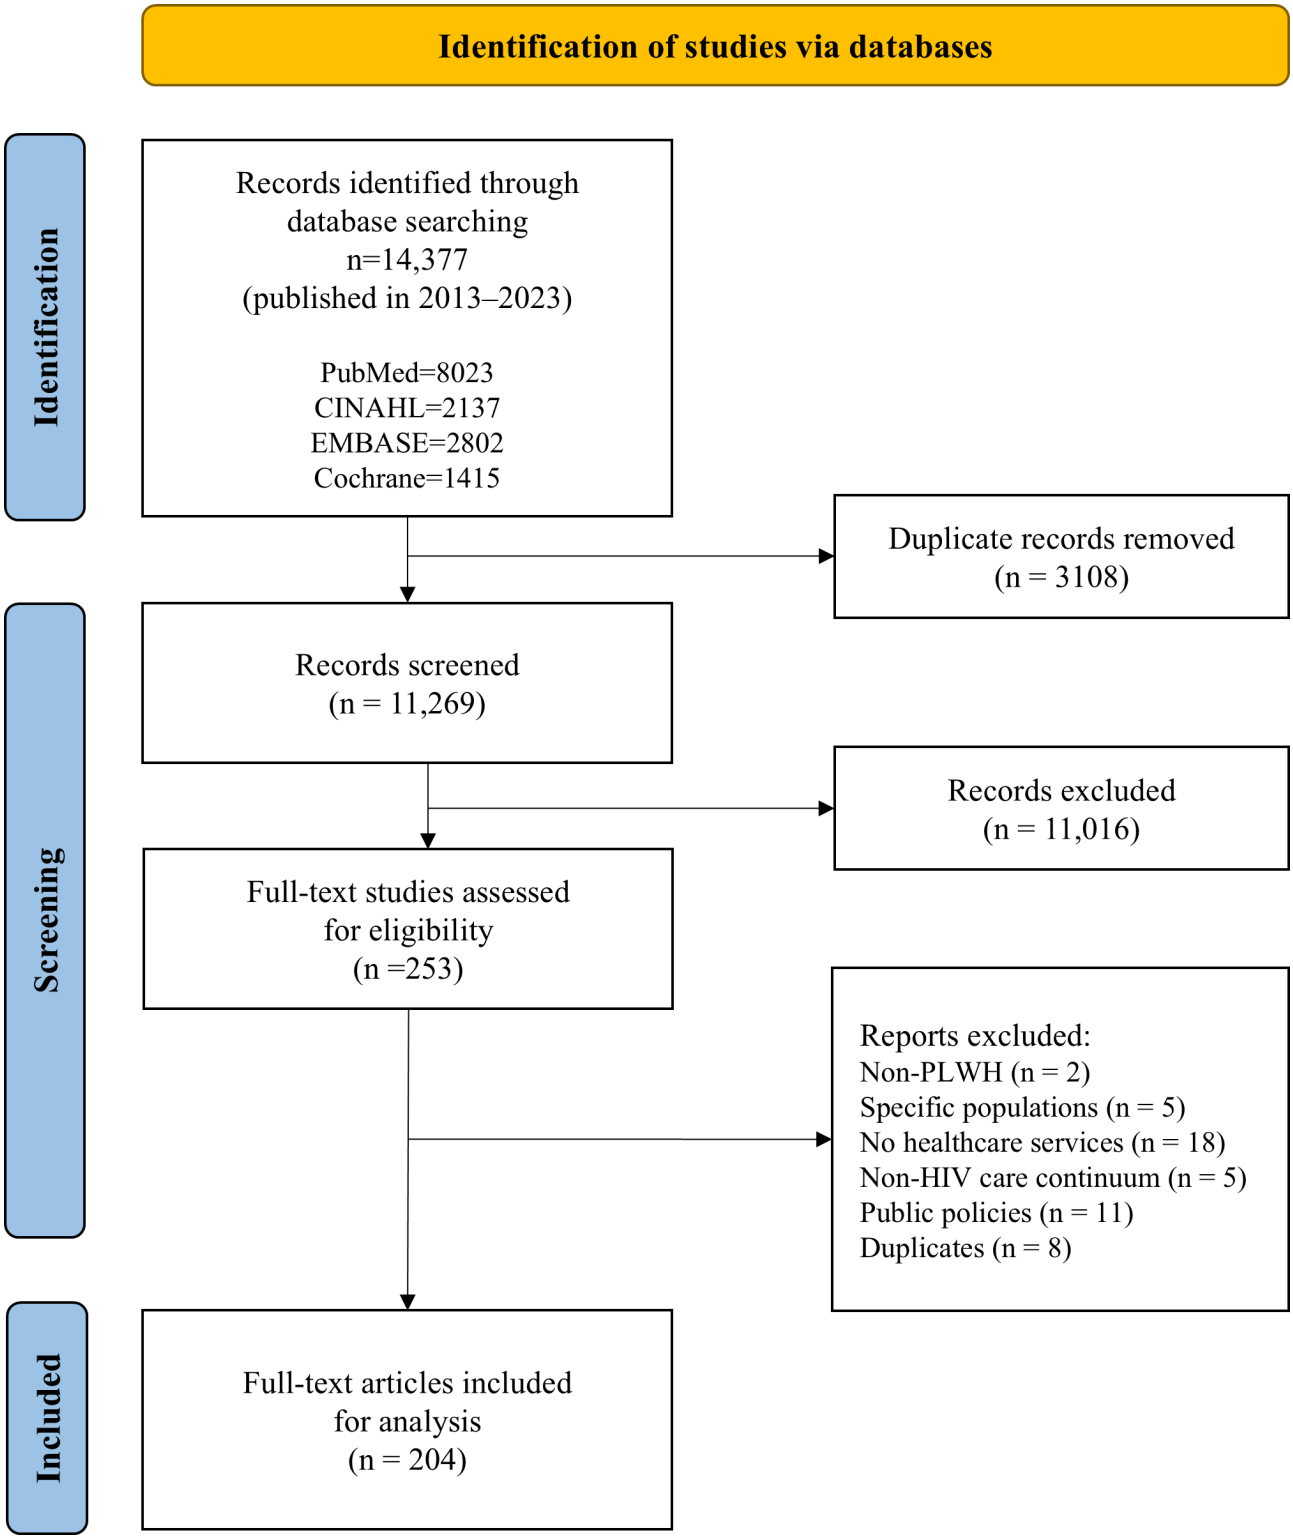
XSL•FO
RenderX

numbers depending on the surrounding contexts). Document clustering applies Uniform Manifold Approximation and Projection to reduce the dimensions [41] and cluster semantically similar words through the Hierarchical Density-Based Spatial Clustering of Applications with the Noise algorithm [42]. Topic representation extracts significant words on class-based term frequency-inverse document frequency, which is a metric to measure the relevance of words [43].

To validate the findings, LDA—a widely used topic modeling method—was also applied. Since no definitive method exists to determine the number of topics, the research team conducted multiple discussions to assess topics generated by the BERT-based approach. The final number of topics was determined by considering evaluation metrics, intertopic distance maps, data characteristics, and interpretability of the results, in comparison to LDA [25,44,45]. The evaluation metrics used to assess topic quality were topic coherence and topic diversity, both ranging from 0 to 1. Topic coherence measures how frequently words co-occur in a dataset, with higher values indicating more interpretable topics, while topic diversity assesses the uniqueness of words within topics, with higher values indicating more distinct topics [46]. The intertopic distance map visualizes topics as circles in a 2D space, where the size of each circle represents the number of studies assigned to that topic, and the proximity between circles indicates the degree of similarity between topics [47]. In this study, the BERT-generated model demonstrated superior evaluation metrics and a more balanced distribution of topics in the intertopic distance maps, with minimal overlap. In addition, the BERT approach yielded more data-related, distinct, and plausible results, outperforming LDA topic modeling in both structure and longitudinal topic trends. In line with the common practice in prior studies using BERTopic, Topic -1—a nonthematic cluster of documents with weak thematic alignment and often containing words commonly found across different topics [48]—was excluded from the interpretation of results. The proportion of nonthematic documents assigned to Topic -1 varied among the studies, ranging from approximately zero to 54% [25,36]. In this study, the analyses were performed twice, with one aimed at broadening the understanding of the literature related to health care services for people living with HIV and the other focused on a specific exploration of the health care services described in the literature.

Ethical Considerations

The study was exempted from the approval process because it was a review and analysis of existing literature. No human participants were not directly involved, and no personal or private information was used.



Results

Data Description

A total of 204 studies were included in the analysis (Figure 1). Over the past decade, an average of approximately 19 studies on health care services for people living with HIV were conducted annually, ranging from 10 to 31 studies (Figure 2). The number of publications increased significantly between 2018 and 2020, but declined in 2016 and from 2021 onwards. Table 1 summarizes the characteristics of the included studies. The majority of studies were conducted in the United States (n=174, 85.3%). Regionally, as defined by the WHO [49], the Region of the Americas (AMR) accounted for the highest representation, while the Eastern Mediterranean Region was represented by only one study. The average age of study participants was 40.52 (SD 10.67) years, with the longest recorded duration since their HIV diagnosis being 30 years. Among the HIV care continuum stages, the treatment retention stage comprised the highest number of studies, totaling 185, while the long-term stage had the fewest studies.

Topic Modeling on Health Care Services Research for People Living With HIV

BERTopic was initially applied to the abstract corpus to identify overarching trends and the knowledge structure within the included publications. Among the 242 documents, 191 were classified into 5 distinct topics, while the remaining 51 (21.1%) were identified as a nonthematic topic. This proportion is relatively small compared to previous studies, where the proportion ranged from 0% to 54% [25,36]. The most frequently occurring keywords within the nonthematic topic included “hiv,” “intervention,” “health,” “use,” and “improve,” which represent broad and general concepts rather than distinct thematic categories.

Table 2 presents the 5 distinct topics, labelled by the research team, alongside their respective keywords and the number of documents assigned to each topic. The 2 prominent topics—“ART adherence” and “Retention and engagement in care”—align with key stages of the HIV care continuum. The remaining 3 topics focus on specific populations: “Minorities-focused” consists of studies concentrating on race and ethnicities, while “Young population-focused,” emerged as an age-specific category. In addition, “Newly diagnosed men who have sex with men (MSM)” encompasses health care services tailored to a specific population at a specific stage.

[a]ART: antiretroviral therapy.

[b]MSM: men who have sex with men.

When comparing the evaluation metrics of the models generated using LDA and BERTopic, the topic coherence scores were 0.2987 and 0.4264, respectively, while the topic diversity scores were 0.4200 and 0.6667, respectively, indicating superior performance of BERTopic in both aspects. In addition, the intertopic distance map of the BERT-generated model presented a more well-balanced distribution of topics with no overlap, whereas the LDA-generated model exhibited substantial topic overlap (Multimedia Appendix 1). Considering these comparisons, including topic interpretability, the BERTopic-generated model was determined to be the optimal choice for analysis.

Figure 3 depicts the distribution of topics over the years. The research focus on “ART adherence” peaked in 2020, while notable declines were observed during mid-2010 and after 2020. “Retention and engagement in care” exhibited fluctuating trends. Coinciding with the onset of the COVID-19 pandemic, studies involving people living with HIV tended to decrease post 2020, but research on “Minorities-focused” topic exhibited recent increases.

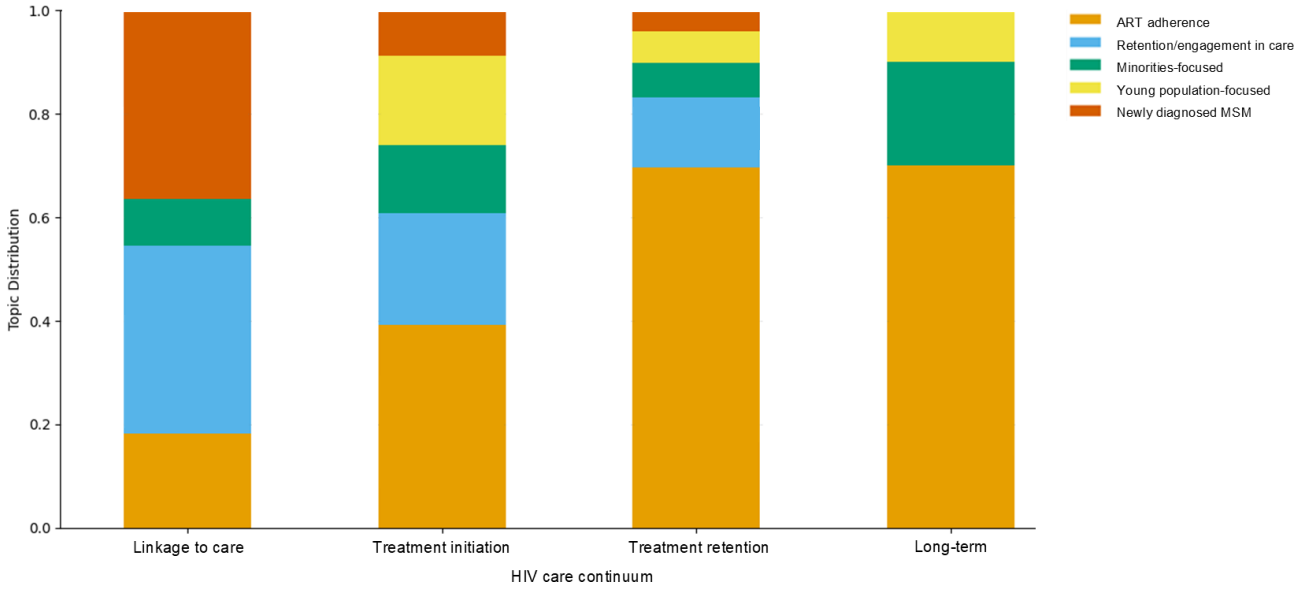

Figure 3. Topic distribution in health care services research for people living with HIV from 2013 to 2023. ART: antiretroviral therapy.

XSL•FO
RenderX

Among the 4 stages of the HIV care continuum, the treatment initiation and retention stages were investigated across all topics (Figure 4). In the first stage (linkage to care), research on young populations was notably lacking, whereas the "Newly diagnosed MSM" topic had the highest representation compared to other stages. In the treatment initiation stage, the "Young population-focused" topic began to emerge, with all topics being more evenly distributed. The "ART adherence" topic accounted for more than half of the studies in the treatment retention stage. Finally, the long-term stage had the fewest studies overall. Regarding the regional distribution of topics by country, only the AMR accounted for all topics, while studies from other regions were limited. Research conducted in the AMR predominantly focused on ART adherence.

Figure 4. Distribution of topics in health care services research for people living with HIV across the HIV care continuum. ART: antiretroviral therapy; MSM: men who have sex with men.

Topic Modeling on Health Care Services for People Living With HIV

The second analysis aimed to provide more comprehensive examination of health care services by using the detailed descriptions of health care services found in the methods section of the articles. When running BERTopic, 181 out of the total 242 documents were categorized into 7 topics, while the remaining 61 (25.2%) fell into a nonthematic category. The most frequent occurring keywords in the nonthematic topic included "care," "participant," "hiv," "patient," and "health," suggesting that these documents contained broad, general concepts rather than distinct thematic distinctions.

Table 3 presents the 7 topics, as labeled by the research team, along with their respective keywords and the number of documents assigned to each. Among these, "ART adherence and counseling" was the most prevalent topic, reflecting strategies to enhance ART adherence, as indicated by the keywords "counseling" and "message." Other topics explore more specific aspects of health care service delivery models, target populations, and service content. The "Peer support" and "Pharmacist involvement" topics highlight the engagement of both health care and non-health care professionals in studies providing health care services to people living with HIV. The "Pharmacist involvement" and "Youth-to-adults transition care" topics specify who delivers health care services and for whom, respectively. "Monetary incentives" pertain to studies using financial rewards as benefits for people living with HIV. The topic "Health promotion and care navigation" focuses on structured interventions designed to guide individuals in maintaining and improving health. Finally, the "Linkage to care" represents studies addressing a specific stage of the HIV care continuum. As reflected in their labels, the 7 topics collectively reflect a combination of delivery methods and content in the provision of health care services to people living with HIV.

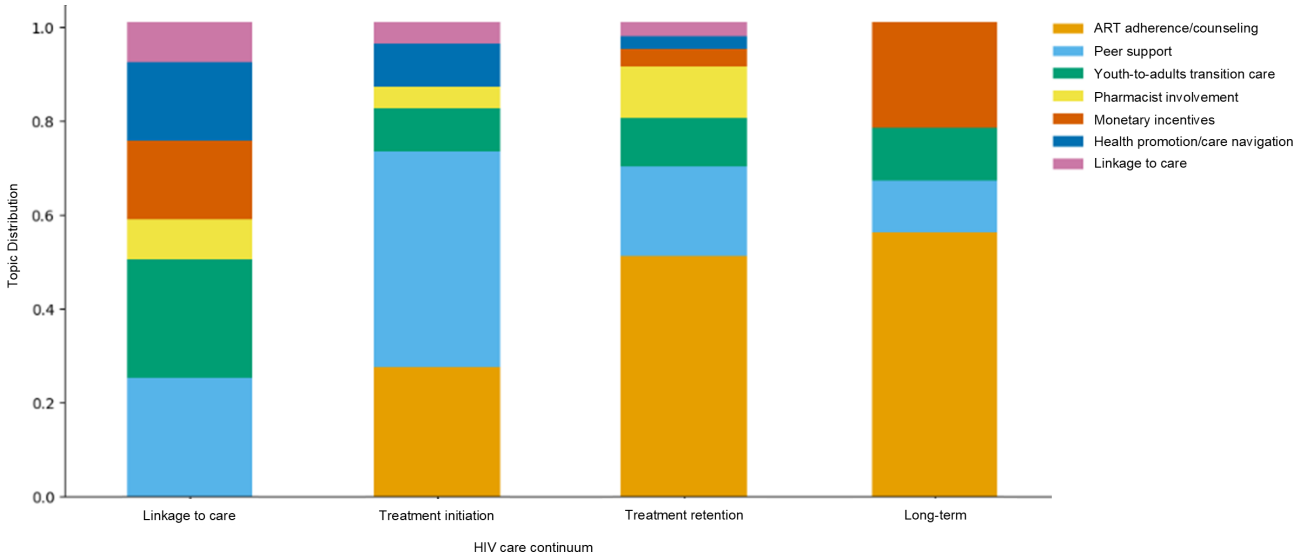
Youth-to-adults transition care	care (0.0572), hiv (0.0473), patient (0.0435), team (0.0329), clinic (0.0276), transition (0.0253), visit (0.0222), service (0.0213), provide (0.0200), adult (0.0183)	20 (11.0%)
Pharmacist involvement	art (0.0606), patient (0.0568), medication (0.0389), pharmacist (0.0382), hiv (0.0375), clinic (0.0304), day (0.0292), drug (0.0283), pharmd (0.0246), hiv-pharmd (0.0246)	17 (9.4%)
Monetary incentives	chance (0.0482), participant (0.0449), point (0.0440), chance-win (0.0437), win (0.0437), hiv (0.0416), component (0.0395), prize (0.0351), tm (0.0328), test (0.0320)	9 (5.0%)
Health promotion and care navigation	hiv-care (0.0662), care (0.0613), hiv (0.0611), health (0.0514), health-promotion (0.0493), promotion (0.0490), care-navigation (0.0480), message (0.0479), navigation (0.0435), participant (0.0434)	8 (4.4%)
Linkage to care	care (0.0684), hiv (0.0554), site (0.0545), people living with HIV (0.0407), hiv-care (0.0347), classify (0.0341), ltc (0.0336), ed (0.0312), program (0.0311), patient (0.0289)	6 (3.3%)



[a]ART: antiretroviral therapy.

When comparing the evaluation metrics of the models generated using LDA and BERTopic, the topic coherence scores were 0.3799 and 0.4458, respectively, while the topic diversity scores were 0.4429 and 0.6125, respectively, demonstrating BERTopic's superior performance in both measures. Furthermore, the intertopic distance map of the BERT-generated model exhibited a well-balanced distribution of topics with no overlap, whereas the LDA-generated model displayed overlapping topics (Supplementary Figure 1 in Multimedia Appendix 1). Considering these factors, including topic interpretability, the BERTopic-generated model outperformed the LDA-generated model and was ultimately selected as the preferred approach.

Figure 5 illustrates the distribution of health care service topics across each stage of the HIV care continuum, highlighting varying levels of research coverage. While research on the initial linkage to care and final long-term stages were similarly scarce, the distribution of health care service topics presented distinct patterns. At the linkage to care stage, all health care services were represented except those related to medication adherence. In the treatment initiation stage, services focusing on medication adherence began to emerge, with peer support being the most prominent. During the treatment retention stage, medication adherence-focused services accounted for more than half of the studies. In the long-term stage, services related to medication adherence and monetary incentives became more prominent, whereas services involving pharmacist involvement and health navigation, which were present in earlier stages, declined. Overall, the diversity of health care services was the highest in the earlier stages of the continuum but became less varied in later stages, where research was more limited.

Figure 5. Distribution of health care service topics for people living with HIV across the HIV care continuum. ART: antiretroviral therapy; MSM: men who have sex with men.

Discussion

Principal Findings

The HIV care continuum is a framework that describes the treatment journey of people living with HIV, encompassing the stages from diagnosis to linkage to care, engagement in care, and viral suppression through ART [7]. Key health care service components within this continuum include HIV testing, medication supply, treatment adherence monitoring, adverse event management, as well as virological monitoring [14-16]. However, like other chronic diseases, the HIV care continuum requires a shift toward an integrated care system centered on patient self-management, equipping individuals with the health care resources needed to manage their condition throughout life [50]. Moreover, as patients are increasingly expected to take active roles in managing their success of HIV treatment and long-term health [51], it is critical to move beyond the sole objective of viral suppression and emphasize overall quality of care for all people living with HIV [12]. Nonetheless, the extent to which current services align with the principles of lifelong continuity of care remains unclear. To address this gap, this study aimed to enhance the understanding of health care service trends and knowledge structures within the HIV care continuum by reviewing the literature using BERT. Given that approximately a decade has passed since the global recognition of the HIV care continuum, reviewing research in this field is essential for identifying both dominant areas and those lacking attention and support.

In this study, research on health care services within the HIV care continuum has primarily focused on the treatment retention stage, with a notable emphasis on ART adherence. While the importance of the HIV care continuum is widely recognized [12], research beyond disease-focused models remains underexplored in the field. Notably, despite longstanding concerns regarding the quality of life (QoL) of people living with HIV—including issues such as comorbidities, stigma, depression, discrimination, and sexual health [52]—these topics were not prominently represented in the extracted themes. The dominance of treatment-focused topics reveals persistent gaps in the literature, even amid global calls for more comprehensive, continuum-based HIV care. To broaden perspectives on life beyond treatment, future research should embrace emerging concepts such as “long-term success” [53] and “healthy living” [54] for people living with HIV, which emphasize a holistic approach addressing the multifaceted needs of people living with HIV. Optimizing health-related QoL and addressing age-related concerns is crucial to ensuring people living with HIV can lead fulfilling lives. This highlights the importance of multidisciplinary teams in delivering integrated, person-centered care and support for people living with HIV.

From a population perspective, there remains a notable lack of research on health care services tailored to minority populations. The topic of MSM emerged as a distinct research focus, reflecting the longstanding dominance of this demographic among people living with HIV. Consequently, research targeting MSM has been abundant. However, research addressing racial and ethnic minorities was consolidated into a single topic, and no distinct topic related to older adults emerged. This gap may be attributable to challenges in engaging these populations, particularly during the COVID-19 pandemic. Such academic trends inadequately address the global HIV epidemic. In high-income countries such as the US, HIV prevalence and incidence estimates are disproportionately higher among Black or African American and Hispanic or Latino individuals compared to White individuals. In addition, women are disproportionately affected among acquiring HIV through heterosexual contact, highlighting their vulnerability despite lower numerical representation [55]. The disease burden attributable to HIV infection among older adults, including prevalence, mortality, and QoL concerns, has increased [56]. These data underscore the critical need for comprehensive actions across the HIV care continuum and increased support tailored to younger and older populations, irrespective of race, ethnicity, and gender. Prioritizing and funding research aimed at understanding the specific needs of diverse and vulnerable populations is critical to fostering a more equitable health care landscape for HIV-infected individuals.

XSL•FO
RenderX

The topics identified on health care services aligned well with the needs of people living with HIV. Peer support and youth-to-adult transition services were prominent in the early stages of the HIV care continuum, when people living with HIV struggle with limited information following diagnosis and must decide whether to undergo ART. This period also represents a high-risk time for disengagement, particularly among young adults with HIV transitioning from pediatric to adult-oriented care [57,58]. ART adherence and counseling services were primarily implemented in the subsequent stages, supporting people living with HIV as they continued treatment and worked toward clinical stability [8]. While the health care services identified in the literature corresponded to different stages of the HIV care continuum, they were predominantly concentrated in the treatment retention stage, with fewer and less diverse services available in other stages. Therefore, more health care services should be developed and implemented across the HIV care continuum, particularly at the long-term stage. Specifically, more varied services to facilitate treatment initiation for people living with HIV at the initial stage are necessary, along with supportive services to promote healthy living and aging with HIV in the long term [59]. Furthermore, the cost-effectiveness, feasibility, sustainability, and confidentiality of these services must be further investigated, particularly for marginalized, younger, and older people living with HIV [60,61].

Pharmacists emerged as a distinct topic in health care services, whereas nurses and physicians were not separately identified. This may be attributed to the unique nature of HIV infection, which heavily relies on ART. Since the introduction of the first ART drug in 1987, ART has been continuously and actively developed and evaluated [62]. Furthermore, the WHO has continuously issued updated evidence-based ART guidelines since publishing its first consolidated guidelines in 2013 [33]. Recent trends have emphasized the cost-effectiveness and accessibility of ART, alongside advancements in potential cures and vaccines [62]. Given the dependency on ART and active trends in its advancement, pharmacies serve as crucial locations for the delivery of HIV treatment, testing, and prevention services, although the scope of services varies among countries. Pharmacists' attitudes and services that are favorable to people living with HIV are essential for enhancing the HIV care continuum [63]. Expanding the services offered by pharmacies and pharmacists as primary service providers for testing and medication, particularly for high-risk and vulnerable populations, should be key consideration [64].

Although physicians and nurses play fundamental roles in HIV care, addressing evolving needs for health and longevity requires extending care beyond primary care to optimal long-term management beyond treatment. This need is particularly pertinent in high-income countries with abundant resources [65,66]. Nurses' practices have been closely aligned with the needs of people living with HIV in HIV care, contributing to interdisciplinary efforts that facilitate the active development and implementation of interventions across the HIV care continuum [67]. However, their involvement in policymaking at local, national, and international levels remains limited [67]. Given their deep understanding of the needs of people living with HIV, nursing professionals should actively participate in decision-making processes to reshape practices and policies within the HIV care continuum. Furthermore, while not a distinct topic in this study, social welfare professionals also play a crucial role in the long-term management of HIV.

In addition, involving family members in health care services is recommended to optimize the HIV care continuum, particularly for key populations such as women and adolescents [10]. Numerous studies advocate a holistic patient-centered approach for people living with HIV, which involves not only pharmacists and peers, but also partners, family, and other individuals. Ensuring a comprehensive approach that encompasses a diverse range of health care and non-health care professionals over the long term is critical for promoting the HIV care continuum, particularly for vulnerable populations.

Overall, a decline in the number of studies on HIV services was observed, likely influenced by the impact of the COVID-19 pandemic. Notable drops in research output occurred between 2014 and 2016, and again in 2021, coinciding with global outbreaks of infectious diseases such as Ebola, Zika, and COVID-19 [68]. Similar to the upwards trend observed after the resolution of outbreaks such as Ebola and Zika, research efforts may increase shortly after the end of the COVID-19 pandemic. Therefore, research published from this perspective is important. As the vast majority of HIV research is conducted in the US, findings from this context may not be generalizable to other countries owing to significant sociocultural differences. Expanding research efforts across diverse countries and tailoring health care services to the specific needs of each country is crucial.

This study has several limitations. First, it focused solely on studies from high-income countries; studies from middle- and low-income countries may present different characteristics. Second, studies that did not explicitly address the HIV care continuum were excluded, necessitating careful interpretation of the findings. Finally, our trend analysis relied on linear models, potentially oversimplifying the intricate evolution of topics influenced by multiple factors.

Conclusions

Despite the evolving nature of HIV care toward lifelong management, the literature predominantly emphasizes medical treatment, highlighting significant gaps in addressing the multifaceted needs of people living with HIV. This study provides a novel contribution by analyzing health care services aimed at enhancing HIV care continuum for people living with HIV using BERT, an advanced machine learning-based topic modeling method. By examining research trends across different stages of the HIV care continuum, this study offers valuable insights into both overarching research trends and specific service-related themes. Notably, it extends beyond traditional treatment-focused disease models to encompass long-term management and holistic well-being considerations, underscoring the importance of interdisciplinary collaboration in meeting the evolving needs of people living with HIV. Overall, this research advances understanding of HIV care and provides critical directions for future interventions and studies in this field.

Abstract

Background: Post–COVID-19 condition presents complex symptomatology involving multifaceted interactions, which has resulted in a current lack of comprehensive understanding of its disease trajectory. This knowledge gap significantly compromises the efficiency of symptom management and adversely affects patients' quality of life.

Objective: This study aims to comprehensively characterize the temporal evolution of post–COVID-19 condition by identifying core symptom clusters and clinical phenotypes, thereby enhancing understanding of the disease trajectory.

Methods: The PubMed, Web of Science, and Embase databases were searched from December 1, 2019, to March 1, 2024. Observational studies related to the prevalence of symptoms in post–COVID-19 condition had been included. We conducted a meta-analysis to synthesize symptom prevalence across different follow-up intervals following PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines and used a network to explore interrelationships and co-occurrence patterns among symptoms, enabling the identification of core symptoms and changes over time. Clustering analysis was used to classify included studies into distinct clinical subtypes.

Results: This study analyzed 155 sets of macrolevel data from 108 clinical studies, encompassing 63,771 patients. Fatigue was the most prevalent symptom across all 4 follow-up points (52%, 48%, 46%, and 54%). Dyspnea peaked at the third and sixth follow-ups (36% and 31%) and then declined steadily (28% and 22%). Subgroup analysis revealed that Africa reported the fewest symptoms overall, yet showed high early incidences of fatigue (68%, 95% CI 50% - 85%) and dyspnea (56%, 95% CI 15% - 98%). The Americas placed greater emphasis on symptom evolution within the first postinfection year, with notably higher prevalence of anxiety (60%, 95% CI 54% - 66%) and depression (36%, 95% CI 16% - 55%). Asia and Europe documented the most comprehensive symptom profiles, with Asia reporting lower early dyspnea rates (29%, 95% CI 18% - 40%) and Europe exhibiting more complex multisystem involvement during long-term follow-up. Network analysis showed that core post–COVID-19 symptoms evolved from early respiratory-neurological manifestations to chronic multisystem symptoms dominated by dizziness. Clustering analysis further indicated a progressive convergence of 2 initially distinct post–COVID-19 subtypes, with the acute inflammatory type becoming less prominent and gradually transitioning into a more chronic, persistent pattern.

Conclusions: This study provides a comprehensive characterization of the dynamic evolution of post–COVID-19 condition symptoms and clinical subtypes, highlighting their multisystem involvement. The results reveal a progressive decline in respiratory symptoms over time, while neurological manifestations emerge as the most persistent and systemically impactful core symptoms. Our findings emphasize the need for region-specific surveillance and early warning systems informed by symptom progression patterns. By continuously monitoring the trajectories of symptom clusters, this approach offers valuable insights for identifying early warning signals and targeted intervention points in the management of postinfectious sequelae arising from future large-scale epidemics.

Introduction

Studies have shown that approximately 10% - 30% of patients continue to experience persistent symptoms after nucleic acid test results turn negative or after discharge from the hospital, significantly impacting their daily lives [1-3]. Furthermore, some patients may experience symptoms lasting more than 2 years [4,5]. The World Health Organization defines the persistent symptoms following the acute phase of COVID-19 as "post–COVID-19 condition," characterized by symptoms that persist or emerge at least 3 months after the initial SARS-CoV-2 infection and cannot be explained by other causes. As of March 2025, a total of 777 million people worldwide have been infected with COVID-19 [6]. Assuming a conservative estimate that 10% of recovered individuals will experience persistent symptoms, over 70 million people may be affected by the long-term sequelae of COVID-19. Post–COVID-19 condition presents with complex symptoms affecting multiple systems and organs throughout the body, with studies reporting over 200 types of symptoms [7]. Common symptoms include fatigue, postexertional malaise, cognitive impairment (brain fog), dyspnea, chest pain, as well as anxiety and depression [8,9]. A single patient may simultaneously exhibit symptoms across multiple systems, with these symptoms interacting and forming a vicious cycle. The heterogeneity and dynamic nature of these symptoms pose significant challenges to the treatment of post–COVID-19 condition. Over the past few years, numerous researchers have conducted studies to understand the pathophysiology, risk factors, and optimal management strategies for post–COVID-19 condition [10-12]. However, no definitive pharmacological treatments or interventions have been established to date, and current approaches primarily rely on comprehensive management or symptomatic relief. Against this backdrop of symptom-based care, existing studies have reported the prevalence of post–COVID-19 condition symptoms and proposed clinical subtypes, such as fatigue-dominant and musculoskeletal-dominant phenotypes. Nevertheless, most of these studies have relied on cross-sectional assessments, failing to capture the dynamic symptom patterns or phenotypic transitions over time, and have not prioritized the identification of core symptoms [13,14].

Since the concept of symptom networks was first introduced by Fried et al [15], this research paradigm has been widely applied in fields such as psychiatry, chronic disease management, and long-term oncology follow-up [16,17]. Symptom networks not only provide direct measurements such as symptom prevalence and severity but also uncover the complex interactions among symptoms through a range of network metrics, including node centrality, predictability, clustering, network connectivity, and transitivity. Core symptoms, identified via centrality and related indicators, often exert a disproportionate influence over the entire network. Targeting these symptoms may yield a "leverage effect," leading to broader improvements in symptom management. Clustering analyses can detect co-occurring symptom patterns, pointing toward potential symptom groups and shared pathophysiological mechanisms [18]. They provide a theoretical and methodological foundation for exploring underlying mechanisms, refining symptom phenotyping, and identifying key therapeutic targets. Constructing dynamic symptom networks, in particular, allows for the identification of changes in intersymptom relationships over time [19]. This approach can help uncover patterns of symptom co-occurrence and mutual influence, contributing to the early detection and diagnosis of complex conditions such as post–COVID-19 condition. By identifying core and bridge symptoms and delivering interventions that specifically target these pivotal nodes, it becomes possible to disrupt symptom interaction pathways, rendering associated symptoms less connected and reducing their impact. This network-based strategy facilitates a shift from the traditional model of treating multiple symptoms independently to a more precise approach that targets the most influential symptom nodes [20], thereby enhancing symptom control and improving quality of life.

Although systematic reviews have investigated the incidence of post–COVID-19 condition symptoms, their inclusion of primary studies was limited to observation periods of up to 1 year at most, thereby precluding assessment of longer-term symptom trajectories [21]. These reviews also failed to explore the dynamic symptom patterns or phenotypic transitions of post–COVID-19 condition over time. Furthermore, the lack of timely updates in these studies has left symptom evolution patterns over the past 3 years largely unexplored. Notably, none of these systematic reviews have specifically examined the dynamic changes in core symptoms and symptom clusters as their primary research focus. Building upon this foundation, this study seeks to conduct a systematic evaluation and dynamic analysis of symptom data derived from published clinical investigations, with the primary objectives of identifying core symptom clusters associated with post–COVID-19 condition, elucidating their characteristic phenotypic evolution patterns, addressing the critical knowledge gap concerning long-term symptom trajectories extending beyond 1 year postinfection, and generating updated epidemiological evidence regarding symptom prevalence rates in this emerging clinical entity. The findings will contribute to providing a scientific basis for public health surveillance and stratified management of post–COVID-19 condition, thereby aiding in the optimization of medical resource allocation and the formulation of rehabilitation policies.

Methods

Study Design

This study was designed as a systematic review and meta-analysis of observational studies investigating post–COVID-19 condition combined with network analysis and clustering to identify longitudinal symptom patterns and clinical subtypes. We conducted a comprehensive literature search of published clinical studies from December 2019 to March 2025, extracting symptom prevalence data across different follow-up intervals (3rd, 6th, 12th, and 24th month). This temporal stratification allowed for the examination of symptom dynamics over time. To standardize the classification of reported symptoms across studies, we categorized each symptom into 1 of 9 system domains, including respiratory, nervous, circulatory, digestive, musculoskeletal, endocrine, skin, urogenital, and

XSL•FO
RenderX

other. The classification framework was primarily based on the *International Classification of Diseases, 11th Revision* (*ICD-11*). For symptoms that could plausibly be assigned to multiple systems, such as fatigue, we determined the most appropriate category based on predominant pathophysiological relevance, as indicated by current literature. For example, fatigue was classified under neurological manifestations due to its established association with autonomic dysfunction and neuroinflammatory processes in post–COVID-19 condition. A complete list of symptoms and their corresponding system classifications is provided in Table S1 in Multimedia Appendix 1 to facilitate the reproducibility of the categorization process. The meta-analysis was used to estimate pooled symptom prevalence rates at each time point, enhancing comparability across studies. To further explore the interrelationships among symptoms and their evolution, we applied network analysis, which revealed the co-occurrence structures and central symptoms within each follow-up period. Subsequently, we performed clustering analysis to group population-level data into distinct clinical phenotypes based on symptom profiles, enabling the identification of population-level subgroups with similar post–COVID-19 condition presentations. This stepwise, multimethod analytical framework was designed to address the complexity and heterogeneity of post–COVID-19 condition symptoms and provide a comprehensive understanding of their temporal and structural patterns. We have registered this meta-analysis on PROSPERO (CRD42024537825). We followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statements for reporting our systematic review (Checklist 1) [22].

Search Strategy

We searched the following databases from December 1, 2019, to March 1, 2025 (with the language restricted to English): PubMed, Embase, and Web of Science. MeSH (Medical Subject Headings) terms were combined with text words in the literature retrieval related to "post–COVID-19 condition," "symptom," and "follow-up"; for specific details on the search strategy, please refer to Multimedia Appendix 2. To find additional studies, we screened the relevant reference lists of the included studies and previous literature reviews including systematic reviews and meta-analyses. All search results were imported to an EndNote (version X9; Clarivate Analytics) tool to facilitate the screening of titles and abstracts.

Data Collection and Extraction

Two independent reviewers (HL and GZ) worked together to screen eligible studies. The complete eligibility criteria are presented in Textbox 1. In the initial screening, they read titles and abstracts to include studies containing 1 or more intervention models. All potentially relevant studies were retrieved for full-text screening. A full-text review of potentially eligible studies then was conducted, and the reasons for exclusion in the full-text screening were recorded in the EndNote database. After screening, data were extracted independently by the reviewers using a data extraction form (LC and NL). The extraction form consists of the following categories: characteristics of studies (eg, years, time of publication, and title), characteristics of participants, follow-up intervals, symptoms, and others. Regarding the extraction of symptom data at different follow-up times, we will follow these criteria: if a single study involves multiple follow-up points, we will sequentially extract the number of patients with post–COVID-19 condition and symptom data for each follow-up point that meets the inclusion criteria. Studies reporting follow-up times that do not align with the predetermined follow-up intervals (eg, 1 month or spanning multiple months or even a year) will be excluded. Additionally, studies must report the number of confirmed post–COVID-19 condition cases at each follow-up; those reporting only the baseline sample size will also be excluded. Discrepancies will be resolved through discussions until reaching consensus with another reviewer (BL).

Textbox 1. Eligibility criteria for study inclusion in the systematic evaluation of symptom incidence in patients with post–COVID-19 condition.

Inclusion criteria

- Document type: Original studies
- Study population: Adults (age≥18 years) after diagnosed with COVID-19
- Data availability: Providing specific details about the follow-up time (≥3 months), sample size, and symptom data of post–COVID-19 condition cases
- Study design: Observational study (cohort study, case-control study, cross-sectional study, and case series)
- Language: English publications

Exclusion criteria

- Document type: Reviews, basic experimental studies, and other unrelated papers
- Study population: Pediatric or adolescent populations
- Data availability: The study has a limited sample size (n≤30)
- Study design: Basic research, randomized controlled trials
- Language: Publications in other languages

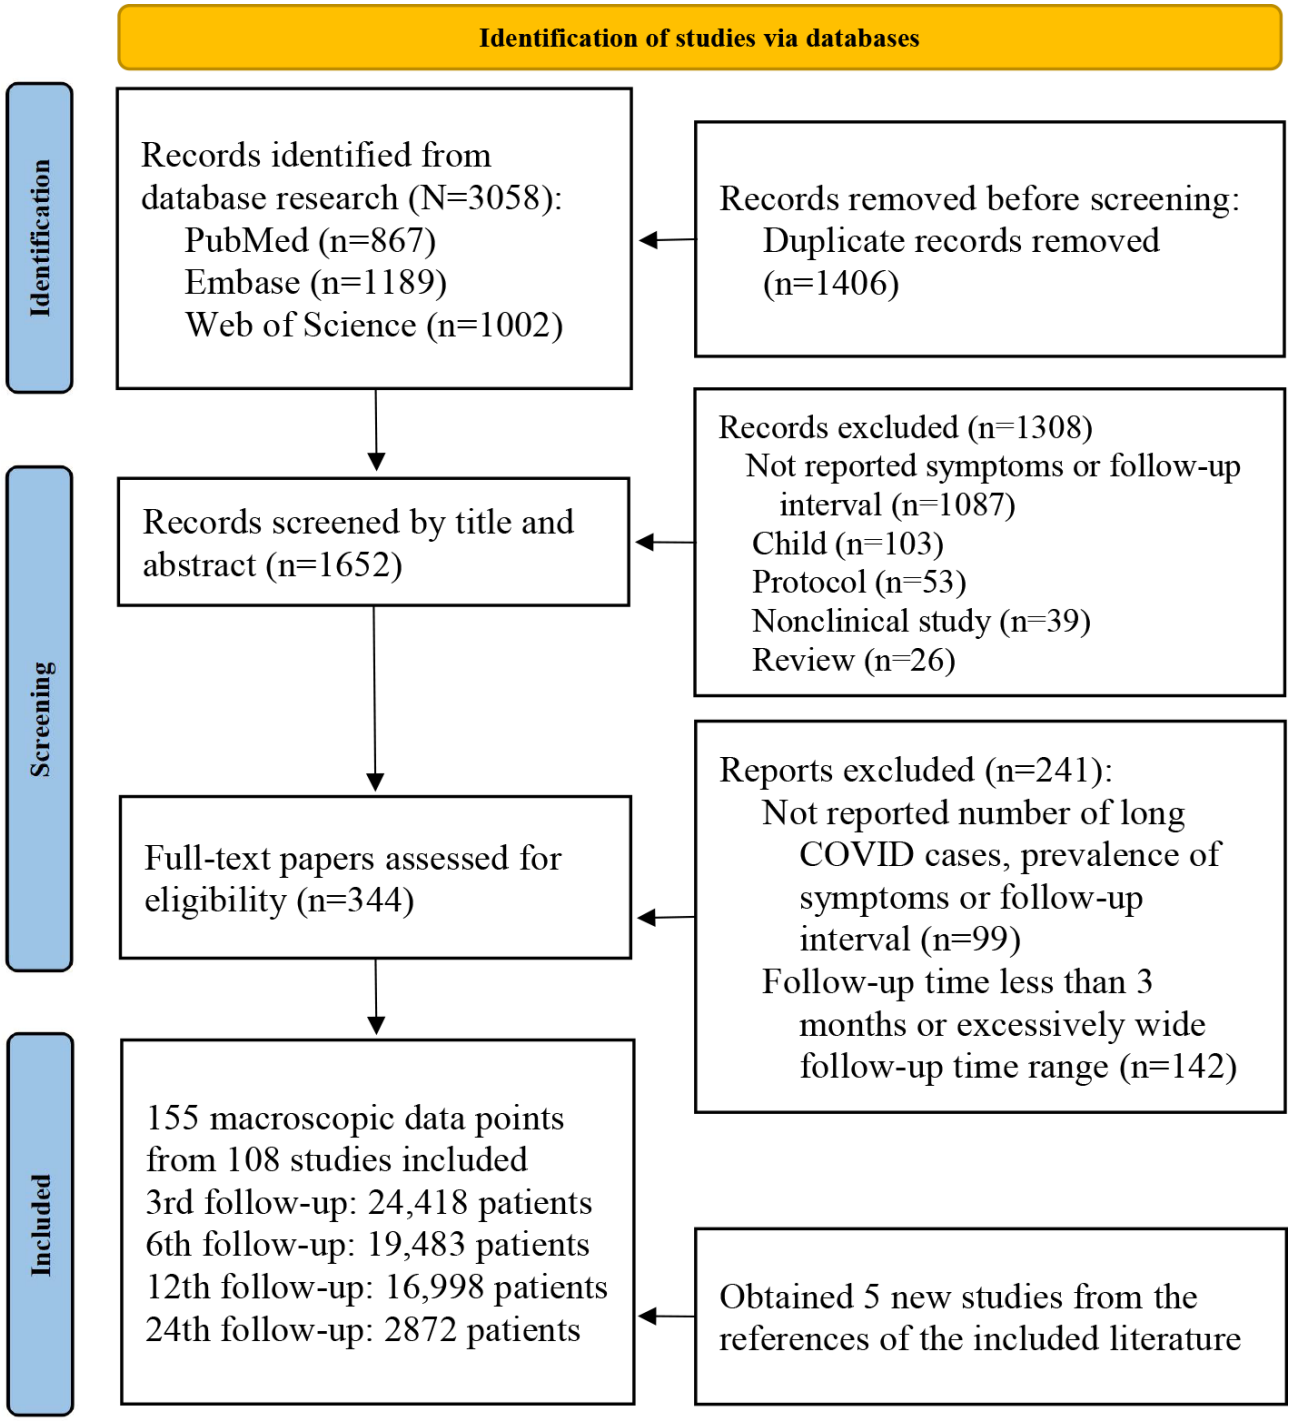
RenderX

Risk of Bias Assessment

The same investigators (LC and NL) assessed the risk of bias for all qualifying studies based on the Joanna Briggs Institute critical appraisal tool for analytic study and cross-sectional study [23]. The investigators independently assessed and ranked the risk of bias for every eligible study as yes, no, unclear, and not applicable.

Statistical Analysis

We conducted a meta-analysis (*metafor* package in RStudio, version 4.2.0; Posit PBC) using random effects models to estimate the prevalence of post–COVID-19 condition symptoms, aggregating data from multiple studies and incorporating study-specific effects into our analysis. The pooled effect results were presented along with their corresponding 95% CIs. To assess the proportion of variation attributable to between-study heterogeneity, analysis was conducted using I^2 to quantify heterogeneity on a scale from 0% to 100%. In parallel, we performed a subgroup analysis based on the regional classification of the patients. Statistical significance for differences in prevalence among regions was determined using a threshold of $P<.05$. An extensive network analysis was performed to investigate the evolution of symptoms over 4 distinct time intervals, providing a comprehensive overview of the interrelations of symptom prevalence. We used Spearman intragroup methods to conduct correlation analysis, with the primary aim of identifying symptom pairs that exhibited statistically significant correlations ($P<.05$). In addition, fuzzy clustering was used to cluster symptoms across various follow-up intervals, providing insight into potential differences in clinical phenotypes among patients. The network was visualized using Cytoscape software (version 3.7.2; NRNB), providing a comprehensive and detailed illustration of symptom interactions over the designated time intervals.



Results

Overview

A systematic review of post–COVID-19 condition identified 3058 records from database searches. After removing duplicates, title or abstract screening yielded 344 potentially eligible papers. The full-text review excluded 241 papers (unmet inclusion criteria), with 5 additional studies identified through reference screening. A total of 108 studies were included in the qualitative synthesis, encompassing 63,771 confirmed cases. These studies reported 64 distinct symptoms spanning 9 organ systems, including respiratory, neurological, cardiovascular, and musculoskeletal manifestations. Neurological symptoms were the most frequent (22/64), followed by respiratory (11/64) and digestive symptoms (9/64). The flowchart of the review process is shown in Figure 1. The studies were mainly conducted in Europe (55/108), Asia (38/108), America (13/108), and Africa (2/108). The number of patients and symptoms decreased over time, with neurological symptoms being the most prevalent. The characteristics of the studies are summarized in Table 1. The symptom classification system after standardization using *ICD-11* is presented in Table 2. The results of the quality assessment of the included studies are presented in Table S2 in Multimedia Appendix 1 [24-131].

Prevalence of Clinical Symptoms

Meta-analysis of symptom incidence rates at different follow-up time points revealed distinct dynamic evolution characteristics. At the third-month follow-up, 43 studies reported on 60 clinical symptoms in a total of 24,418 patients. Fatigue (52%, 95% CI 45% - 59%) and dyspnea (36%, 95% CI 29% - 43%) were the most common symptoms, while neurological and psychiatric symptoms such as weakness in the limbs (36%, 95% CI 20% - 53%) and anxiety (31%, 95% CI 17% - 44%) had already begun to emerge. Additionally, there are 56 other symptoms (attention deficit, myalgia, insomnia, hair loss, and cough) with an incidence rate of less than 30% (Figure S1A in Multimedia Appendix 1). A total of 51 studies (n=19,483) reported the prevalence rates of 50 symptoms at the sixth-month follow-up. Although fatigue (48%, 95% CI 42% - 54%) remained the most prevalent symptom, dyspnea (31%, 95% CI 26% - 36%) showed a declining trend, and neurological and psychiatric symptoms (anxiety: 24% and insomnia: 23%) persisted. At the 12th-month follow-up, 50 studies with a combined total of 16,998 patients detailed the prevalence rates of 50 symptoms. Beyond the persistently high prevalence of fatigue (46%, 95% CI 41% - 52%), dyspnea has declined to the fourth most reported symptom, while neurological manifestations (attention deficit: 32%, 95% CI 22% - 43%; memory impairment: 28%, 95% CI 19% - 37%; and insomnia: 28%, 95% CI 21% - 35%) and cardiovascular symptoms (arrhythmia: 29%, 95% CI 12% - 46%) have emerged as more prominent clinical features. At the 2-year follow-up, the prevalence rates of 45 symptoms were reported across 11 studies involving 2872 patients. Fatigue remained the most prevalent symptom (54%, 95% CI 45% - 64%), with neurological manifestations (particularly memory deficit at 42%, 95% CI 28% - 56%) constituting the predominant clinical presentation. Notably, emerging symptoms including gastrointestinal bloating (45%, 95% CI 38% - 51%) and respiratory nasal congestion (38%, 95% CI 32% - 45%) have become increasingly apparent. Please refer to Figure S1 in Multimedia Appendix 1 for a detailed illustration of forest plots of symptom prevalence at different follow-ups.

Overall, fatigue consistently ranked as the most prevalent symptom, particularly prominent among patients with post–COVID-19 condition. Moreover, neurological symptoms demonstrated a progressive worsening trend. Most importantly, as the disease duration extended, the symptom spectrum shifted from a predominance of respiratory symptoms in the early stages to multisystem involvement, including cardiovascular, digestive, and neurological systems, ultimately forming a complex clinical presentation characterized by fatigue as the core feature and multisystem dysfunction at the 2-year follow-up. The prevalence rates of the 12 most frequently reported symptoms across the 4 follow-up time points are presented in Figure 2.

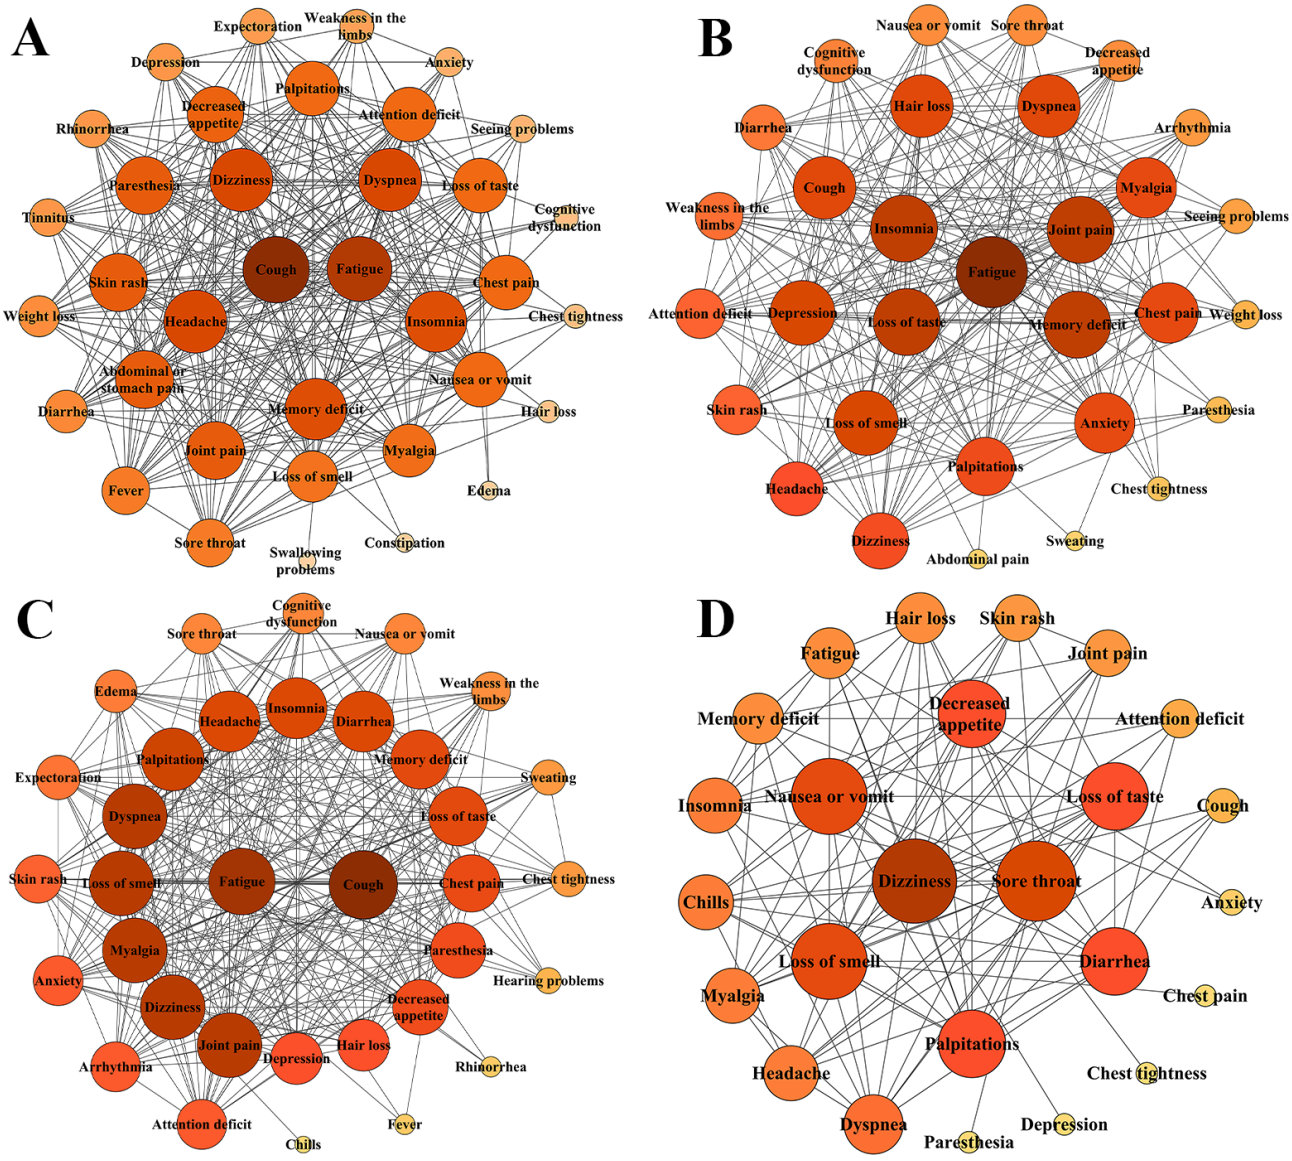
Figure 2. Trends in the prevalence of major post–COVID-19 condition symptoms across 4 follow-up time points (3rd, 6th, 12th, and 24th month) in studies conducted between December 2019 and March 2025, highlighting the progression of symptoms with fatigue as the core symptom and the shift from respiratory involvement to multisystem dysfunction.

Subgroup Analysis

To account for the comprehensive impact of temporal and spatial dynamics on symptom prevalence, we conducted a subgroup analysis based on the geographical locations of the studies. The results revealed notable differences in symptom prevalence across different regions. Overall, Africa reported the fewest symptoms, while Asia and Europe reported the highest number of symptoms. The Americas focused more on symptom incidence within 1 year. At the third-month follow-up, fatigue (68%, 95% CI 50% - 85%) and dyspnea (56%, 95% CI 15% - 98%) had the highest prevalence rates in Africa. However, insufficient attention to other symptoms has resulted in limited data availability, making further symptom comparisons challenging. The Americas exhibited a distinct neuromusculoskeletal symptom profile during short-term

XSL•FO
RenderX

follow-up, with significantly higher prevalence rates of anxiety (60%, 95% CI 54% - 66%) and depression (36%, 95% CI 16% - 55%) compared to other regions. Notably, joint pain (51%, 95% CI 33% - 68%) and weakness in the limbs (57%) were particularly prominent. Over time, both anxiety and joint pain maintained persistently high prevalence rates, reflecting a substantial long-term disease burden. During early follow-up periods, Asian cohorts demonstrated the highest reported symptom diversity (n=58 distinct manifestations) while exhibiting comparatively lower prevalence rates of dyspnea relative to other continental populations. This epidemiological pattern suggests a milder degree of respiratory involvement in Asian patient populations during the acute-postacute transition phase. Limb weakness was more commonly observed initially, but gradually diminished over time, evolving into a predominantly neurological symptom profile characterized by insomnia, depression, and memory impairment. The European region exhibited a more complex symptom spectrum during long-term follow-up, including an increasing prevalence of fatigue (66%, 95% CI 52% - 79%) and worsening cognitive dysfunction. Additionally, a range of new-onset symptoms emerged, such as bloating (45%) and other multisystem manifestations. Concrete details are provided in Table S3 in Multimedia Appendix 1.



Association and Clustering Analysis of Symptoms

We conducted the Spearman rank correlation analysis of symptoms across different follow-up periods, identifying positively correlated symptom pairs with statistically significant differences. These correlations were visualized using Cytoscape to display the core symptom clusters for each follow-up period.

The third-month follow-up analysis revealed significant positive correlations between core symptoms (cough, fatigue, headache, dizziness, and dyspnea) and other persistent symptoms. Network analysis demonstrated a complex symptom interaction pattern during early follow-up, comprising 36 distinct symptoms (Figure 3A). Cough showed the highest closeness centrality (0.875), node degree (Degree=30), and significantly elevated stress centrality (424) compared to other symptoms, indicating its critical role in symptom propagation pathways. Notably, fatigue, dyspnea, dizziness, and headache demonstrated comparable closeness centrality and topological coefficients, suggesting early stage respiratory-neurological system interactions. The network analysis at the sixth-month follow-up identified a core symptom cluster consisting of fatigue, memory impairment, ageusia, arthralgia, and insomnia. Fatigue demonstrated significantly higher betweenness centrality and closeness centrality compared to other symptoms, with the highest node strength in the entire network (Degree=26), indicating its pivotal role as a central hub connecting multiple symptom subgroups. Comparative analysis revealed a progressive reduction in symptom complexity, with the number of nodes decreasing from 36 at 3 months to 31 at 6 months. Notably, respiratory-related acute symptoms (eg, dyspnea and chest pain) became marginalized in the network topology. The neurocognitive-somatic symptom cluster, including memory impairment, arthralgia, insomnia, and ageusia, showed converging topological coefficients (0.614-0.625), suggesting that these symptoms may share neural network connectivity, potentially reflecting common neuroinflammatory mechanisms. The 12th-month follow-up network analysis revealed a newly formed core symptom cluster consisting of fatigue, cough, dizziness, anosmia, myalgia, and arthralgia. Dizziness emerged as the most central symptom, exhibiting the highest betweenness centrality (0.067) and stress centrality (322) in the network, along with a closeness centrality of 0.846. Fatigue maintained its prominent position with equally high betweenness centrality (0.067) and significant stress centrality (322), confirming both symptoms as critical information hubs and key propagation nodes within the symptom network. Notably, myalgia and arthralgia demonstrated nearly identical topological coefficients (0.645), suggesting shared immunoinflammatory pathway involvement. The analysis further identified cough as having the highest closeness centrality (0.891) in the entire network while showing topological coefficient similarity with anosmia (0.61), potentially indicating common inflammatory pathway mechanisms underlying these symptom pairs. Comparative analysis revealed a significant reduction in network complexity at a 2-year follow-up, with the number of nodes decreasing to 25 and the complete disappearance of respiratory symptoms (eg dyspnea and chest pain) and acute inflammatory manifestations (fever). Dizziness maintained its network dominance, exhibiting persistently high betweenness centrality (0.189) and closeness centrality (0.75) while achieving the highest node degree (Degree=16), indicating substantial strengthening of its role as the primary information hub. In contrast, cough exited the core cluster, demonstrating marked reductions in both node degree (to 4) and stress centrality (to 14), reflecting its substantially diminished role in symptom propagation. Gastrointestinal and cardiovascular manifestations emerged as increasingly prominent over time, demonstrating that post–COVID-19 condition follows a characteristic evolutionary trajectory culminating in chronic, persistent multisystem involvement. Complete symptom network analysis results appear in Table S4 in Multimedia Appendix 1.

XSL•FO
RenderX

Figure 3. Symptom network diagrams of post–COVID-19 condition at different follow-up time points showing symptom interactions and core nodes. Longitudinal symptom network analysis revealed a transition from respiratory-neurological symptom clusters to chronic, multisystem symptoms over time. (A) 3rd-month follow-up, (B) 6th-month follow-up, (C) 12th-month follow-up, and (D) 24th-month follow-up; nodes represent individual symptoms and edges to illustrate the correlations between symptoms for each interval. Each node's color and size represent the degree of the symptom, with darker colors and larger size indicating a higher number of symptoms correlated with it.

Furthermore, we conducted a clustering analysis on longitudinal symptom prevalence data, which revealed 2 distinct clinical subtypes of post–COVID-19 condition. To avoid subjective severity-based labeling, we adopted descriptive terms based on symptom distribution patterns and classified the clusters as the "dispersed type" and the "concentrated type." The dispersed type (cluster 1) was characterized by a broader diversity of symptoms with generally lower prevalence rates across multiple organ systems. In contrast, the concentrated type (cluster 2) showed a narrower symptom spectrum but with higher prevalence rates, predominantly involving neurological and respiratory systems. This clustering analysis finding was most pronounced within 1 year of follow-up. At the third-month follow-up, notable differences in symptom distribution were evident (Multimedia Appendix 3): cluster 1 showed a wide (n=59) but lower-range distribution of symptom prevalence (ranging from 0.5% to 20%), whereas cluster 2 demonstrated a narrower (n=39) but higher-range distribution (from 20% to 50%), indicating a more focused and severe symptom profile. The different colors in the legend represent different systems, with symptoms of the same system shown in the same area. The letter "n" represents the number of macro data points, and the percentages indicate the average prevalence of symptoms within each cluster. These findings suggest 2 distinct trajectories of post–COVID-19 condition: one subtype characterized by chronic, multisystem, and persistent symptoms (cluster 1), and another with concentrated, inflammation-related symptoms of greater severity (cluster 2). The longitudinal analysis further revealed a progressive convergence in the number of reported symptoms between the 2 clusters over time, suggesting a potential evolutionary trend toward more chronic and diffuse symptomatology in the postacute phase of SARS-CoV-2 infection. Figure S2 in Multimedia Appendix 1 illustrates the 6th- and 12th-month follow-up findings.

Discussion

The Complex Network Dynamics of Long COVID Symptoms

The intricate interactions of post–COVID-19 condition symptoms are reflected in their dynamically evolving network characteristics. During the early follow-up phase (third month), respiratory symptoms (cough and dyspnea) showed significant correlations with neurological manifestations (headache and dizziness), suggesting potential shared pathways linking respiratory inflammation and neurological dysfunction, likely attributable to persistent multisystem impacts of residual viral components from the acute infection phase. Current evidence highlights autonomic dysfunction, particularly manifesting as postural orthostatic tachycardia syndrome–like symptoms (postural orthostatic tachycardia, dizziness, and gastrointestinal dysregulation), as a defining pathophysiological characteristic of post–COVID-19 condition. The proposed mechanisms include direct viral neurotropism, immune-mediated autonomic nerve injury, and chronic inflammatory modulation of autonomic regulatory circuits [132-134]. As the disease progressed, fatigue emerged as a persistent central node connecting multiple symptom clusters, with its centrality becoming particularly prominent at 6 - 12 months, demonstrating strong associations with neurocognitive symptoms (memory impairment and insomnia) and musculoskeletal symptoms (arthralgia and myalgia). This pattern may reflect chronic neuroinflammation or autoantibody-mediated damage mechanisms. Previous studies have similarly identified that post–COVID-19 condition is characterized by persistent immune dysregulation, manifesting as chronic inflammation and sustained immune activation following acute infection [135]. The underlying pathogenic mechanisms may include viral antigen persistence, autoimmune responses, and cytokine-mediated tissue damage, which collectively contribute to its multisystem clinical manifestations. Autoimmunity has been specifically implicated as a driver of symptoms such as joint pain and neurological manifestations, while prolonged immune activation may lead to progressive tissue injury and chronic symptomatology [136-139]. Of particular note, by the 2-year follow-up, the symptom network complexity had significantly diminished, with respiratory manifestations having largely resolved, while neurological, circulatory, and digestive system symptoms (including dizziness, nausea, vomiting, and palpitations) emerged as the predominant clinical features. Some researchers have proposed the hypothesis that the gut-brain axis constitutes a bidirectional neuro-immune-endocrine network, with vagal-mediated signaling and microbial metabolite production (particularly serotonin, predominantly gut-derived) critically modulating both enteric and central nervous system functions. Mounting evidence indicates that gut dysbiosis and impaired microbiome-immune crosstalk contribute to neuropsychiatric and systemic manifestations [140,141]. Another key hypothesis posits that vascular compromise leads to tissue hypoperfusion and hypoxia, particularly affecting high-metabolic organs (brain, heart, and skeletal muscle), potentially explaining fatigue, cognitive impairment, and myalgia [142-144]. Thus, it can be seen that the pathophysiology of long COVID is characterized by a multifactorial interplay of immune dysregulation, persistent vascular or organ injury, chronic inflammation, and neuroendocrine dysfunction, resulting in heterogeneous clinical manifestations [145-147]. This complex pathophysiology complicates mechanistic elucidation while accounting for the condition's diverse clinical phenotypes.

Regional Variations in Symptom Reporting and Underlying Factors

The study identified significant regional variations in symptom reporting, likely driven by multiple interacting factors. Disparities in health care resource distribution play a critical role—well-established follow-up systems in Europe and North America may capture a broader spectrum of symptoms, whereas Africa's constrained health care infrastructure and overburdened medical service systems may contribute to both significant underreporting of symptoms and elevated prevalence of primary clinical manifestations [148]. Genetic background differences also contribute; for instance, the high prevalence of arthralgia in the Americas may be linked to specific human leukocyte antigen genotypes [149,150]. Divergent vaccination strategies, particularly the varying protective effects of mRNA versus inactivated vaccines, might modulate immune responses and influence long-term symptom profiles. The spatiotemporal distribution of viral variants is another key factor, as the study period spanned both the Delta and Omicron waves. The Delta variant may induce long-term sequelae characterized by hyperinflammatory or neurotropic pathological patterns [151], whereas Omicron infection appears to confer a lower risk of developing post–COVID-19 condition [152]. Additionally, cultural factors, such as differing perceptions of mental health, may lead to underreporting of psychiatric symptoms (eg, anxiety) in Asian populations. These variations underscore the need for a globally standardized core symptom assessment tool and careful consideration of contextual factors when interpreting cross-regional findings.

Symptom Dynamics and Targeted Management

Fatigue, as a common nonspecific symptom, frequently overlaps with various other clinical manifestations, complicating the identification of condition-specific patterns. Notably, network analysis based on symptom prevalence suggests that cough and dyspnea may serve as key sentinel symptoms for early detection of post–COVID-19 condition. Within the context of long-term sequelae, symptoms such as dizziness, nausea or vomiting, and palpitations play a critical role in its recognition and diagnosis. The nonspecific nature of fatigue and its frequent overlap with diverse clinical manifestations complicate the identification of disease-specific patterns. Symptom prevalence–based network analysis highlights cough and dyspnea as potential sentinel symptoms for early recognition of post–COVID-19 condition, while neuro-circulatory-gastroenteric symptom clusters (particularly dizziness, nausea or vomiting, and palpitations) emerge as critical diagnostic markers in the chronic phase. This evolving understanding warrants dynamic, phase-adapted management approaches: early-stage interventions should prioritize respiratory rehabilitation and inflammatory response modulation, whereas chronic-phase care requires focused neurological symptom management integrated with

XSL•FO
RenderX

multidisciplinary strategies addressing concomitant digestive and circulatory system involvement. Regionally tailored public health strategies are essential, exemplified by musculoskeletal symptom–focused interventions in the Americas and enhanced cognitive rehabilitation frameworks in Europe, reflecting geographical variations in disease manifestation and health care system capacities.

Study Limitations and Future Directions

With regard to sampling constraints, the limited representation of data from Africa and certain parts of Southeast Asia may restrict the global generalizability of our conclusions, as region-specific symptom patterns or subtypes may remain unidentified. This regional imbalance could also introduce bias, as symptom prevalence and reporting practices are likely influenced by local health care infrastructure, follow-up systems, and cultural perceptions of illness. Moreover, the included studies largely lacked adjustment for socioeconomic determinants of health. Given that many countries have lifted containment measures, resumed economic activities, and reopened borders, this global shift toward adaptive coexistence with SARS-CoV-2 may lead to systematic underreporting of symptoms, especially mild or chronic manifestations. Additionally, the predominant reliance on passive follow-up methods may have missed clinically relevant but less severe cases, further contributing to data skewness. Another notable limitation is the absence of variant-specific data. The study period spans multiple waves of the pandemic, including those driven by the Delta and Omicron variants, which have been associated with distinct clinical trajectories. However, due to data availability constraints, we were unable to stratify symptom trajectories by viral strain, limiting the capacity to attribute observed patterns to specific viral characteristics. These limitations underscore the need for future studies to adopt a more standardized, comprehensive, and globally inclusive approach. We recommend prospective cohort studies with individual-level, longitudinal follow-up, stratified by region, socioeconomic status, and viral variant. Active surveillance in underrepresented regions, combined with systematic collection of social determinants and clinical metadata, is essential to generate more robust, equitable, and actionable insights into post–COVID-19 condition.

Conclusions

Building upon these findings, a comprehensive synthesis of post–COVID-19 condition research reveals a complex and evolving clinical landscape. Across varying follow-up periods encompassing diverse symptoms and affected organ systems, we demonstrate that the chronic and persistent effects of post–COVID-19 condition pose significant challenges for both patients and health care providers. Symptom prevalence exhibits temporal fluctuations, with neurological manifestations emerging as the disease's most prominent feature. In regions with limited research coverage, such as Africa, greater attention should be directed toward understanding specific symptom patterns and disease progression. Consequently, the establishment of a stratified management system based on disease staging and regional characteristics becomes imperative to address this heterogeneous condition. However, given the limitations of population-level data, our findings should be used as a guideline for understanding the broader trends of post–COVID-19 condition, but clinical decisions should be personalized, taking into account each patient's unique characteristics. Future studies incorporating individual-level data are needed to provide more granular insights and inform precision medicine strategies for post–COVID-19 care.

Acknowledgments

The study is supported by the China Academy of Chinese Medical Sciences key collaborative project of Innovation Fund, Analysis of Dynamic Temporal and Spatial Characteristics of TCM Syndrome of COVID-19 and Research on Its Biological Connotation (CI2022C004-01), National Key R&D Program of China (2023YFC3503400), 2023 Agency/National Special Fund Project of National Administration of Traditional Chinese Medicine (F0212), and the 2022 Qi Huang Young Scholar program of the National Administration of Traditional Chinese Medicine (NS; Z0841 and Z0865).

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

MH, BL, and NS conceptualized the study. MH, BL, and ZG prepared the original draft of the manuscript. MH and TS conducted all statistical analyses. HZ developed the systematic review workflow and created Figure 1. ZG prepared Figure 3. HL, GZ, LC, NL, and BL collaboratively conducted literature screening and data extraction. QC and JG contributed to reviewing and editing the manuscript. All authors read and approved the final manuscript.

Conflicts of Interest

Conflicts that the editors consider relevant to the content of the manuscript have been disclosed. All authors have submitted the International Committee of Medical Journal Editors Form for Disclosure of Potential.

Abstract

Background: Although agricultural health has gained importance, to date, much of the existing research relies on traditional epidemiological approaches that often face limitations related to sample size, geographic scope, temporal coverage, and the range of health events examined. To address these challenges, a complementary approach involves leveraging and reusing data beyond its original purpose. Administrative health databases (AHDs) are increasingly reused in population-based research and digital public health, especially for populations such as farmers, who face distinct environmental risks.

Objective: We aimed to explore the reuse of AHDs in addressing health issues within farming populations by summarizing the current landscape of AHD-based research and identifying key areas of interest, research gaps, and unmet needs.

Methods: We conducted a scoping review and bibliometric analysis using PubMed and Web of Science. Building upon previous reviews of AHD-based public health research, we conducted a comprehensive literature search using 72 terms related to the farming population and AHDs. To identify research hot spots, directions, and gaps, we used keyword frequency, co-occurrence, and thematic mapping. We also explored the bibliometric profile of the farming exposome by mapping keyword co-occurrences between environmental factors and health outcomes.

Results: Between 1975 and April 2024, 296 publications across 118 journals, predominantly from high-income countries, were identified. Nearly one-third of these publications were associated with well-established cohorts, such as Agriculture and Cancer and Agricultural Health Study. The most frequently used AHDs included disease registers (158/296, 53.4%), electronic health records (124/296, 41.9%), insurance claims (106/296, 35.8%), population registers (95/296, 32.1%), and hospital discharge databases (41/296, 13.9%). Fifty (16.9%) of 296 studies involved >1 million participants. Although a broad range of exposure proxies were used, most studies (254/296, 85.8%) relied on broad proxies, which failed to capture the specifics of farming tasks. Research on the farming exposome remains underexplored, with a predominant focus on the specific external exposome, particularly pesticide exposure. A limited range of health events have been examined, primarily cancer, mortality, and injuries.

Conclusions: The increasing use of AHDs holds major potential to advance public health research within farming populations. However, substantial research gaps persist, particularly in low-income regions and among underrepresented farming subgroups, such as women, children, and contingent workers. Emerging issues, including exposure to per- and polyfluoroalkyl substances, biological agents, microbiome, microplastics, and climate change, warrant further research. Major gaps also persist in understanding various health conditions, including cardiovascular, reproductive, ocular, sleep-related, age-related, and autoimmune diseases. Addressing these overlooked areas is essential for comprehending the health risks faced by farming communities and guiding public health policies. Within this context, promoting AHD-based research, in conjunction with other digital data sources (eg, mobile health, social health data, and wearables) and artificial intelligence approaches, represents a promising avenue for future exploration.

Introduction

Background

Public health research seeks to identify and understand the factors that influence population health to effectively prevent diseases and promote health and well-being for all [1,2]. A broad range of environmental determinants can impact health across the life span. One of the core areas of public health research, known as the exposome, investigates how cumulative environmental influences contribute to disease etiology and pathogenesis [3-18]. The exposome, which complements genomic research, refers to the comprehensive examination of all environmental exposures experienced throughout an individual's lifetime, including physical, chemical, biological, psychosocial, and behavioral factors, from conception to death [3-18]. The exposome classically includes 3 overlapping domains: the general external exposome (eg, climate and built environment); the specific external exposome (eg, chemical exposure, lifestyle, and occupations); and the internal exposome (eg, aging, oxidative stress, metabolism, and gut microbiome) [8,14,16,17,19,20]. Understanding the exposome is crucial for enabling both population-wide and precision prevention [3,21-23]. However, fully describing the exposome is challenging due to the vast diversity and the temporal and spatial variability of environmental factors [3]. Public health research in this area requires data on both risk factors and adverse health outcomes to progress effectively [3,14,24,25].

The volume of data collected has grown exponentially as the world becomes increasingly reliant on technology and digitization [26,27]. Data are omnipresent in our everyday lives, leading science toward data-driven research [27,28], in particular in the health field. The digital transformation in health care has enabled unprecedented data availability, collection, storage, and analysis capabilities, leading to a paradigm shift in health care systems, with entire care pathways becoming digitized [29,30]. Health-related data now represent approximately 6% of all digital data globally, a figure that continues to rise [31]. This explosion of data has transformed research, providing new opportunities, especially in public health, to enhance disease understanding and evaluate intervention effectiveness [27,28,32-35]. The integration of digital technologies and digital data in public health has led to the emergence of "digital public health," an evolving field focused on using digital data to achieve public health goals [33,36-41]. Public health research is moving from isolated data systems to more integrated, accessible, and reusable data resources [42]. Reusing data allows researchers to explore various health determinants, including environmental, occupational, behavioral, and organizational factors, fostering a holistic approach to disease prevention and health promotion strategies [14].

Within the digital public health framework, 2 main types of data are being used, namely primary and secondary data. Primary data are tailor-made, designed for a specific purpose, and often used once or repeatedly for the same goal [43-45]. Primary data are the cornerstone of traditional public health policy and decision-making. These data are derived from several types of studies [46-50], in particular observational cohorts (eg, the Framingham Cohort study [51,52]) [46-50,53,54], case-control studies [46-50], cross-sectional surveys (eg, the China Health and Retirement Longitudinal Study [55,56]) [46-50,53], and experimental studies [46-50]. Primary data have many advantages [46-50]. They are rich, of high quality, and are designed to answer specific research questions for public health and epidemiological purposes. Primary data are usually available at the individual level and are derived from studies that control for certain biases. By contrast, they are cumbersome, time-consuming, and costly to set up and maintain [53,54,57]. The representativeness of primary data is also limited in size, geographic scope, and temporal coverage and can erode with time [46-50,53]. Primary data are not free from bias, such as selection, healthy worker, recall, or prevarication biases [53,58].

Unlike traditional public health, digital public health does not rely solely on primary data but takes advantage of the myriad of existing digital data that have not been generated originally for research purposes (ie, secondary data) to overcome some limitations intrinsic to primary data and complement them [28,43,44,53,59-68]. Indeed, some data can have an additional impact when used beyond the context for which they were originally created [68,69]. Secondary data are collected for purposes other than public health or epidemiology and include contextual data (eg, air quality and climate data) [14,24,26,29,70-74], person-generated data (eg, social media, crowdsourcing, and mobile health) [2,24,26,31,43,61,62,73,75-86], synthetic data (eg, digital twin) [87-91], and administrative health databases (AHDs) [26,64,68,81,92-102].

AHD is a broad term encompassing a wide range of routinely collected data on individuals' health and sociodemographic information collected for registration, billing, record keeping, and other administrative purposes [26,64,81,93,95,98,100-102]. For this review, based on previous works [93,95,96,103-105], AHDs included population registers, claims databases, disease registers, electronic health or medical records, and hospital discharge databases that were collected at a local, regional, national, or international level (Table 1) [26,61,62,93,95,96,100,103-110].

XSL•FO
RenderX

Table 1. Definition and characteristics of administrative health databases included in this review.

	Population register	Claims database	Disease register	Electronic health or medical record	Hospital discharge database
Definition	Digital sociodemographic information on the residents of a country	Routinely collected digital information on individual data regarding reimbursement, records of health services, medical procedures, prescriptions, and medical diagnoses	A continuous and exhaustive digital collection of individual data regarding 1 or more health events in a geographically defined population	Systematized digital record of a patient's medical information collected in real time	Digital records of service use with information about patients, their care, and their stay in the hospital
Source	Local or national authorities	Insurance programs or schemes and health care providers	Health care institutions (eg, hospitals)	Hospitals, physicians, health care centers, and institutions	Hospitals
Population	All individuals residing in a country	All individuals covered by an insurance program or scheme	All individuals diagnosed with a specific health event in a population on a geographically defined scale	All patients using the health care system	All patients from a hospital
Purpose or finality	For the administrative purposes of government: to provide reliable information	To store financial and administrative information for medical insurers' and providers' use	For clinical and research purposes: to collect information about people diagnosed with a specific health event	For clinical and billing purposes: to document patients' clinical condition	For billing or accounting purposes
Health event	None	Health events covered by insurance or a health care provider	Specific health events (eg, cancer)	Health events requiring care that are reported in medical records	Health events from hospital admission

AHDs offer many advantages for research. Such data are collected as part of routine administrative processes, reducing additional costs for researchers. Therefore, AHDs offer relatively inexpensive access to a large number of individuals who can be tracked with time for several years, guaranteeing the representativeness of the populations studied [26,54,78,93,95,104,105,111-114]. Data recorded within AHDs are structured, coded in a standardized way, and less affected by participation and recall biases [54,58,95,106,113,115]. AHDs enable the study of rare events and populations underrepresented in studies using only primary data [95,111-113]. AHDs have limitations inherent to their nature, such as the absence of some confounding factors, the limited granularity of certain information, the data complexity, and confidentiality issues [73,78,93,95,115-125].

Rationale

AHDs are increasingly used in population-based health research due to their complementarity with traditional sources of public health and epidemiological data (ie, primary data) [42,59,64,87,93,95,96,126-128]. The reuse of AHDs, referring to their application beyond their original or intended purpose, holds major potential to advance public health and epidemiological research, offering insights that can guide public health decision-making [42,59,64,87,93,95,96,105,126-131]. Although several reviews have previously explored the general use of AHDs in research [42,95,107,129,132-135], others have focused on their application within specific countries [96,136], examined individual AHDs [108,137], or investigated their role in studying specific diseases and adverse health outcomes [44,93,104,138-142]. However, to the best of our knowledge, no study has synthesized how AHDs are reused for epidemiological and public health research within a specific population group.

To address this gap, we conducted a comprehensive scoping review and bibliometric analysis aimed at identifying how AHDs are used to address health issues in a specific population. We selected farming populations as an illustrative example because they present unique health and disease patterns [143-147]. Globally, approximately 27% of the workforce is engaged in occupational farming, and this group is exposed to numerous risk factors (ie, exposomes), including pesticides, biological agents, and limited access to health care [148]. These exposures put them at heightened risk for a wide range of adverse health outcomes [143,145,147,149]. Although agricultural safety and health have become a major public health issue in recent decades, most research on the health of farming populations has relied on traditional epidemiological and community-based studies, which often face limitations in terms of sample size, geographic scope, temporal coverage, and the range of health events examined [145,150,151].

In this context, AHDs offer valuable opportunities to enhance public health and epidemiological research in farming populations by providing broader insights, identifying at-risk subgroups, and informing health services and policy development [152]. The primary objectives of this scoping review were two-fold: (1) to summarize the current state of AHD-based research in farming populations by examining which types of AHDs are used and why, whether AHDs are integrated with other data sources, which farming populations have been studied, and what exposures and health outcomes have been explored and (2) to identify key areas of interest and potential research gaps and unmet needs in this field.

XSL•FO
RenderX

Methods

Overview

This scoping review was conducted and reported according to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) and evidence maps guidelines (Table S1 in Multimedia Appendix 1) [153] following a single screening approach. The protocol of this study was not registered. A 7-step procedure was used: research question formulation, identifying relevant publications, title review, abstract review, full-text review, data extraction, and data analysis.

To formulate our research question, we followed the Joanna Briggs Institute guidelines, using the population, concept, and context criteria framework [154]. Our population included all individuals engaged in farming and all individuals exposed to farming-related exposures. The concepts included all possible public health and epidemiological research works that involved the study of a health outcome of interest. The context was the use, in any setting, of at least one of the AHDs, as defined in Table 1.

Search Strategy and Selection Criteria

To develop and validate the search strategy, previous reviews that examined the reuse of AHDs for population-based research were identified and refined [93,96,103,104]. Our initial search revealed that electronic health records (EHRs) are often interchangeably referred to as electronic medical records (EMRs). A distinction between EHR and EMR is sometimes made, with EMR describing patients' care from only 1 practice (eg, specific encounters in hospitals), which is contrary to EHR [105]. In that case, EMR serves as a data source for EHR. This distinction was not considered in this paper. In addition, to ensure comprehensiveness, the search terms were broadened by searching for their synonyms. For example, search terms such as "electronic health record," "digital health record," "electronic medical record," "EHR," or "EMR" were used as synonyms for electronic health or medical records. A total of 72 terms pertaining to 2 categories (farming and AHDs) were used (Textbox 1). The search terms were reflective of our research topic and question.

Textbox 1. Search terms.

Farming

- husbandry* OR agriculture* OR farming OR farm* OR agricultural* OR farmworker*

Administrative health databases (combined using AND)

- "health record" OR "health records" OR "digital record" OR "digital records" OR "health administrative register" OR "health administrative registry" OR "health register" OR "health registry" OR "medical register" OR "medical registry" OR "electronic health record" OR "electronic health records" OR "EHR" OR "EMR" OR "electronic medical record" OR "electronic medical records" OR "digital medical record" OR "digital medical records" OR "digital health record" OR "digital health records" OR "health administrative data" OR "health administrative database" OR " health administrative dataset" OR " health administrative datasets" OR "health administrative databases" OR "administrative health data" OR "administrative health database" OR "administrative health dataset" OR "administrative health datasets" OR "administrative health databases" OR "insurance data" OR "insurance database" OR "insurance databases" OR "insurance dataset" OR "insurance claim" OR "insurance claims" OR "cancer registry" OR "cancer register" OR "health insurance" OR "health surveillance program" OR "health surveillance programs" OR "Mutualite Sociale Agricole" OR "MSA" OR "health insurance system" OR "record-linkage" OR "population register" OR "population registry" OR "insurance scheme" OR "social security scheme" OR "hospital discharge" OR "administrative claim" OR "administrative claims" OR "medical claims" OR "medical claim" OR "electronic claim" OR "electronic claims" OR "mortality register" OR "mortality registry" OR "mortality record" OR "mortality records" OR "disease register" OR "disease registry" OR "illness register" OR "illness registry" OR "disorder register" OR "disorder registry"

To develop the eligibility criteria, an initial search of the literature was conducted on PubMed, with a review of the first 100 articles that used AHDs for public health and epidemiological research. In our pilot run, disease and morbidity registers were initially not considered as AHD because they were created for clinical and research purposes [47-50,53,76,155,156]. However, because disease registers contain some information derived from medical records, we decided to consider them as AHD for this review. The eligibility criteria are presented in Textbox 2. The search was restricted to original peer-reviewed records (all types were included) written in English or French but not constrained by the year of publication [93,106,157]. Publications that examined partly farming populations, with, for instance, studies reporting health risks for various sectors of activity, were included.

XSL•FO
RenderX

Textbox 2. Eligibility criteria for selection of publications.

Inclusion criteria for articles

- Data had to originate at least partly from the administrative health database (AHD)
- The study had to pertain at least partly to the farming population
- The study had to relate to public health or epidemiological research
- Original peer-reviewed publications
- Publications in English or French

Exclusion criteria for articles

- Publications not describing the use of an AHD
- Animal or in vitro studies
- Publications not in English or French

The final literature search was conducted on both PubMed and Web of Science Core Collection databases. Regarding the Web of Science Core Collection, a topic search was performed. To reduce the bias induced by daily database changes, all data collection (literature retrieval and data download) was conducted and completed on the same day, that is, April 15, 2024. Titles, abstracts, and full-text publications were screened based on pre-established inclusion and exclusion criteria. The inclusion criteria for each phase of the literature search are provided in Table S1 in Multimedia Appendix 1. When abstracts did not contain enough information about correspondence to inclusion or exclusion criteria, the article was considered for full-text review. Reference lists of included publications were not searched, although they might have also yielded new relevant studies.

Data Collection and Processing

A total of 29 metadata were extracted from each publication included in the scoping review (Table 2).

The data underwent rigorous manual validation, cleaning, and harmonization following a structured 5-step process. First, duplicate items (eg, keywords and institutions) were removed. Second, leading and trailing white spaces were eliminated. Third, items were standardized by converting text to lower case, with only the first letter capitalized. In the fourth step, items were harmonized to either singular or plural forms consistently. Finally, synonyms or terms with similar meanings (eg, “illness” and “disease”) were unified under a single term. For instance, “Pesticide,” “Pesticide exposure,” and “Pesticide use” were standardized to “Pesticide,” while “Pulmonary disease copd,” “Copd,” and “Chronic obstructive pulmonary disease” were unified as “COPD.” For cancer-related keywords, the International Classification of Diseases, eleventh revision, was used to consolidate varied terms (eg, “lung cancer,” “lung cancer risk,” “lung and bronchus cancer,” “lung tumor,” “lung tumour,” “lung neoplasm,” and “basal cell carcinoma of the lung”) into standard categories (eg, lung cancer). Quality appraisals were not performed because they were beyond the aim of this review [106,157].

Data Analysis

To analyze the research directions (ie, hot spots and gaps) on the use of AHDs for public health and epidemiological research in farming populations, a bibliometric approach was conducted [158-160]. This analysis examined the number of publications, countries of publications, most active journals, institutions, authors, funding bodies, subject areas, citations of publications, and keywords of publications. Seven bibliometric metrics were computed, including the h-, g-, m-, and Y-indices; dominance factor; annual growth rate (AGR); and fractionalized frequency (Table S3 in Multimedia Appendix 1). The h-index attempts to measure both the productivity and citation impact of the published body of work of an entity (eg, author, institution, and journal) [161,162]. It refers to the total number of publications by a particular entity with at least the same number of citations. The m-index is calculated by dividing the h-index by the number of years of an entity's productive life (eg, researcher) [161]. The g-index of an entity corresponds to the largest number g such that the top g publications have at least $\geq g^2$ citations together [162]. The Y-index refers to the sum of both the total number of first-authored publications and the total number of corresponding author publications [163]. The dominance factor refers, for a particular researcher, to the proportion of multiauthored publications as a specific author's rank to the total number of multiauthored publications [164]. The fractionalized frequency intends to reflect an author's contribution. The AGR refers to the variable's change in

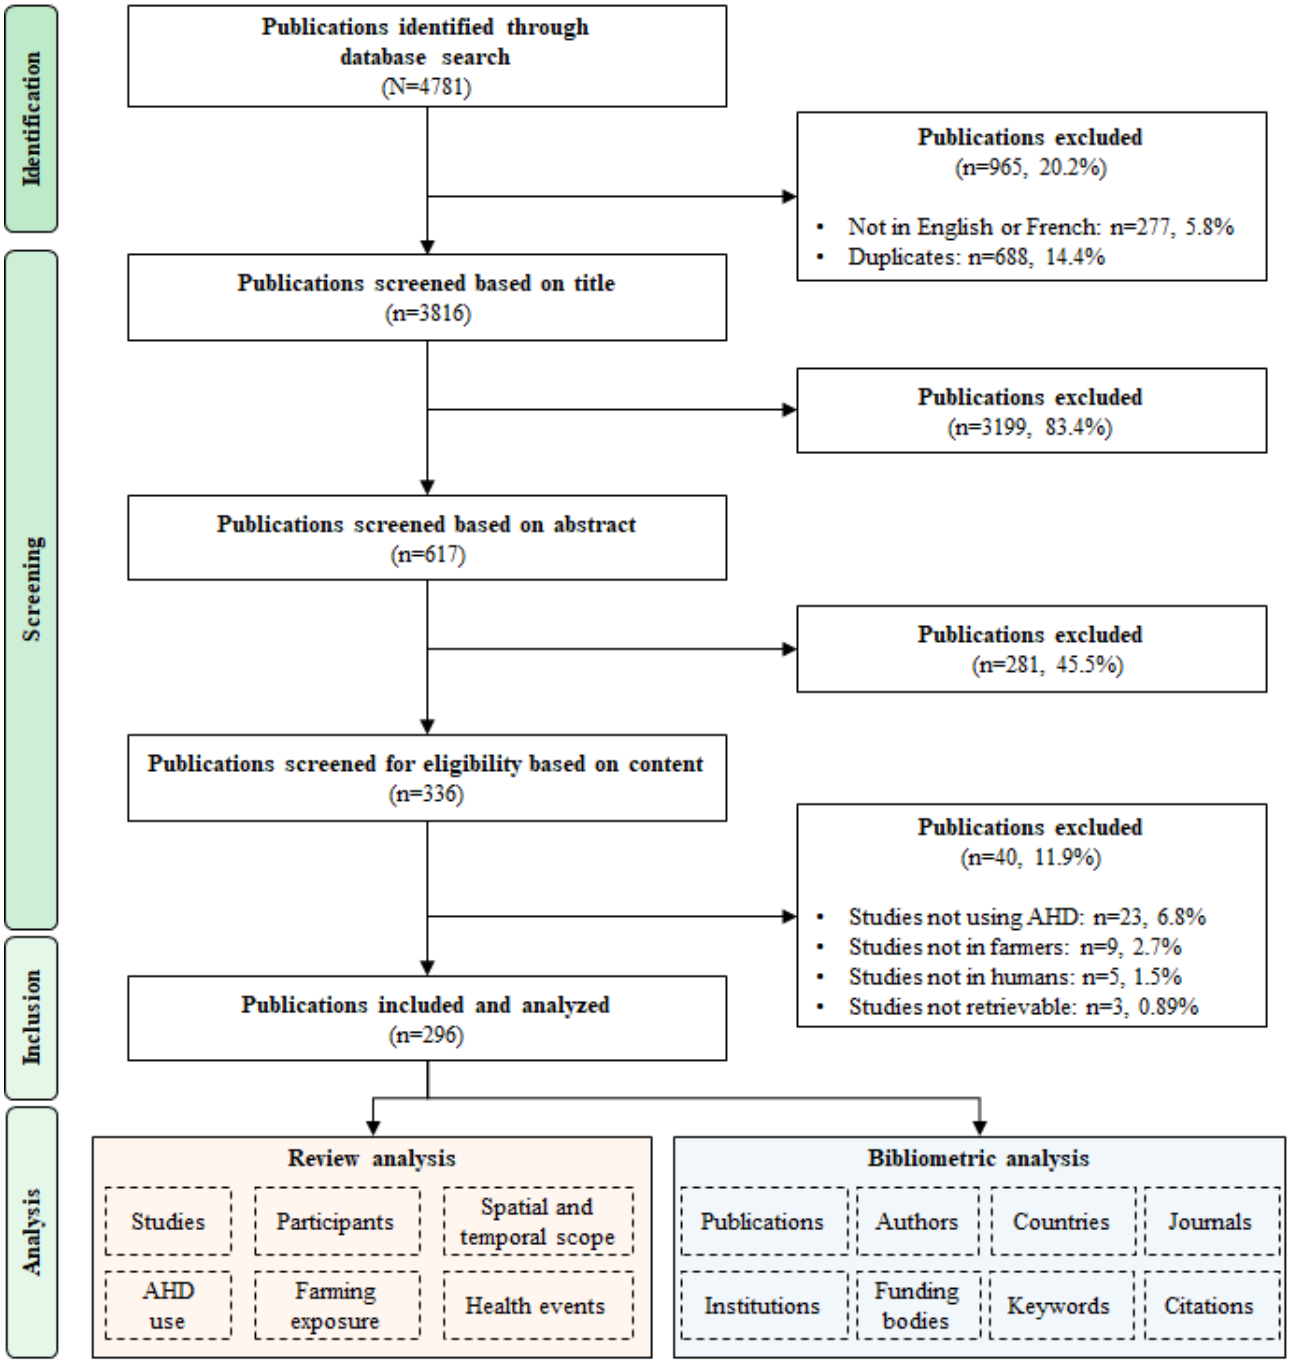
percentage as a year-over-year statistic [165]. The most up-to-date journals' impact factors and ranks were retrieved manually using the Journal Citation Report in April 2024.

Spearman correlations were calculated to examine the association between the number of publications and gross domestic product (GDP); population size [166]; and the total labor force, the number of researchers in research and development (per million people), fertilizer consumption (in both % of fertilizer production and kilograms per hectare of arable land), agricultural land (km^2), agricultural land (% of land area), land under cereal production (hectares), permanent cropland (% of land area), cereal production (metric tons), crop production index, food production index, livestock production index, cereal yield (kilogram per hectare), female individual employment in agriculture (% of female employment), male individual employment in agriculture (% of male employment), employment in agriculture (% of total employment); and agriculture, forestry, and fishing, value added (% of GDP). These country characteristics were obtained from the World Bank. The most recent country characteristic (eg, GDP) was used when available.

Research directions, including hot spots and gaps, were investigated with keyword frequency, co-occurrence (counting of paired keywords), and thematic mapping analyses. Thematic mapping and keyword co-occurrence network are 2 complementary but distinct approaches that serve different purposes and offer different insights. In summary, thematic mapping focuses more on the strategic positioning of research themes within a field, while keyword co-occurrence networks emphasize the relationships and connections between specific keywords in the literature [158,167]. Both methods complement each other and are usually used to provide a more comprehensive understanding of research landscapes. The co-occurrence of 2 keywords was defined by the frequency with which they appear together in publications and was quantified using association strength (AS) or equivalent index, calculated as , where c_{ij} is the number of publications in which keywords i and j co-occur, while c_i and c_j are the number of publications in which each keyword appears, respectively [158,167]. AS measures how close 2 keywords are to each other. An AS value of 1 indicates keywords always appear together, while 0 indicates they never co-occur. These keyword co-occurrences can be visualized using a co-occurrence network graph, where a vertex or node represents a keyword, the size of the node represents the keyword frequency, and the edge represents the association between 2 keywords [158,167]. On the basis of the keyword co-occurrence network graph, a community detection procedure can be used to identify groups of words highly associated with each other [158,167]. In other words, equivalent keywords based on AS can be grouped together to identify research themes [158,167]. A strategic diagram or thematic map is based on Callon centrality (x-axis) and Callon density (y-axis) [158,167]. Callon centrality measures the degree of interaction of a theme with other themes. It is defined as , where k is a keyword belonging to a theme and h is a keyword belonging to another theme [158,167]. Callon centrality can be interpreted as an indicator of the importance of a particular topic within the broader research landscape. Callon density measures the internal strength of a theme. It is defined as , where i and j are keywords belonging to the same theme and w is the total number of keywords in a theme [158,167]. Callon density serves as a metric for assessing the progression and maturation of that topic [158,167]. A strategic diagram is divided into 4 quadrants according to Callon centrality and density values, which correspond to 4 types of topics. Hot spots or hot topics are defined by both high density and high centrality values (upper-right quadrant), while basic topics are defined by high centrality but low density values (lower-right quadrant). Peripheral topics are defined by both low centrality and low density values (lower-left quadrant), while niche topics are defined by low centrality and high density values (upper-left quadrant) [158,167].

To focus on agricultural or farming exposome research, a bibliometric profile of the "farming exposome" was constructed, which restricts the exposome concept to environmental exposures specific to farming populations [152,168]. This bibliometric farming exposome picture examined co-occurrences between keywords related to potential risk factors and specific health events (eg, cancers and reproductive disorders).

The bibliometric analysis was conducted and reported according to the preliminary guideline for reporting bibliometric reviews of the biomedical literature (BIBLIO; Table S4 in Multimedia Appendix 1) [169]. All analyses were performed using R software (version 4.3.2; R Foundation for Statistical Computing) for Windows 10 (Microsoft Corporation). The bibliometric analysis was performed using the *bibliometrix* R package (version 4.1.4) [170].



Results

Overview

After excluding 4485 irrelevant records, 296 publications were analyzed (Figure 1). The majority were articles (293/296, 98.9%), with a small number of reviews (2/296, 0.7%) and editorial materials (1/296, 0.3%; Table 3). Only one-third of the publications (107/296, 36.1%) were open access (Table 3 and Figure S1 in Multimedia Appendix 1).

Average number of citations per funding body	77.7

[a]Total, n indicates that the respective parameter has been cited n number of times, as in 296 publications have been cited 9379 times.

The average publication age was 14.2 (SD 11.8) years, ranging from the oldest in 1975 [171] to the most recent in April 2024 [152]. From 1975 onward, there has been a steady increase in publications using AHDs to address health issues in farming populations, with an AGR of 5.2%. Notably, almost one-third of these articles (91/296, 30.7%) were published in the last 5 years, highlighting the rising interest in AHD-based public health research in this population (Figure S2 in Multimedia

XSL•FO
RenderX

Appendix 1). Collectively, the publications received 9379 citations, averaging 31.7 citations per publication. Figure S3 in Multimedia Appendix 1 presents the historical direct citation network. The body of work involved 1225 authors from 338 institutions, with 1882 author appearances and an average of 6 authors per paper (Table 3). Four (1.4%) out of the 296 publications were single-author publications. On average, each paper cited 30 references.

Studies were led by authors from 34 countries, predominantly high-income nations, with 24.3% (72/296) of studies involving multicountry collaborations (Figure S4 in Multimedia Appendix 1). US-based authors contributed the most publications (91/296, 30.7%), followed by authors based in France (71/296, 24%) and Finland (35/296, 11.8%). US authors also had the most citations (3495/9379, 37.2%), with France and Finland ranking second and third, respectively.

Of 296 publications, the 25 (8.4%) most cited ones, appearing in 17 different journals, received between 83 (83/9379, 0.9%) and 485 (485/9379, 5.2%) citations (Table S5 in Multimedia Appendix 1) [150,172-196]. Of these 25 publications, 10 (40%) were published before 2000, another 10 (40%) between 2000 and 2010, and 5 (20%) after 2010. Most of these studies focused on cancer risk (16/25, 64%), while others investigated neurodegenerative disorders (5/25, 20%); respiratory conditions (2/25, 8%); and multiple health outcomes, such as sleep disorders, mental health disorders, and musculoskeletal disorders (2/25, 8%).

Table S6 in Multimedia Appendix 1 provides details on the most productive countries, prolific authors, active journals, institutions, and funding bodies.

Study Characteristics

Table 4 provides an overview of the included publications. Longitudinal study designs were the most common, including retrospective cohorts (129/296, 43.6%) and prospective cohorts (56/296, 18.9%). Case-control studies (62/296, 20.9%), cross-sectional studies (39/296, 13.2%), and ecological studies (17/296, 5.7%) were less common (Multimedia Appendix 2). A few studies (10/296, 3.4%) used multiple study designs [188,194,197-204].

The median follow-up period was 9.5 (IQR 5-17) years. On average, there was a 7-year gap (90% CI 3-14) between the most recent data used and the year of publication, with considerable variation depending on the publication year (Figure 2). The oldest data were from 1801 [205], and the most recent data were from 2022 [206]. Notably, one-third of the data used (98/296, 33.1%) were from before 2000, while nearly three-quarters (214/296, 72.3%) were from before 2015 (Figure S2 in Multimedia Appendix 1). Of 296 studies, only 10 (3.4%) used data from the last 5 years (from 2020), while 80 (27%) used data from the last 10 years (from 2015).

Studies were conducted in all continents, but most participants were from Europe (249/296, 84.1%), followed by North America (85/296, 28.7%), Asia (24/296, 8.1%), Oceania (17/296, 5.7%), Africa (4/296, 1.4%), and Central and South America (4/296, 1.4%). France (70/296, 23.6%) and the United States (67/296, 22.6%) were the most represented countries, followed by Finland (36/296, 12.2%), Sweden (32/296, 10.8%), Denmark (28/296, 9.5%), and Norway (26/296, 8.8%; Figure 3 and Figure S5 in Multimedia Appendix 1). Most studies had a regional or local scope (177/296, 59.8%), in particular, traditional epidemiological studies, such as Agriculture and Cancer (AGRICAN) [207] and Agricultural Health Study (AHS) [172], which used AHDs to either identify potential individuals for inclusion or enrich their cohorts.

Figure 2. Number of years between the most recent data used and publication for all included articles (1975-2024). Points refer to the average number of years or gap between the most recent data used and publication (x-axis) for each publication year (y-axis). Error bars refer to the 90% CI of the number of years between the most recent data used and publication.

XSL•FO
RenderX

Figure 3. World map of the number of publications per country of the farming population studied between 1975 and 2024.

Most studies included 1001 to 10,000 participants (67/296, 22.6%), followed by studies with 10,001 to 100,000 participants (65/296, 22%) and 100,001 to 1 million participants (53/296, 17.9%; Table 4). Larger studies (>1 million participants) accounted for 16.9% (50/296) of the included publications. Smaller studies, with 100 to 1000 participants, were less common (47/296, 15.9%), and very few (8/296, 2.7%) had <100 participants. Most studies included adult participants (284/296, 95.9%). Of 296 studies, 169 (57.1%) examined male individuals, 130 (43.9%) examined female individuals, and 188 (63.5%) examined both sexes, but 108 (36.5%) did not specify the participants' sex.

More than half of the studies (156/296, 52.7%) aimed to explore the relationship between farming activities (eg, dairy farming) and health events, while 131 studies (44.3%) focused on individual characteristics, such as occupation, age, sex, and socioeconomic status (Figure S6 in Multimedia Appendix 1). Among those studies examining individual characteristics, farming was often considered broadly and compared to other occupations (95/131, 72.5%). Conversely, in studies investigating health outcomes specifically related to farming activities, agriculture was treated as a broad category in only 27.6% (43/156) of the cases. Most studies (277/296, 93.6%) used the general population or other nonfarming groups as the reference category without differentiating farmers by job role (eg, farm managers vs farm workers). Descriptive statistics and multivariable regression were the most commonly used methods. Notably, only 2 studies (2/296, 0.7%) incorporated artificial intelligence (AI) in their analysis [208,209].

Few studies investigated health outcomes in farmers' family members or nonfarmers exposed to farming. Of 296 studies, only 3 (1%) focused on health events in farmers' partners [177,210,211], 5 (1.7%) on farmers' children [179,212-215], and 6 (2%) on nonfarmers exposed to farming-related risks [209,216-221]. There were 11 (3.7%) studies that explored health risks in migrant workers.

Some publications reported findings from the same cohorts (Figure S7 in Multimedia Appendix 1). The 10 most prolific cohorts included France-based AGRICAN (18/296, 6.1%) [207], the US-based AHS (17/296, 5.7%) [172], Nordic Occupational Cancer Study (NOCCA; 12/296, 4.1%) from Nordic countries (Finland, Denmark, Norway, Sweden, and Iceland) [189], France-based Tracking and Monitoring Occupational Risks in Agriculture (TRACTOR; 7/296, 2.4%) [222], and Cancer in the Norwegian Agricultural Population (7/296, 2.4%) [182] cohorts. Other notable cohorts included the US-based United Farm Workers of America (6/296, 2.0%) [223], France-based BALISTIC (5/296, 1.7%) [224], the international (29 countries) consortium agricultural cohort (AGRICOH; 4/296, 1.4%) [150,225], AIRBAg (4/296, 1.4%) from France [226], and the US-based National Agricultural Workers Survey (3/296, 1%) [227]. Among these top 10 cohorts, only NOCCA, United Farm Workers of America, and TRACTOR exclusively used AHDs.

AHD Use

There was high heterogeneity in the coding systems used and the granularity of the information available regarding health events (outcomes), population, and exposure determinants, depending on the AHD and study considered. Regardless of the publication reviewed, AHDs and other datasets were never reported as adhering to the findable, accessible, interoperable, and reusable (FAIR) data principles [228-230]. In addition, none of them could be considered as FAIR data because, with a few exceptions [222], most AHDs were not precisely described, and data availability statements were rare. Furthermore, mainly due to privacy concerns, AHDs were not available for open and free access.

XSL•FO
RenderX

The most commonly used AHDs were disease registers, used in more than half of the studies (158/296, 53.4%), followed by electronic health or medical records (124/296, 41.9%), insurance claims (106/296, 35.8%), population registers (95/296, 32.1%), and hospital discharge databases (41/296, 13.9%; Table 4). Among disease registers, cancer (120/158, 75.9) and mortality registers (75/158, 47.5%) were the most frequently used (Figure S8 in Multimedia Appendix 1 and Multimedia Appendix 2). Nearly one-third of the studies (91/296, 30.7%) relied on a single AHD, with disease registers being the most common (38/91, 42%), followed by insurance claims (29/91, 32%), electronic health or medical records (18/91, 20%), population registers (5/91, 5%), and hospital discharge databases (1/91, 1%). Other types of digital data were used less frequently, including pesticide registration records (13/296, 4.4%), job-exposure matrices (JEMs; 12/296, 4.1%), crop-exposure matrices (11/296, 3.7%), pesticide use records (8/296, 2.7%), climate data (7/296, 2.4%), and air quality data (2/296, 0.7%). While contextual data were sometimes used (9/296, 3.0%), person-generated data, smart agriculture data, and omics were never used.

The AHDs and other digital data were primarily used to obtain sociodemographic information (272/296, 91.9%) and health event data (269/296, 90.9%). They were also used to identify farmers (147/296, 49.7%) or individuals (140/296, 47.3%), gather occupational information (117/296, 39.5%), assess exposure (57/296, 19.3%), obtain data on farming activities (43/296, 14.5%), or track climate conditions (7/296, 2.4%).

Nearly two-thirds of the studies (181/296, 61.1%) relied exclusively on digital data (AHDs or other), while more than one-third (112/296, 37.8%) incorporated self-reported information/active data (requiring active participant involvement) as part of epidemiological cohorts. A total of 111 (37.5%) out of 296 studies used participant-completed questionnaires (paper or electronic) to gather sociodemographic data and confounding factors (98/296, 33.1%), assess exposure (96/296, 32.4%), or collect health information (83/296, 28%). Some information was obtained through interviews (44/296, 14.9%) or clinical examinations (32/296, 10.8%). Biological monitoring (24/296, 8.1%) and airborne monitoring (2/296, 0.7%) were sometimes used, whereas no study reported dermal monitoring (Figure S9 in Multimedia Appendix 1).

Among all the AHDs used, the Mutualité Sociale Agricole (MSA) is a singularity. To the best of our knowledge, it is the only AHD specifically dedicated to the entire farming population of a country. Indeed, MSA is the French national insurance scheme that covers the entire farming workforce (5% of the overall French population) [115,128]. MSA was used in 60 studies (60/296, 20.3%). These studies were often part of cohorts with multiple publications, such as AGRICAN (18/60, 30%), TRACTOR (7/60, 12%), BALISTIC (5/60, 8%), AIRBAg (4/60, 7%), Aging Multidisciplinary Investigation (2/60, 3%) [151], BM3R (2/60, 3%) [231], FERMA (risk factors of the rural environment and allergic and respiratory disease; 1/60, 2%) [232], and Phytoner (1/60, 2%) [233]. Of these, TRACTOR was the only cohort using exclusively MSA data [222].

Farming Exposure

A variety of exposure proxies were used to assess farming-related exposure. The most common proxy was a job title, which generally referred to whether the individual was a farmer (184/296, 62.2%). Other proxies included specific farming activities, such as dairy or crop farming (111/296, 37.5%), general pesticide exposure (yes or no; 62/296, 20.9%), and exposure to specific pesticide compounds (eg, glyphosate or paraquat) or pesticide classes (eg, insecticides; 51/296, 17.2%; Figure S10 in Multimedia Appendix 1 and Multimedia Appendix 2). The number of farming activities studied ranged from just 1 [226] to 78 [222], with an average of 8 farming activities per study. Similarly, the number of pesticide compounds assessed ranged from 1 [234] to 943 [235], with an average of 42 pesticides per study. Only 1 study investigated the mixture effect of exposure to multiple pesticide combinations on human health [236]. Investigations into other chemical exposures were also limited, with only 2 papers each addressing silica exposure [237,238] and air pollution [194,217] (2/296, 0.7%). Notably, no studies examined exposure to per- and polyfluoroalkyl substances or micro- and nanoplastics. Research on the broader farming exposome was rare (5/296, 1.7%) and typically used farming activities as proxies [152].

Of 296 studies, few explored exposure to physical agents, with 5 studies (1.7%) focusing on radiation [187,218,239-241]. No studies investigated the effects of climate change on farmers' health. Exposure to biological agents was rarely studied as well, with just 3 (1%) out of 296 papers addressing mycotoxins [241-243]. Finally, only 3 studies (1%) examined psychological factors related to farming exposure [244-246].

Health Events

The most frequently studied health events were cancer (142/296, 48%), followed by mortality (44/296, 14.9%), injuries (38/296, 12.8%), workplace accidents (32/296, 10.8%), respiratory disorders (30/296, 10.1%), neurodegenerative diseases (28/296, 9.5%), and mental health issues (26/296, 8.8%; Figure S11 in Multimedia Appendix 1 and Multimedia Appendix 2). Less frequently studied conditions included cardiovascular diseases (16/296, 5.4%), autoimmune disorders (11/296, 3.7%), musculoskeletal disorders (11/296, 3.7%), reproductive disorders (3/296, 1.0%), sleep disorders (1/296, 0.3%), and frailty (1/296, 0.3%). Notably, no studies explored the farming microbiome.

Among cancers, lung cancer was the most commonly investigated cancer (43/142, 30.3%), followed by prostate cancer (38/142, 26.8%), leukemia (37/142, 26.1%), colorectal cancer (35/142, 34.6%), multiple myeloma (35/142, 34.6%), non-Hodgkin lymphoma (35/142, 34.6%), bladder cancer (31/142, 21.8%), and brain cancer (31/142, 21.8%; Figure S12 in Multimedia Appendix 1). Respiratory disorders were primarily focused on asthma (15/30, 50%) and COPD (chronic obstructive pulmonary disease; 14/30, 47%). Parkinson disease was the most studied neurodegenerative condition (16/28, 57%), followed by multiple sclerosis (6/28, 21%). Fewer publications examined Alzheimer disease (2/28, 7%) and amyotrophic lateral sclerosis (2/28, 7%; Figure S13 in Multimedia Appendix 1). In the mental health field, suicide (12/26, 46%) and depression

XSL•FO
RenderX

(8/26, 31%) were the most investigated issues (Figure S14 in Multimedia Appendix 1).

Keyword Analysis

Overview

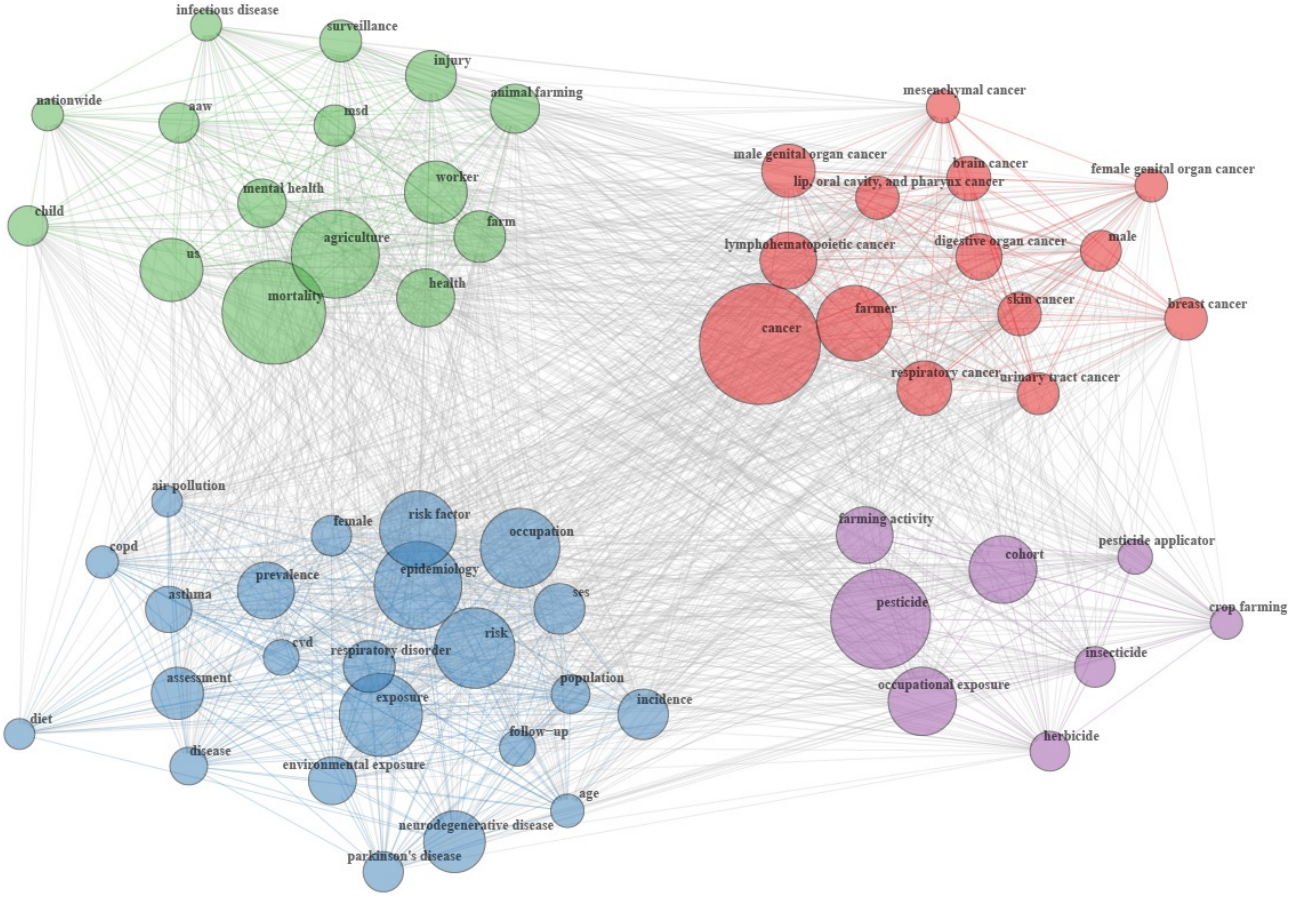
Following an initial extraction of 1259 authors' keywords, manual harmonization was performed. Duplicate keywords were removed through singular or plural standardization (130/1259, 10.3%) and synonym unification and grouping of cancer-related terms (553/1259, 43.9%), yielding a final set of 576 (45.8%) harmonized keywords, which were all used in subsequent analyses to prevent selection bias.

On average, each publication included 8.90 keywords (90% CI 0-17), although 35 (11.8%) out of 296 publications lacked any keywords, in line with the journal guidelines. Keyword analysis confirmed prior findings regarding farming exposure and health outcomes. It also provided deeper insights into emerging research hot spots, directions, and gaps.

Of the total 576 keywords, 301 (52.3%) appeared only once, while 68 (11.8%) were mentioned at least 10 times. More frequently used keywords included 39 that appeared at least 20 times (39/576, 6.8%) and 11 that featured in at least 50 publications (11/576, 1.9%). The 50 most frequently used keywords were mentioned in at least 17 (5.7%) out of 296 publications, while the top 10 appeared in at least 51 publications (17.2%; Table S7 in Multimedia Appendix 1). The most frequently cited keyword was "cancer" (150/296, 50.7%), followed by "mortality" (96/296, 32.4%), "pesticide" (88/296, 29.7%), "occupation" (82/296, 27.7%), "farmer" (77/296, 26.0%), "agriculture" (74/296, 25%), "exposure" (57/296, 19.3%), and "epidemiology" (57/296, 19.3%).

In terms of overall citations, "cancer" (5766/9379, 61.5%), "pesticide" (3569/9379, 38.1%), and "mortality" (3097/9379, 33%) were the most cited keywords. During the past decade, the frequency of the top 5 keywords has drastically increased (Figure S15 in Multimedia Appendix 1). Notably, keywords such as "cancer," "mortality," "occupation," "pesticide," "agriculture," and "farmer" have been consistently present in publications spanning at least 30 years (not necessarily consecutively; Figure S16 in Multimedia Appendix 1). In the last decade, emerging keywords, such as "big data," "administrative health database," "dust," and "BMI," have gained prominence (Figure S17 in Multimedia Appendix 1).

Keyword Co-Occurrence



A keyword co-occurrence network illustrating the frequency of keyword co-mentions in publications was constructed, thereby revealing relationships and conceptual connections (Figure 4). In this network, nodes or vertices represent keywords, with their sizes indicating frequency, while edges denote co-occurrences. The network's density and arrangement reveal topic interconnectivity, with larger vertices representing more frequently mentioned keywords. The network visualization helps identify clusters of related topics and highlights core research areas.

Using a community detection algorithm (spin-glass model with simulated annealing), 4 distinct clusters or communities of keywords were identified. Each cluster groups keywords that are often mentioned together, with stronger internal associations and weaker connections to keywords in other clusters.

The most frequently used keywords for each cluster were "cancer" (red cluster), "pesticide" (purple cluster), "mortality" (green cluster), and "exposure" (blue cluster). The red cluster highlights associations between various types of cancer, reflecting the fact that studies investigating cancer risks often examine multiple types of cancer. The green cluster links "mortality" with terms such as "mental health," "injury," and "animal farming," explained by the association between workplace accidents, mental health issues (eg, suicide), animal farming, and mortality. In the purple cluster, "pesticide" connects with "occupational exposure" and "farming activity," emphasizing that pesticide exposure is primarily studied in occupational settings across different types of farming. The blue cluster connects "exposure" to terms such as "neurodegenerative disease," "respiratory disorder," "cardiovascular disorder," "risk factor," "air pollution," "age," and "diet," indicating the study of various risk factors in relation to several health events. These clusters highlight current research hot spots that focus on 4 main interconnected themes: the associations between risk factors, pesticide exposure, farming activities, and a range of diseases.

XSL•FO
RenderX

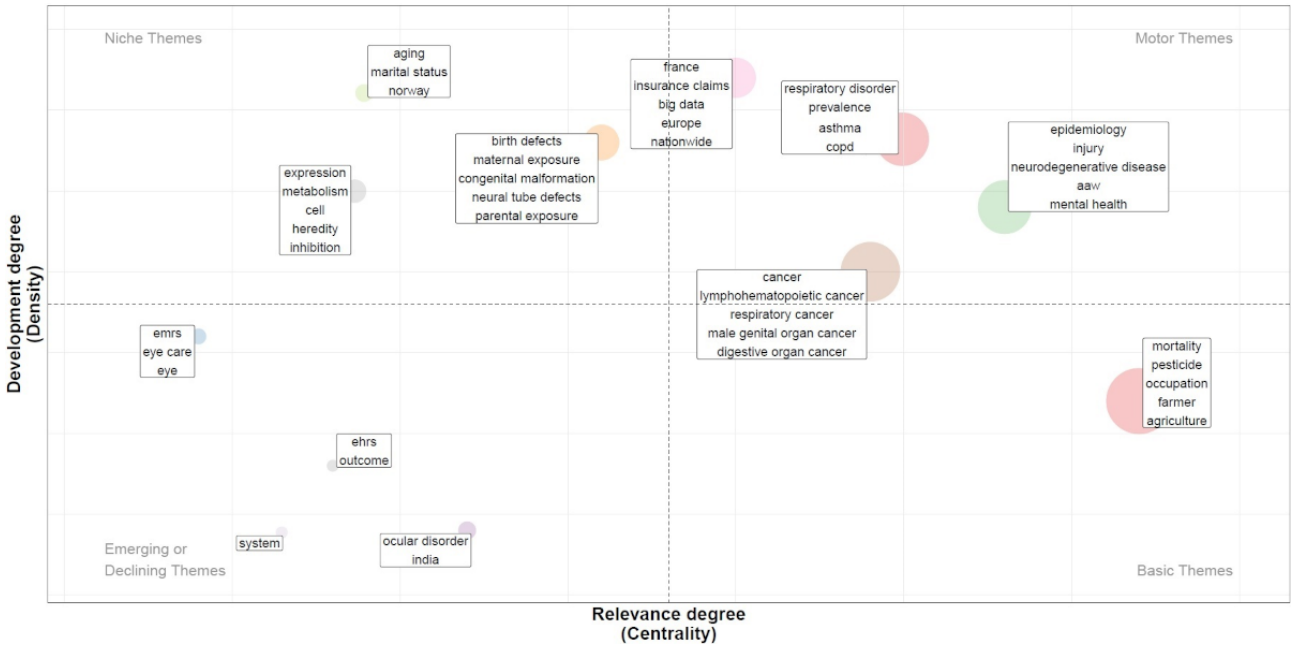
Figure 4. Keyword co-occurrence network of the 296 articles published between 1975 and 2024. Each vertex or node represents a keyword, while edges represent the co-occurrence between keywords. Two keywords are connected when they co-occur in the same publication, and the size of each vertex indicates the frequency of a keyword: larger vertices represent more frequently mentioned keywords. Keywords with the same color (cluster) represent a research area. AAW: workplace accident; COPD: chronic obstructive pulmonary disease; CVD: cardiovascular disorder; MSD: musculoskeletal disorder; SES: socioeconomic status.

Thematic Mapping: Research Hot Spots

Figure 5 presents a thematic map that illustrates current research directions. Thematic mapping visualizes the relationship between research themes or topics, enabling the identification of directions, emerging areas, and gaps in the literature. The result is a strategic diagram that shows how themes relate to each other and their relevance within a specific field. The graph is divided into 4 quadrants, categorizing topics based on their relevance (x-axis, Callon centrality) and maturity (y-axis, Callon density) within the broader research landscape. Each circle represents a theme or topic (ie, a cluster of equivalent keywords), with the circle size corresponding to the frequency of the keywords associated with that theme.

The upper-right quadrant represents “hot topics,” which are both highly relevant and mature in the research landscape. Four key hot topics drive AHD-based public health research in farming populations. These include 1 topic focused on cancer research; another on respiratory disorders; and a third encompassing neurodegenerative diseases, workplace accidents, injuries, and mental health issues. The final hot topic involves large-scale studies in France and Europe using big data and insurance claims.

The lower-right quadrant contains “basic topics,” which are relevant but not yet mature in the research landscape. Only 1 such theme emerged: research related to pesticide exposure, mortality, and farming.



In the upper-left quadrant, “niche themes” refer to mature research topics that have not yet achieved full relevance. Three niche themes were identified: the first involves studies examining aging and research conducted in Norway; the second focuses on reproductive disorders and parental exposure, a theme poised to potentially evolve into a hot topic; and the final niche theme covers genetics and metabolism.

Finally, the lower-left quadrant contains “peripheral topics,” which represent either emerging or declining themes with low relevance and maturity. Four peripheral topics were observed, of which 2 (50%) were primarily centered on research on ocular disorders, 1 (25%) on the use of electronic health or medical records, and 1 (25%) on studies conducted in India.

This thematic map helps highlight both well-established and emerging areas of research, as well as gaps that may be ripe for future investigation.

Figure 5. Thematic mapping: research hot spots based on keywords from the 296 articles published between 1975 and 2024. The graph shows how themes relate to each other and their relevance within a specific field. This graph is divided into 4 quadrants, categorizing topics based on their relevance (x-axis and Callon centrality) and maturity (y-axis and Callon density) within the broader research landscape. Each circle represents a theme or topic (ie, a cluster of equivalent keywords), with the circle size corresponding to the frequency of the keywords associated with that theme. AAW: accident at work; COPD: chronic obstructive pulmonary disease; EHR: electronic health record; EMR: electronic medical record.

Bibliometric Farming Exposome

To identify research directions and gaps in the farming exposome literature, a bibliometric keyword co-occurrence analysis was conducted to explore the farming exposome by examining the co-occurrence between keywords associated with potential risk factors and specific health outcomes. This analysis was restricted to exposome-related and health event–related keywords. Of 576 keywords, 130 (22.6%) were related to the exposome, among which 93 (16.1%) were related to the specific external exposome (eg, pesticide), 19 (3.3%) to the general external exposome (eg, climate), and 18 (3.1%) to the internal exposome (eg, oxidative stress). Furthermore, there were 70 (12.2%) health event–related keywords (eg, brain cancer).

The results of this analysis are provided in Tables 5 and 6 and Multimedia Appendix 3, with each cell representing the percentage of occurrences of an exposome-related keyword (eg, air pollution) in all publications mentioning a specific health event–related keyword (eg, Alzheimer disease). For example, a value of 33.3 indicates that an exposome-related keyword appeared in 33.3% of all publications mentioning a specified health event–related keyword. To facilitate interpretation and ease the reading of Tables 5 and 6, exposome-related keywords were categorized into 19 groups (eg, chemical agent) and health event–related keywords into 20 groups.

Distinct keyword exposome profiles were developed for each health event–related keyword (Figures S18-S43 in Multimedia Appendix 1), as illustrated in Figure 6 for mental health disorders. Most exposome-related keywords associated with keywords related to mental health disorders pertained to the type of occupations as well as chemical, lifestyle, socioeconomic, and psychological factors. Cancer-related keywords were associated mostly with keywords related to the internal (sex) and specific external exposome (chemical agents, lifestyle, and type of occupations). Autoimmune disease–related keywords co-occurred mostly with external exposome–related keywords (chemical agents, lifestyle, type of occupations, and socioeconomic factors). Neurodegenerative disease–related keywords were associated mostly with keywords related to the specific external exposome (lifestyle, chemical agents, and type of occupations). Reproductive disorders co-occurred mostly with internal (sex and BMI) and specific external exposome–related keywords (chemical agents and type of occupations). Keywords related to both musculoskeletal disorder and injury were associated with keywords from all 3 exposome components, in particular sex, type of occupations, lifestyle, biomechanical factors, chemical agents, and psychological factors. Infectious disease–related keywords co-occurred with specific external exposome–related keywords (biological agents and type of occupations), while respiratory disorder–related keywords were associated mostly with internal (sex) and specific external exposome–related keywords (lifestyle, chemical and biological agents, and type of occupations). Cardiovascular disorder–related keywords were associated with keywords from all 3 exposome components, in particular the sex, type of occupations, lifestyle, chemical agents, and socioeconomic and psychological factors.

Discussion

Principal Findings

This review provides the first comprehensive and objective synthesis of research on the use of AHDs to address health issues in farming populations. It identifies major contributors, key publications, and existing research gaps while also suggesting future directions for leveraging AHDs to study health issues in farming populations. Overall, findings indicate that only a small part of the exposome and a limited range of health events have been examined within farming populations through the reuse of AHDs.

Current Directions in AHD Use for Public Health Research in Farming Populations

Research using AHDs in farming populations has been predominantly conducted in developed countries [150,225], with the United States [172,223,227]; France [207,222,224]; Canada [145,186,195]; and Scandinavian nations [182,189], including Denmark, Finland, Norway, and Sweden, leading the field. This dominance is linked to considerable funding from these regions and international collaborations. Scandinavian countries are particularly advanced in AHD use, offering databases that are highly complete, accessible, and well-integrated into public health research. AHDs from Denmark, Sweden, Canada, and France also provide comprehensive data on a patient's digital trajectory within their respective health systems [93,98,104,108,113,115,128,247]. France stands out further, with an AHD dedicated specifically to the entire farming population (MSA). This may explain the frequency of large-scale and long-term studies from these countries, some of which included >100,000 participants. However, many studies still had a regional focus, partly due to the use of AHDs by traditional epidemiological studies such as AGRICAN [207] and AHS [172], which rely on limited resources [47-50,53,54,57]. These studies often used AHDs to identify farming populations for inclusion or to supplement cohort data. The international AGRICOH consortium, initiated by the US National Cancer Institute and the International Agency for Research on Cancer, includes 11 (38%) of the 29 cohorts identified in this review [150,225]. However, several cohorts in AGRICOH were not identified, potentially due to lack of publications, language barriers, or limited use of AHDs. There were many publications associated with these well-established cohorts, for which many of the most prolific authors were working [172,182,189,207,222-227].

The most frequently used AHDs in farming population health research were disease registers, followed by electronic health or medical records and insurance claims. More than two-thirds of the studies used disease registers, in particular, cancer and mortality registers. This is not surprising because disease registers are created for clinical and research purposes with a continuous, exhaustive, and optimal digital collection of individual data regarding ≥1 health event in a geographically defined population [53,105]. The coding systems and the granularity of information related to health outcomes, populations, and exposure determinants varied widely across studies. Most studies (291/296, 98.3%) used AHDs to collect sociodemographic and health event information [222].

There was no consensus on the best methods or proxies to assess farming exposure. A variety of exposure proxies and determinants were used across studies, with indirect methods being the most common. Many studies (237/296, 80.1%) dichotomized proxy, for example, classifying individuals as farmers or nonfarmers or as pesticide-exposed versus nonexposed. In nearly two-thirds of the included studies, job title (ie, "being a farmer") served as the primary exposure proxy. About one-third of studies took into account specific farming activities (eg, dairy farming and crop farming) to reflect the diversity of farming practices. This approach is a valuable proxy for agricultural exposure, offering a broader representation of the farming exposome, which involves multiple stressors beyond just pesticides [147,152,188,201,248,249]. Farming activity information was often derived from digitalized data, such as agricultural censuses or self-reported data from mandatory insurance enrollments [152]. Many studies (111/296, 37.5%) combined AHDs with self-reported data (eg, questionnaires) [172,207], which allowed for more comprehensive data collection but tended to restrict the scope to regional studies due to resource constraints. These studies typically yielded high-quality data, with more potential confounders considered compared to studies relying solely on AHDs. Most studies (68/111, 61.3%) using self-reported data focused on single exposures, mainly pesticides, with only 1 study addressing multiexposure to pesticides [236]. Biological monitoring and airborne chemical sampling were rarely conducted, likely due to practical and financial constraints and the short half-lives of most pesticides [250]. Dermal chemical monitoring has not been reported, even though it is the main exposure route for pesticides [251]. The high number of studies investigating exposure to pesticides may be explained by the fact that AHS focuses on pesticide applicators and their spouses [172] and because many pesticides have adverse health effects on humans, such as neurotoxicity or endocrine disruption [252-256]. Beyond pesticides, farmers face exposure to other chemicals [257], such as air pollution; micro- and nanoplastics [258-263]; biological agents (eg, endotoxins and zoonoses) [264-266]; physical agents (eg, UV radiation, noise, and vibrations) [187,267]; biomechanical factors (eg, repetitive movements, heavy load, and working posture) [198,268,269]; and psychosocial stressors [270-274], which have been less studied than pesticides. Despite these multiple exposures, the broader farming exposome remains understudied.

In addition to AHDs, some studies integrated other secondary data, such as climate data [187,275], air quality data [194,217], JEMs [212,276,277], or crop-exposure matrices [278]. JEMs provide exposure level estimates for various chemicals and stressors based on job categories [250,279]. Although JEMs can provide valuable exposure data, they often lack the specificity of individual-level data, making it difficult to account for task-specific risks, temporal variations, and the inclusion of specific worker subgroups such as female individuals [250,279-282]. The lack of a universal standard for JEMs further complicates their application, which may explain why many

XSL•FO
RenderX

studies still rely on self-reported data for more accurate exposure assessment despite the risk of recall bias [250,279-282].

The health outcomes studied were predominantly cancer [145,150,151,171-175,177-179,182,183,185,189,190,196,207,210-212,223], mortality [173,186,194,195,202,205], workplace injuries [198,208], respiratory disorders (eg, asthma and COPD) [151,180,181,213,224,226], neurodegenerative diseases (eg, Parkinson disease) [111,151,176,184,187,188,193,197,201,248,249,283], and mental health issues [151,244,273], which represent focal points within the research field. This is not surprising because many well-established cohorts centered on cancer research, in particular AGRICAN [207], Cancer in the Norwegian Agricultural Population [182], and NOCCA [189]. In addition, arsenic and inorganic arsenic compounds are classified as carcinogenic to humans by the International Agency for Research on Cancer [252,253,284], while malathion, glyphosate, diazinon, dichlorodiphenyltrichloroethane, and occupational exposures in spraying and application of nonarsenical insecticides are classified as probably carcinogenic to humans (group 2A), and several other pesticides are ranked as possibly carcinogenic to humans (group 2B), such as tetrachlorvinphos and parathion. Regarding mortality, it is often cancer and suicide mortalities that are investigated [186,195,202,244]. Furthermore, several pesticides are neurotoxic [252,255], but existing studies focused mainly on Parkinson disease and multiple sclerosis, with a paucity of data on Alzheimer disease and other neurodegenerative diseases [147,283]. In contrast, certain areas, such as cardiovascular diseases [151,194,203,227,285,286], autoimmune disorders [168,219,237], musculoskeletal disorders [192,204,245,287,288], reproductive disorders [242,289,290], sleep disorders [191], aging-related conditions [151,291], hearing impairment [267,292], and the microbiome [8,293-298], remain underexplored, despite their potential relevance to farming populations.

Challenges of Reusing AHD for Public Health Research in Farming Populations

Each AHD presents unique advantages and limitations. For example, large sample sizes and a large number of available health events are strengths, while generalizability and the absence of key confounders are challenges [64,93,95,105,115]. Access to AHDs is frequently restricted by a variety of factors, including governance and technical barriers, such as language, data structure, interoperability, and coding systems. Additional challenges stem from the type of AHD (eg, insurance claims or cancer registers), inadequate documentation (eg, absence of a data dictionary), limited accessibility due to costs or conditions, and jurisdictional and legal constraints [30,62,64,81,113,115]. Identifying the optimal AHD for a given research question is also complex, especially when considering the heterogeneity in coding systems and country-specific data structures. In countries such as Scandinavia, Canada, and France, individual identifiers facilitate data linkage across multiple AHDs, enhancing research opportunities [93,104,113,115,128,247]. However, many AHDs are not ready for research and require significant processing, cleaning, and understanding before they can be analyzed [93,105,113,222,299]. Another major challenge is the long lag between data access, analysis, and research publication. On average, studies used data that were 7 years old at the time of publication, largely due to delays in data access, administrative approvals, and the need to prepare complex datasets for analysis [223,300]. For instance, the TRACTOR project took 2 years to clean and prepare its dataset for research use [222]. These delays are compounded by the time required to conduct statistical analyses and prepare manuscripts for publication, as well as review and publication times (delay from submission to acceptance and from acceptance to publication). Another limitation of AHDs is the lack of detailed exposure data. AHDs rarely include exposure information due to their administrative focus, requiring researchers to supplement with additional data sources, such as JEMs or self-reported data. When exposure information is recorded in AHDs, it is often too generalized, typically only reflecting broad job classifications, such as farming, without specifying detailed activities or stressors. There are some exceptions, such as MSA data, which capture a wider range of specific farming activities (eg, dairy farming) [222]. However, exposure to specific stressors (eg, chemical compounds) is largely absent from AHDs.

The reference populations used in farming studies vary, which precludes direct comparisons and limits the generalizability of the findings. For example, AGRICAN used the general population as a reference [207], while TRACTOR used a farming population [152,168]. Furthermore, studies differ in their focus on specific farming populations, such as the entire agricultural workforce [207], farm managers [152], or pesticide applicators [172], which may lead to distinct exposure profiles that influence health outcomes because these farming populations have different socioeconomic status, experiences, and behaviors. Hence, to avoid or lessen bias, some studies focused on specific farming populations [152,172]. Moreover, the scope of farming populations included in studies is often limited, omitting subgroups, such as farm families, nearby residents, or consumers exposed to agricultural products, which limits the broader application of the findings. In addition, farming practices can vary significantly between countries and studies, and there is no international standardized classification for farming activities. In some cases, farming categories are derived from legal or administrative sources, as seen in the MSA data [152,168,283]. This lack of standardization limits the comparability and generalizability of findings across studies. In addition, the generalizability of the findings to other countries when using AHDs may be limited because of the differences in health care systems [93].

There are several well-known limitations of AHDs that complicate the investigation of health outcomes [301]. Health events captured in AHDs are typically limited to those requiring medical attention, which may not reflect the true incidence of diseases. In addition, the level of detail varies across diseases, even within the same AHD [92]. Although diagnostic accuracy is generally higher in disease registers, these are often geographically limited and cover only a subset of health conditions. For example, in France, cancer registers only cover 23 (24%) out of 96 administrative regions [155]. In addition, certain conditions, such as depression, are not covered by any registers. Identifying health outcomes in AHDs often requires complex algorithms that combine data from multiple sources,

XSL•FO
RenderX

such as drug reimbursements, disease declarations, or medical procedures [104,105,128,152,302-304]. In addition, inconsistencies in case definitions and algorithms across studies and countries hinder the ability to compare and pool risk estimates [104,302,304]. Some AHDs also lack critical clinical information, such as laboratory results and genetic data [115,128,305], and the recorded diagnosis or treatment date may not correspond to the actual onset of the disease. Furthermore, diagnosis codes are not always indicative of a confirmed diagnosis.

Emerging Opportunities and Research Needs

While AHDs are well-used in certain countries, there are underexplored opportunities in regions such as the United Kingdom, where AHDs exist but are underused for research [113]. For low- and middle-income countries, the development and access to AHDs remain limited, and international support is needed to expand this research infrastructure. As already reported by Habib et al [306], there is a notable lack of sex-specific data, even though occupational exposures and health outcomes can vary significantly between sexes due to genetic, physiological, psychological, and behavioral factors [307-311]. Future research should address these disparities to provide a more comprehensive understanding of health risks in farming communities. Although there are inherent delays in using AHDs due to the time required for data generation, consolidation, and access, we advocate for the continued publication of studies, even those using older data. Historical data remain vital for better understanding long-term health patterns, particularly for diseases such as cancer, where tumor initiation can span decades [312,313]. Editors should encourage the publication of studies using older datasets, especially when addressing long-term health outcomes (eg, cancer and neurodegenerative diseases) or when recent data are not available [312].

None of the analyzed AHDs fully adhere to the FAIR principles, possibly because most were developed before the establishment of these principles in 2016 [228-230]. Moreover, the assessment of FAIR compliance of AHDs relied solely on information presented in publications, which may not provide a comprehensive evaluation. Nevertheless, there is a critical need to advocate for the integration of FAIR principles within AHDs to enhance public health research [228-230]. Currently, the landscape is favorable for data reuse, particularly with initiatives such as the forthcoming European Health Data Space [314-316]. Data reuse extends beyond mere access; it encompasses data discovery, a fundamental aspect of FAIR principles that involves recognizing the existence of databases [228-230]. To facilitate this, the creation of data catalogs is essential [228]. Numerous data repositories, such as Re3Data [317], Zenodo [318], CANUE [319], Figshare [320], “Epidémiologie – France” [321], data.gouv [322], Dataverse [320], or Data Europa [320], already exist. In addition, specialized multidisciplinary open-access and peer-reviewed journals such as *Scientific Data* and *Data in Brief* publish datasets [318]. A dataset search can also be conducted using the Google (Google LLC) platform [323]. However, the documentation and access conditions for datasets can highly vary across inventories, complicating the selection process for researchers. The absence of indicators or scores for data reusability further hampers efforts to identify the most suitable datasets for specific research questions [45,69]. To our knowledge, no comprehensive catalog of AHDs currently exists to date. A web-based inventory of AHDs, modeled after existing resources, such as OccupationalCohorts.net [324], OccupationalExposureTools.net [325], and Toxicological and Exposure Database Inventory [10], could greatly enhance research endeavors. The motivation for analyzing AHDs often stems from the data they contain. Consequently, as data availability increases, researchers will be better positioned to formulate research questions and engage in a parallel process of “datagraphy” or “datagraphic search” akin to traditional bibliographic research. The objective of datagraphy would be to determine which datasets are best suited for addressing specific research questions, highlighting the need for accessible catalogs to support this goal.

There is also an opportunity to integrate other secondary data, such as person-generated data (eg, mobile health, social media, digital footprints, and wearable sensors); contextual data (eg, climate and air quality); and smart agriculture data [2,83,84,326-328]. These datasets, largely untapped in farming population research, could provide new insights into health outcomes and environmental exposures [101].

Nationwide studies using big data were a hot spot. AI, such as machine learning, is particularly useful for analyzing big data and holds substantial promise for future research [329-331], particularly for identifying predictors of health outcomes in farming populations [332]. To date, AI has been underused, with only 2 studies using it, 1 identifying occupational injuries in agriculture [208] and 1 reviewing the development of chronic kidney disease risk prediction models [209]. Incorporating AI, along with cohort enrichment and interdisciplinary expert interpretation, could open new avenues for research.

Many studies continue to examine agriculture as a broad category, highlighting the need for more detailed investigations into specific farming activities and tasks [147,152,188,201,248,249]. Our analysis reveals major research gaps in understanding environmental and occupational exposures among farming populations, particularly with regard to emerging concerns such as per- and polyfluoroalkyl substances, biological agents, micro- and nanoplastics, and the impact of climate change. Climate change is a critical issue for agriculture, as it may drive shifts in pests, diseases, and farming practices [274,333-339]. Parental exposure appears to be a theme that will soon become a hot topic. Furthermore, research is needed to explore the farming exposome, particularly focusing on the “mixture effects” of multiple simultaneous exposures [340,341]. Omics data, which have not been used in farming population studies to date, represent a promising avenue for future research because genetics and metabolism were found to be a niche theme. Omics data refer to the large-scale datasets generated from various omics technologies that analyze biological molecules (eg, genomics, transcriptomics, proteomics, and metabolomics), which provide comprehensive insights into different biological layers and processes [11,342,343].

To enhance the characterization of farming exposome research using keyword analysis, there is a pressing need for standardized keyword reporting. We advocate for the development of a

XSL•FO
RenderX

standardized approach to reporting keywords in scientific journals, including defining a minimum set of information (eg, study type, health outcome, population studied, data sources, and positive, negative, or null associations) and adopting a list of standardized terms. Although challenging, this approach would improve literature searches, make data more comparable and FAIR [228-230], and lead to more efficient, frugal (less time and energy spent to identify relevant information), and accurate synthesis of the scientific literature, such as in reviews and bibliometric analyses.

The prominence of topics such as cancer, neurodegenerative diseases, mortality, injuries, and mental health issues underscores the need for targeted prevention strategies. The thematic map analysis indicates that reproductive disorders (eg, birth defects, endometriosis, and infertility) are on the verge of becoming a central research focus. Emerging and understudied health conditions, including ocular disorders, autoimmune diseases (eg, inflammatory bowel disease and rheumatoid arthritis), sleep disorders (eg, sleep apnea), cardiovascular diseases, and musculoskeletal conditions (eg, low-back pain), warrant increased attention and further research. Aging-related health issues, such as frailty, also represent promising avenues for future research, particularly given the growing aging population and associated health care challenges [24].

Limitations

The findings of this review should be considered in view of their limitations. Because of time and resource constraints, a single screening approach was used, with only 1 author (PP) conducting the review and bibliometric analysis. While single screening is an efficient use of time and resources, there is a higher risk of missing relevant studies than when using dual screening [344,345]. However, when completed by an experienced reviewer familiar with the research topic, the proportion of missed studies is limited and estimated to be around 3% [344]. Therefore, we cannot exclude the possibility that some studies may have been missed. Nevertheless, we are confident that none of these methodological limitations would change the overall conclusions of this work. Our restriction on articles published in English and French may have inadvertently excluded potentially relevant publications. We cannot exclude the possibility that publications using AHDs for addressing health issues in farming populations may have been missed if there was no mention of AHD in the publications' titles and abstracts. However, it is important to mention that our search strategy was similar to recent reviews that specifically examined the use of AHDs for population-based research [93,96,103,104]. We further broadened our search by including synonyms to improve the comprehensiveness of our literature search. Some details and specificities on the AHDs and other digital data used may be limited because only information reported in each study was used. Shortcomings inherent to bibliometric analysis cannot be excluded. Some authors may have duplicate names, and namesakes could exist. This limitation could not be prevented as a unique author identifier (eg, Open Researcher and Contributor ID number) was not available. Self-citation could not be identified.

While our keyword analysis helped map the farming exposome in AHD-based public health research, this profile is incomplete and potentially biased. Because our review focused on AHD-based studies, we likely missed relevant epidemiological studies not using AHDs, leaving gaps in our understanding of the complete farming exposome across public health. In addition, the variability in keyword reporting practices across journals introduced bias into our keyword analysis. Some journals limit the number of keywords, and the lack of standardized keyword ontologies adds further variability. To mitigate this bias, we manually harmonized the keywords (eg, the use of 1 unique term for a given entity). While this approach is time-consuming, it allows for a more accurate analysis. For instance, if this approach was not performed, the same entity could be designated by various terms that would have been considered separate entities or terms, potentially resulting in underestimates (eg, in the number of publications). Despite these challenges, the findings from our scoping review were consistent with the keyword analysis.

Notwithstanding the aforementioned limitations, most of which are inherent to all scoping reviews and bibliometric analyses [93,96,103,104,158-160], we are confident that our findings can provide a comprehensive picture of what has been published until now (the current state of research and general directions) regarding the use of AHDs for addressing health issues in farming populations. This study may lay the groundwork for researchers to quickly identify research priorities and emerging research directions investigating health issues in farming populations using AHDs.

Conclusions

Technological advancements have greatly increased the volume of research data available, positioning AHDs as critical resources for population-based public health studies [41]. Our review underscores the broad public health implications of AHDs, providing actionable insights for researchers, physicians, and policy makers (Textbox 3). Addressing the identified research gaps is crucial to comprehensively understanding health risks in farming populations.

The insights derived from AHDs can inform meaningful recommendations for policy makers and guide future research directions, ultimately aiding health services and health policy development. Our findings underscore the necessity of comprehensive, interdisciplinary approaches to better understand and mitigate the health risks encountered by farming populations. Such efforts will improve data comparability and research quality while also supporting the formulation of targeted prevention strategies. This, in turn, will enhance health outcomes for farming populations and promote the sustainability of agriculture in an increasingly dynamic environment. The findings from this review offer insights that are not only relevant to farming populations but also potentially generalizable to other populations.

Textbox 3. Take-home messages.

Farming population

Research focusing on low- and middle-income countries, as well as on underrepresented subgroups within farming communities (eg, women, children, and contingent workers), remains insufficiently developed. These areas warrant further investigation to ensure more comprehensive insights.

Administrative health database (AHD) use

The use of AHDs in public health research among farming populations is expanding, offering major potential to enhance epidemiological studies and inform public health decisions. Promoting AHD-based research alongside the integration of other secondary data and artificial intelligence approaches represents a promising direction for future exploration. There is also a need to promote findable, accessible, interoperable, and reusable principles. Creating an AHD catalog or inventory could be a solution that would allow researchers to conduct a "datagraphic search" akin to traditional bibliographic research.

Farming exposure

Published studies on farming-related exposures often rely on broad proxies, such as job titles, neglecting to capture the nuances of specific agricultural tasks. While pesticide exposure remains a predominant research focus, emerging concerns, such as per- and polyfluoroalkyl substances, biological agents, micro or nanoplastics, and the effects of climate change, require urgent attention. The farming exposome remains underexplored despite its potential to uncover important associations between risk factors and a diverse range of health outcomes.

Health outcomes

Cancer, respiratory diseases, neurodegenerative disorders, and mental health issues are among the most frequently studied health outcomes in farming populations. However, significant gaps exist in understanding other critical conditions, such as cardiovascular diseases, reproductive disorders, ocular conditions, autoimmune diseases, musculoskeletal disorders, age-related health issues, and microbiome impacts. Addressing these overlooked areas is essential for a more complete understanding of the health risks faced by farming communities.

Acknowledgments

This work was partly funded by MIAI@Grenoble Alpes (Multidisciplinary Institute in Artificial Intelligence at Grenoble Alpes; grant ANR-19-P3IA-0003, 2019) and the French National Research Agency within the framework of the Investissements d'avenir program (grants ANR - 10 - AIRT - 05, 2012; ANR - 15 - IDEX - 02, 2016). The funding sources had no role in the study design and conduct of the study; collection, management, analysis, and interpretation of data; writing of the report; preparation, review, or approval of the paper; or decision to submit the paper for publication. The authors were not precluded from accessing data in the study, and all authors took final responsibility for the decision to submit for publication.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author upon reasonable request and also in the multimedia appendices.

Authors' Contributions

PP was involved in the conceptualization, methodology, software selection, validation, formal analysis, investigation, data curation, writing the original draft and reviewing and editing, visualization, project administration, and funding acquisition of the study. NV was involved in the conceptualization, reviewing and editing, resource collection, and funding acquisition of the study.
All authors meet all 4 criteria for authorship in the International Committee of Medical Journal Editors recommendations. All authors affirm that the manuscript is an honest, accurate, and transparent account of the study being reported; that no important aspects of the study have been omitted; and that any potential discrepancies from the study as originally planned (and, if relevant, registered) have been explained.

Conflicts of Interest

None declared.

Abstract

Background: Epidemics and outbreaks present arduous challenges, requiring both individual and communal efforts. The significant medical, emotional, and financial burden associated with epidemics creates feelings of distrust, fear, and loss of control, making vulnerable populations prone to exploitation and manipulation through misinformation, rumors, and conspiracies. The use of social media sites has increased in the last decade. As a result, significant amounts of public data can be leveraged for biosurveillance. Social media sites can also provide a platform to quickly and efficiently reach a sizable percentage of the population; therefore, they have a potential role in various aspects of epidemic mitigation.

Objective: This systematic literature review aimed to provide a methodical overview of the integration of social media in 3 epidemic-related contexts: epidemic monitoring, misinformation detection, and the relationship with mental health. The aim is to understand how social media has been used efficiently in these contexts, and which gaps need further research efforts.

Methods: Three research questions, related to epidemic monitoring, misinformation, and mental health, were conceptualized for this review. In the first PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) stage, 13,522 publications were collected from several digital libraries (PubMed, IEEE Xplore, ScienceDirect, SpringerLink, MDPI, ACM, and ACL) and gray literature sources (arXiv and ProQuest), spanning from 2010 to 2022. A total of 242 (1.79%) papers were selected for inclusion and were synthesized to identify themes, methods, epidemics studied, and social media sites used.

Results: Five main themes were identified in the literature, as follows: epidemic forecasting and surveillance, public opinion understanding, fake news identification and characterization, mental health assessment, and association of social media use with psychological outcomes. Social media data were found to be an efficient tool to gauge public response, monitor discourse, identify misleading and fake news, and estimate the mental health toll of epidemics. Findings uncovered a need for more robust applications of lessons learned from epidemic "postmortem documentation." A vast gap exists between retrospective analysis of epidemic management and result integration in prospective studies.

Conclusions: Harnessing the full potential of social media in epidemic-related tasks requires streamlining the results of epidemic forecasting, public opinion understanding, and misinformation detection, all while keeping abreast of potential mental health implications. Proactive prevention has thus become vital for epidemic curtailment and containment.

Introduction

Background

The global community braved the COVID-19 crisis, with multiple emerging variants, more than 6 million deaths, and 764 million cases being registered [1]. COVID-19 was dubbed "an individual and collective traumatic event," and has "directly or indirectly affected every individual in the world" [2]. Four years later, the world is still grappling with the emotional and socioeconomic aftermath of this crisis [3].

However, COVID-19 has not been the first crisis of its kind to affect global public health. Multiple epidemics have spanned the last 2 decades, causing varying degrees of instability and disease burden [4]. An epidemic is defined as "the occurrence in a community or region of cases of an illness, specific health-related behavior, or other health-related events clearly in excess of normal expectancy" [5]. When an epidemic "occurs worldwide or over a very wide area, crosses international boundaries, and affects a large number of people," it qualifies as a pandemic [5].

Epidemics are often linked to major feelings of uncertainty and loss. The 2014 Ebola outbreak caused rampant fear behaviors in West Africa [6]. The SARS outbreak has created a range of psychiatric conditions, including posttraumatic stress disorder, depressive disorders, and other anxiety spectrum disorders, such as panic, agoraphobia, and social phobia [7]. COVID-19 was associated with major stigma and psychological pressure, further aggravating feelings of guilt, shame, regret, sadness, self-pity, anger, internalized emotions, overwhelmed feelings, negative self-talk, unrealistic expectations, and perceived sense of failure [2]. During epidemics and outbreaks, mistrust of governments and health workers, misinformation, rumors, and conspiracies [8] present challenges to containment and can have a negative impact on mitigation efforts [9-11]. The particular vulnerability surrounding epidemics could render social media users highly suggestible and at risk for fake news acceptance and dissemination [12]. The substantial financial and medical burden imposed by outbreaks and epidemics, in addition to the substantial challenges arising in their progression and aftermath, further complicates the mental health toll they take on the affected population and on vulnerable communities [13].

The control strategies put in place in public health crises to contain the spread of infection are highly dependent on the transmission method and rate [14]. For instance, during COVID-19, various containment measures were adopted, including school closures, shut-downs of nonessential businesses, bans on mass gatherings, travel restrictions, border closures, and curfews [14]. These measures, although necessary for mitigation, can worsen emotional states, contribute to the exacerbation of preexisting socioeconomic inequalities in mental health [15], and lead to unhealthy coping mechanisms, such as problematic internet use, social media addiction, and emotional overeating [16-18].

During epidemics, social media platforms fulfill various functions ranging from informational support to emotional and peer support [19]. They are often a solemn companion offering a tool for connection, a space to grieve, and an instrument of outrage [19]. It is not surprising that the use of social media platforms massively increased during the COVID-19 pandemic [20], rendering them almost essential, ubiquitous, and a catalyst for change, for better and for worse [21].

Social media platforms offer significant amounts of data that can be leveraged for biosurveillance and syndromic surveillance of epidemics and outbreaks [22]. Biosurveillance provides early warning and situational awareness of events using diverse data streams [22]. Efforts directed at facilitating both the early detection and forecasting of disease outbreaks have been increasing in the past 2 decades [22]. Through the analysis of a variety of data sources, syndromic surveillance aims to discern individual and population health indicators before confirmed diagnoses are made [23] using trackable or exhibited behavioral patterns, symptoms, signs, or laboratory findings [23].

Understanding how social media shapes our experiences and preparedness during epidemics, and characterizing the roles it can fulfill, could allow for an improved apprehension of how to efficiently harness this resource for prevention efforts or alleviation of burden of disease [24].

Literature reviews have shown interest in understanding the roles social media fulfills during times of crisis, especially in the last decade [12,25-27]. Social media roles related to the facilitation of public health management, prevention of misinformation, and management of public health behavior and response were found to be of utmost priority [24], and social media topics related to surveillance and monitoring of public attitudes and perceptions, as well as mental health, misinformation, and fake news, were found to be the most well-developed research topics [28]. These 3 particular facets of social media's intersection with epidemics have not been approached in existing reviews; therefore, a gap remains for the research questions (RQs) proposed in this systematic literature review.

This Review

This review aimed to examine the "epidemic-social media" relationship and delineate its various aspects, as well as identify the methods used in harnessing social media in epidemics, with a particular focus on monitoring and surveillance, misinformation, and mental health. In light of the current state of global public health, it is vital to understand how a tool as influential as social media can shape the population's response in times of crisis and how it can be leveraged.

This systematic literature review outlines 3 RQs as follows: (1) How is social media harnessed for epidemic monitoring and management? (RQ1); (2) How is social media used for capturing and managing misinformation during epidemics? (RQ2); and (3) How is social media related to mental health during epidemics? (RQ3).

The remainder of this paper is organized as follows. Methods pertaining to the search strategy and extraction process are detailed in the Methods section. Results of the systematic review are synthesized in the Results section. Discussion of the major issues and practical implications as well as identified directions

XSL•FO
RenderX

for future research are presented in the Discussion section. Conclusions are summarized in the Conclusion section.

Methods

Overview

This systematic review builds upon the preferred reporting items outlined in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement [29] (Multimedia Appendix 1).

Proposed RQs

The RQs proposed in this systematic literature review examine the epidemic-social media relationship from different perspectives. The first RQ aims to identify potential uses of social media in the context of epidemic management and mitigation. The second RQ examines potential methods used in the context of social media misinformation as it relates to epidemics. Furthermore, the third RQ aims to discern potential aspects of the relationship between social media and public mental health during epidemics.

Search Strategy

A systematic literature search was undertaken at the beginning of June 2021. A collaborative planning and task allocation process was developed and updated at each stage of the study. The systematic search was conducted across multiple digital libraries—PubMed, IEEE Xplore, ACM Digital Library, ScienceDirect, MDPI, ACL, SpringerLink, arXiv, and ProQuest. Gray literature sources (arXiv and ProQuest) were used to complement the search and reduce publication bias as they provide a venue for authors to share studies with null or negative results that might otherwise not be disseminated.

The RQs were used as a guideline to identify search keywords. The search terms used included “social media” and “epidemics,” with variations depending on the RQ’s objectives and the database searched. For RQ1, the search results of the query (“social media” AND “epidemics”) were complemented by the results of the query (“social media” AND “epidemics” AND “monitoring” AND “tracking”). The combination of these 2 queries allowed for result-filtering without overlimiting the output. The query (“social media” AND “epidemics” AND “fake news”) was used for RQ2. A combination of the queries (“social media” AND “epidemics” AND “mental health” AND “support system”) and (“social media” AND epidemic AND “mental health” AND addiction) was used for RQ3.

These queries were adapted to each database based on its settings. All searches used the parameters *full-text* or *all metadata* in the queries. All searches covered the time range 2010 to 2022.

Table 1 details the number of publications (without duplication) retrieved for screening from each database for each RQ.

Table 1. Output of search strategy for research questions (RQs) 1, 2, and 3.

Database	RQ1	RQ2	RQ3
IEEE Xplore	259	27	54
ScienceDirect	1180	371	240
SpringerLink	2189	367	2188
ACL	90	20	121
ACM Digital Library	672	923	1795
MDPI	178	113	70
arXiv	1544	5	0
ProQuest	226	26	127
PubMed	54	149	217

Study Selection and Data Extraction Strategy

At the initial screening stage, 3 authors assessed the titles and abstracts against the inclusion criteria. Publications included after this screening stage were then retrieved in full-text version, and subsequently screened in the eligibility stage. Three of the authors read the full-text articles independently to ascertain their relevance with regard to the search terms and the research aims. All disagreements on the included articles were resolved by consensus.

To organize the screening process, Rayyan [30], a web application facilitating the collaborative review process and screening process for systematic literature reviews, was used by the authors to import all articles initially collected and screen them following a “blind on” setting, where decisions and labels of any collaborator were not visible to others. Publications with inclusion disagreements were then identified after dropping the “blind on” setting and resolved among authors.

The inclusion and exclusion criteria specified the aims of the review and were agreed upon by all authors (Textbox 1). For a publication to be selected, it needed to address the RQs and be published within the time range. The publication was excluded if it was not a journal paper, conference proceedings paper, or peer-reviewed workshop or symposium paper. Long abstracts and posters were excluded. Publications related to the HIV or tuberculosis epidemic were excluded to preserve the homogeneity of the review. Tuberculosis is a bacterial infection with a high burden of disease, especially in developing countries, while HIV is the virus responsible for AIDS [1]. Both tuberculosis and HIV or AIDS are classified as ongoing worldwide public health issues by the World Health

XSL•FO
RenderX

Organization (WHO) and the Centers for Disease Control and Prevention [1]. Given the particularities of both tuberculosis and HIV or AIDS and the high volume of literature review publications related to them [31], the authors agreed to consider both beyond the scope of this review.

Textbox 1. Inclusion and exclusion criteria for the study selection process.

Inclusion criteria for studies

- Within the scope of one of the research questions
- Published between 2010 and 2022
- Relates to an epidemic or pandemic within the last 2 decades
- Includes the use of a social media site
- Is a journal, conference, or workshop paper

Exclusion criteria for studies

- Tuberculosis, HIV, or, noninfectious diseases
- Online forums or traditional media
- Book, e-book, letter to editor, magazine, abstracts, case reports, comments, reviews, or poster

In the data extraction stage, the final list of papers was analyzed to answer the RQs and extract pertinent information. The final stage of the PRISMA guidelines [29] was considered in this phase. The following data were extracted from selected papers: authors, publication year, epidemic studied, social media site used, theme, identified method, and key findings. All the related data were extracted independently by 2 investigators. When necessary, differences were resolved by discussing, examining, and negotiating with a third investigator.

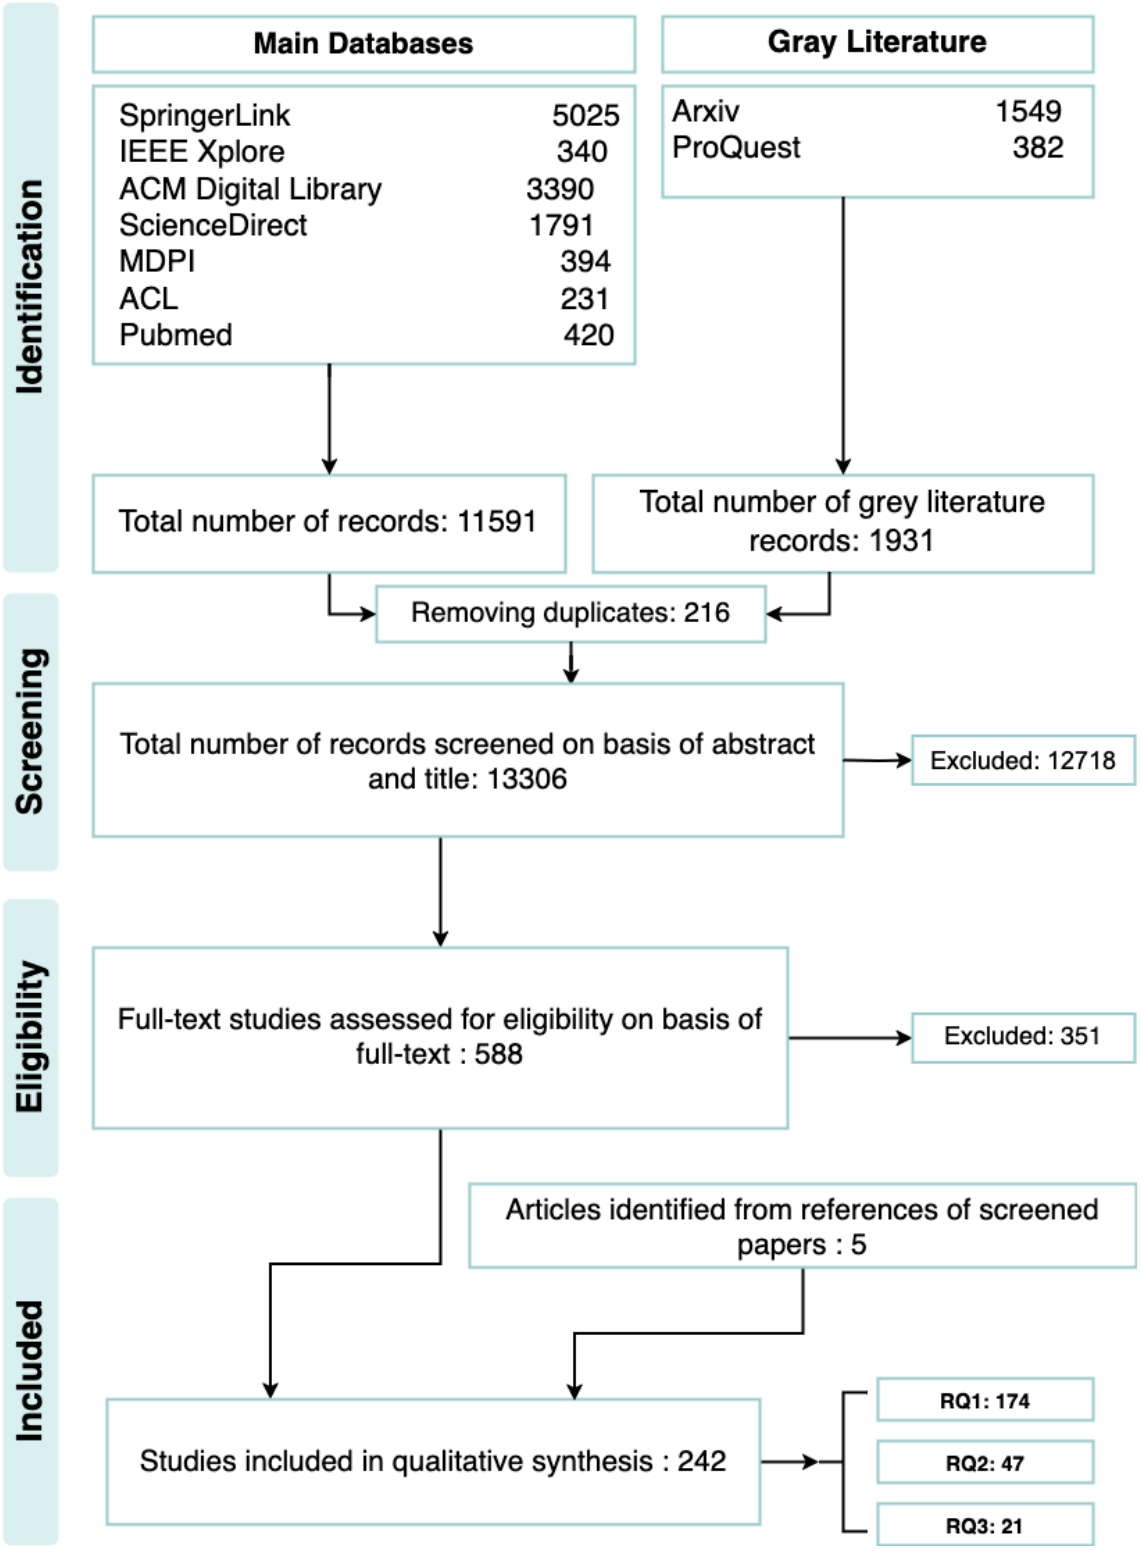
Quality Assessment

The quality of the included studies in this review was appraised using a set checklist of quality criteria. Papers that did not fulfill at least 4 out of the 5 quality criteria were excluded. The checklist was defined as follows:

1. Are the study objectives clearly defined?
2. Are the methods clearly defined and applied?
3. Are the methods applied successfully and correctly?
4. Are accuracy values and efficiency and confidence levels reported?
5. Are limitations clearly reported and adequately represented?
6. Do the contributions outweigh the limitations of the study?

The quality criteria were formulated based on our understanding of the current state of research in this field and the research gap this systematic review is attempting to fill. The papers were assessed for their ability to answer the RQs and enrich the literature while fulfilling quality standards.

Bias was evaluated in this systematic literature review from 2 aspects. First, the risk of bias based on inclusion was limited through the use of multiple reviewers. Second, publication bias was limited by including gray literature which reports negative and null results. To enhance the quality of this review, the authors monitored the planned review tasks and ensured continuous progress monitoring. Collaborative worksheets were created to keep track of scheduled tasks and deadlines, and to note pertinent observations. Validation of the extracted data from selected papers was conducted by the authors and peer-reviewing was maintained at every stage of the systematic review process.



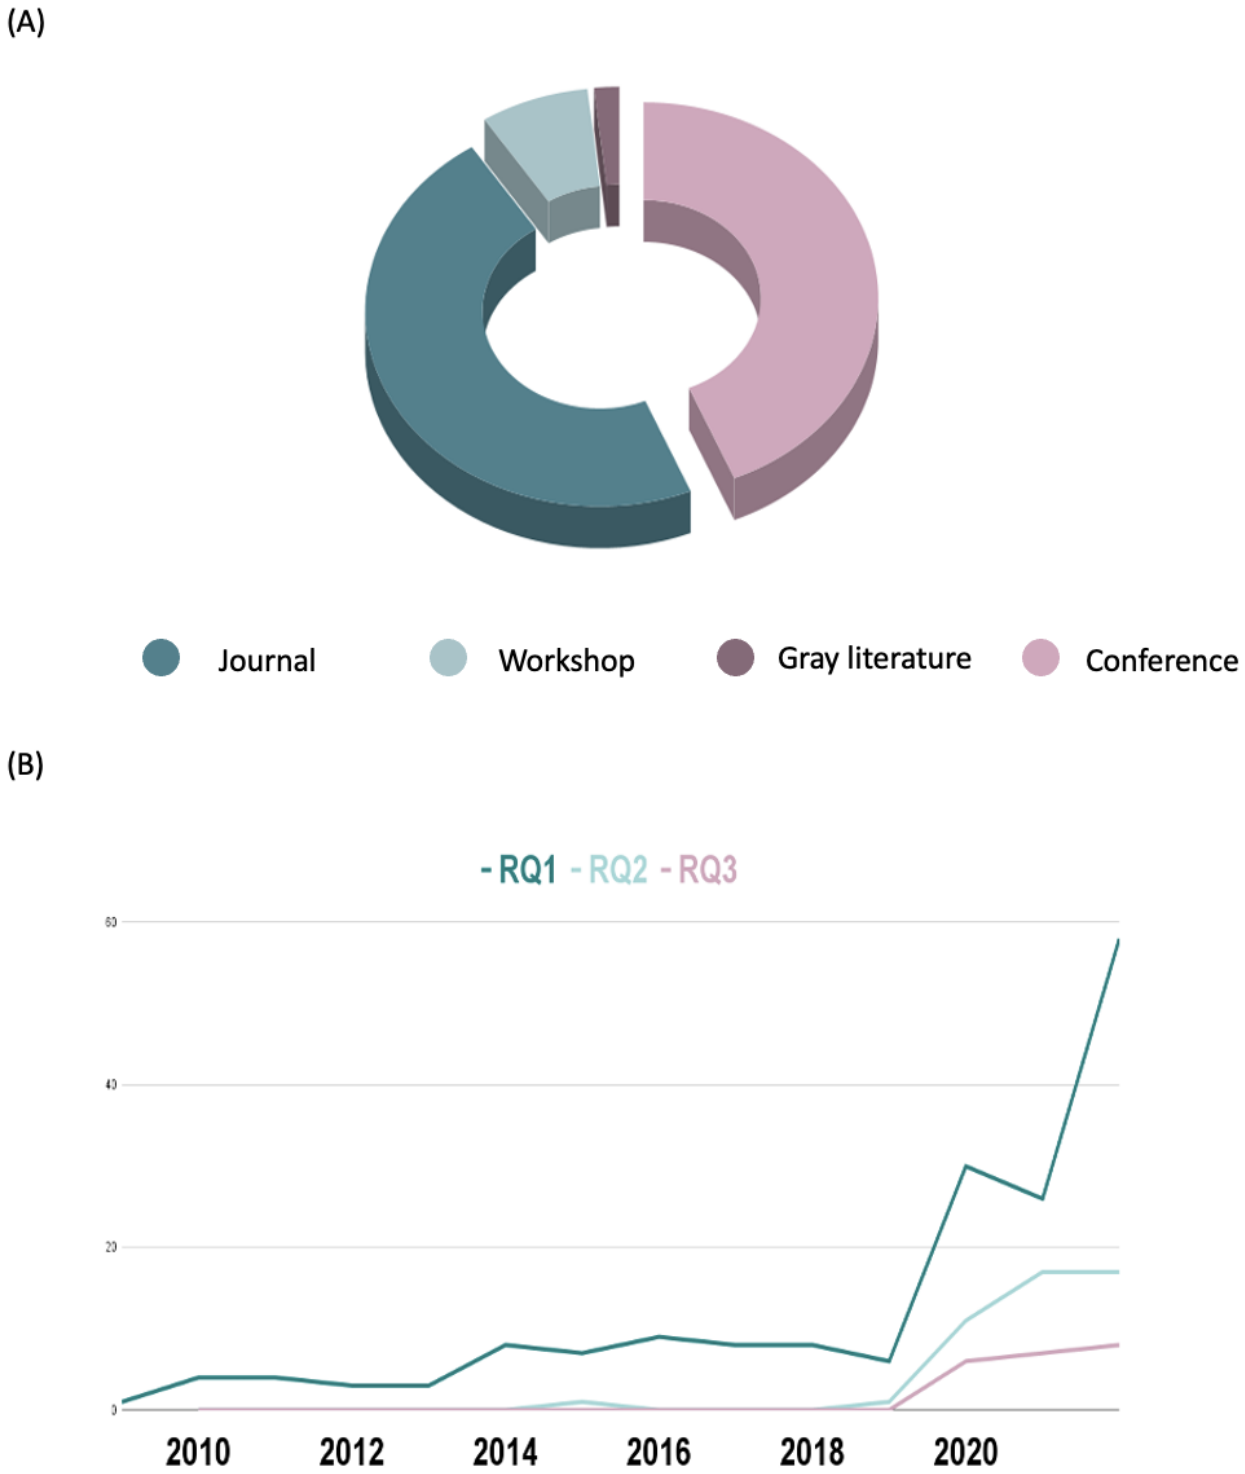
Results

Characteristics of the Selected Papers

The search process resulted in a total of 13,522 articles distributed over both the main and gray databases used. After the removal of duplicates, 13,306 (98.4%) titles remained. Of these, 12,718 (95.58%) studies were excluded after the title and abstract screening, as they did not fulfill the inclusion criteria. A flow diagram of the results of literature collection, screening, eligibility, and inclusion is presented in Figure 1.

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram for the selection of articles of the literature reviewed. RQ: research question.



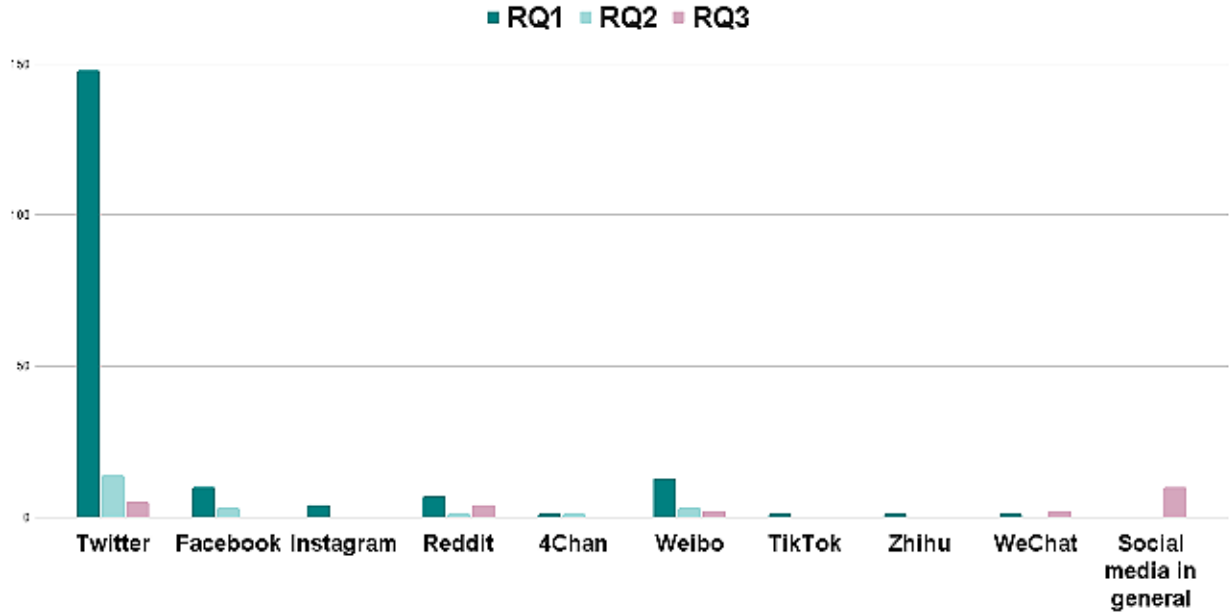
Of the 588 studies that were full-text screened, 351 (59.7%) did not meet the inclusion criteria. 5 (1.4%) papers were identified from reference lists of included papers. A total of 242 (67.9%) studies were selected for inclusion in this review as summarized in subsection Answers to RQs.

The papers included in the review were distributed as follows: 47.1% (114/242) were journal papers, 43.8% (106/242) were publications of conference proceedings, 7.4% (18/242) were workshop and symposium publications, while 1.7% (4/242) were gray literature (Figure 2A).

XSL•FO
RenderX

Figure 2. Distribution of selected papers by (A) type and (B) year. RQ: research question.

The publications spanned from 2010 to 2022. As can be seen in Figure 2B, the number of publications peaked in 2020 and continued to increase for all RQs. All the selected papers that answeredRQ3 spanned the from 2020 to 2021. A similar distribution was seen in papers that answeredRQ2, where selected papers were from 2015, 2019, 2020, and 2021. RQ1, which studies the aspects of epidemic management and mitigation using social media, included the highest number of papers and spanned the entire decade.



Social Media Platforms Used

Several social media platforms were used in the literature selected for this systematic review. X (formerly Twitter) is one of the most widely used platforms for sharing "microblogs." These short messages are called tweets and can take up to 280 characters. In contrast, Weibo, is a popular platform to share and discuss individual information and life activities as well as celebrity news in China. As can be seen in Figure 3, X followed by Weibo seems to be the platform of choice for most works aiming to study epidemic monitoring and mitigation through

XSL•FO
RenderX

social media (RQ1) and epidemic-related misinformation on social media (RQ2). For epidemic and social media–related mental health aspects, most works seem to take a generalist approach rather than a platform-specific one. Compared with other social media sites, such as Facebook and Instagram, which predominantly include heterogeneous posts, X offers a more concise "microblog" format.

Figure 3. Number of selected publications using each social media platform included in the systematic literature review. RQ: research question.

Epidemics Studied

The selected literature discussed multiple epidemics (Figures 4 and 5), including vital hemorrhagic fevers and influenza-like illness (ILI).

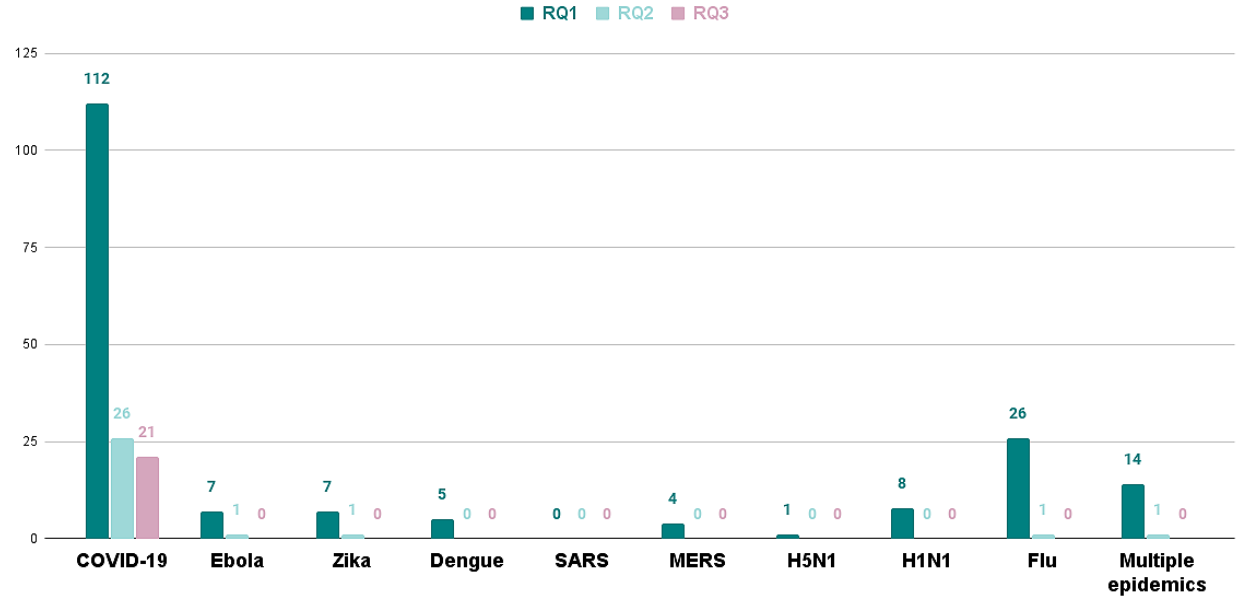
Dengue fever and Zika fever are mosquito-borne diseases caused by the dengue virus and Zika virus, respectively, and spread by several species of female mosquitoes of the Aedes genus [1]. The disease is now endemic in more than 100 countries with potential risk in other areas [1,32]. The WHO declared the Zika outbreak of 2016 and the Ebola outbreak in 2019 as public health emergencies of international concern (PHEICs) [1].

ILI is a nonspecific respiratory illness characterized by fever, fatigue, cough, and other symptoms. Cases of ILI can be caused either by influenza strains or by other viruses, such as coronaviruses. Influenza remains a global and year-round disease burden and causes illnesses that range in severity and sometimes lead to hospitalization and death. Seasonal influenza epidemics are mainly caused by influenza A and B viruses [1]. The influenza A virus subtype strain H1N1, commonly referred to as the swine flu, disproportionately affects children and younger people. H1N1 was declared a PHEIC in 2009 and then designated a pandemic [1]. Coronaviruses include SARS, MERS (Middle East respiratory syndrome), which can be contracted through direct or indirect contact with infected animals [1], as well as COVID-19 caused by the SARS-CoV-2 virus. The latter was designated a PHEIC and a pandemic by the WHO. As of April 26, 2023, the official death toll from COVID-19 reached 6,915,268 [1].

The highest number of selected publications for all RQs related to COVID-19, followed by influenza (Figure 4). This trend is due, in part, to the volume of the COVID-19 research output [33].

XSL•FO
RenderX

Figure 4. Number of selected publications pertaining to each epidemic included in the systematic literature review. MERS: Middle East respiratory virus; RQ: research question.



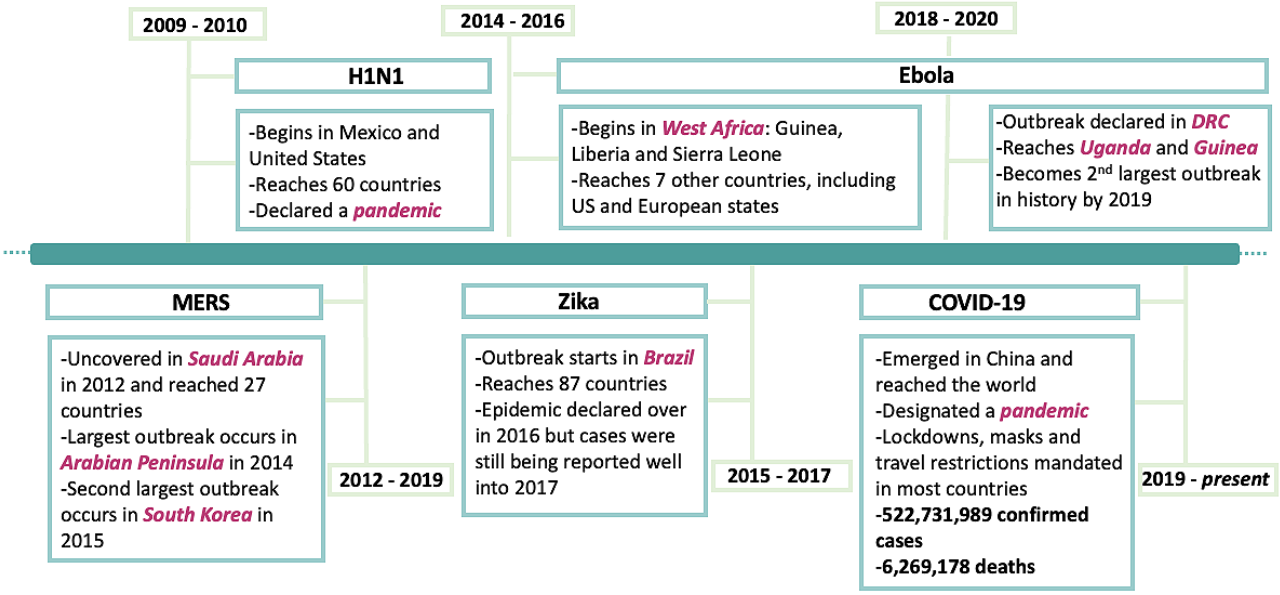


Figure 5. Timeline of the epidemics and pandemics spanning the last decade and included in the systematic literature review. SARS is pre-2009 and dengue fever has caused multiple outbreaks. Both are not illustrated in the timeline but are included in the systematic literature review. DRC: Democratic Republic of the Congo; MERS: Middle East respiratory syndrome.

Answers to RQs

Overview

A thematic analysis of the selected literature was conducted with the aim of identifying the main themes of each RQ. Themes were identified following the objectives of the paper and its results. For each theme, papers were organized by method, social media platform used, and the epidemic studied. Methods were grouped categorically. For instance, content analysis includes automated, linguistic, thematic, qualitative, or quantitative analysis, while dictionary-based classification entails a lexicon-based classification. Machine learning (ML) classification includes conventional ML models, while deep learning (DL) entails methods based on artificial neural networks with representation learning. Although it must be acknowledged that overlaps exist, the categorization used in this paper is based on the most distinctive and predominant use or theoretical approach of each method. This categorization is meant to facilitate a structured analysis and discussion of the literature by grouping papers according to their primary methodological approach, thus allowing a clearer comparison and contrast of their contributions, strengths, and limitations.

RQ1. Social Media for Epidemic Monitoring and Management

Overview

Social media platforms offer significant amounts of data, which can be potentially useful in biosurveillance and syndromic surveillance of epidemics and outbreaks.

Two main themes were identified in the selected papers that addressed how social media could be used in epidemic management, namely, (1) *epidemic surveillance and forecasting*, and (2) *public opinion understanding*.

Epidemic Surveillance and Forecasting

Several works proposed a dictionary-based classification of X for the surveillance of COVID-19 [34,35], dengue fever [36,37], Ebola [38,39], H1N1 [40,41], influenza [42-50], Zika [51,52], MERS [53], and a combination of epidemics [53-55]. Similar epidemic surveillance applications using dictionary-based classification were conducted using data from Weibo for Ebola [56] and influenza [57,58], Reddit for Zika [59], and Facebook for MERS and other epidemics [53].

Reported results indicated that epidemic surveillance can be achieved using varying strategies. For instance, social distancing–related tweets can be grouped into categories, such as implementation, purpose, social disruption, and adaptation, and used to quantify the spatiotemporal prevalence and evolution of COVID-19 social distancing on X [34]. Similarly, official social media channels of information and health organizations, such as the Centers for Disease Control and Prevention, WHO, and National Institutes of Health (NIH) can be monitored, and their X data can be classified to recognize “alarming” news and “concerning” news [35]. Dengue fever reported surveillance strategies to include systems aggregating social media data with weather and flood information [36], and using volume, location, time, and public perception as spatiotemporal dimensions [37].

Results also reported keyword-based data extraction and classification as a strategy for the creation of an Ebola monitoring platforming in China using Weibo data [56] and in Africa using X data [39], and for multiple epidemics [53-55].

Regression analysis was reported to be used for tracking and forecasting influenza [46,47,49,57] and Zika [52], and the Markov switching model was used for real-time early-stage influenza detection with emotion factors for epidemic and nonepidemic segmentation [58]. Statistical analysis was used to study the relationship between human activities collected from Sina Weibo and morbidity patterns and at-risk areas during COVID-19 in China [60].

Correlation analysis reported that X, in addition to other sources, could not provide an Ebola alert more than a week before the WHO and that X’s message volume was correlated more with news article volume than with the number of Ebola cases [38].

Additional dictionary-based surveillance methods include quantitative analysis, filtering, and normalization of X data for H1N1 [40,41] and Zika [51]; mathematical modeling of influenza trends using geo-tagged X streams [42]; time series for X symptom reporting matching ILI [43]; keyword analysis for Zika risk assessment [59,61] as well as influenza risk surveillance [44] and condition aggravation [45], and upcoming influenza spike detection [50], sentiment analysis [48].

Different methodologies using conventional ML were reported to be used for dengue-related event monitoring [62] and lazy associative classification [63]; influenza detection [64-66]; influenza activity monitoring [67]; seasonal influenza trend prediction [68,69]; ILI prevalence prediction [70] and awareness or infection classification [71]; location-specific influenza state detection [58,72,73]; avian influenza outbreak detection [74]; disease-related category classification [75-77] for Ebola, MERS, and dengue fever; guideline-related category classification for ILIs [78]; supervised text classification [79]; topic classification for symptomatic manifestation and prevention of mosquito-borne diseases [80]; infectious disease analytics [81,82] and COVID-19 case forecasting [83], and X-enabled contact tracing [84] and early detection [85].

Conventional ML models used for epidemic surveillance and monitoring include support vector machine (SVM), naive Bayes (NB), and logistic regression (LR).

Several DL techniques were applied for epidemic monitoring [86-90]; fine-tuning of semisupervised model with unlabeled COVID-19 dataset [91]; disease-infected individual detection in tweets using bidirectional encoder representations from transformers (BERT)–based model and disease-infection region identification using spatial analysis [92]; classification of Zika- and Ebola-related tweets [93], COVID-19 related tweets [94], and influenza-related information [95,96]; H1N1 outbreak forecasting and individual-level disease progressing using semisupervised multilayer perceptron and a online stochastic training algorithm [97]; and correlation of X reports on H1N1 infectious disease control using gray wolf optimizer and least square method [98]. Results reported that mathematical modeling can be used to understand the influence of X on the spread of H1N1 [98,99] and information entropy to quantify the impact of social network information [100].

Results showed that social network theory and social network analysis can be used for the prediction of infected groups and early detection of contagious outbreaks in social media [101-104], and that topic modeling techniques, such as latent Dirichlet allocation (LDA) can be used for epidemic intelligence [105-110] to detect major epidemic-related events [111], monitor information spread [112], and rank epidemic-related tweets [113].

Understanding Public Opinion

Several methods were used in the selected literature to extract and analyze public opinions expressed on social media. These methods were based on content analysis of social media data, linguistic analysis, qualitative analysis, lexicon-based analysis, sentiment analysis, valence aware dictionary and sentiment reasoner–based sentiment analysis, topic modeling, conventional ML models, and DL models.

Social media content analysis was used to analyze public discourse around H1N1- [114] and Zika-related risks [61], inspect social media coverage related to influenza vaccinations [115] and COVID-19 vaccinations [116-127], measure public

XSL•FO
RenderX

health concerns [128], identify stances toward policies, such as social distancing and face masks [129], identify emotional composition of online discourse before and after COVID-19 [130], and inspect the presence and escalation of negative sentiments toward China [131]. Latent semantic analysis and LDA were used to mine opinions on X related to the hashtag #IndiaFightsCorona [132]. Topic detection and sentiment analysis were performed for opinion mining, concern exploration, and public opinion analysis in the context of epidemics [133-142], and for pattern analysis [143-145]. Social media content analysis was also used for tracking information spread [146], narratives and information voids [147], monitoring engagement [148-152] and emotional response [153-161], requests for medical assistance [162], health behavior changes [163], governmental response [164,165], and physicians' opinions [166].

Public reaction tracking and investigation were performed using SVM and NB for topic and sentiment analysis [127,167-175]; SVM, NB, and random forest (RF) for social media content classification (eg, caution, advice, notifications, donations, etc) [176]; crisis analysis [177,178]; clustering for topic extraction [179]; and LR for prevention category tweet classification [180]. ML was used to analyze public discourse against masks [181], extract insights on policy response [182], and understand expressions of help-seeking during COVID-19 [183].

BERT-based models were used for public sentiment assessment of data related to COVID-19 available in X [184-186]. Multilingual COVID-19 emotion prediction was performed using a fine-tuned BERT "BERTmoticon" [187], while bias and user opinion were identified using a GPT [188]. A language model for Arabic Moroccan dialect was used for topic modeling, emotion recognition, and polarity analysis [189]. long short-term memory (LSTM), BERT, and enhanced language representation with informative entities were used to analyze the evolution of sentiments in the face of the public health crisis due to COVID-19 [190]. Bi-LSTM with an attention mechanism was used for sentiment analysis of COVID-19–related tweets [191]. Term-frequency analysis was adopted to build an emerging topic graph [192], while the k-means algorithm, LR, SVM, and NB were used to identify COVID-19–related topics [193]. An extra tree and convolutional neural network-based ensemble model was reported to have outperformed conventional ML models in a sentiment classification task [194]. French COVID-19 tweet classification was performed using FlauBERT [195], while opinion monitoring was achieved using a combination of LSTM and global vectors for word representations [196]. Convolutional neural network was used for COVID-19 personal health mention detection [197].

Findings of analyses performed in the context of Ebola, Zika, and influenza revealed that social media posts from health organizations were highly effective when incorporating visuals and that public response was more affected by these communications when they acknowledged the concerns and fear of the community [198]. In the context of Ebola, findings highlighted that online blame was directed toward the affected populations as well as figures with whom social media users had preexisting political frustrations [199].

Analysis of X discussions in relation to COVID-19 revealed the presence of negative sentiments and an association between the words "coronavirus" and "China" [200]; a gradual increase in calls for social distancing, quarantining, and working from home among social media users [201]; a growing number of anger expressions directed at individuals refusing sanitary protocols; and the frequent use of the words "family," "life," "health," and "death" [201]. Analysis of X hashtags also revealed categories, such as quarantine, panic buying, school closures, lockdowns, frustration, and hope [201], as well as mentions of mental health issues and gratitude for essential workers [201]. Other categories and themes identified or used for manual annotation of topics discussed on social media include resource provision, employment and strategies [87], statistics, prevention, hygiene, diagnosis, politics, world news [202], conspiracy, economy, mortality, origin, and outbreak [203].

Findings also indicated increased levels of connectivity and agency coordination during the early-stage response to COVID-19 [87]. Disregarding COVID-19–imposed sanitary and government recommendations was potentially linked to uncertainty in times of crisis, overwhelm by "noise" presented on social media, and varying socioeconomic factors [204].

Results revealed that social media analytics were an efficient approach to capture the attitudes and perceptions of the public during COVID-19 as mentioned in studies by Yigitcanlar et al [205] and Xia et al [206]. Fear and collectivism were identified as predictors of people's preventive intention in the context of COVID-19 [207]. "Sadness" appeared to spike after the WHO declared COVID-19 as a pandemic, while "anger" and "disgust" spiked after the death toll surpassed the hundred thousand in the United States [187].

Tables 2 and 3 summarize the methods, epidemics, and social media used in studies pertaining to epidemic forecasting and prediction and understanding of public opinion.

RQ2. Social Media for Misinformation Management During Epidemics

Overview

Misinformation, or "fake news," has become a social phenomenon and has received increased attention in the past few years. Although the term, "fake news" has been around since the 1890s [208], the emergence and exponential rise in popularity of social media platforms has brought the term to the "front page." Fake news can fall into multiple categories depending on the intent and form it takes [208]. For instance, fake news can be false information and rumor fabrication (eg, celebrity gossip), hoaxes (eg, doomsday 2012), conspiracy theories (Q-Anon), and satire (eg, The Onion). The intent can range from deception for the purposes of monetary or personal gain to satirizing real news.

One main theme was identified in the selected papers that addressed how social media could be used in misinformation management during epidemics, namely, misinformation detection and characterization. Three subsequent subthemes were identified based on the scope of selected literature, namely: fake news identification, fake news characterization, and information distortion and conspiracy theories.

Misinformation Detection and Characterization

Overview

The selected literature focused on the inspection of news or claims shared on social media, with the aim of classifying them based on trustworthiness. Several methods were used to analyze social media content and detect misleading information, such as expert annotation, DL models, and social network analysis. While some papers focused on technical approaches to the detection of fake news, other studies tried to identify various characteristics related to the source or propagation of fake news.

Fake News Identification

Several works performed fake news identification using DL models [209-211] with conventional ML models for comparison or as baselines. A modified 3-layer-each LSTM and gated recurrent unit were used along with 6 conventional ML classification models (decision trees, LR, k-nearest neighbors, RF, SVM, and NB) on a "Covid-19 fake news Twitter dataset" [212] to identify fake news [210]. Findings reported that the best test results were obtained by LSTM (2 layers), with an accuracy of 98.6%, a precision of 98.55%, a recall of 98.6%, and an F_1-score of 98.5% [210]. Similarly, a multilayer perceptron, LR, decision trees, RF, NB, SVM, and gradient boosting were used for COVID-19 fake news detection in tweets and concluded that RF outperformed other models with an accuracy of 78%, a recall of 100%, a precision of 85%, and an F_1-score of 83% [211]. Expert annotated tweets were used to evaluate the performance of a BERT-based misinformation detection system [213]. Findings suggest that knowledge about the domain vocabulary helps domain-adapted models in predicting the correct stance, as it did for retrieval.

Detecting misleading and fake news was also performed by several studies using methods based on pretrained transformer models, bi-LSTM networks, artificial neural networks, convolutional neural networks, deep transfer learning [214-220], and using hybrid methodologies [221-227].

A semisupervised probabilistic graphical model that aimed to jointly learn the interactions between user trustworthiness, content reliability, and post credibility for influenza posts' credibility analysis outperformed baseline models (RF and Bayesian network) with an accuracy of 71.7% on data from Sina Weibo [209]. LR was performed on a small dataset of Facebook comments to detect fake news [228]. Several ML models, including gradient boosting classifier, LR, RF classifier, and decision tree classification were used in multiple works for fake news classification on social media [229-233].

Other works seeking to curtail the misinformation of COVID-19–related news and support reliable information dissemination used manual analysis through fact-checkers as well as consensus to verify the veracity and correctness of selected tweets and social media posts [234,235]. This is illustrated in a use case analyzing Facebook and X content in both English and Amharic [234] and an Ebola study [235].

XSL•FO
RenderX

Fake News Characterization

A manual annotation of tweet sources following 5 categories (academic, government, media, health professional, and public) allowed for the creation of a gold standard dataset for training a LR model based on 6 million Arabic tweets related to infectious viruses, such as MERS and COVID-19 [236]. Rumor detection using a top-down strategy consisting of extracting posts associated with previously identified rumors reported an 84.03% accuracy for the LR classifier [236]. Higher precision was obtained at the expense of higher runtime using ML models [232]. Similarly, topic modeling based on the k-means algorithm was used to identify sources of COVID-19–related rumors [193]. An entropy-based method was used to investigate the potential control of COVID-19 rumors [237] and content analysis was used to evaluate rumor dissemination and official responses during COVID-19 [238].

Semantic correlations between textual content and attached images were mined using a pretrained convolutional neural network to learn image representations and use them to enhance textual representations and train a fake news detector [239].

Content analysis showed that fake news from multiple sources could be classified using a taxonomy of health and non–health-related types and reported that the response of the public health system was debilitated by the propagation of fake news [240]. Roots of misinformation were categorized as politically related, false medical information, celebrity and pop culture related, religious belief related, and fraud and criminality related [241]. A comparison of fake news sources between China, Iran, and the United States showed that fake science is the main “root” of misinformation in China, while counterexpertise, that is, the rejection of mainstream academic expertise, politically motivated and governmentally sourced misinformation is the most prevalent source of fake news in the United States. In Iran, discourse about COVID-19 was found to be politically manipulated by the government, while official religious figures hindered the dissemination of accurate information [241]. Statistical analysis found bias of sentiment in fake news, as well as biases of gender of the user and media use with respect to real news [242].

Bot detection using BERT was performed as a potential strategy to improve fake news detection [243]. Findings imply that the ratio of real news to fake news is very similar between human accounts and bot accounts, and bot detection could not improve the performance of the fake news detection model [243].

Findings of an information mutation study using A Lite BERT reported that misinformation propagation could potentially be exacerbated by user commentary and found a positive association between information mutation and spreading outcome [244].

The findings of a propagation analysis showed that false claims propagate faster than partially false claims and that tweets containing misinformation are more often concerned with discrediting other information on social media [245].

An investigation leveraging neural networks and quantitative content analysis that aimed to reveal the conditions that lead audiences to accept and disseminate a fake claim as it relates to the Zika virus showed that Zika tweets, including threat cues and protection cues, are positively associated with the likelihood of sharing fake news [246]. In addition, findings of a descriptive analysis showed that the quality of news sources varies considerably with regard to information on COVID-19 [247], Results of a computational analysis indicated that the COVID-19 infodemic is highly characteristic of community structure, shaped by ideological orientation, typology of fake news, and geographic areas of reference [248]. Data from X indicated that content could be labeled according to political affiliation, media source, and type of source (political, satire, mainstream media, science, conspiracy or junk science, clickbait, and fake or hoax) [248].

Information Distortion and Conspiracy Theories

Information distortion in X cascades was found to be linked to oversimplification, distortion of logical links, omission of facts, and a shift in the medical topic to political and business disputes [249]. Risk amplification by information dramatization appeared to be linked to controversial topics as well as social and cultural influences [250].

Manual content and semantic analysis and topic modeling (LDA) techniques of tweet content were conducted through an examination of key term distribution, context, and medical terminology verification [249]. In a COVID-19 5G conspiracy use case, LDA and social network analysis were used to identify several topics from dataset of tweets [251] related to “5G conspiracy” and “5G threat” and discuss topics, including 5G towers, radiation effects, network, and radiation [252,253]. Emerging COVID-19–related conspiracy theories were detected by estimating narrative networks with an underlying graphical model and using a collection of data from Reddit subreddits and 4Chan threads related to the pandemic [254]. Findings identified multiple central conspiracy theories illustrated by examples, such as incorporating the COVID-19 conspiracy into Q-Anon conspiracy, #scamdemic and #plandemic [255], 5G as the cause of COVID-19 [252,253], antivax conspiracy, Bill Gates, #filmyourhospital conspiracy [256], and Pizzagate conspiracy [254]. Table 4 summarizes the methods, epidemics, and social media used in studies pertaining to misinformation management and detection.

RQ3. Social Media's Relationship With Mental Health During Epidemics

Overview

During the implementation of restrictive measures requiring limited social contact, social media can become one of the few methods to safely engage with others, rendering it the sole support system of vulnerable populations. Mental health deterioration can manifest in expressions shared on the internet and be used to gauge the toll epidemics and subsequent containment strategies could potentially take on individuals.

Two main themes were identified in the selected papers addressing how social media can be integrated in aspects of public mental health management during epidemics, namely, (1) social media as a tool to gauge the mental health toll of epidemics, and (2) impact of social media consumption during epidemics on mental health.

Mental Health Assessment Using Social Media

Assessment of mental health state was performed using conventional ML [257-259], DL [260-262], and topic modeling techniques [263,264]. Psychological profiles of Weibo users were predicted using ML and online ecological recognition with emotional measures and cognitive indicators, such as anxiety, depression, Oxford happiness, social risk judgment, and life satisfaction [257]. LSTM was used to estimate the rate of depression in the population during the COVID-19 pandemic using Reddit data [260]. Topic modeling, expert intervention, and X data were used to evaluate the possible effects of critical factors related to COVID-19 on the mental well-being of the population in a psychological vulnerability study [263].

Findings revealed that negative emotional indicators of psychological traits increased in anxiety and depression after COVID-19 was declared an epidemic or pandemic [257,262], while life satisfaction and happiness decreased [257]. A 53% average increase in depression rate of Reddit users was noted in selected months after the pandemic [260], and negative psychological vulnerability manifested in negative emotions toward social distancing and hospitalization [263]. Financial burden was found to increase the odds of depressive nonsuicidal thoughts for individuals who suffered job loss during COVID-19 [264]. Results indicated the beginning of recovery following the immediate mental health impact of the COVID-19 pandemic [259].

Table 5 summarizes the methods, epidemics, and social media used in studies pertaining to the use of social media as a tool to gauge the mental health toll of epidemics.

Association of Social Media Consumption and Mental Health

Multiple papers conducted cross-sectional studies and statistical analysis to investigate the association between social media consumption and mental health complications during epidemics, particularly during COVID-19. Several studies relied on regression analysis, online surveys, the Generalized Anxiety Disorder Scale, and the Patient Health Questionnaire.

Findings revealed that frequent Sina Weibo use was associated with higher anxiety, depression, and a combination of both [265], and compulsive WeChat use was associated with social media fatigue, emotional stress, and social anxiety [266]. Frequent use of WeChat during COVID-19 was also associated with depression and secondary trauma and was found to be a significant predictor of both [19], while close contact with individuals with COVID-19, along with spending ≥2 hours daily on COVID-19–related news on WeChat was associated with probable anxiety and depression in community-based adults [267]. The association between social media consumption and anxiety and depression was found to be statistically significant

XSL•FO
RenderX

[265,268,269] and positively associated with emotional overeating and anxiety in individuals with neuroticism [18].

The association between the mental health of students receiving higher education and social media use during COVID-19 confinement was analyzed, and results indicated that students in the 18 to 24 years age group, who were not in a relationship and who had lower academic results, presented the highest levels of addiction to social media [16]. Significant positive associations were found between relatedness, need, frustration, and social media addiction, as well as between social media addiction, depressive symptoms, and loneliness [17]. Excessive social media use was also found to fully mediate the relationship between COVID-19–related life concerns and schizotypal traits [270].

Appropriate guidance of adolescents in the use of social networking sites was found to have a potential impact on the mitigation of negative emotions during the COVID-19 pandemic [271].

On the positive side, social media use was found to be rewarding for Wuhan's residents through information sharing and emotional and peer support [19]. Social media breaks were reported to have the potential to promote well-being during the COVID-19 pandemic [19]. In addition, positive mental health and mindfulness appeared to serve as protective factors, and positive mental health was found to be a mediator between the COVID-19 burden and addictive social media use [272].

Table 6 summarizes the methods, epidemics, and social media used in studies pertaining to the association of social media use with mental health issues during epidemics.

Table 6. Summary of methods used in papers addressing the second part of research question 3 (association of social media consumption with mental health).

Discussion

Principal Findings

This systematic literature review conceptualized 3 RQs to investigate if, when, and how social media can be harnessed for successful epidemic management and mitigation, effective curtailment of fake news propagation, and a refined understanding of social media's relationship with mental health during epidemics. It presented a systematic categorization and summary of methods, social media sites, and epidemics broached in the 242 selected works and identified potential research directions and practical implications related to the RQs.

Papers selected pertaining to RQ1 comprised the highest number of papers and included publications from all years of the decade, illustrating continuous and ongoing efforts by the scientific community to harness social media's potential for improved containment measures during epidemics.

COVID-19 was found to be the epidemic most studied in selected papers. This is due to the rapid increase of COVID-19–related publications since the first year of the pandemic. The frequency of publication and the volume of the academic output contributed to the creation of the COVID-19 Open Research Dataset [33]. A similar rising trend was seen in RQ2. This can be explained by the emergence of the "fake news" phenomena on social media and its particular increase in times of crisis. The selected publications answering RQ3 were published from 2020 to 2022. Papers that pertained to RQ3 were much lesser in number than those that pertained to RQ1 and RQ2. Given the mental health aspect of this particular RQ, a potential inference can be made suggesting a very recent interest in mental health as it relates to social media and epidemics. X was found to be the most used social media site in the selected literature, potentially suggesting its attractiveness to works conducting linguistic analysis and classification tasks. This can also be due to the differences in the popularity of social media sites by geographic location and key demographics. The availability of application programming interfaces to crawl data is also a major factor in choosing specific social media platforms as data sources.

General Discussion

The systematic literature review presented in this paper differs from existing reviews and aims to cover a different gap in the literature. Existing works have taken an interest in a broader range of crises, including noninfectious diseases and health risk behaviors [12], disasters in general [25], and new and reemerging infectious diseases [26]. Focus was directed toward effectively targeting vulnerable populations to test interventions and improve health outcomes [12], collective behavior [25], and generalized perspectives on emergency situations [27]. Differences other than scope include data sources, time range, and volume of literature. The review presented in this paper covered a broader time range, included gray literature, and reviewed a sizable volume of research papers.

The review's findings indicated that social media was found to be an effective way to understand the public's reactions and engagement during epidemics [205]. Monitoring topics of discussion during epidemics allowed for insights on whether aspects of epidemic management needed improvement, whether the public agrees with government decisions, and which emotions are linked to the onset of epidemics and mitigation

XSL•FO
RenderX

protocols [198,204-206]. Analysis of opinions related to aspects, such as COVID-19 vaccinations were proposed and could be used to give feedback to governments and health organizations to implement better suited protocols [116,122,124-126] for mitigation, and to identify topics of misinformation, and therefore offer clarifications or conduct further awareness efforts to combat rumors and conspiracies [254]. Results also indicated that social media can be used in case forecasting [83], X-enabled contact tracing [84], early detection [85], tracking adherence to preventive guidelines, such as wearing masks and social distancing [205,206], and monitoring symptomatic self-expressions of infection [80]. Misinformation detection on social media was performed as a classification task, manually using experts and fact checkers, and using artificial intelligence techniques; however, presented several challenges. Misinformation often used language styles of academics and health professionals to deceive the public [236] and propagated faster when it included higher levels of threat due to the collective stress reaction it generated [246]. "Troll" accounts were found to play the second most prominent role is misinformation spread and present a "substantial cause for concern" [248]. Other challenges of misinformation detection related to limitations of studies due to the use of small batches of data [252], false positives [228], and a "politicization" of neutral health emergency crises [235].

Although epidemics were found to cause negative emotions and mental health issues [260,262,263], many expressions of positive emotions were noted [257], reflecting group cohesiveness rather than pure personal emotions. Group threats contributed to the manifestation of more beneficial behaviors and social solidarity [269]. Viewing heroic acts, speeches from experts, and knowledge of the disease and prevention methods were associated with more positive effects and less expressions of depression [269]. Media content, including useful information for self-protection was found to be potentially helpful to people during epidemics and may enhance active coping, prevention behaviors, and instill a sense of control [269]. The use of social media during epidemics, although linked with manifestations of anxiety and depression, appeared to benefit Wuhan residents and was perceived as an important activity during lockdown [19]. Balancing social media use to obtain ample informational as well as emotional and peer support, while avoiding the potential mental health toll, is a difficult task for users, especially without the availability of alternative and easily accessible sources of health information [19].

Using social media data for mental health assessment has its challenges and limitations. It can add a population or demographic bias to results, given that some social media sites are predominantly used by younger people or are more or less popular depending on the country [257,263]. Depending on the social media site (eg, Reddit), the user pool skews younger, and thus could be more prone to depression [260]. Moreover, some analyses are based on a weekly basis, with a relatively large granularity, which has certain influences on reflecting the changing trend of social mentality in a timely manner [257]. The qualitative nature of the results obtained and interpreted by domain experts limits the generalization of the findings and requires more corroborating results. Consequently, findings may need additional data to be strengthened [260,263]. As for works pertaining to the association of social media consumption with psychological outcomes, a causal link has not been established due to the cross-sectional nature of the contributions. Studies reflected a single point in time for participants, therefore, further longitudinal studies are necessary. In addition, the surveys were conducted on the web, and consequently, respondent bias is possible [265]. The recruitment of all participants from the same country and from one social media platform can introduce bias to studies [266,268], in addition to potential gender biases and sample representativeness [18,19], and recall bias related to self-reporting [269]. The results could not exclude the possibility of residual confounding caused by unmeasured factors.

A change can be seen in the evolution of research themes over time and through different epidemics. A sizable number of works focused on the influenza epidemic surveillance using lexicon-based and dictionary-based classifications, as well as classical ML techniques. This volume of literature could potentially be linked to the influenza prediction "wave" that preceded, paralleled, and followed the dereliction of the "Google flu trend" after its failure to predict major outbreaks [274]. Although various methods were used, ML and DL techniques were most frequently used for COVID-19 surveillance. Scientific contributions evolved with the emergence of more epidemics. COVID-19 appeared to have benefited from the digitization of literature as well as the development and improvements taking place in the fields of natural language processing, ML, DL, social network analysis, and topic modeling. The global nature of the COVID-19 crisis generated an influx of publications and contributions. The theme of misinformation management has also evolved with epidemics and with the proliferation of social media fake news, bots, troll accounts, and widely propagated conspiracy theories. COVID-19 has been the subject of multiple controversies and conspiracies, which encouraged scientific efforts to study potential curtailment methods. As for the mental health aspect, all publications pertaining to the scope of RQ3 were related to COVID-19, and it appeared that previous epidemics were not subject to social media association analysis. This could be due to the fear linked to COVID-19 and the challenging nature of sanitary measures such as global lockdowns and social distancing, which led to an increase in social media reliance. It could also be due to the decade's zeitgeist which brought online mental health discussions and awareness front and center.

Identified Issues

One of the major issues identified was the lack of preemptive measures building on the results of previous studies and aiming to implement social media–enabled processes in real time or near real time. Lessons learned are not efficiently integrated in crisis mitigation measures nor used as building blocks for optimized proactive prevention. A synergy between government health agencies, research communities, and the public would allow for the success of social-media public health initiatives. Such collaborative efforts require effective and trustworthy interactions. This highlights an additional issue related to the relative inefficiency of social media campaigns. Populations need to be targeted for both informative purposes and for active

XSL•FO
RenderX

emotional support. Understanding public opinion is useful to gauge sentiments and reactions, and therefore it is important to remedy the gap for applications integrating extracted opinions in targeted epidemic management.

Because of the medical and financial burden of epidemics, mental health concerns are often ignored by both governments and the public. As a result, the manifestation of several mental health–related symptoms becomes more prevalent as epidemics progress. In the case of the Ebola outbreak in 2014, symptoms of posttraumatic stress disorder and anxiety-depression were more prevalent even after a year of the Ebola response [199]. When limited resources are geared for epidemic containment, the health care system focuses majorly on emergency services. Therefore, individuals with substance abuse and dependency disorders may see deterioration in their mental health [13]. During community crises, event-related information is often sought in an effort to retain a sense of control in the face of fear and uncertainty and their psychological manifestations. When misleading misinformation is propagated on social media, perceptions of risk are distorted, leading to extreme public panic, stigmatization, and marginalization [13]. Psychological interventions and psychosocial support would have a direct impact on the improvement of public mental health during epidemics.

Directions for Future Research

We identified several issues and gaps in the literature related to the RQs of this systematic literature review and suggest potential paths for future research.

Given the recognized impact of epidemics on mental health and the prevalent use of social media platforms during times of crisis, it is necessary to explore the aspects of social media leading to mental health deterioration during epidemics. Potential factors range from increased consumption levels of social media, social media addiction, emotional fatigue due to overwhelm, and consumption of “sad” content. Investigating which aspects of social media use are responsible for worsening states of mental health and mental health disorders would allow a targeted approach to curbing this negative impact during times of crisis. As for health-related fake news, it is important to understand what makes citizens prone to engaging in fake news sharing. Specifically, features identifying both an individual’s and a group’s susceptibility to believe and share misinformation need to be determined and categorized. Levels of education, geographic and demographic profiles, cultural influences, and psychological vulnerability are potential features requiring further investigation in their association with fake news dissemination on social media and within communities.

Epidemics are rapidly changing phenomena requiring fast interventions and decision-making. Although postcrisis analysis is imperative for an improved understanding of lessons learned, proactive epidemic management is vital and would have the most impact on mitigation efforts. Integrating artificial intelligence techniques into this proactive surveillance could further optimize this process.

In addition, misinformation propagation has a significant impact on the success of interventions given that both the components of exaggerated fear and apathy linked to misinformation can hinder management efforts. However, the investigation of misinformation needs to be extended to include potential links between misinformation and mental health deterioration.

Practical Implications

This work has several potential practical implications pertaining to different entities.

Implications for governing entities include the development of an efficient misinformation correction strategy to fight incorrect information, rumors, and conspiracy theories related to epidemics; the development of clear communication channels for knowledge dissemination to build trust with the public; the development of interventions to limit the impact of epidemics on stress responses (anxiety, depression) due to distorted risk perceptions; the bolstering of public awareness efforts on sanitary measures and proactive protection; and the insurance of the supply of medical staff available to treat patients, as well as psychological support staff to assist patients and their families in navigating the ramifications of infection and loss of loved ones.

Implications for social media platforms include taking a leadership position in the management of epidemic-related fake news by implementing built-in fact-checking processes and assisting health agencies and scientific entities in disseminating factual information about the disease, its symptoms, its potential risk, and efficient sanitary measures for the public to adopt.

Implications for the public include improving community resilience during epidemics using social media groups and assisting in combating misinformation.

Limitations

The results of this review should be considered in light of several limitations. The data sources used in this review did not cover all existing scientific databases, and therefore, cannot generalize findings to the entirety of the literature. The scope of the review focused on specific aspects of the epidemic-social media relationship, and so does not provide a general overview. Although the process of data extraction and analysis was undertaken with extreme diligence, there can be potential for bias. Despite our recognition of the inherent limitations of any search strategy, we have ensured our commitment to the rigor and transparency of the systematic review process.

Conclusions

Given the collective experience of epidemics, responses by communities can often provide insight into the degree of adherence toward preventive measures as well as mitigation protocols. In an effort to control the spread of epidemics, governments, public health institutions, and health care professionals generally issue guidelines for the public through online portals, news sources, and in the past decade, social media. Online “chatter” can indicate the public’s response to these guidelines, and their sentiments toward the epidemic itself or specific topics related to it, such as vaccinations, treatments, mortality rates, etc. Mitigation efforts require collaborative strategies and public involvement; therefore, gaining insight

XSL•FO
RenderX

into public opinion and response can prove vital in the success or failure of such efforts.

It is evident that epidemic preparedness and mitigation protocols need to be adjusted to deal with the special challenges that accompany the technological revolution taking place, especially in light of the considerable impact of the ongoing infodemic. In addition, it is vital to have effective ways to exploit the full potential of social media without risking the toll it could potentially take on users' mental health. The systematic literature review presented in this paper covers several key aspects of the relationship between epidemics and social media, especially with respect to fake news and mental health. Methods used to answer RQs are categorized. The findings of this review could shed light on broader implications related to data quality concerns and privacy considerations in epidemic surveillance, thus highlighting the lack of works proposing ethical, legal, and technical frameworks to accompany scientific efforts. Learning from past crises and integrating a digital and social media-enabled infrastructure into public health protocols could make a difference in future preparedness levels.

Acknowledgments

The authors thank the anonymous reviewers for their remarks and improvements to the paper. This work was carried out as part of the eCovid and CovInov projects which are funded by the Centre National de la Recherche Scientifique et Technique and the Rabat-Salé-Kénitra region.All authors declared that they had insufficient funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article.

Data Availability

The datasets generated during and analyzed during this study are available in the Github repository [275].

Authors' Contributions

CA and MG conceived the study. CA and IK designed the experiments. CA, IK, and MG carried out the research. CA and IK prepared the first draft of the manuscript. MG and KB contributed to the experimental design and preparation of the manuscript. All authors were involved in the revision of the draft manuscript and have agreed to the final content.

Conflicts of Interest

None declared.

Abstract

Background: Adolescents, particularly those in Sub-Saharan Africa, experience major challenges in getting accurate and comprehensive sexual and reproductive health (SRH) information because of sociocultural norms, stigma, and limited SRH educational resources. Digital educational tools, leveraging the widespread use of mobile phones and internet connectivity, present a promising avenue to overcome these barriers and enhance SRH education among adolescents in Sub-Saharan Africa.

Objective: We conducted a systematic review to describe (1) the geographic and demographic distributions (designated objectives 1a and 1b, respectively, given their interrelatedness) and (2) the types and relevant impacts of digital educational tools (objective 2).

Methods: We followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines, using databases, such as Ovid-MEDLINE, Google Scholar, PubMed, and ERIC, to conduct literature searches. The selection criteria focused on studies that specifically addressed digital educational tools used to assess or deliver SRH education, their implementation, and their effectiveness among the adolescent population in Sub-Saharan Africa. We used the JBI critical appraisal tools for the quality assessment of papers included in the review.

Results: The review identified 22 studies across Sub-Saharan Africa that met the inclusion criteria. The 22 studies spanned populations in West, Central, East, and South Africa, with an emphasis on youth and adolescents aged 10-24 years, reflecting the critical importance of reaching these age groups with effective, accessible, and engaging health education (objectives 1a and 1b). There was a diverse range of digital tools used, including social media platforms, mobile apps, and gamified learning experiences, for a broad age range of adolescent youth. These methods were generally successful in engaging adolescents by providing them with accessible and relevant SRH information (objective 2). However, challenges, such as the digital divide, the cultural sensitivity of the material, and the necessity for a thorough examination of the long-term influence of these tools on behavior modification, were noted.

Conclusions: Digital educational tools provide great potential to improve SRH education among adolescents in Sub-Saharan Africa. These technologies can help enhance relevant health outcomes and accessibility by delivering information that is easy to understand, interesting, and tailored to their needs. Future research should focus on addressing the identified challenges, including bridging the digital divide, ensuring cultural and contextual relevance of content, and assessing the long-term impact of digital SRH education on adolescent behavior and health outcomes. Policymakers and educators are encouraged to integrate digital tools into SRH educational strategies that target adolescents in order to improve the SRH of this age group and contribute to improving public health in Sub-Saharan Africa.

KEYWORDS

digital health; adolescents; Africa; sexual health; reproductive health; human-centered design

Introduction

According to the World Health Organization, there are more than 1.2 billion adolescents aged 10 to 19 years with sexual and reproductive health (SRH) problems, such as sexually transmitted infections (STIs) and unplanned pregnancies, many of whom face significant barriers to accessing SRH-related education. With the increasing rates of SRH problems and mental health issues among adolescents, there is a pressing global need for effective educational tools that address the SRH needs of adolescents [1,2]. There are global disparities in adolescents' access to SRH education, with those in low- and middle-income countries (LMICs) facing the greatest barriers to accessing knowledge and resources due to sociocultural norms, beliefs, practices, and stigma, and yet, these parts of the world have the greatest burden of poor adolescent SRH outcomes [3]. For example, over 80% of all adolescents living with HIV are in Sub-Saharan Africa [4], which also has the highest prevalence of adolescent pregnancy globally [5]. Melesse et al [6] conducted a review of demographic and health survey data from 33 African countries and reported that despite improvements in SRH among adolescents in Sub-Saharan Africa, young people in this part of the world continue to have disproportionately high rates of unwanted pregnancies and STIs (including HIV/AIDS). These persistently high rates of poor health outcomes have been attributed, at least in part, to limited access to SRH education, more formally referred to as comprehensive sexuality education, in many Sub-Saharan African countries [7]. Challenges impacting access to sex education in Sub-Saharan Africa include cultural and societal norms that serve as barriers to youths' access to information, especially taboos regarding the open discussion of topics such as family planning, menstruation, and contraception [8]. Additionally, comprehensive sexuality education programs have been constrained by inconsistent funding and poor accountability [9]. It is crucial to promote SRH education to combat the challenges faced by adolescents and foster a more inclusive and equitable society as these young people transition into adulthood. Additionally, universal access to SRH is an essential component of sustainable development goals [10].

Digital educational tools have the potential to effectively provide SRH education for adolescents in Sub-Saharan Africa. Such technologies use the widespread availability of mobile phones and internet infrastructure to innovatively address the unique challenges faced by the youth in accessing current information and resources [11,12]. The use of social media platforms, websites, games, and mobile apps has become prevalent in digital education. These tools can provide instructional content with the potential to stimulate teenagers' interest in learning and promote favorable attitudes and knowledge that may lead to desirable SRH outcomes. The integration of digital tools into SRH education offers a promising avenue to overcome health disparities [13,14]. Mobile health (mHealth), which is the practice of medicine and public health that uses mobile devices, has exploded over the last few years, with mobile phone penetration reaching 90% in some LMICs [15]. The increased usage of mobile phones among younger populations in LMICs presents a valuable opportunity to use mHealth, for example, as a tool to overcome barriers to accessing SRH information and service [16]. Digital technology has the potential to close the information gap for adolescents in LMICs, ensuring equitable access to essential health knowledge for all adolescents irrespective of their geographical location or socioeconomic status.

We have conducted a systematic review to describe: (1) the geographic and demographic distribution (designated objectives 1a and 1b, respectively, given their interrelatedness) and (2) the types and formats of digital educational tools available for delivering SRH education to adolescents in Sub-Saharan Africa and, as appropriate, the impacts of these digital innovations on target populations (objective 2). A systematic review is appropriate for this work as it allows us to comprehensively synthesize the current state of the literature on such an underresearched topic, identify gaps in knowledge, and provide insights on moving the field forward [17]. The public health significance of this review lies in its potential to inform policy and practice by highlighting successful digital interventions that can enhance SRH education for adolescents. Given the increasing prevalence of internet and mobile device usage in Sub-Saharan Africa, identifying effective educational strategies is crucial for addressing the high rates of unintended pregnancies, STIs, and other reproductive health challenges faced by young people in the region. Ultimately, our findings can be used to support the development of targeted evidence-based digital interventions that can significantly improve health outcomes for adolescents in this part of the world.

Methods

Definitions of Digital Tools and Adolescents

We have defined the terms "digital tools" and "adolescents" as presented below.

Digital Tools

Digital tools are technological resources or applications used in the provision of information, support, and resources related to SRH. These tools use digital technology to enhance access, outreach, and effectiveness in the delivery of SRH education and services. They are available through a variety of digital platforms, such as websites, mobile apps, and social media platforms [11]. The use of such tools has become increasingly prevalent in recent years as they offer a convenient and efficient means of accessing information and resources related to SRH. These tools have gained considerable popularity owing to their ease of use and convenience in terms of obtaining information related to SRH.

XSL•FO
RenderX

Adolescents

Adolescents, who are individuals in the intermediate stage of development between childhood and adulthood, commonly referred to as teenagers or young adults, experience substantial transformations in physical structure, thinking, interpersonal relationships, and emotions [18]. As adolescents face major educational and health challenges, especially in the context of SRH-related information, our review is focused on this age group. We used the World Health Organization's definition of "adolescents" as individuals aged 10 to 19 years, "youth" as those aged 15 to 24 years, and "young people" as those aged 10 to 24 years [19]. Therefore, if any studies included these age groups, we erred on the side of caution and included them to ensure we were being as comprehensive as possible in capturing the breadth and scope of the research in this field.

Database and Search Dates

This systematic review adhered to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) criteria [20] to ensure that all relevant primary materials match the review requirements [21]. Additionally, we used the JBI critical appraisal tools for the quality assessment of all papers included in the review [22] (Multimedia Appendix 1). A systematic search of peer-reviewed articles was conducted in November 2023 using Ovid-MEDLINE, with the assistance of a University of Pittsburgh Health Sciences Library System (HSLS) professional, to identify original research articles published between 2013 and 2024. The first Ovid-MEDLINE search was developed using a mix of Medical Subject Heading (MeSH) phrases, keywords, and Boolean operators (eg, "adolescent* or teen* or youth"; "digital health education/ or health promotion/ or sex education/"; "Africa or Angola or Benin or Botswana or Burkina Faso or Burundi or Cabo Verde or Cameroon or Central African Republic or Chad or Comoros or Congo or Cote d'Ivoire or Djibouti or Eritrea or Eswatini or Ethiopia or Gabon or Gambia or Ghana or Accra or Kumasi or Tamale or Sekondi-Takoradi or Guinea or Kenya or Lesotho or Liberia or Madagascar or Malawi or Mali or Mauritania or Mozambique or Namibia or Niger or Nigeria or Rwanda or Sao Tome or Principe or Senegal or Seychelles or Sierra Leone or Somalia or Sudan or Tanzania or Togo or Uganda or Zambia or Zimbabwe.ti,ab,kf.") (Multimedia Appendix 1). The search results were managed and tracked in SciWheel.

Study Selection

We restricted the search to studies conducted in humans and written in the English language. Additional articles were identified by cross-referencing bibliography lists. In alignment with the PRISMA standards, the methodology encompasses 4 phases: identification of sources, assessment of eligibility, detailed screening, and final selection for inclusion [21]. Initially, potential sources were selected by examining their titles and abstracts, ensuring relevance to the research question. This meticulous process facilitated the systematic evaluation and filtering of records, governed by rigorously defined inclusion and exclusion criteria. Articles that advanced beyond the preliminary screening phase were subjected to a comprehensive review of their full texts to determine their eligibility for inclusion in the systematic review. Articles were first reviewed by the first author (RHAHA) in collaboration with the co-author NJA and under the supervision of the second author (CLH) to ensure they met the eligibility criteria. The JBI critical appraisal tools for the quality assessment of all papers included in the review were further used to ensure the papers met the necessary standards for research and publication (internally valid, appropriately randomized, participants appropriately consented, etc). The eligibility criteria are presented in Textbox 1.

Textbox 1. Eligibility criteria.

Inclusion criteria

- Region: Focuses on the Sub-Saharan African region or has significant relevance to Sub-Saharan African populations
- Target population: Adolescents and youth
- Area of focus: Addresses sexual and reproductive health, including sexually transmitted infection education, mental health, sexuality, and positive sexuality
- Mode of delivery: Digital tools, including apps, websites, gaming, e-learning modules, social media, etc
- Timeline: Published within the last 10 years (2013-2024) to ensure relevance
- Language: In English to ensure comprehension and interpretation by research teams who are primarily English speaking

Exclusion criteria

- Region: Excluded Sub-Saharan African populations or did not have a Sub-Saharan Africa focus
- Target population: Outside of the age range of adolescents and young people
- Area of focus: Does not specifically address sexual and reproductive health
- Mode of delivery: Excludes digital tools
- Timeline: Outside of the specified dates
- Language: Not in English

RenderX

Results

Included Studies

Figure 1 outlines the systematic and comprehensive search and selection process employed in this systematic review, focusing on digital educational tools for adolescent SRH in Sub-Saharan Africa. Initially, a total of 1877 records were identified through meticulous searches across major databases, including OVID-MEDLINE, Google Scholar, PubMed, and ERIC. An additional 4 records were identified through citation searching, augmenting the pool of potential studies. Before screening, 203 records were removed due to duplication, leaving 1674 records for detailed screening. The screening process, grounded in rigorously defined inclusion and exclusion criteria, led to the exclusion of 1656 records for reasons such as not directly addressing SRH digital educational tools, not focusing on the Sub-Saharan African region or LMIC context, targeting populations outside the adolescent age range and young people, and duplications. After the exclusion process, 18 reports were retrieved and assessed for eligibility, and 4 additional studies were identified and included in the review alongside the initially identified studies, bringing the total number of studies included in the review to 22 (Figure 1; Table 1) [22].

Figure 1. Flowchart for our systematic review of digital educational tools for adolescent sexual and reproductive health (SRH) in Sub-Saharan Africa. LMIC: low- and middle-income country.

XSL•FO
RenderX

Table 1. Summary of studies on the availability of digital sexual and reproductive health education for adolescents in Sub-Saharan Africa.

Study (authors and year)	Study population/region/country	Study design	Digital tool type	Findings
Dulli et al [23], 2020	349 youth aged 15-24 years from Nigeria	Randomized controlled trial. Participants were randomized into 2 groups: those receiving the SMART Connections intervention and those receiving standard care services.	Social media	Primary results: The intervention did not significantly improve retention (50% vs 45% retention in treatment vs control groups) or social support but did significantly improve HIV-related knowledge (t=–2.96; P=.003).
Fakoya et al [24], 2022	111 adolescents aged 15-19 years from Nigeria, Tanzania, and Ethiopia	Application of youth-led participatory action research (PAR) approaches within human-centered design (HCD)	Youth-engaged version of HCD as part of the Adolescents 360 initiative	Primary results: Successful engagement of youth as project partners and action researchers. Identified opportunities to improve program empathy and responsiveness. Challenges in recruiting “extreme users” due to high competencies needed in HCD. Empathy and design standards during prototyping helped in decision-making. Real-world testing of services and products emphasized the importance of continuing youth-adult partnership.
Feroz et al [16], 2021	Young people (adolescents and youth) aged 10-24 years in low- and middle-income countries (LMICs), specifically Sub-Saharan Africa and Asia	Systematic review	Mobile phones used for mHealth interventions aimed at improving sexual and reproductive health (SRH) outcomes	Primarily used for client education and behavior change communication (n=14, 93%), followed by financial transactions and incentives, and data collection and reporting. Studies evaluated the effect mHealth interventions had on access to SRH services (n=9) and SRH outcomes (n=6). mHealth interventions improved access to SRH services and outcomes by addressing barriers such as provider prejudice, stigmatization, discrimination, and issues of privacy and confidentiality. Included decreased technological literacy, inferior network coverage, and lower linguistic competency.
Gonsalves et al [25], 2018	705 young people aged 13-24 years from Kenya and Peru	Protocol of an open, 3-arm, individually randomized trial. Participants will be randomized into one of three arms: (1) intervention arm receiving SRH information (using ARMADILLO) via mobile phones, (2) control arm receiving no intervention, and (3) a third arm with variations by site (Kenya and Peru).	Mobile phone sexual health information	If proven to be effective, interventions like ARMADILLO can bridge an important gap in achieving universal access to SRH information and education for an otherwise difficult-to-reach group. Outcomes will be assessed via questionnaires administered at baseline, intervention end, and 8 weeks after intervention end. Statistical analysis will include comparisons of proportions (chi-square tests) and means (t-tests) between arms and difference-in-difference techniques.
Haruna et al [26], 2019	348 secondary school participants (students) aged 11-15 years from 3 schools were recruited to participate in this study from Tanzania	Design-based research (DBR)	Digital gamified learning platform named “My Future Begins Today”	A paired t-test revealed a statistically significant improvement in sexual health literacy scores from pretest (mean 26.40, SD 7.29) to posttest (mean 74.12, SD 16.21) (t_{347}=52.230; P<.000), with an average increase of 47.72 points. A 1-way ANOVA showed no significant differences among the 3 groups’ pretest scores, but significant differences were found in posttest scores ($F_{2,345}$=210.43; P<.001), with follow-up Tukey post hoc tests indicating better performance by the gamified learning platform group compared to the traditional teaching group. Positive stakeholder and participant feedback on the gamified approach. Effective use of participatory design in developing educational tools.

XSL•FO
RenderX

Study (authors and year)	Study population/region/country	Study design	Digital tool type	Findings
Nalwanga et al [27], 2021	1086 Kyambogo University students aged 18-30 years from Uganda	Cross-sectional analysis of data from an endline survey of a randomized controlled trial (RCT) and data from use of a mobile phone app over a 6-month period.	Mobile phone app	The mobile phone app demonstrated predominantly positive (responsiveness, nondistracting in-app advertisements, and ease of use) attributes. 86% (n=464) of students who received a recommendation to download the app accepted and downloaded it. Of these students, 81% (n=374) used the app to access SRH information, goods, and services over 6 months. In terms of responsiveness, 55.1% (n=206) of students stated that clinics were responsive (*P*=.11). 75.4% (n=282) said the in-app advertisements were not distracting (*P*=.23). 44.4% (n=166) found that in-app instructions were very easy to use (*P*=.50).
Ippoliti et al [28], 2017	Adolescents and youth aged 10-24 years from Africa (67%), Eurasia (26%), and Latin America (13%)	Global landscape analysis. The authors issued a global call for project resources in 2014 and reviewed the submissions to confirm they met specific inclusion criteria.	Mobile phones (including SMS text messaging and mobile phone apps)	Most projects (n=12, 70%) relied on text messaging to transmit SRH information. The majority of projects were based in Africa (67%), followed by Eurasia (26%) and Latin America (13%). Mobile phones were effectively used to increase the reach of SRH information and services, especially in conservative societies where SRH topics are stigmatized. 70% of the projects relied on text messaging to transmit SRH information. Several projects have been adapted and scaled to other countries, demonstrating the scalability of mHealth interventions.
L'Engle et al [29], 2016	Review targeted adolescents aged 10-24 years and included studies that provided results from mobile phone interventions designed to improve adolescent SRH	Systematic review	Mobile phone interventions, primarily text messaging	Most programs (n=23, 82%) used text messaging. An average of 41% of essential mHealth criteria were met. An average of 82% of methodological reporting criteria were met. Evidence suggests improvements in health promotion campaigns, sexually transmitted infection (STI) screening and follow-up, and medication adherence.
Nolan et al [30], 2020	6000 youth aged 12-19 years across 8 districts in Rwanda	3-arm cluster-randomized. Arms: (1) CyberRwanda self-service, (2) CyberRwanda facilitated, and (3) control schools, which will receive the standard services that are available in the community.	CyberRwanda, a digital health intervention consisting of interactive stories, questions and answers, videos, and an online shop for health products	The study protocol describes the design and intended impact evaluation of the CyberRwanda program using a 3-arm cluster randomized noninferiority trial, but it does not report on the outcomes or effectiveness of the intervention. The primary outcomes are measurements of uptake of a modern method of contraception, initiation of childbearing, and HIV testing, all measured at the participant level. Data analysis will consist of a generalized linear mixed model.
Onukwugha et al [31], 2022	Review includes individuals aged 10-19 years, with consideration for interventions focusing on young people aged 10-24 years in Sub-Saharan Africa	Systematic review	mHealth interventions	mHealth interventions were effective in improving adolescents' uptake of SRH services across a wide range of services, with the strongest evidence for contraceptive use. Interventions with 2-way interactive functions and more behavior change techniques embedded were more effective. Limited data suggested that interventions were inexpensive, but cost-effectiveness was not evaluated.
Patel et al [32], 2022	Adolescents in LMICs (countries not specified by the authors)	Environmental scan is used to identify current SRH mobile apps available in the iOS App Store and Android Play Store.	Mobile apps	2165 mobile apps were initially identified, with only 8 apps meeting the inclusion criteria and assessed using the Mobile App Rating Scale (MARS) tool. The functionality subdomain scored the highest at 4.6. The information subdomain scored the lowest at 2.5. None of the assessed apps contained information on the MARS items related to the evidence base and goals. "Too Shy to Ask" had the highest individual app mean score of 4.1, while "e-SRHR" scored the lowest at 2.3.

RenderX

Study (authors and year)	Study population/region/country	Study design	Digital tool type	Findings
Pfeiffer et al [33], 2014	60 adolescents aged 15-19 years in Dar es Salaam and Mtwara, Southern Tanzania	Mixed methods study	Social media, with a particular focus on Facebook	Adolescents access the internet mainly through mobile phones (68%). Facebook is the most popular internet site among the youth (73%). Adolescents expressed interest in receiving reproductive and sexual health messages through social media, with 92% of respondents saying Facebook should be used. Youth role models, such as music stars and actors, are influential in delivering health messages.
Rogers et al [34], 2019	Adolescents aged 10-19 years living in Zambia	Content analysis of the TuneMe website	Mobile-optimized website (TuneMe)	The TuneMe platform provided extensive information on SRH and HIV. Topics on relationships (21%) as well as sexual rights and sexual citizenship (11%) were also covered, albeit to a lesser extent. Areas, such as pleasure, violence, diversity, and gender, received significantly less attention. Content was presented in culturally relevant contexts but sometimes portrayed mixed or problematic views on gender norms. 89% of the TuneMe content falls within the IPPF Framework components for CSE, with 37% falling in the SRH and HIV primary category. The Gunning Fog Index score indicated that a minimum of an 8th grade reading level would be required to fully understand TuneMe content.
Rokicki et al [35], 2017	756 female adolescents aged 14-24 years enrolled in secondary schools in Accra, Ghana	Cluster randomized controlled trial. Unidirectional intervention (n=12 schools): participants received text messages with reproductive health information; interactive intervention (n=12 schools): participants engaged in text messaging reproductive health quizzes; control (n=14 schools): did not receive reproductive health–related text messages.	Text messaging program	The unidirectional intervention increased reproductive health knowledge by 11 percentage points (95% CI 7-15). The interactive intervention increased knowledge by 24 percentage points (95% CI 19-28) from a control baseline of 26%. No significant changes in reproductive health outcomes overall. Both interventions lowered the odds of self-reported pregnancy for sexually active participants (unidirectional: OR 0.14, 95% CI 0.03-0.71; interactive: OR 0.15, 95% CI 0.03-0.86). Results showed that text-messaging programs may help improve reproductive health knowledge among adolescents.
Soehnchen et al [13], 2023	77 young adults aged 18-35 years in the resource-poor regions of Kenya	Survey based on the Unified Theory of Acceptance and Use of Technology (UTAUT)	Web-based prototype designed to provide essential sexual health information	77 responses were included in the analysis. High acceptance and usability of the digital tool among the target population. Perceived usefulness, attitude toward health care–integrated evidence technology, and usability had significant positive impacts on acceptance and intention to use. Having the resources and knowledge necessary for the usage of a digital tool had a significant negative impact. The chi-square test statistic was 532 (P<.001), meaning it was highly significant compared to the original model. A System Usability Scale (SUS) score of 67.3 indicated the tool's usability as "okay."
Soehnchen et al [8], 2023	17 young female individuals aged 15-25 years from Kenya	Qualitative research design, with a sample size of 12 pilot phase interviews and 5 expert interviews.	Web-based sexual health education app	Stigmatization around sexual health in Kenya leads to myths and a lack of information. Sexual health education is not part of the Kenyan school curriculum, leading to insufficient knowledge about safe contraception, menstruation, and female genital mutilation. A digital app could support and provide education and information for universal equal access. Barriers to using a digital sexual health education app include conservative cultural background, classic text communication, and social affiliation influence.

XSL•FO
RenderX

Study (authors and year)	Study population/region/country	Study design	Digital tool type	Findings
Frankline et al [36], 2020	398 female adolescents aged 10-19 years from Cameroon	Single-centered randomized controlled single-blinded trial. Intervention group: received weekly educational 1-way text messages on sexoreproductive health (199 participants); control group: did not receive the text messages (199 participants).	Mobile phone text messaging (SMS)	Significant increase in mean knowledge, attitude, and practice scores from baseline to the end of the study (from 6.03, 4.01, and 3.45 to 7.99, 5.83, and 4.99, respectively). Statistical significance in the overall improvement in adolescents' perception of sexoreproductive health as a result of the intervention (F=15.12; P=.02 for knowledge; F=60.21; P=.001 for attitudes; F=57; P=.01 for practices). Majority (65.3%) of participants were satisfied with the SMS text messaging service.
Akande et al [37], 2024	1280 in-school adolescents aged 15-17 years from Nigeria	Cluster randomized controlled trial. Intervention group: received the mHealth-based intervention; control group: did not receive the mHealth intervention.	mHealth-based sex education program	Significant improvements in SRH knowledge (F=2117.252; P<.001) and attitudes (F=148.493; P<.001) in the intervention group. No significant change in risky sexual behavior scores in the intervention group (P=.57). Females had higher odds of having good SRH knowledge (aOR 2.5, 95% CI 1.04-6.13). Males had lower odds of practicing protective sexual behavior (aOR 0.3, 95% CI 0.15-0.55), and higher class levels (SS2: aOR 5.2; SS3: aOR 6.2) were associated with more protective behavior.
Rokicki and Fink [15], 2017	756 female adolescents and young women aged 14-24 years from Ghana	Randomized controlled trial. Unidirectional intervention (text messages with reproductive health information), interactive intervention (engaged adolescents in text messaging reproductive health quizzes), and control (no intervention).	Interactive mobile phone quiz (mHealth intervention)	The mHealth intervention was effective in engaging adolescent girls across sociodemographic strata. Participants showed increased health knowledge regarding SRH. Knowledge scores increased from 26% to 32% in the control group, 30% to 45% in the unidirectional group, and 31% to 60% in the interactive group when looking from baseline to the 3-month follow-up. The interactive intervention was more effective than the unidirectional intervention, increasing knowledge scores by 13 percentage points (95% CI 8-18). The intervention reached adolescents who may be at higher risk of poor SRH outcomes.
Haruna et al [38], 2018	120 lower secondary school students aged 11-15 years from Tanzania	Randomized controlled trial. Groups: (1) game-based learning (GBL), (2) gamification, (3) control group (traditional teaching).	GBL and gamification platforms	The Adolescent Sexual Health Literacy Test (ASHLT) showed a significant increase in scores from pretest (mean 29.26, SD 8.689) to posttest (mean 70.36, SD 18.201) (t_{119}=–23.787; P=.001). GBL and gamification methods significantly improved students' motivation, attitude, knowledge, and engagement (MAKE) compared to traditional teaching methods, as evidenced by higher scores in these areas and supported by positive feedback from focus group discussions. Pairwise comparisons revealed significant differences between traditional and experimental methods, with no substantial differences between GBL and gamification, indicating that both experimental approaches were more effective in enhancing sexual health education.
Alhassan et al [39], 2019	250 adolescents and young people aged 18-24 years at the University of Ghana, Legon in Accra, Ghana	Cross-sectional analytical study	Mobile phones (including smartphones)	99% of participants owned mobile phones, with 58% being smartphone users. Male young adults and young adults who owned a smartphone were more likely to use mobile phones for STI education and prevention (P=.000 and P=.01, respectively). The study suggests high mobile phone penetration among young adults, with a belief in the efficacy of mobile phone programs for STI education and prevention.
Ippoliti et al [40], 2021	Adolescents aged 12-19 years from Rwanda	HCD approach	CyberRwanda, a web-based digital health platform	Over 1000 Rwandan youth, caregivers, teachers, health care providers, and government stakeholders engaged. Revealed participants' beliefs, behavioral preferences, and experiences related to family planning and reproductive health. Designed for urban and periurban young people and pharmacy staff. Evaluations will be conducted across 60 schools and 9 youth centers in 8 districts in Rwanda (n=6082 at baseline).

Objectives 1a and 1b: Geographic and Demographic Focus

As shown in Figure 2, the geographical scope of research on digital interventions for SRH education spans diverse settings in Sub-Saharan Africa, each offering unique insights into the challenges and opportunities inherent in deploying technology-based solutions within various cultural and infrastructural contexts. The studies span populations in West, Central, East, and South Africa. This geographical diversity is not merely a backdrop for these studies but a critical factor that shapes the design, implementation, and impact of digital health interventions across the continent; it underscores the importance of contextually adapted solutions. As depicted in Table 1, the studies included youth and adolescents of various ages, integrating variations of human-centered designs (HCDs) that resonated with their lived experiences and preferences. In Nigeria, Dulli et al [23], Fakoya et al [24], and Akande et al [37] highlighted the country's engagement with digital platforms to address SRH among youth and adolescents. Feroz et al [16] and Ippoliti and L'Engle [28] also included studies from Nigeria. Nigeria, with its vast population and significant digital penetration, represents a critical context for understanding how social media and participatory design can be harnessed to meet young people's health education needs. The focus on Nigeria underscores the potential of digital tools to transcend traditional barriers to health education, leveraging the widespread use of social media and mobile phones among the youth. Besides Nigeria, this study included some other countries in West Africa, such as Ghana [16,31,35,39], Senegal, and Mali [28].

Figure 2. Map of Africa showing the countries included in the reviewed studies (green).

The reviewed studies extend beyond West Africa to include Kenya, as illustrated by Gonsalves et al [25], who explored the impact of mobile phone–based sexual health information among young people, as well as Soehnchen et al [13], who assessed acceptance of a digital tool for delivering sexual health education. Some other authors, namely Feroz et al [16], Ippoliti and L'Engle [28], Onukwugha et al [31], and Soehnchen et al [8], also included studies that were performed in Kenya in their reviews. Kenya's inclusion in this body of research is indicative of its role as a hub for technological innovation and digital health initiatives in East Africa. Nalwanga et al [27] performed a cross-sectional analysis to assess the use of a mobile phone app by university students in Uganda, another East African country. Haruna et al [26] focused on secondary school

XSL•FO
RenderX

participants in Tanzania, using a gamified learning platform to engage students in SRH education. This emphasis on educational settings highlights the potential of integrating digital tools into formal education systems, showing how gamification can enhance learning outcomes and engagement among school-aged youth. Data from Tanzania, Rwanda, and Ethiopia, which are also East African countries, were included in studies by Fakoya et al [24], Feroz et al [16], Haruna et al [26,38], Ippoliti and L'Engle [28], Ippoliti et al [40], Onukwugha et al [31], Nolan et al [30], and Pfeiffer et al [33]. The cross-regional approach of Gonsalves et al [25], encompassing participants from both Kenya and Peru, further emphasizes the global relevance of digital health interventions and the importance of considering diverse cultural and infrastructural landscapes in their design and deployment.

This review also included some countries in southern Africa, including South Africa, Mozambique, and Zambia. For example, Rogers et al [34] performed a content analysis of TuneMe, a mobile-optimized website that offers extensive information on SRH and HIV. Importantly, the content was presented in culturally relevant contexts. In addition to that study, Feroz et al [16], Ippoliti and L'Engle [28], and Onukwugha et al [31] included data from southern African countries in their systematic reviews.

Democratic Republic of Congo [16] and Cameroon [36] were the 2 Central African countries included in this review. Collectively, these studies paint a picture of a continent actively engaging with digital technologies to overcome the challenges in delivering SRH education. The wide geographical reach of this research, ranging from the populous country of Nigeria to the tech-savvy environments of Kenya, reflects the varied landscapes in which these digital interventions are implemented. Each setting provides unique insights into the interplay between cultural norms, technological accessibility, and health education needs, contributing to a richer understanding of how digital tools can be adapted and scaled across the Sub-Saharan African context.

Target Demographics

Among the studies reviewed, there was a notable emphasis on youth and adolescents, spanning ages 10 to 24 years, which reflected the critical importance of reaching these age groups with effective, accessible, and engaging health education. Although the focus of this study is the adolescent age group, they are often included in broader age groups, such as young people and youth, as shown in Table 1. For instance, Dulli et al [23] concentrated on youth aged 15 to 24 years in Nigeria. The authors performed a randomized controlled trial using social media as a platform to deliver sexual health interventions (SMART Connections). Similar populations were targeted by Gonsalves et al [25] in Kenya and Rokicki et al [35] in Ghana. Similarly, Fakoya et al [24] engaged adolescents aged 15 to 19 years from Nigeria, Tanzania, and Ethiopia, incorporating youth-led participatory action research with an HCD to create interventions that resonate with the lived experiences and preferences of young individuals. The authors directly engaged the target demographic in the study design process. In Rwanda, Nolan et al [30] analyzed data from 6000 youth aged 12 to 19 years in a cluster-randomized trial and Rogers et al [34] studied a similar age group (10 to 19 years) in Zambia.

Further broadening the demographic spectrum, Feroz et al [16] extended their review to young people aged 10 to 24 years in Sub-Saharan Africa and Asia. The Sub-Saharan African countries in that study included Tanzania, Nigeria, Ghana, Uganda, and Kenya. The authors performed a comprehensive review of mHealth interventions, identified a wide range of options, and elucidated their applications as well as barriers and facilitators for adoption.

The inclusive age range spanning from early adolescence to young adulthood acknowledges the diverse needs and challenges faced by individuals as they navigate through different stages of the early life course, emphasizing the importance of tailoring interventions to meet these varying requirements. The more expansive approach of Gonsalves et al [25], by including young people aged 13 to 24 years in Kenya and Peru, illustrates the global relevance of digital sexual health interventions and the need to consider cross-cultural applicability and customization in their design and implementation. This cross-regional study underscores the universal challenges related to sexual health education, while acknowledging the specific nuances that different cultural contexts bring to the fore. Finally, Haruna et al [26] involved secondary school participants from Dar es Salaam, Tanzania in the development of a digital gamified learning platform. This engagement not only emphasizes the educational context as a critical setting for sexual health education but also showcases the potential of gamification as a strategy to enhance learning outcomes and retention among school-aged youth.

Collectively, the studies reflect a strategic and inclusive approach, which is aimed at bridging gaps in access and engagement. By examining the implementation and impact of these digital tools across various African settings, researchers and practitioners can gain valuable insights into the factors that drive the success and scalability of health education interventions, thus paving the way for more inclusive and effective public health strategies.

Objective 2: Digital Tool Types and Effectiveness

The landscape of digital tools deployed for SRH education in various African contexts not only signifies a shift toward more accessible and engaging formats for health education but also reflects the adaptability of health practitioners and researchers to leverage technology to meet the needs of target populations.

With regard to design, Fakoya et al [24] introduced a youth-engaged version of HCD, a problem-solving participatory process that centers the needs, perspectives, and experiences of target populations, when developing solutions to complex challenges. The authors used HCD as part of Adolescents 360, a transdisciplinary initiative to increase the use of modern contraception among 15- to 19-year-old girls in Nigeria, Ethiopia, and Tanzania. The youth-led participatory approach involved 111 "youth designers" trained in HCD methods to inform the design and implementation of the interventions. The authors had successfully engaged youth as project partners and action researchers involved in an iterative cycle of program

XSL•FO
RenderX

research, design, and evaluation. However, they noted challenges in recruiting "extreme users" due to the high competencies needed in HCD and emphasized the need for real-world testing (not just prototyping to enhance adolescents' experiences) and the importance of planned and dedicated financial and human resources. An HCD approach was also deployed in Rwanda by Ippoliti et al [40] for their web-based digital health platform CyberRwanda. The involvement of not only youth but also caregivers, teachers, health care providers, and government stakeholders revealed participants' beliefs, behavioral preferences, and experiences related to family planning and reproductive health. The authors noted that the HCD process, although iterative, resulted in significant pivots to the design and implementation of the digital platform and resulted in a superior digital health intervention with and for Rwandan youth.

For deployment and implementation, the ubiquity and accessibility of mobile phones make them an ideal platform for reaching a wide audience, particularly in regions where mobile technology may be more readily available than traditional health care services. In fact, Alhassan et al [39] report that 99% of 250 surveyed adolescents and young people aged 18 to 24 years owned mobile phones and 58% were smartphone users. Young male adults and those who owned a smartphone were more likely to use mobile phones for STI education and prevention. In their systematic review of the use of mobile phone technology in LMICs for mHealth SRH interventions, Feroz et al [16] noted that most of the included mHealth intervention studies (n=14, 93%) focused on behavioral change and patient education using a variety of modalities, including SMS text messaging, video clips, images, and voice communication. mHealth tools improved young people's SRH knowledge, ensured safer sexual behavior, maximized reach and access to family planning information, and improved several HIV outcomes. Barriers to mHealth uptake for SRH included high cost of service, infrastructural or network quality, request for sociodemographic information that could break anonymity, and sociocultural beliefs and norms. Ippoliti and L'Engle [28] also echoed these findings in their global landscape analysis of the use of mobile phones for SRH content among adolescents and youth aged 10 to 24 years in Africa, Eurasia, and Latin America. The authors reported that mobile phones (particularly text messaging) were effectively used to increase the reach of SRH information and services, especially in conservative societies where SRH topics are stigmatized. Nalwanga et al [27] assessed the use of a mobile phone app to increase access to SRH information, goods, and services among university students in Uganda and reported high use of the frequently asked questions portal (71%) and high product use by both sexes (condoms for males [77% use]; sanitary pads for females [94% use]), and the most popularly accessed service was HIV testing and counseling (60% use). Participants appreciated the responsiveness, nondistracting in-app advertisements, and "ease of use" attributes of the mobile phone app. One interesting aspect of this study was the inclusion of a modest co-payment (paid by users), which, interestingly, was not a barrier to usage. Contrary to what has been reported by others, the youth in this study did not find the co-pay to be cost prohibitive. In fact, its incorporation ensured the utility of client payments in future iterations of the app after the pilot period. In a cluster randomized controlled trial of 756 adolescent female individuals aged 14 to 24 years enrolled in secondary schools in Accra, Ghana, Rokicki et al [35] compared the following 3 arms: unidirectional intervention (n=12 schools), where participants received text messages with reproductive health information; interactive intervention (n=12 schools), where participants engaged in text messaging reproductive health quizzes; and control (n=14 schools), where students did not receive reproductive health messaging. They found that the unidirectional intervention increased reproductive health knowledge by 11 percentage points (95% CI 7-15); however, the inclusion of quizzes in the interactive intervention increased knowledge by 24 percentage points (95% CI 19-28) from a control baseline of 26%. Both interventions lowered the odds of self-reported pregnancy for sexually active participants (unidirectional: OR 0.14, 95% CI 0.03-0.71; interactive: OR 0.15, 95% CI 0.03-0.86). These studies highlight the versatility of mobile phones in delivering tailored health education and interventions ranging from SMS text messaging–based information dissemination to more interactive app-based learning experiences and quizzes to reinforce knowledge retention and behavioral change. They can act as a one-stop shop, offering not only educational and clinical counseling services but also condoms, contraceptives, and menstrual products, which give users a holistic experience that can be anonymized to ensure privacy and protection.

The digital gamified learning platform developed in Tanzania by Haruna et al [26,38] represents an innovative leap in engaging and educating secondary school participants in the African setting. The authors used game-based and participatory designs to evaluate the ability of the game to motivate students, improve their attitudes, increase their acquisition of knowledge, and engage them in learning. A paired *t*-test revealed a statistically significant improvement in sexual health literacy scores from pretest (mean 26.40, SD 7.29) to posttest (mean 74.12, SD 16.21) (t_{347}=52.230; P<.000), with an average increase of 47.72 points. Additional analyses with ANOVA testing showed no significant differences in pretest scores among the 3 groups, but significant differences were found in posttest scores ($F_{2,345}$=210.43; P<.001), with follow-up Tukey post-hoc tests indicating better performance in the gamified learning platform groups than in the traditional teaching group. These findings suggest that gamified learning platforms can enhance motivation, attitude, knowledge acquisition, and engagement in sexual health education more effectively than traditional methods [26].

The research team took the intervention further in a 3-armed randomized clinical trial to compare the effectiveness of game-based learning and gamification to a control approach (traditional teaching method) [38]. The results showed that the average posttest scores were significantly higher for game-based learning (mean 79.94, SD 11.169) and gamification (mean 79.23, SD 9.186) than for the control approach (mean 51.93, SD 18.705) ($F_{2,117}$=54.75; P=.001). Additionally, statistically significant differences (P≤.05) were found for the constructs of motivation, attitude, knowledge, and engagement (MAKE) for the 2 intervention groups compared to the control arm. Gamification not only enhances learning outcomes but also introduces an element of fun and interaction that can

XSL•FO
RenderX

significantly increase participant engagement and knowledge retention [38]. Such gamified platforms offer promising avenues for making health education more appealing and effective for younger people.

Web-based platforms may eliminate the costs associated with the implementation of gamified learning platforms. In a content analysis of the TuneMe website, designed to deliver SRH information to Zambian adolescents aged 10 to 19 years, Rogers et al [34] reported that the website comprehensively covered topics of reproductive anatomy and STIs, including HIV, as well as relationships and sexual rights. However, the challenge of presenting SRH education in culturally relevant contexts was apparent when topics of sexual pleasure and gendered norms, behaviors, expectations, and violence were introduced, demonstrating nuanced beliefs around sexual rights.

Finally, social media emerged as a significant platform in the digital toolbox, with Dulli et al [23] exploring its utility among youth aged 15 to 24 years in Nigeria. The authors performed a randomized controlled trial using social media to deliver sexual health interventions for youth living with HIV (SMART Connections). The design and content of SMART Connections were as informed through workshops conducted with stakeholders and youth living with HIV. The content was delivered anonymously through Facebook over approximately 22 weeks to the intervention and control groups, with daily activities to promote engagement. The primary outcome was retention in HIV treatment, while secondary outcomes included antiretroviral therapy (ART) adherence, HIV knowledge, and social support. Although the intervention did not significantly improve the primary outcome of retention (50% and 45% retention in the treatment and control groups, respectively), there was a significant improvement in HIV-related knowledge for the SMART Connections group compared to controls (t=–2.96; P=.003). Intervention group participants overwhelmingly reported that the intervention was useful, that they enjoyed taking part, and that they would recommend it to peers. Similarly, Pfeiffer et al [33] found that Facebook was the most used social media platform for sexual health promotion in Southern Tanzania for youth aged 15 to 19 years. Adolescents were most interested in SRH messages through humorous posts, links, and clips, as well as through youth role models like music stars and actors in a manner that reflected up-to-date trends of modern youth culture. Both studies highlighted the integral role of social media in the daily lives of youth, positioning it as a critical channel for delivering sexual health education.

Collectively, these digital tools, ranging from social media and participatory design to mobile phone apps and gamification, reflect a dynamic and multifaceted digital ecosystem for SRH education. Each tool, with its unique features and applications, contributes to a broader strategy aimed at enhancing the accessibility, engagement, and effectiveness of health interventions in different African settings. These diversified digital tools not only address the varied needs and preferences of target demographics but also showcase the potential of technology in transforming health education and empowerment.

Discussion

In this research endeavor, we conducted a systematic literature review to achieve the following two objectives: (1) describe the geographic and demographic distributions of digital educational tools for SRH education for adolescents in Sub-Saharan Africa (objectives 1a and 1b) and (2) examine the types, formats, and impacts of these digital tools on target populations (objective 2). For the first objective, we identified 22 studies conducted across West, Central, East, and South Africa that focused on digital educational tools for SRH education targeting youth and adolescents aged 10 to 24 years. These studies offer valuable insights into the types of digital tools currently being employed in SRH education and highlight the regions where such tools are being most actively implemented. For the second objective, we found that a variety of digital tools, including social media, mobile apps, and gamified learning, were used to engage adolescents with accessible SRH information. These methods were generally effective, although challenges, such as the digital divide, cultural sensitivity, and the need for assessing long-term behavior change, were noted.

The 22 studies included in this review covered a broad spectrum of digital interventions, ranging from mobile apps to social media campaigns, and reflected a growing interest in digital platforms as a means of delivering SRH education to young people in Sub-Saharan Africa. The geographical distribution of the studies indicates that digital tools are being used across various cultural contexts, with notable contributions from West (eg, Nigeria and Mali), East (eg, Kenya and Tanzania), Central (eg, Cameroon and Democratic Republic of Congo), and Southern Africa (eg, Mozambique and South Africa). This regional diversity is significant as it shows that digital SRH interventions are becoming increasingly accessible across different subregions of Africa, each with unique sociocultural challenges and opportunities. Our findings suggest that digital tools can overcome geographic barriers, offering a means to engage with youth who may otherwise be excluded from formal SRH education programs due to geographical isolation, economic constraints, or cultural taboos around discussing SRH topics [41,42]. These findings are consistent with the broader literature on digital health interventions in the African region, which has highlighted the promising role of digital tools in expanding access to SRH education [31,43]. For example, in Nigeria, mobile apps focused on HIV prevention and sexual health have been shown to improve knowledge and self-efficacy among adolescents [44]. In Kenya, WhatsApp-based health campaigns have successfully increased awareness of sexual health issues among young people [45]. Conducting cross-country comparisons through systematic reviews, as performed in this work, provides valuable insights into the best practices that can be adapted and scaled across diverse African contexts. For example, WhatsApp is widely used around the world, and rather than reinventing the wheel, could developers in Nigeria adapt and implement the WhatsApp-based intervention designed for Kenyan youth by Chory et al [45] for a similar population in Nigeria? What would be the short- and long-term impacts of such an approach? Moreover, would policymakers be more inclined to support a “repackaged”

XSL•FO
RenderX

intervention that is cost-effective, evidence-based, and already proven in another African context? Future research should explore these cross-country comparisons in greater depth, examining the potential for scaling successful digital interventions across African nations. By redesigning these tools to reflect the cultural, linguistic, and societal contexts of each country, researchers can assess the feasibility and cost-effectiveness of adapting existing interventions, potentially saving time and resources compared to developing entirely new solutions.

Our second objective revealed that while a variety of digital tools were used to engage adolescents with accessible SRH information, mobile apps and gamified learning emerged as particularly popular and effective approaches. Mobile apps allow adolescents to access information in a flexible, anonymous, and user-friendly format, which helps overcome the barriers posed by traditional methods of SRH education [46]. This flexibility is particularly important in contexts where discussing sexual health is stigmatized, as it empowers youth to seek information discreetly and at their own pace. Additionally, gamified learning, by integrating interactive elements, not only captures adolescents' attention but also reinforces learning through engaging experiential methods, which may result in better knowledge retention and a deeper understanding of SRH topics [31]. Gamified learning, in particular, aligns with the preferences of a digitally native generation, where interactive and visually stimulating content is highly favored. Social media, including platforms like Facebook, WhatsApp, and Instagram, were also used to reach adolescents, leveraging peer influence and interactive communication strategies. This social aspect of learning enhances engagement by making the information feel more relevant and personal for youth. However, a major issue noted across the studies was the "digital divide," which is used to describe the unequal access to technology and internet connectivity that can limit the effectiveness of digital SRH education programs [47]. While mobile phones are widespread in Sub-Saharan Africa, reliable internet access remains a significant barrier, particularly in rural and underdeveloped regions [45]. This digital divide may result in inequitable access to SRH resources, especially for marginalized youth [45]. Innovative solutions, such as an artificial intelligence–powered phone, have the potential to bridge the digital divide [48]. This system delivers information and advice through voice calls, eliminating the need for a smartphone or internet connection and making information accessible to individuals without reliable internet or those who cannot afford smartphones and data plans [48]. By using artificial intelligence to understand natural language queries and provide tailored information from a knowledge base, these technologies can significantly improve access to SRH education in underserved areas with limited technological infrastructure [48]. Future research should explore effective solutions to overcome the digital divide, such as offline digital tools as described, low-cost data plans, and internet infrastructure development in rural and underserved areas.

Cultural sensitivity also emerged as a critical issue. In many African contexts, cultural norms and values significantly shape how SRH topics are perceived and discussed, and failure to account for these factors can limit the effectiveness of digital SRH interventions. For instance, discussions around issues like sexual consent, gender equality, and contraception can be seen as a taboo in some regions, which may lead to resistance or disengagement from the target audience [41]. Thus, tailoring content to reflect local values, languages, and cultural norms around sexuality is critical, as failing to consider these factors could undermine the effectiveness of SRH interventions. Involving adolescents in the creation and assessment of these tools can provide essential insights into their preferences, needs, and challenges, which can significantly enhance the acceptability and effectiveness of digital interventions [49]. Moreover, including parents could create opportunities to address cultural taboos and foster more open discussions between parents and adolescents on SRH [42]. Such involvement could lead to long-term benefits, as parent-adolescent communication is a key factor in reducing adverse sexual behaviors and improving overall sexual health outcomes [42]. According to Agbeve et al [42], African parents who hold sex-positive attitudes are more inclined to engage in discussions with their adolescents that help them make informed decisions regarding their sexual health and overall well-being. When parents are actively involved in the design and implementation of digital interventions, they can provide support, guidance, and reinforcement of the messages delivered through digital platforms [50,51]. Parental involvement can help create a more comprehensive approach to sexual education, ensuring that teens not only receive the digital information but also have a trusted adult to turn to for advice and clarification [50,51]. By fostering open communication between parents and teens, digital interventions can be better tailored to the specific needs of the family, ultimately promoting healthier decision-making and outcomes for young people.

Future studies could also explore avenues for incorporating comprehensive SRH education into the formal education system, expanding the scope of topics to include healthy relationships, positive sexuality, mental health, gender equality, and consent, as was done by Fakoya et al [24]. Integrating these topics into the curriculum would not only equip adolescents with essential knowledge about SRH but also foster a more holistic understanding of well-being and personal development. By addressing issues like mental health and gender equality alongside traditional SRH topics, this approach could help challenge harmful stereotypes, promote healthier attitudes toward sexuality, and empower young people to make informed decisions, leading to positive long-term social and health outcomes.

Finally, there was a noted gap regarding the impact of these digital tools on long-term adolescent sexual behavioral change. The majority of studies measured short-term outcomes, such as knowledge acquisition, while long-term studies assessing outcomes, such as improved contraceptive use and reductions in risky sexual behavior, remained limited. The anonymity and privacy afforded by digital platforms can empower adolescents to seek information and services without fear of stigma, promoting more proactive and informed health behaviors that can be tracked over time [46]. Tracking tools can be incorporated in the design phase of the intervention development

XSL•FO
RenderX

and can have input from adolescent end users. Long-term data support the sustainability of digital interventions, providing valuable information that can aid in the buy-in of investors, software developers, public health enthusiasts, and policymakers. Regardless, the implications of our findings are multifaceted and show that digital SRH tools are a promising avenue for enhancing adolescent sexual health education across the African region.

The use of a systematic literature review approach in this work has some limitations that are worth mentioning. The main limitations of our work are related to the methodology. There is a risk of selection bias, meaning that some relevant studies may have been omitted or that the included studies may not fully represent all available research on the topic. However, we believe that our extensive use of multiple databases (Ovid-MEDLINE, Google Scholar, PubMed, and ERIC) mitigated the risk of selection bias inherent in systematic reviews. A meta-analysis could further inform the selection bias risk and the heterogeneity of the included studies, and quantify the associations reported.

In conclusion, although digital SRH tools are a promising avenue for enhancing adolescent sexual health education in Sub-Saharan Africa, there is a need for infrastructure improvements to ensure the tools are equitably accessible and a need for understanding long-term impacts and sustainability. Policymakers, educators, and public health researchers must collaborate to ensure that digital innovations in SRH education are grounded in evidence, culturally sensitive, and widely accessible to all adolescents, regardless of socioeconomic status or geographical location. This will address the sustainable development goals of reducing the global disparities in SRH health (goal 10) and achieving good health and well-being across nations (goal 3).

Abstract

Background: Ethiopia is faced with poor measles-containing vaccine second dose (MCV2) coverage, leading to recurrent outbreaks.

Objective: This meta-analysis and systematic review aimed at combining evidence of MCV2 uptake in Ethiopia and its determinants to inform interventions for increased vaccination uptake and control of public health challenges.

Methods: This review examined observational quantitative research on measles second dose vaccination among children in Ethiopia using databases such as PubMed Central, Cochrane Library, Web of Science, Scopus, MEDLINE, and Embase. The quality of the included studies was assessed using the Newcastle-Ottawa Scale. Heterogeneity was evaluated using I^2 statistics and the Cochran *Q* test, and the analysis used a random-effects model. Publication bias was assessed through funnel plots, the Egger test, and nonparametric trim-and-fill tests.

Results: The overall MCV2 uptake among children aged <5 years in Ethiopia was only 34.4% (95% CI 18.8%-49.9%). Significant determinants of MCV2 uptake included high level of maternal education (adjusted odds ratio [AOR] 3.31, 95% CI 1.32-5.30), attendance to antenatal care follow-ups (AOR 2.02, 95% CI 1.12-2.92), use of postnatal care services (AOR 3.03, 95% CI 1.77-4.28), reduced waiting times at vaccination sites (AOR 2.56, 95% CI 1.98-3.13), good awareness of measles vaccination (AOR 2.17, 95% CI 1.59-2.74), and positive perceptions of the vaccine (AOR 3.58, 95% CI 1.97-6.30).

Conclusions: This study found that the uptake of MCV2 among children aged <5 years in Ethiopia was 34%, which is far below the global and national goal of 95%. Key factors contributing to low coverage include mothers' educational levels, use of antenatal and postnatal care services, waiting times at vaccination sites, and mothers' awareness of the measles vaccine. Improving community-based education programs, increasing access to antenatal and postnatal care services, reducing waiting times, and raising awareness about immunization all contribute to increasing vaccine uptake.

Introduction

Background

Measles, a virulent viral disease caused by the measles morbillivirus, continues to exert a significant global health burden despite decades of vaccination efforts. The disease is characterized by fever, maculopapular rash, cough, coryza, and conjunctivitis. Alongside these symptoms, severe complications such as encephalitis, severe pneumonia, and even death may occur. These complications tend to be worse in young children, malnourished individuals, and people with a weakened immune system [1,2]. The highly contagious nature of measles is further highlighted by its basic reproductive number (R0), which is estimated to be between 12 and 18. This elevates the threshold population immunity required to prevent sustained transmission of the virus to >95% immunization [3].

The lack of global progress made toward measles control in the early 21st century is concerning, especially with the recent regressions observed. One study revealed the increasing rate of measles infections worldwide, projecting that 10.3 million people were infected in 2023, which is a shocking 20% increase from the previous year's estimate. Moreover, the number of countries with outbreaks also increased from 36 to 57 [4].

This surge critically underscores the precarious state of global immunity, a condition made even more fragile by disruptions to routine immunization services—such as those observed during the COVID-19 pandemic—and compounded by prevailing vaccine hesitancy across many populations [5,6]. In fact, insufficient coverage of immunization is the main impetus for these increasing outbreaks. More than 22 million children worldwide missed their first dose of the measles vaccine in 2023 alone—this creates growing susceptible cohorts that fuel epidemics [5].

The burden of measles falls on low- and middle-income countries. That is where health systems become even more strained, in many cases due to infrastructural, financial, and geographical barriers preventing access to strong equitable routine immunization services [7]. Measles can certainly be a disaster for morbidity and mortality within vulnerable populations but also severely strain already weak health care infrastructures by taking away badly needed resources from other important frontlines of public health, as well as increasing existing inequities in these vulnerable populations. The big picture goal of global measles elimination—as so unmistakably articulated in the World Health Organization (WHO) Immunization Agenda 2030—is decidedly imperiled at present by exactly such gaps in coverage, thus demanding recommitment and inspiring novelty in contextualized strategies directed toward achieving the lofty coverage rates necessary for eradication [8-10].

Prevention of measles and its complications is best achieved through vaccination. There are several live, attenuated measles vaccines that range from monovalent vaccines to combinations under the "measles-containing vaccine" name that also provide immunity against rubella, mumps, and varicella. Both doses of the measles vaccine currently in use worldwide are safe and effective. The first dose of the measles-containing vaccine (MCV1) was introduced in 1963, and by the 1980s, the WHO recommended that all countries implement routine MCV1 vaccination in their childhood immunization schedules. Ethiopia followed suit and introduced the MCV1 in the late 1980s [11,12].

Even following the introduction of the MCV1, which provides immunity to 85% of vaccine recipients, up to 15% of individuals do not develop long-term immunity following a single dose. MCV1 in some cases will also not generate an adequate immune response to provide immunity, a condition that comes to be known as primary vaccine failure. Identifying this gap, the WHO recommended in 2009 that countries introduce a second dose of the measles-containing vaccine (MCV2) into the national immunization schedules after they achieved 80% MCV1 uptake for 3 consecutive years. However, in 2017, the WHO revised this and recommended the introduction of MCV2 into national immunization schedules regardless of the level of uptake of MCV1 [13,14]. In response, Ethiopia introduced the MCV2 in February 2019 [15].

To maximize the effectiveness of vaccination, WHO guidelines stipulate that, in regions where the risk of measles mortality among infants is high, the MCV1 should be administered at 9 months of age followed by the MCV2 at the ages of 15 to 18 months. In lower-risk countries, the MCV1 may be administered at 12 months, with MCV2 timing adjusted to achieve the highest uptake by children [13]. Given the high risk of measles mortality in Ethiopia, both doses are administered at 9 and 15 months, respectively [16-18].

Even with national efforts and strategic frameworks adopted by the Ethiopian government as part of measles elimination efforts by 2030—strengthening routine immunization services, supplementary immunization activities, and surveillance—there remains a profound burden of measles in Ethiopia. Recent data clearly show an alarming reality that underscores gaps left behind in immunization coverage [19]. The United Nations Children's Fund and Centers for Disease Control and Prevention reports place Ethiopia consistently among those countries that have a large number of unvaccinated children [20,21]. Furthermore, it has always been among the topmost countries reporting measles cases, with both periodic and significant outbreaks across its regions [21].

Recent studies on measles epidemics in Ethiopia have described the entire picture of systemic and operational factors that contribute such challenges. A detailed review of outbreak investigations carried out in 2024 highlighted critical issues such as staff absenteeism, vaccines being out of stock at different levels of the supply chain, and shortage of operational funding leading to high dropout rates in vaccination and compromised service delivery [22]. Studies carried out in 2023 and 2024 further detailed such barriers from a qualitative perspective by introducing community-based factors—rural residence; low educational level of mothers among their sociodemographic characteristics; perceived safety of vaccines; inadequate health facilities within accessible distance; and inadequate community mobilization that impedes attainment of adequate coverage, particularly for the second dose [23,24]. Consequently, MCV2

XSL•FO
RenderX

uptake in Ethiopia persistently remains below both national targets and the critical 95% threshold necessary for achieving population-level herd immunity, contributing directly to the ongoing susceptibility of communities and the perpetuation of the disease [18,25]. Therefore, addressing this *last mile* gap in MCV2 coverage is identified as an urgent public health priority.

Objectives

Even though individual studies have looked at different aspects of vaccine acceptance and uptake across various regions of Ethiopia, there is still a lack of clear, comprehensive, and quantitative insights into the specific factors influencing MCV2 uptake at the national level. This systematic review and meta-analysis aimed to bring together all available data from Ethiopia on MCV2 uptake and its key determinants. By thoroughly synthesizing the existing evidence, we aimed to deepen the understanding of this pressing public health issue and support the development of more effective, evidence-based strategies to protect the health of Ethiopian children—and, ultimately, help achieve global and national measles elimination goals.

Methods

Study Design and Reporting

This systematic review and meta-analysis aimed to provide an estimate of the overall MCV2 uptake and determinants among children aged <5 years in Ethiopia. This review used the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. In addition, this review has been registered with PROSPERO with protocol CRD42024619031.

Inclusion and Exclusion Criteria

The inclusion and exclusion criteria for this review can be found in Textbox 1.

Textbox 1. Inclusion and exclusion criteria for the systematic review and meta-analysis on the uptake of the second dose of the measles vaccine and its determinants among children aged <5 years in Ethiopia (criteria defined for study selection and rationale; 2025).

Inclusion criteria

- Setting: research conducted only in Ethiopia
- Population: studies involving children
- Language: published in English
- Study design: observational studies (longitudinal, cohort, cross-sectional, or case-control)
- Outcome variables: clearly defined outcome variables
- Quality: studies of sufficient quality
- Access: accessible through electronic resources

Exclusion criteria

- Setting: studies conducted outside of Ethiopia
- Population: studies focusing on adults or other populations
- Language: published in languages other than English
- Study design: experimental studies or reviews
- Outcome variables: undefined or unclear outcome variables
- Quality: low-quality studies
- Access: studies for which necessary information could not be obtained due to unavailability of the full text

Search Strategy and Source of Information

The search strategy was built using an adapted population, exposure, outcomes, study design, and setting framework to generate the MeSH (Medical Subject Headings) terms necessary to search for appropriate studies in the databases as follows:

1. Population: “children” and “pediatrics population”
2. Exposure: “second-dose measles vaccine” and “second-dose measles-containing vaccine”
3. Outcome: “uptake,” “utilization,” “coverage,” “associated factors,” “predictors,” “barriers,” or “determinants”
4. Study design: “observational studies”
5. Setting (context): “Ethiopia”

For a systematic review with primary studies as part of these studies, review questions focused on Ethiopia based on the aforementioned format were as follows: (1) what is the aggregate uptake of MCV2 among children aged <5 years in Ethiopia? (2) What associated factor explains the uptake of the MCV2 among children in Ethiopia?

A systematic search was conducted in various electronic databases: PubMed Central, Cochrane Library, Web of Science, Scopus, MEDLINE, Embase, and Google Scholar. The search used specific free-text terms and Boolean operator strings to locate studies pertinent to the aforementioned questions: (“Second-dose measles vaccine” OR “Second-doses measles-containing vaccine” OR “two-doses of measles vaccine” OR “measles vaccination”) AND (“children” OR “pediatrics”)

XSL•FO
RenderX

AND (“uptake” OR “utilization” OR “coverage” OR “acceptance” OR “adherence”) AND (“associated factors” OR “predictors” OR “barriers” OR “determinants” OR “influencers” OR “challenges”) AND (“Ethiopia” OR “Ethiopian context” OR “Ethiopian children”). After retrieving accessible articles, all the results were sorted, and duplicates were removed.

Study Selection and Quality Assessment

Two investigators, TEH and TAK, conducted a preliminary screening of studies by reviewing titles and abstracts to identify potentially relevant research before retrieving the full texts. If additional clarification was required to determine eligibility, they reached out to the corresponding author (MAA). Any disagreements between the investigators were resolved through discussion to achieve a consensus on inclusion or exclusion. All retrieved articles were imported into EndNote (version 20; Clarivate Analytics), where duplicate entries were eliminated. Next, the researchers reviewed the articles independently based on their structures and purposes, searching titles, abstracts, and full texts for studies that met the predetermined inclusion criteria. The articles for this review were selected and analyzed jointly by both reviewers.

To ensure the quality of each study, the adapted Newcastle-Ottawa Scale was used, which was reviewed by 3 independent assessors. The assessors undertook an inclusive review of all articles that met the inclusion criteria and study purpose. Differences between the reviewers were resolved through consensus, and a fourth reviewer was involved in adjudication as necessary.

The criteria for the assessment addressed a series of key areas: representativeness of the sample, adequacy of the sample size, response rates, respondent and nonrespondent characteristics, quality of the intended measurement tools for exposure or risk factors, comparability of outcome groups based on study design, controlling for major confounding variables, and measurement of outcome and use of appropriate statistical tests. Each of the studies was scored out of 10 points, with scores of >7 indicating low risk of bias for inclusion. All studies included in the analysis had a low risk of bias, with scores ranging from 9 to 10 (the full Newcastle-Ottawa Scale results can be found in Table S1 in Multimedia Appendix 1 [26-36]).

Data Extraction

The data extraction form was developed using a Microsoft Excel spreadsheet. Two independent reviewers (MAA and ABZ) systematically extracted data from the full-text articles. The data extraction form included key variables such as the first author’s name, year of publication, study region, study design, sample size, age of the participants, sample distribution by sex, uptake or coverage, and the number of children vaccinated with MCV2.

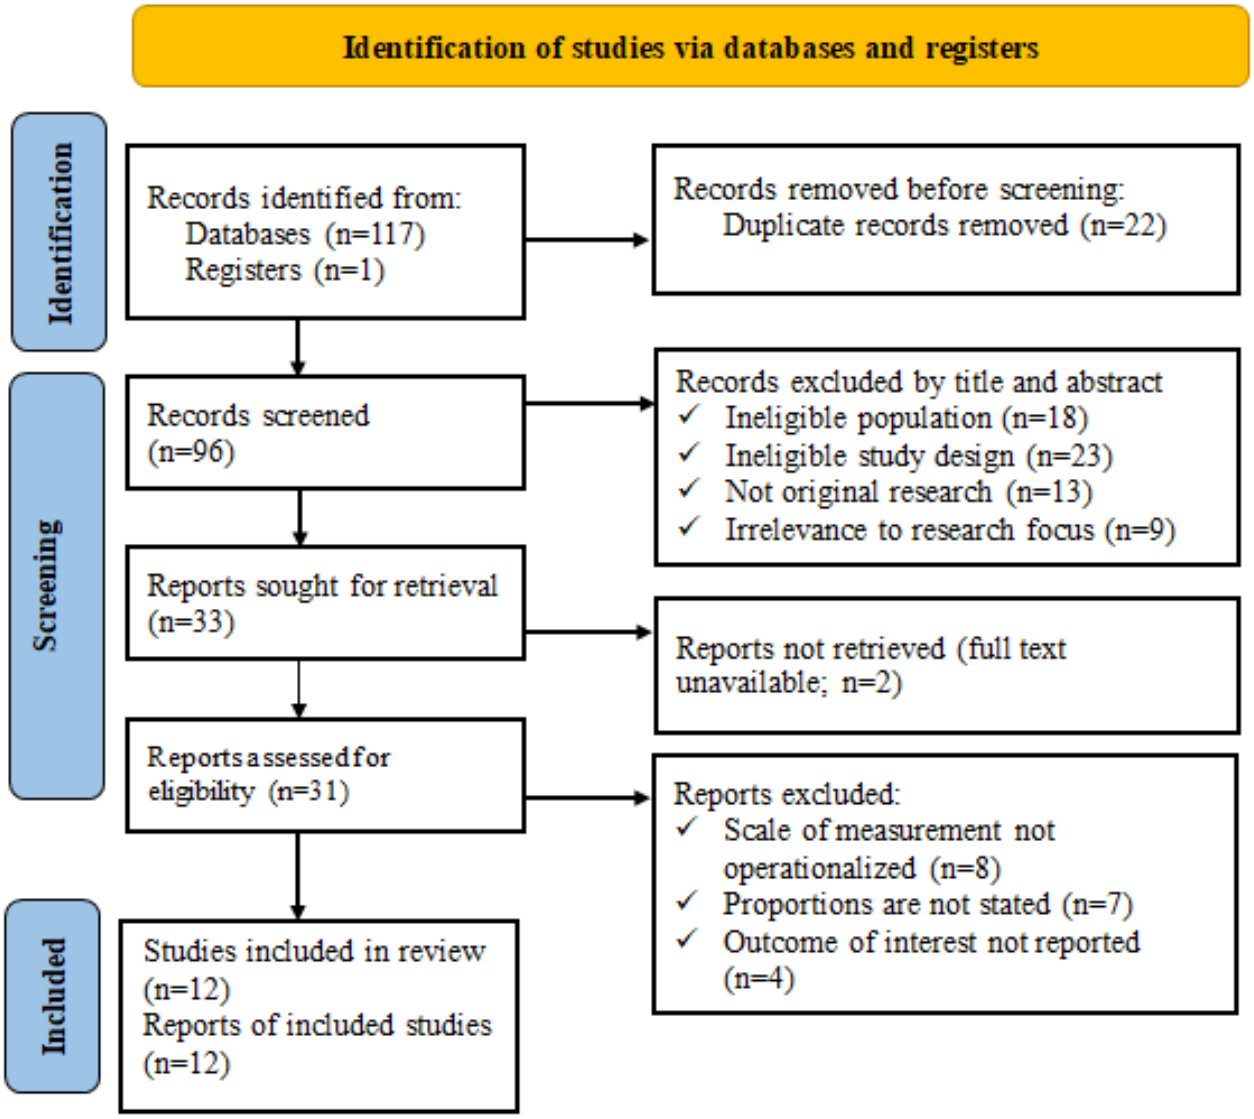
For each primary outcome, the uptake of MCV2 was recorded, whereas adjusted odds ratios (AORs) for each associated factor (secondary outcome) were also noted along with 95% CIs. Any discrepancies between the data extractors were addressed through discussion and consensus with another author.

Statistical Analysis

After extracting the data, a meta-analysis was conducted using Stata (version 17; StataCorp). Uptake estimates were calculated along with their corresponding SEs using the formulas $p = r/n$ and $SE = \sqrt{p(1-p)/n}$, where p represents the proportion, r is the total number of children vaccinated with MCV2, and n is the sample size. The results of the meta-analysis are presented as the pooled uptake of MCV2 accompanied by 95% CIs. A significance threshold was established at P values of <.05.

To investigate the factors influencing the uptake of MCV2, Stata (version 17) was used. A random-effects model was applied as heterogeneity between studies was high, as confirmed through an I^2 statistic of >75% and a P value of <.05. The I^2 index and Cochran Q test were used for testing heterogeneity. The I^2 statistic ranges from 0% to 100%, with 0% indicating no heterogeneity and 100% indicating high heterogeneity.

The effect of individual studies on the overall prevalence estimate was tested using sensitivity analysis. Publication bias was also tested using funnel plots for symmetry assessment, as well as the Egger test and nonparametric trim-and-fill tests. Although both these tests were used, the Egger test is commonly deemed superior for detecting publication bias because it provides actual effect sizes along with their accuracy. Contrary to this, the funnel plot is a less objective measure of potential asymmetry and may hint at publication bias.



Results

Literature Search

This systematic review and meta-analysis followed the PRISMA guidelines (Multimedia Appendix 2). A comprehensive search of PubMed Central, Cochrane Library, Web of Science, Scopus, MEDLINE, and Embase initially yielded 118 articles addressing MCV2 uptake and its predictors among Ethiopian children. Of these 118 articles, after removing 22 (18.6%) duplicate records, 96 (81.4%) underwent title and abstract screening. Of these 96 articles, 63 (66%) were excluded for the following reasons: ineligible population (n=18, 29%), ineligible study design (n=23, 37%), nonoriginal research (n=13, 21%), or irrelevance to the research focus (n=9, 14%). The remaining 33 full-text articles were assessed for retrieval, with 2 (6%) records unavailable. Of the 31 articles evaluated in full text, 19 (61%) were excluded due to non-operationalized measurement scales (n=8, 42%), unstated proportions (n=7, 37%), or unreported outcomes of interest (n=4, 21%). Ultimately, 12 studies met all the inclusion criteria and were included in the final analysis (Figure 1).

XSL•FO
RenderX

Figure 1. Identification of studies via databases and registers.

Study Characteristics

The total review comprised 12 studies on 7847 children from all regions of the country. Specifically, the proportion of studies by region was 50% (6/12) of the studies conducted in Amhara, 25% (3/12) in Oromia, 8% (1/12) in Somalia, and 17% (2/12) from all regions. A total of 92% (11/12) of the studies were cross-sectional, and 8% (1/12) were case-control studies. All studies (12/12, 100%) were conducted during the period from 2019 to 2023. The average number of participants per study was 654 (SD 254; range 372-1172). Almost half (49%) of the participants were female (Table 1).

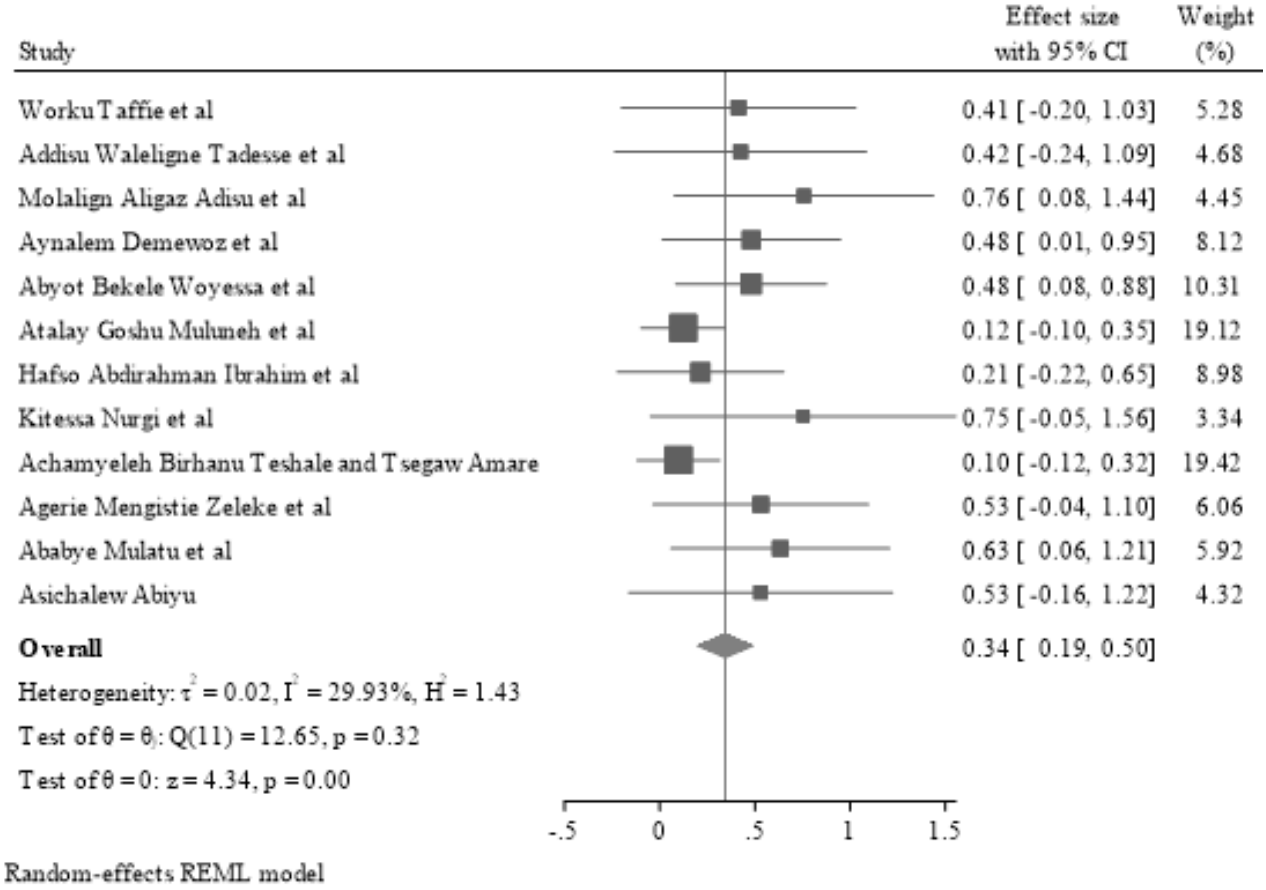
Publication Bias

The publication bias was estimated through funnel plot analysis and the Egger regression test. The funnel plot revealed an asymmetrical shape, intuitively suggesting the presence of publication bias (Figure 2). The Egger regression test also yielded a *P* value of .001, indicating statistical evidence of publication bias. This agreement between subjective and objective analysis strengthens the likelihood of bias in the published studies.

XSL•FO
RenderX

Figure 2. Funnel plot illustrating publication bias for second-dose measles vaccine uptake among children younger than 5 years in Ethiopia (analysis conducted in 2025), reflecting study distribution and variability.



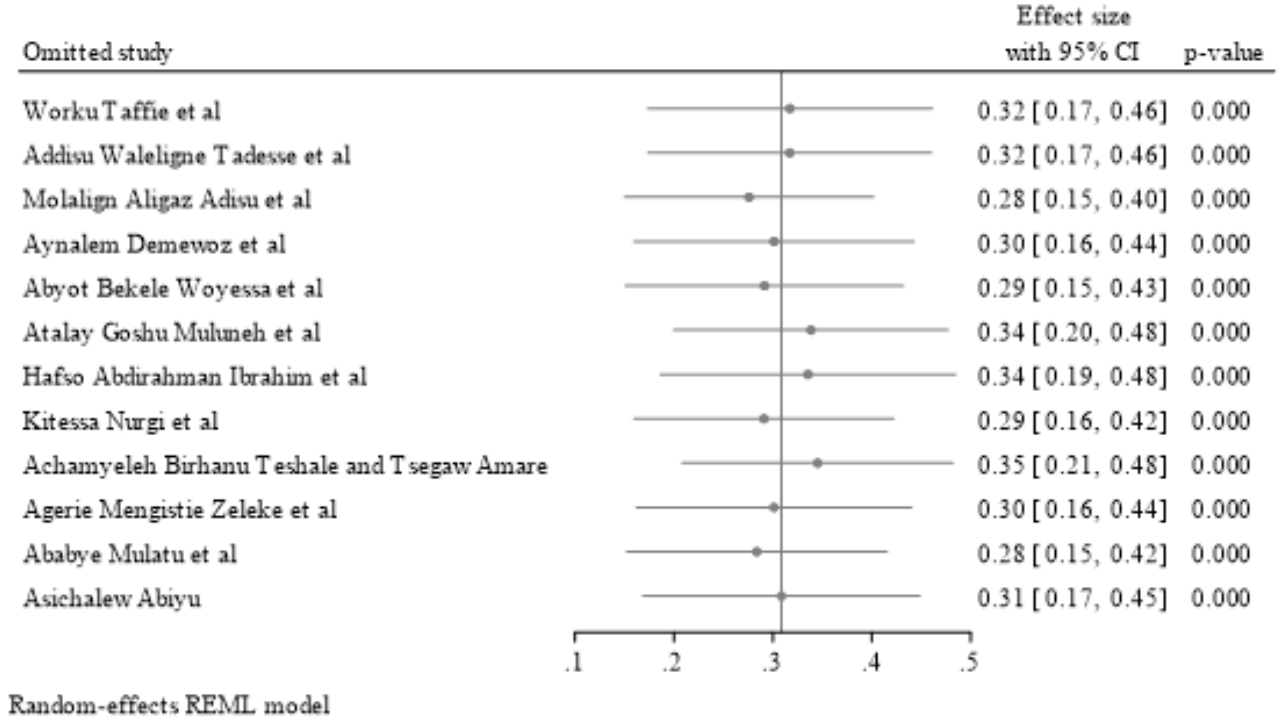
To explain the potential issue of publication bias indicated by the asymmetrical funnel plot, a nonparametric trim-and-fill analysis was conducted to calculate the overall effect. The trim-and-fill analysis flagged 18 studies and imputed 6 studies to calculate the potential bias. The observed effect size was 34.4 (95% CI 18.8-49.9). Following imputation of the studies, the effect size was 20.6 and was well within the CI of the observed effect. This means that the imputed studies had zero or negligible contribution to the overall effect size. The trim-and-fill analysis was used to include any missing studies due to publication bias and provide a better estimate of the true effect size. The tiny difference between the observed and adjusted effect sizes informed us that publication bias was likely not a significant problem in this dataset.

Pooled Uptake of MCV2 Among Children in Ethiopia

The pooled uptake of MCV2 among children in Ethiopia was 34.4% (95% CI 18.8%-49.9%), and there was low heterogeneity between the studies (P=.32; τ^2=0.02; I^2=29.9%; H=1.41; Figure 3 [26-36]).

XSL•FO
RenderX

Figure 3. Forest plot depicting the pooled uptake of second-dose measles vaccine among children younger than 5 years in Ethiopia.



Sensitivity Analysis

Sensitivity analysis was conducted to evaluate the influence of outlying or potentially influential studies on the overall uptake estimate of the MCV2 among children. Through a random-effects model, the results of this analysis showed that there were no influential studies or outliers detected because all the point estimates fell within the limits of the 95% CI. This finding indicates that the overall estimate of uptake was robust and not determined to a large degree by a single study, thus providing additional strength for the validity of the pooled results. The full sensitivity analysis results are presented in Figure 4 [26-36].

Figure 4. Results of the sensitivity analysis on the uptake of second-dose measles vaccine among under-five children in Ethiopia.

Factors Associated With the Uptake of MCV2 in Ethiopia

The pooled odds ratio for mothers with the highest educational attainment as indicated in the studies was 3.31 times greater for vaccinating their children with MCV2 than for mothers with low or no education (AOR 3.31, 95% CI 1.32-5.30). Moreover, mothers who attended antenatal care (ANC) follow-ups were over twice as likely to vaccinate their children with MCV2 compared to those who did not attend ANC follow-ups (AOR 2.02, 95% CI 1.12-2.92). Similarly, mothers who used postnatal care (PNC) services were 3 times more likely to vaccinate their children with MCV2 than mothers who did not use PNC services (AOR 3.03, 95% CI 1.77-4.28).

In addition, mothers who had a waiting time of <30 minutes at vaccination centers were 2.5 times more likely to vaccinate their children than those with waiting times of >30 minutes (AOR 2.56, 95% CI 1.98-3.13). Moreover, mothers who were highly aware of measles vaccination were twice as likely to vaccinate their children with the second dose as mothers who were lowly aware (AOR 2.17, 95% CI 1.59-2.74). Similarly, the odds of being vaccinated with the MCV2 were 3.5 times higher (AOR 3.58, 95% CI 1.97-6.30) among children of mothers who had a positive perception of the measles vaccination compared to those of mothers with a poor perception (Table 2).

Table 2. Pooled estimates of determinants affecting the uptake of the second dose of the measles vaccine among children aged <5 years in Ethiopia (analyzed in 2025).

Associated factors	Pooled effect size (95% CI)	I^2 (%)	Egger test *P* value	Studies pooled
Mothers who attained the highest level of education	3.31 (1.32-5.30)	0	—[a]	[23,31]
Mothers who attended ANC[b] service follow-up	2.02 (1.12-2.92)	0	.40	[28,34]
Mothers who attended PNC[c] service follow-up	3.03 (1.77-4.28)	18.64	.19	[26,28,31,32]
Waiting time of <30 min at the vaccination site	2.56 (1.98-3.13)	0	.62	[27,34]
Mothers who had good awareness	2.17 (1.59-2.74)	0	.01	[26-29,31]
Mothers who had a positive perception	4.30 (2.63-5.97)	0	.35	[28,29]

Discussion

Principal Findings

Pooled uptake of MCV2 among children aged <5 years in Ethiopia was 34.4% (95% CI 18.8%-49.9%). This result is in line with the statistics from Nigeria, Madagascar, and Afghanistan, where low uptake rates have been documented [37-39]. However, this figure is significantly lower than the WHO target of 95% for MCV2 uptake, as well as the national immunization targets set by Ethiopia and other countries [38,40-42]. A WHO report showed that there are countries even below this level of uptake, such as the Democratic Republic of the Congo, Uganda, and Angola [38], which poses a substantial risk to public health in these regions. Several factors contribute to the low vaccination rates in Ethiopia. Ongoing strife and instability in certain regions have significantly hampered health care provision and access to vaccine services. Internal displacement and conflict have led to destruction of health infrastructure, which is making it increasingly difficult for families to access core immunization services. In addition, socioeconomic obstacles for several families, such as illiteracy and poverty, further compound the problem, leading to poor awareness and prioritization of vaccination. The consequences of the very low uptake are extensive. A high level of vaccination uptake should be reached if measles epidemics are to be avoided and herd immunity is to be achieved. All this emphasizes once more the imperative of urgent specific interventions aimed at improving vaccine uptake. Some likely options include increasing public awareness regarding the importance of the second dose, enhanced health service access, and targeting obstacles keeping families from vaccinating their children. Without significant improvements in these areas, the goal of measles elimination in Ethiopia and similar contexts will remain unattainable.

The pooled odds ratio indicated that mothers with the highest educational attainment were 3.31 times more likely to vaccinate their children with MCV2 compared to mothers with low or no education. Similar observations have been recorded in other sub-Saharan countries [41,43]. This is because those mothers who are better educated to some level will understand the benefit of vaccination, appreciate the hazard of vaccine-preventable diseases, and be in a position to avail their children care. This underscores the value of targeted educational interventions to increase awareness and knowledge of the importance of immunization, particularly among more poorly educated communities. Through investment in education, public health interventions will be able to improve levels of vaccination uptake and, ultimately, child health outcomes among high-risk groups.

The findings indicate that maternal attendance to ANC and PNC services significantly influences whether children are immunized with MCV2. Specifically, mothers who attended ANC follow-ups had twice the chances of vaccinating their children compared to those who did not attend ANC follow-ups. Similarly, mothers using PNC services were 3 times more likely to vaccinate their children with MCV2 than those who did not receive PNC services. Similar results have been reported in sub-Saharan African and South Asian countries [41,44]. This is because women attending ANC and PNC are most likely to know more about health habits, including the significance of vaccinations. During these visits to health care facilities, there are opportunities for health care workers to inform mothers of the advantages of vaccination, clarify queries, and provide support for appropriate timing of vaccination. All these findings demonstrate the importance of maternal health care uptake in the initiation of immunization.

The combined outcome revealed that mothers who waited for <30 minutes at the vaccine center were 2.5 times more likely to vaccinate their children compared to those waiting for >30 minutes. This is consistent with findings reported in other studies [45]. This is because shorter waiting times enhance perceived convenience in attending vaccination sessions. When mothers enjoy a smooth experience, they tend to perceive vaccination as possible and, hence, have a high compliance. In contrast, longer waiting times provide opportunities for mothers to become exhausted and stressed, especially with respect to children, who are most likely to become restless. Reduced waiting times create a smoother experience, allowing mothers to proceed with vaccinations easily. Apart from this, time is a valuable resource for most families, with women typically having a work schedule as well as caring duties. Thus, it is preferable to minimize waits to counter the opportunity cost of attending vaccinations. This provides evidence of the significant impacts of waiting times on acceptance of vaccinations, suggesting the role of the efficiency of the vaccination process in shaping immunization uptake.

The combined findings indicate that maternal perception and awareness of measles vaccination exert a significant influence on children vaccination uptake. Mothers with high awareness of measles vaccination were more than twice as likely to vaccinate their children with the second dose compared with mothers with low awareness. In addition, the odds of vaccinating children with the second dose were 3.5 times higher among mothers with a positive perception of measles vaccination. This outcome is consistent with those of a study conducted in sub-Saharan Africa [43,46]. This is because educated mothers who comprehend the value and advantages of measles vaccination are most likely to place greater emphasis on immunization among their children. Effective awareness helps in clearing misconceptions and myths that could lead to vaccine hesitation [46,47]. Moreover, when mothers believe in the efficacy and safety of vaccines, they are more likely to adhere to immunization schedules. Such beliefs may be based on personal experience, social norms, or successful health promotion. These findings highlight the exceptional significance of enhancing maternal attitudes and perceptions regarding measles vaccination. Vaccine benefit knowledge can significantly boost rates of vaccination among children. Public health interventions should be grounded in educational activities and community mobilization to establish an enabling environment for immunization.

This study has several limitations that warrant acknowledgment. First, the small sample size and cross-sectional design restrict both statistical power and the ability to infer causality or temporal relationships concerning vaccine acceptance. A

XSL•FO
RenderX

significant limitation stems from the potential publication bias observed among the included studies (Egger test: *P*=.001), which, despite mitigation efforts such as trim-and-fill analysis, could still influence the pooled estimates. This is compounded by the reliance on self-reported data within many of the included studies, introducing potential social desirability and recall biases, particularly for subjective measures such as awareness. Furthermore, there was a notable geographical imbalance, with a disproportionate number of included studies originating from the Amhara region and underrepresentation of other diverse Ethiopian contexts. This limits the generalizability of our findings across the nation's varied cultural and health care landscapes. Finally, the analysis did not fully account for the impact of temporal factors and policy changes, especially given the introduction of MCV2 in Ethiopia in 2019 and the varying time frames of the included studies. Important covariates such as cultural beliefs; accessibility challenges (eg, rural vs urban disparities); and conflict-related disruptions, which are known to influence vaccination rates in Ethiopia, were also not explicitly explored. Future research should aim to address these gaps to provide a more comprehensive understanding of vaccine uptake determinants.

Conclusions and Recommendations

The pooled MCV2 uptake among Ethiopian children aged <5 years was 34%, which is far below the national target of 95%. The level of education of mothers, use of ANC and PNC services, waiting time at vaccination sites, and mothers' awareness and perceptions of measles vaccination were statistically significant predictors of uptake of MCV2. To increase the uptake of MCV2 in Ethiopia, it is necessary to target interventions. Interventions should target the strengthening of community-based educational programs, mobile clinics for remote areas, enhanced access to ANC and PNC services, reduction of waiting times at the point of vaccine delivery, and raising awareness about the benefits of measles vaccination. These multistakeholder initiatives are crucial in achieving the national immunization objective.

Acknowledgments

The authors acknowledge the authors of the included studies for their original contributions.

Abstract

Background: Typhoid fever, a significant global health problem, demonstrates a multifaceted transmission pattern. Knowledge of the factors driving its transmission is critical for developing effective control strategies and optimizing resource allocation.

Objective: This review aimed to comprehensively synthesize evidence on risk factors associated with typhoid fever transmission from 1928 to 2024.

Methods: We searched PubMed, Scopus, Google Scholar, and Semantic Scholar databases using keywords related to risk, contributors, determinants, and causes of typhoid fever. We followed a registered protocol to support our search and triangulated the results.

Results: Overall, we retrieved 1614 articles, of which 219 were reviewed. Of these, 109 addressed multiple, non–mutually exclusive typhoid fever risk factors. Unsurprisingly, of the total articles reviewed on risk factors, approximately 70.6% (77/109) originated from the Asian continent (51/109, 46.8%) and the African continent (26/109, 23.9%). Half of the articles (55/109, 50.5%) focused on risk factors related to demographic and socioeconomic transmission, while 44% (48/109) of the articles examined foodborne transmission. Additional risk factors included water, sanitation, and hygiene practices: waterborne transmissions (45/109, 41.3%) and sanitation and hygiene practices (34/109, 31.2%), travel-related risk (19/109, 17.4%), antimicrobial use (14/109, 12.8%), climate-related factors (15/109, 13.8%), environment-related factors (9/109, 8.3%), typhoid carriers (11/109, 10.1%), and host-related risk factors (6/109, 5.5%).

Conclusions: This review identifies demographic and socioeconomic factors as key drivers of typhoid transmission, underscoring the need for targeted interventions. Strengthening street food regulation in urban Asia and investing in water infrastructure in rural Africa can significantly mitigate risk. Integrating water, sanitation, and hygiene interventions with typhoid vaccines can reduce immediate exposure while enhancing long-term immunity. Prioritizing these strategies in schools and high-risk communities is essential for sustainable typhoid control. Future research should focus on longitudinal studies to assess risk factor causality and vaccine impact, guiding more effective public health interventions.

KEYWORDS

typhoid fever; risk factors; foodborne; waterborne; systematic review

Introduction

Background

Typhoid fever is a potentially fatal febrile systemic disease caused by *Salmonella enterica* serotype Typhi (*Salmonella* Typhi or *S* Typhi), a rod-shaped gram-negative bacterium belonging to the Enterobacteriaceae family. *S* Typhi exists exclusively in humans and causes illnesses (typhoid fever) that resemble many other febrile diseases [1]. In this study, the terms "typhoid fever" and "typhoid" are used interchangeably. A description of the infection was reviewed by Cunha [2], clearly separating it from other febrile illnesses and associating its clinical manifestation with significant pathological abnormalities in the spleen, mesenteric lymph nodes, and intestines. Nonetheless, the mainstay of diagnosis is a microbial culture, usually with blood or bone marrow samples. Although bone marrow culture is highly sensitive, it is both invasive and technically unfeasible in most settings. As a result, the disease is usually diagnosed with blood culture, despite its limited sensitivity of approximately 40% to 80%, partly due to antibiotic exposures before the patient visits the health facility [3].

The disease transmission is by the fecal-oral route and can take 2 main forms: direct transmission, where food and water in the immediate environment are contaminated through poor hygiene and sanitation practices, either by transient or chronic carriers; and indirect transmission, where the broader environment becomes contaminated when sewage pollutes water supplies, raw human feces or untreated sewage is used as fertilizer for crops, or piped water is inadequately treated [4].

Typhoid fever is reported to affect people of all ages, although children are more susceptible than other age groups [5]. Before 2000, the global burden of typhoid fever was estimated at 16 million illnesses and 600 thousand deaths annually [6]. In 2000, approximately 21.7 million illnesses and 216,000 deaths occurred [7]. By 2010, annual estimates indicated approximately 26.9 million cases and 200,000 fatalities [8]. However, a more recent estimate from 2017 to 2024 suggests a decline in the annual incidence of typhoid cases [9,10]. Despite this decrease, typhoid fever remains a significant public health concern, particularly in areas with limited access to clean water and sanitation. Typhoid fever can be prevented and controlled concurrently with vaccinations and advancements in food safety, water quality, hygiene, and sanitation [11]. Three main generations of typhoid vaccines are presently approved for use by the World Health Organization (WHO): typhoid conjugate vaccines (TCVs), live attenuated Ty21a, and the unconjugated Vi polysaccharide vaccines [4]. The WHO strongly recommends using TCVs for all ages due to their superior immunological properties, suitability for use in younger children, and predicted longer period of protection above 2 years, which was a major limitation for using the Vi polysaccharide. However, to inform the choice of vaccination in a country, evidence is needed on both the scope of the problem and the risk factors contributing to disease transmission [11]. Despite notable progress in typhoid control, the disease remains a significant cause of morbidity and mortality to which billions of people worldwide are continuously exposed, particularly in Asia and sub-Saharan Africa.

Typhoid fever susceptibility involves multiple factors, each contributing through distinct transmission pathways. In endemic countries, knowledge of typhoid fever risk factors is critical for developing effective control strategies and allocating resources. Several epidemiological and modeled studies [12-14] have explored location- and time-specific risk factors for typhoid fever. In addition, various review studies have been undertaken to comprehensively understand and address the risk of typhoid across different transmission routes. For instance, Lee et al [15] used geospatial modeling to develop a typhoid risk index based on factors such as water sources, toilet facilities, and population density, providing insight into the geographical distribution of typhoid risk in impoverished countries. Similarly, Kim et al [16] investigated the relationship between observed incidence rates and geospatial covariates, such as access to improved water and sanitation, as well as broader health and environmental conditions influencing the transmission of *S* Typhi. Furthermore, Brockett et al [17] systematically reviewed case-control studies to uncover associations between water, sanitation, and hygiene (WASH) practices, food exposures, and typhoid fever. Similarly, Mogasale et al [18] conducted a meta-analysis spanning 1990 to 2013 to estimate the risk of typhoid associated with inadequate access to safe water. In addition, Wang et al [19], in a systematic review and meta-analysis, described the patterns of salmonellosis outbreaks in China from 1970 to 2023. Other reviews have examined specific aspects of typhoid transmission. For instance, the study by Ma et al [20] reviewed human genetic variants affecting susceptibility to enteric fever infection, while Levantesi et al [21] assessed the contribution of natural freshwater and drinking water as routes of *Salmonella* contamination from 2000 to 2010.

Objectives

While these studies provide valuable insights into different aspects of typhoid risk, a holistic synthesis of socioeconomic, environmental, and other factors remains lacking. Furthermore, previous reviews have often been limited in temporal scope or focused on specific transmission pathways. To address this gap, this study examined typhoid risk factors across a broader time frame (1928-2024) and incorporated a multidimensional perspective on transmission dynamics. By systematically integrating evidence from diverse sources, we aimed to provide a more comprehensive understanding of typhoid fever risk factors, which can inform targeted interventions to reduce typhoid incidence worldwide.

Methods

Search Strategy

We searched PubMed, Scopus, Google Scholar, and Semantic Scholar databases for articles published on risk factors for typhoid fever. The search was conducted in June 2023, and titles and abstracts from databases were downloaded and saved. Each database was searched using the following terms and keywords: risk factors, factors, contributors, determinants, causes, predictors, susceptibility factors, factors of exposures, predisposing factor, typhoid fever, typhoid, *Salmonella* typhoid, *Salmonella* Typhi, *S* Typhi, typhoid disease, typhoidal salmonellosis, and typhoidal *Salmonella*, and searches excluded terms related to perforation, complication, virulence, severity, and nontyphoidal infections. We placed no restrictions on the publication year, but the language was restricted to English. We followed a protocol adapted from the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines, which was registered with the Open Science Framework in January 2024 [22] to structure our search. See Multimedia Appendix 1 for the PRISMA checklist. This study used published articles, and as such, permission from the institutional review board was not required.

Study Screening and Selection Criteria

We screened and selected studies on typhoid fever risk factors based on the inclusion and exclusion criteria summarized in Textbox 1.

Textbox 1. Inclusion and exclusion criteria for the desk review search strategy on typhoid fever risk factors.

Inclusion criteria

- Studies with confirmed S Typhi infections or outbreaks identified through the following: culture of bodily fluids or stool; polymerase chain reaction; Widal or other serological methods
- Epidemiological or modeled studies of any design

Exclusion criteria

- Studies on severe infections (complications and mortality)
- Studies that classified typhoid fever solely based on clinical indicators (ie, signs and symptoms) or with unclear diagnostic methods
- Studies involving nonhuman participants (animals, water, and farm produce)
- Articles whose full text was not available in English or those inaccessible

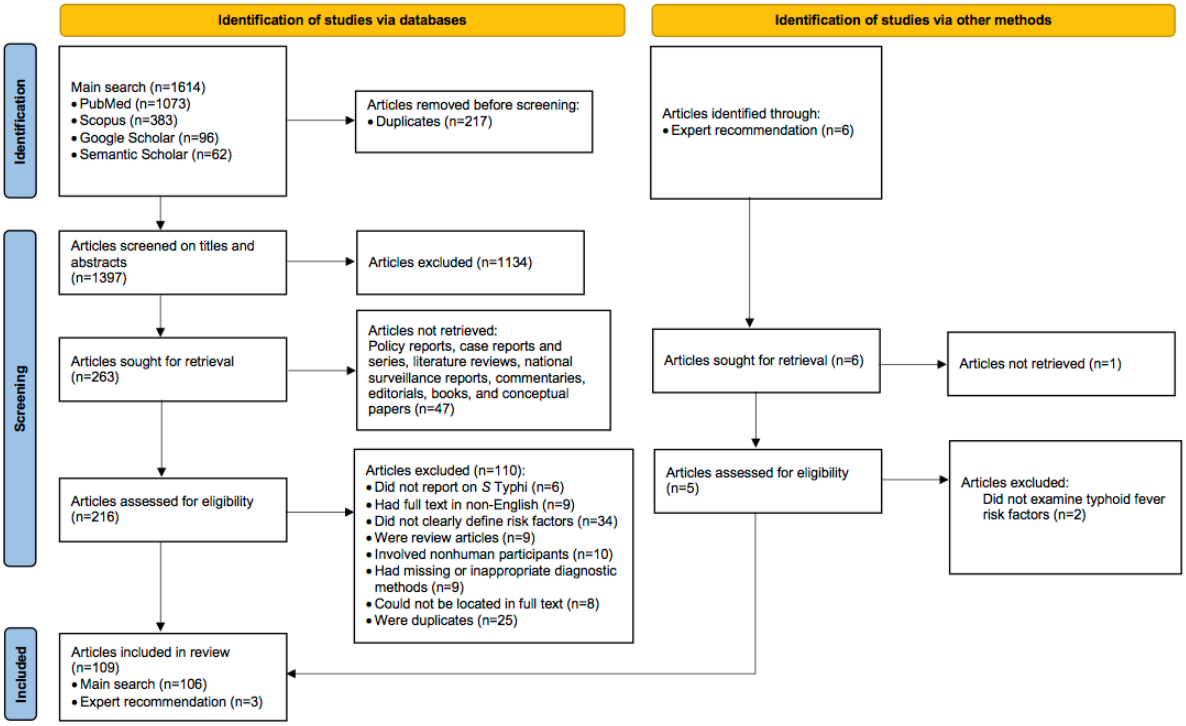
Further details on inclusion and exclusion criteria can be found in the review protocol [22].

The titles and abstracts retrieved from each database were imported into EndNote X8.2 (build 13302), merged into a single reference list, and duplicates were eliminated. The deduplicated list was then uploaded to a web-based systematic review tool, Rayyan (Qatar Computing Research Institute) [23] for title and abstract screening. All included citations were exported into Microsoft Excel (version 16.16.27) for full-text retrieval and screening. Each subsequent process, including title and abstract review, full-text review, and data extraction, was performed using predefined screening guidelines outlined in the screener instruction section of the review protocol [22] to ensure consistency. One author (PBO) performed the initial screening with supervision from coauthors (EO-D, SN, and ST-A). Discrepancies in the study selection were resolved through discussion among authors (PBO, EO-D, SN, and ST-A), with unresolved cases adjudicated by EO-D. Additional relevant articles were identified through other sources (expert input) and included after being assessed using the same eligibility criteria. Data were then extracted into Microsoft Excel and a shared Google Sheets spreadsheet (Google LLC; Multimedia Appendix 2). All authors reviewed the final dataset for completeness and accuracy.

Data Extraction

Electronic searches were performed using the internet to locate all eligible articles, and all relevant data relating to the research question were manually extracted into Microsoft Excel after reading the full text. The extracted data included specific risk factors for typhoid fever in all eligible articles. In addition, data on the route of transmission, sources of infection, year of publication, data collection period, town or district, country and continent of the study, study setting (outbreak or endemic), diagnostics method, study type, number of *S* Typhi cases, total participants enrolled, ages of participants, study design, and citations were extracted (Multimedia Appendix 2). We grouped the ages of participants into 3 categories based on inclusion age and age ranges: “children” were ≤15 years, “adults” were >15 years, and “mixed ages” were both children and adult participants. Information on typhoid fever susceptibility was grouped according to their transmission routes: waterborne and foodborne transmissions, host risk factors, vaccination, travel-related risk, health education, occupational risk, population growth and overcrowding, sanitation and sewage systems, climate and meteorological factors, antimicrobial resistance factors were extracted.

Results



Overview

Our search strategy initially identified 1614 articles published between 1928 and 2023. After removing 217 duplicates, 1397 titles and abstracts remained for screening. Of these, 1181 were excluded, with the majority (687 articles) not examining typhoid fever risk factors. After a full-text review of 219 articles from the main databases (216 articles) and expert recommendations (3 articles). Other reasons for exclusion included 25 duplicates

XSL•FO
RenderX

of the same study published by different authors in different journals; 10 studies involving nonhuman participants such as farm-produced and water samples; 17 articles with non-English full texts or unavailable full texts; 6 articles not specifically related to *S* Typhi; and 9 articles with missing or inappropriate diagnosis based on recall typhoid fever episodes, unclear diagnosis, and clinical indicators (signs and symptoms). Furthermore, to avoid content duplication, 9 review articles were excluded, as shown in Figure 1. Finally, 109 published articles were included in this study [12-14,24-128] (Multimedia Appendix 2).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram of search strategies and article selection of risk factors for typhoid fever (2024).

Study Characteristics

Among the 109 eligible articles, data were extracted from publications spanning 1972 to 2024 (Multimedia Appendix 2), covering 6 continents: 24% (26/109) from Africa, 46.8% (51/109) from Asia, 0.9% (1/109) from South America, 8.3% (9/109) from North America, 10.1% (11/109) from Europe, and 6.4% (7/109) from Australia. Furthermore, 2.8% (3/109) of the articles collected data from mixed continents, while one article (1/109, 0.9%) relied on the GeoSentinel Surveillance Network database, lacking specific location details (Table S1 in Multimedia Appendix 3). Regarding transmission routes, multiple non–mutually exclusive typhoid risk factors were identified across the eligible articles (Table 1) for both common and specific risk factors. Waterborne transmission was reported in 41.3% (45/109) of the articles, while 44% (48/109) of the articles focused on foodborne transmission. Demographic and socioeconomic factors were identified in more than 50.5% (55/109) of the studies, with hygiene and sanitation discussed in 31.2% (34/109) of the studies. Additional risk factors included travel-related exposure (19/109, 17.4%), climatic influences (15/109, 13.8%), and antimicrobial use (14/109, 12.8%; Table S2 in Multimedia Appendix 3). Across 103 papers, 253,951 typhoid fever cases were reported, with a median (IQR) of 110 (51-283). The diagnosis was confirmed predominantly through culture in 84.4% (92/109) of the articles, with approximately 9% (10/109) of articles using Widal and other serological tests and 6.4% (7/109) of the articles using polymerase chain reaction and other sequencing techniques. Age distribution data were available in 103 articles. Most of the articles (83/103, 80.6%) included participants of mixed ages, while approximately (14/103, 13.6%) of the articles focused exclusively on those aged ≤15 years and 5.8% (6/103) of the articles focused on those aged >15 years (Table S1 in Multimedia Appendix 3).

Table 1. Common and specific risk factors for typhoid fever.

Common risk factors	Specific risk factors
Waterborne transmission	
Water sources	Household sources of drinking water [24,58], having multiple drinking water sources [68], using water from other sources than the municipal water networks for bathing, brushing teeth or drinking [112], primary water sources with unpleasant smell [37], obtaining water from an outside tap [46], unsafe water source [53,115], obtaining water from municipal pipe for drinking [107], obtaining water from a river or stream [12,115]
Water supply	Water supplied by an outdated gravity-fed network [53], intermittent water availability [12], inadequate safe water supply [14], defective water systems [113], household water supply from public wells and boreholes or merchants [98], water from a community [34], water from government overhead tanks [43]
Contaminated or unsafe water	Drinking unsafe or contaminated water [28,33,63,79,95], using substandard water [83], *Escherichia coli* in stored drinking water [79], water sold in small plastic bags [80], use of ice cubes from a street vendor [29,123]
Untreated water	Drinking water from a well [96], untreated household drinking water [37,46-48,70,120], use of untreated public water after rains [32], drinking water from untreated open sources [12,27,89], drinking water at the work site [34], use of bore water [107], accidental ingestion of contaminated river water during swimming or bathing [28], cooking and cleaning with river water or an open dug well [68]
Water storage	Storing water in plastic containers without a lid [98], not storing water for drinking in a narrow-mouthed container [38], not using tipped containers to draw water [38], water sold in small plastic bags [80]
Foodborne transmission	
Street stall or restaurant food	Eating out from commercial food stalls, restaurants, or mobile food vendors in the street or outside home [26,34,45,91,101,122], eating outdoors at least once a week [29,30,117], eating food from a roadside cabin during the summer [34], mothers eating food from street vendors [70], eating cold beverages outside home [45], not dining at a tea-house [47], consuming French fries with sauce and poppadum from street vendors [107], eating commercially available foods or drinks [120], eating food at community market [97]
Poor food hygiene	Eating unwashed farm produce [12], unwashed guavas [38], not washing vegetables before eating [47]
Food handlers	Consuming food items from vendors [108,122], male food handlers [40], consuming food with the mother's or caregiver's assistance [30], drinking orange juice with hand contact [50], poor or unhygienic food handling practices or procedures [14,100], eating food prepared at home [97]
Salads or other contaminated food	Eating contaminated foods [63], including cucumber salad [94], potato salad [114], lettuce salad [31], and raw salads (onion, cucumber, and tomato) [103]
Uncooked or raw food	Eating raw traditional foods such as cig kofte [31], raw onions and cabbage [38], raw milk and meat [58], uncooked shellfish [118], papaya [37], and unwashed guava [38]
Frozen food	Eating ice cream [30,34,49], ice cubes in beverages [29], frozen tropical fruit (mamey) shakes [84], and fresh ice cream during the hot season [13]
Milk products	Eating butter and yogurt [38], fresh yogurt made from cow and sheep in the summer [13], and homemade cheese [13]
Local or traditional food	consuming locally made beverages [80], eating locally prepared popsicles [103], and consuming locally prepared flavored beverages [103]
Other	Eating food brought by relatives from endemic areas [91], sharing food from the same plate [123], and sharing food plates [53]
Demographic, socioeconomic, hygiene, and sanitation factors	
Demographic background	Age [25,58,87,126], older age [39,86], younger age [33,42,59,82,108,109], sex of the individual [102,126], being female [108,121] or male [87,101], presence of preschool children in the household [103], young adult [121], demographic status [56], and low BMI [128]
Socioeconomic status	Poor or low socioeconomic status [25,56,76,83,104], attending a gathering [96], per capita disposable income of all residents, and per capita gross domestic product [102], unemployment or part-time work [29,128], being part of a nuclear family [49], wealth index [90], being a student [47], and attending school or daycare [68]
Education level	No or low educational level [27,48,120], educational level [58], years of schooling [90], students in conventional institutions of higher learning [102], and illiteracy rate [49,104,105]
Occupational risk	Mishandling of *S* Typhi samples by clinical microbiology laboratory staff [72]; medical and laboratory personnel and sewage workers occupationally exposed to *Salmonella* bacteria [91]; household member growing crops [68]; farmers [87,128]; rearing chicken or goats [92]; job-related cause [63]
Population growth and overcrowding	Rising or bigger household size [104,127], living in a crowded household [31], crowding poor living conditions [63], and increased population density [33,113]
Housing system or condition	Poor housing conditions [79]

XSL•FO
RenderX

Common risk factors	Specific risk factors
Hygiene and behavioral factors	Scarcity of soap near a hand washing facility [127], nonuse of soap for handwashing [12,49,69,108], nonuse of medicated soap [127], nonavailability of soap to wash hands after toilet use [68,104], a habit of not washing hands before cooking or after defecating [53], infrequent hand washing after latrine use [12,97], poor hand washing practices [105], occasionally or never washing hand with water and soap [26,122], never or rarely washing hands before preparing or handling food, and eating or feeding [29,30,120]
Water, sanitation, and hygiene (WASH) practices	Poor WASH practices [74], not living in a better WASH household [75,106]
Sanitation and sewage systems	Use of pit latrine [27,92], open defecation [92], improper disposal of solid waste [27], burst sewer pipes at home [96], living in houses with open sewers [29], visible urine or feces [53], poor sanitary practice [14,63,95,98,113], having home latrines [38], no toilets in the residence [108,115], poor excreta disposal [79], having unimproved or malfunctioning sanitation infrastructure [12], unsterilized water from the hospital disposal and residential sewage used to irrigate vegetable farmlands [110], inadequate public sewerage system [90], and poor toilet drainage soil [79].
Other	
Antimicrobial use	Frequent use of antimicrobials or history of antimicrobial use [34,47,55,62,63,76,81,101], chloramphenicol-resistant *S* Typhi strain [44,79], ceftriaxone-resistant *S* Typhi strain [119], multidrug resistant or extensively drug-resistant *S* Typhi strains [121], circulation of virulent *S* Typhi strain (H58-lineage) [60,103]
Host risk factors	Polymorphism in intronic variable number tandem repeat of IL-4 [35], presence of serum anti–*Helicobacter pylori* immunoglobulin G antibodies [49,109], history of chronic underlying disease [69], HIV infections [71], and haplotype of tumor necrosis factor locus from single nucleotide polymorphisms [124]
Typhoid carriers	Recent or close contact with a patient with confirmed or active typhoid fever [32,48,63,88,101,105], hospitalization of household member with febrile illness [68], history of typhoid fever infections [69], having typhoid carrier at home [65], recent typhoid fever case in the household [108], and having a housekeeper (a boy or girl) [120]
Vaccination	No or lack of vaccination [63,75,106], vaccine hesitancy [120], vaccine ineffectiveness [94], and poor vaccination coverage [103]
Health education	Lack of knowledge regarding typhoid fever contact [127] and poor awareness of typhoid fever disease [97]
Travel-related risk	Longer duration of stay in the endemic area [39]; returning from or visiting endemic countries [76,86,116,126]; visiting friends and relatives in endemic areas [39,73]; travel destination [64]; travel outside the United States, Sweden, or United Kingdom (international travel) [41,59,93,129]; Asian travelers [52]; children visiting friends and relatives in endemic places (particularly South Asia) [61,99]; recent travel to endemic areas [85,125]; transient male workers [82]; living in a metropolitan area [86]; urbanization [90]; and number of foreign tourists received (tourism) [102]
Environmental conditions or factors	Living in geographically lower elevation areas [42], neighbors to a typhoid fever case [54], potentially floodable areas [57], proximity to major rivers and creeks [57], housing (external condition) [79], a lack of agricultural land [115], hydrological catchment areas [119], residing closer to waterbodies, residing near typhoid study treatment centers [104], anthropogenic alteration of land cover and hydrology [78], and environmental factors [56]
Climate or meteorological factors	Seasonal variation or fluctuations [25,82,102,110], high temperatures during summer [103], rainfall [57,115], temperature and precipitation [111,115,126], high vapor pressure [115], rainy and harmattan seasons [36], extreme weather conditions [77], higher or hot temperatures [66,86], flooding [87], and wind speed [90]

Discussion

Principal Findings

This study synthesizes typhoid fever risk factors from 1928 to 2024; however, the included studies span from 1972 to 2024, as few earlier publications met the inclusion criteria. We have identified demographic and socioeconomic factors as the predominant pathways for typhoid fever transmission, with additional contributions from waterborne and foodborne routes, hygiene and sanitation, travel-related exposures, antimicrobial use, and typhoid carriers. These findings highlight the multifaceted nature of typhoid fever transmission and underscore the importance of targeted interventions. This evidence is crucial for clinicians, public health experts, and policy makers in designing effective control strategies and optimizing resource allocation, particularly in endemic regions.

Approximately 70.6% (77/109) of the reviewed articles collected data from Asia and Africa, where most developing countries are located. This aligns with the global burden of typhoid fever estimation, which shows that Asian and African countries bear the greatest burden [130]. The low number of articles in Europe, North America, and Australia can be attributed to the introduction of control programs such as the treatment of municipal water, pasteurization of dairy products, and strict food safety regulations [1,131]. Similarly, the lack of studies from South America can be attributed to the decline in typhoid burden, given the economic transition with improved water and sanitation in the area [1]. Despite the lower disease burden in these underrepresented regions (Europe, North and South America, and Australia), the risk factors identified in this study, such as socioeconomic, foodborne and waterborne transmission, and antimicrobial use, remain relevant to these regions. Emerging threats, including climate change, urbanization, and

XSL•FO
RenderX

increased global travel, may contribute to the reemergence of typhoid in areas where it was previously controlled. In addition, the rise of antibiotic-resistant strains presents an ongoing challenge, underscoring the need for public health preparedness in these regions.

Waterborne Transmission

Water sources greatly impact the spread of typhoid fever, with protected wells and piped water classified as safe, while rivers, streams, and other unprotected sources are deemed unsafe [132]. This study identified several specific risk factors associated with typhoid fever and water sources, including having multiple drinking water sources [68], use of nonmunicipal water sources for various purposes [29,68,107], and main water sources with a foul smell [37]. Households with access to multiple water sources may be at increased risk of typhoid fever, particularly when they face challenges with potable water access such as limited supply hours, high tariffs, low-pressure, and long distances to collection points. These challenges often impede their ability to meet daily needs. Consequently, some households, particularly those located close to open dug wells, rivers, or streams, may use these alternative sources for bathing, cooking, or even drinking [115]. Although such sources offer convenience, they often lack chlorination and may be contaminated with fecal matter, thereby posing a risk for typhoid fever transmission.

A water supply system defect can facilitate the transmission of typhoid fever. Our study discovered a typhoid fever outbreak associated with a gravity-fed network [53], indicating a probable spread through an outdated mains system. This was attributed to low water pressure, insufficient chlorination, and fecal infiltration [12].

Furthermore, we uncovered an intermittent piped water supply as a risk factor for typhoid transmission. Intermittent piped water supply is a common challenge in many developing countries, potentially compromising water supply quality by allowing contaminants in nonpressurized pipes and creating negative pressure conditions that enable pathogens such as *S* Typhi to infiltrate the system [12,133]. Such interruptions often compel households to rely on water storage, which may introduce additional contamination risks, and to seek alternative sources that may not be microbiologically safe [12,29]. Sources such as government overhead tanks [43], community or public taps, and protected wells [34,115], which are often considered safe, can become contaminated due to environmental exposures, including industrial activities, sewage discharges, agricultural runoff, and animal waste [28,80]. Under these conditions, the presence of *Escherichia coli* (*E coli*) in drinking water is commonly regarded as an indicator of fecal contamination and, by extension, a potential risk factor for typhoid fever due to the possible presence of enteric pathogens [79]. However, the relationship between *E coli* and typhoid fever risk remains inconclusive. For instance, Karkey et al [134] observed a link between high *E coli* concentrations and the presence of *S* Typhi nucleic acids in drinking water, suggesting that *E coli* contamination may serve as a proxy for typhoid transmission risk. In contrast, Luby et al [34] found no significant difference in the levels of *E coli* in water samples between households with typhoid cases and control households, challenging the consistency of this connection. These discrepancies may stem from environmental conditions, regional differences in water treatment practices, and microbial competition. For instance, in settings with inadequate chlorination, *E coli* presence may serve as a proxy for recent fecal contamination, thereby increasing typhoid risk. Conversely, in areas with intermittent water supply and biofilm formation within pipes, *S* Typhi may persist independently of *E coli*, complicating its use as a universal indicator.

In addition, water storage practices emerged as a risk factor for typhoid fever in our study. Evidence suggests that the microbiological quality of water often deteriorates after collection, particularly during storage and handling [98]. The risk of contamination is influenced by the type of vessel used for storing or drawing drinking water. Wide-mouthed containers, in particular, are associated with a higher risk of infection due to their larger open surface area, which increases exposure to environmental contaminants and the likelihood of fecal contamination, compared to narrow-tipped or covered containers [38,98].

Moreover, the use of untreated water, both inside and outside the home, poses significant risks for typhoid fever transmission [27,32,48,89]. Although municipal water systems may incorporate filtration and chlorination, cross-contamination with *S* Typhi through wastewater intrusion remains a concern [46]. In such contexts, household-level water disinfection may be necessary to enhance water quality [37]. However, some households opt out of water treatment due to the perceived reliability of their water sources [98]. While water from piped or otherwise protected sources may contain insufficient bacteria to cause typhoid fever, untreated water from unprotected sources may carry high *S* Typhi levels, sufficient to cause clinical disease [28,34,47]. All the aforementioned risk factors are listed in Textbox 1.

Foodborne Transmission

Food serves as a highly efficient medium for the growth of *S* Typhi compared to water [34]. This study revealed specific risk factors indicating potential foodborne transmission of typhoid fever, with street stalls (restaurants) emerging as a major factor in this category. Street food stalls are typically small, with outdoor seating and without refrigerators or easy access to potable water or adequate facilities for washing food and utensils [29,34,45]. Therefore, persons who frequently consume food from such establishments are at increased risk of developing typhoid fever [29]. This increased risk may stem from using untreated or tap water stored or served in contaminated containers for food preparation and drinking purposes [45]. In addition, poor hygiene practices among street food vendors, including irregular handwashing [122], and the potential exposure to carriers of *S* Typhi further contribute to the risk of infection [135]. In addition, many of these food preparers and handlers in the street eateries lack adequate knowledge of safe food handling practices necessary to avert *S* Typhi infection transmission. Often, they operate without licenses or registration from food safety authorities; as a result, they are neither trained nor subject to regular inspections. Consequently, they may

XSL•FO
RenderX

unknowingly share food and drinks using poorly cleaned cups and utensils among multiple clients [97,120]. Furthermore, this study discovered a relationship between the consumption of frozen foods, including ice cream [13,30,49], fruit shakes [84], and iced beverages [29], and typhoid fever. A potential source of contamination lies in the ice used by street vendors, who often purchase large blocks of ice produced from untreated water, typically intended for industrial use, such as fisheries, rather than for human consumption. Despite this, the ice is commonly served in drinks for customers. Notably, research has shown that *S* Typhi can survive in ice for extended periods, underscoring its potential role as a vehicle for transmission [29,45,122]. Moreover, iced drinks may be further contaminated by street vendors who are asymptomatic carriers of *S* Typhi during the distribution chain [29]. In contrast, dining at tea houses decreases the risk of typhoid fever, as customers are typically served boiled water and tea, practices that limit exposure to *S* Typhi through thermal inactivation of the pathogen [47]. In addition, consumption of uncooked or raw foods such as onions, milk, meat, shellfish, papaya, cabbage, and other traditional raw ingredients poses a considerable risk, as these items may harbor *S* Typhi if not properly handled or sourced [31,37,38,58,118]. For instance, failure to wash fruits and vegetables before consumption increases the risk of infection due to surface contamination [12,38,47]. Cross-contamination during meat handling is another concern; for example, using the same knives and cutting boards for both infected and uninfected meat in butcheries and restaurants. Similarly, if contaminated water is used to wash carcasses or clean food-contact surfaces, *S* Typhi may be introduced during processing [58]. Moreover, inadequate hygiene practices during milk processing may contribute to the contamination of dairy products, including butter, yogurt, and homemade cheese [13,38,58]. Although dairy animals do not harbor *S* Typhi [136], improperly handled dairy products can serve as effective growth media for the pathogen [58].

Demographic and Socioeconomic Factors

This study identified mixed findings regarding sex-based susceptibility to typhoid fever. While a study suggests that men face greater exposure due to occupational differences, mobility patterns, dietary factors, or a lack of immunity [82], other studies indicate that women, influenced by their physiological status, hormonal imbalance, and gender-specific activities, are more susceptible [120,121]. Building on this, we propose the hypothesis that occupational exposure may explain the higher risk in men, whereas caregiving roles could contribute to increased susceptibility among women. Nonetheless, a study by Rasul et al [137] concludes that typhoid fever incidence is independent of gender, affecting men and women equally across all age groups. Age serves as a significant factor in typhoid transmission, with both young children and older adults identified as vulnerable groups [121,138]. Young children, characterized by their underdeveloped immune systems [33,42,87] and a limited understanding of disease transmission [58,87], face heightened risks of infection. While younger adults are predisposed to infections due to their adventurous lifestyle or unsanitary activities, such as eating junk food, and an increased number of social gatherings [25,42,58], older adults are more likely to be *S* Typhi resistant due to continual immune boosting [138]. Conversely, older adults may experience susceptibility due to a waning immune system or increased exposure to occupational and environmental risks. These exposures may include involvement in farming-related water contact activities [58,68], rearing chicken or goats [68], handling *S* Typhi specimens in clinical settings [72,91], and working in sewage management [91]. Although *S* Typhi is a human-adapted pathogen and not naturally harbored by animals, the association with poultry and livestock rearing may act as a confounder, reflecting underlying poor sanitary and hygienic conditions within the household rather than direct transmission from animals [92].

Our investigation further revealed that socioeconomic status correlates with an increased likelihood of *S* Typhi infection [96]. While studies suggest that typhoid fever is more common in low-income countries and is connected to poor public health and low socioeconomic indicators [25,83], one study [90] identified a protective effect of the wealth index. This suggests that residing in affluent districts within low- or middle-income countries may significantly mitigate the risk. This may be attributed to the per capita gross domestic product and individual disposable income within a community [102]. Wealthier households are more likely to afford preventive measures such as clean drinking water, improved sanitation, and timely medical consultations, thereby reducing the risk of infection. Conversely, individuals in lower socioeconomic brackets often face health care barriers, leading to underdiagnosis and delayed treatment. The protective effect of a higher wealth index underscores the need for targeted interventions. Public health strategies should prioritize health care accessibility and sanitation improvements in economically disadvantaged areas. Investments in water and sanitation infrastructure, subsidized vaccination programs, and awareness campaigns tailored to low-income communities could help reduce the disproportionate burden of typhoid fever. In addition, strengthening diagnostic capacity in resource-limited settings can improve case detection, ensure timely treatment, and curb typhoid transmission while enhancing health outcomes.

In the context of education, our research highlights the lack of certificate education as a significant risk factor influencing the perception of typhoid fever. Individuals who have never attended school tend to possess limited knowledge about the disease and its modes of transmission, highlighting a strong link between lower educational attainment and reduced awareness [102,120]. Previous studies [90,104,105] emphasize that formal education increases understanding, with uneducated individuals more likely to contract typhoid fever. Interestingly, being a student [47] or attending school (daycare) [68] may also pose risks, likely due to certain exposures in educational settings. While essential health knowledge, such as WHO-recommended practices of handwashing with soap, can be acquired outside formal education, a general lack of awareness significantly increases the risk of infection. Individuals who do not recognize the risks are less likely to take preventive actions [97,127]. Another significant factor for typhoid transmission, besides knowledge, is awareness of the presence of a patient with typhoid at home [120]. Individuals who are unsure of the presence of a patient with chronic or current typhoid at home

XSL•FO
RenderX

are more likely to have typhoid or a recurrence than those with full awareness. This may be attributed to the continued shedding of *S* Typhi in the stool and urine of infected individuals, even after initial antimicrobial treatment. Up to 10% of patients may continue shedding the bacteria for as long as 3 months, with some proceeding to become long-term asymptomatic carriers [1]. These transient or chronic carriers can be sources of infection within households [139,140]. In contrast, household members who are well informed of such cases are more likely to acquire knowledge about the disease, its transmission routes, and effective preventive measures. Recent contact with patients with typhoid has also been observed as a potential risk factor, further emphasizing the role of household-level awareness in reducing transmission [48,88]. In many communities, traditional practices of visiting the sick can increase interpersonal contact and inadvertently raise the risk of exposure. Close contacts are often residents of the same area and may share communal water sources, suggesting that transmission could still occur via water contamination (broader environment) rather than direct person-to-person spread. Therefore, health education initiatives should consider addressing the risks associated with visiting infected individuals, alongside broader messaging on water hygiene and disease prevention.

Hygiene and Sanitation Risk Factors

This study further identified risk factors that underscore the significant impact of hygiene and sanitation on the spread of typhoid fever. Poor handwashing practice is a critical risk factor, given the crucial role hands play in transmitting *S* Typhi through the fecal-oral cycle [26,30,120,123]. While handwashing with soap and clean water effectively removes pathogens [29], inadequacies in technique, such as rinsing without soap [53,122] or neglecting handwashing after defecation [12,97], can increase the risk of bacterial spread [106]. Furthermore, using medicated soaps is an added advantage because it is more effective in eliminating bacteria from hands compared to regular soaps [127].

In addition, the condition of the sewerage system in the house has an important impact on typhoid fever incidence. According to Prasad et al [12], people lacking access to improved sanitation facilities or with damaged improved sewerage systems are particularly vulnerable to infections. In many cases, household toilets are built without professional expertise, often on permeable soil, and in flood-prone areas, increasing the likelihood of leakage and pollution of surface water and crops with human waste [79]. Strengthening the construction and maintenance of sanitary excreta disposal facilities, alongside effective solid waste management, is essential for preventing typhoid fever transmission. Studies have shown that poor sanitation, including improper disposal of solid waste and excreta in residential settings, is directly correlated with higher typhoid prevalence [27,79]. Inadequate waste disposal infrastructure, such as pit latrines, open defecation sites, burst sewer pipes, and the presence of visible feces or urine, has been consistently identified as a significant risk factor [29,53,92,96]. Notably, preventing human excreta from entering the domestic arena has a greater impact on interrupting typhoid transmission than behaviors preventing pathogens in the environment from being ingested by humans (eg, hand washing).

Finally, the discharge of unsterilized water from hospitals and residential areas into rainwater canal systems, often used for irrigating farmlands, contributes to the contamination of vegetables cultivated in these areas [110]. These contaminated crops are frequently consumed without thorough washing, thereby increasing the risk of typhoid fever. Particularly, the risk is pronounced during the rainy season, when heavily polluted irrigation water is more commonly used, and runoff from farms mixed with garbage is more likely to spread into residential zones, further endangering public health.

Other Risk Factors for Typhoid Fever

Other typhoid risk factors identified in this study include antimicrobial exposure, host-related factors, vaccination status, travel history, and environmental or climate conditions. Among these, antimicrobial use has the greatest impact on *S* Typhi infection. Several studies have shown that prior or recent use of antibiotics, particularly within 4 weeks before disease onset, is associated with an increased risk of typhoid fever, particularly in cases involving multidrug resistant or extensively drug-resistant strains [63,81,101]. Antimicrobial exposure can induce prolonged alterations in gut flora and compromise the barrier against bacterial colonization, thereby reducing the threshold of *S* Typhi required for infection [47]. Studies by Yousafzai et al [119], Srinivasan et al [103], and Kamal et al [81], further highlight antimicrobial resistance as a major contributor to typhoid fever, with certain resistant strains capable of causing epidemics. This resistance is largely caused by the routine presence of *S* Typhi in the human intestine and the indiscriminate use of antibiotics [44,63]. Consequently, drug-resistant *S* Typhi strains, often carrying multiple virulence factors, are becoming increasingly prevalent worldwide. Notably, this study also identified specific risk factors associated with *S* Typhi–resistant strains harboring virulence genes, including those within the H58 lineage, which enhance their ability to infect and interact with host cells [60,62,103,121].

Host-Related Factors

Host genetic factors influence susceptibility to infectious diseases in humans. This study referenced research by Manal et al [35], which explored the relationship between genetic polymorphisms and typhoid fever risk. Their findings suggested that individuals carrying the 2R3R heterozygote of the intronic variable number tandem repeat in the *IL4* gene may have a genetic predisposition to typhoid fever. However, a study by Dunstan et al [124] reported that a specific haplotype within the tumor necrosis factor gene locus offers protection from typhoid. These associations may be explained by the influence of genetic variation on immune response pathways. Another study [49] found a link between serum anti *H pylori* immunoglobulin G (IgG) levels and an increased risk of typhoid fever. Serum IgG antibodies indicate either prior or active *H pylori* infection, as these antibodies can persist even after infection clearance [49,141,142]. A possible explanation for this association lies in the role of the gastric acid barrier as a crucial defense mechanism against ingested pathogens such as *S* Typhi. *H pylori* infection has been associated with hypochlorhydria, a condition characterized by reduced stomach acid production, which weakens this protective barrier [49,109].

XSL•FO
RenderX

This impairment may facilitate the survival and subsequent colonization of *S* Typhi in the gastrointestinal tract, thereby increasing susceptibility to typhoid fever.

In addition, this review identified a significant association between typhoid fever and the presence of chronic underlying conditions [69]. A plausible explanation is that chronic illnesses can weaken the immune system, impairing the body's ability to clear *S* Typhi and increasing the risk of persistent or severe infection. For instance, although *S* Typhi is not widely associated with AIDS in developed countries, studies from endemic areas suggest a different pattern. We uncovered a study by Gotuzzo et al [71] that reported an increased risk of typhoid in patients infected with HIV from typhoid-endemic areas. In addition, the study noted that a large proportion of HIV-positive participants were men who have sex with men, raising the possibility that direct fecal-oral transmission may contribute to increased incidence in this subgroup. However, further research is needed to clarify the specific transmission dynamics within this population and to distinguish the role of immunosuppression from that of behavioral factors.

Travel-Related Risk

Typhoid fever, once prevalent in industrialized countries, is now effectively controlled [91,93]; however, imported infections remain a significant public health concern [39,52,85]. The risk of infection among travelers varies depending on factors such as age, destination, duration, and purpose of travel [99]. Travelers visiting friends or relatives are in a high-risk category for typhoid fever [39,61,73]. As they are much less likely than other travelers to seek pretravel counseling, they may visit more rural, remote areas and engage closely with local people as well as eat high-risk foods and beverages [51]. Children and young adolescents who are visiting friends or relatives are also at high risk of contracting typhoid fever due to a lack of immunity or the possibility of traveling under unhygienic conditions [61,82,99]. We also discovered that traveling to endemic locations increases the risk of contracting typhoid [52,59,86,93]. According to Lin et al [86], more than half of all travelers with typhoid returning to developed countries have visited Asia or Africa, where the disease is widespread. This trend likely reflects increased exposure associated with travel to these endemic areas, particularly during extended stays. In contrast, short-term visitors to endemic areas face a comparatively lower risk of infection [39]. Furthermore, increasing global mobility driven by economic globalization has facilitated the movement of travelers for business, tourism, or labor migration, thereby contributing to disease spread. This growing influx of individuals, often without adequate vaccination or awareness of preventive measures, contributes to the continued transmission and global spread of typhoid fever [82,102].

Vaccination

Vaccination is essential for the control of typhoid fever in endemic and epidemic settings as well as among travelers moving between nonendemic and endemic areas. The WHO recommends the programmatic use of typhoid fever vaccines in endemic areas [4]. We retrieved 2 studies [75,106] that demonstrated a reduced risk of typhoid fever among individuals who received effective typhoid vaccines and resided in households with improved water. Conversely, poor vaccination coverage, particularly when combined with inadequate WASH infrastructure, can exacerbate typhoid transmission in a given area [63,103]. Moreover, the effectiveness of vaccination may also be compromised by factors, including defective vaccine batches, incorrect immunization procedures, or the interval since vaccination. Evidence from this study suggests that individuals vaccinated more than 3 years prior may face a heightened risk of infection, likely due to waning immunity [94]. This is particularly relevant for polysaccharide vaccines, which have an estimated cumulative efficacy of approximately 55% over 3 years, with the strongest protection occurring within the first 2 years after immunization.

Environmental, Seasonal, and Climate Factors

Typhoid fever transmission exhibits distinct seasonal patterns influenced by environmental and climatic factors such as temperature, humidity, and precipitation. This study identified diverse peak periods across different endemic regions. For example, Taiwan experiences a surge in cases during the fall (September-November) and winter seasons (December-February) [86], whereas in India, the peak occurs in June in Allahabad [25], and during the monsoon season (July-November) in Ahmedabad [77]. A study by Corner et al [56] discovered that approximately half of the yearly typhoid cases in the Dhaka Metropolitan Area, reaching up to 11 per 100,000 individuals, occurred during summer and fall (July-October). Similarly, Srinivasan et al [103] found a positive correlation between summer temperatures (June-August) and increased typhoid cases. These seasonal fluctuations may stem from a complex interplay of climatic conditions, hygiene practices, and local cultural dynamics [86,143]. In warmer climates or during summer, elevated temperatures enhance the proliferation of *S* Typhi in contaminated foods [103]. Conversely, in colder and more humid conditions, *S* Typhi survive longer in water and soil, thereby increasing the likelihood of environmental transmission [144]. In addition, heavy rainfall during the rainy season can trigger flooding and sewage overflows, leading to contamination of water sources and an increase in typhoid incidences [25,66]. This risk is particularly high in low-lying or flood-prone areas where surface water is commonly used for drinking, cooking, and cleaning [42,56,57]. Settlements in hydrologically vulnerable terrains, such as river floodplains, face particularly heightened risks during these periods due to increased sewage runoff and widespread contamination of water and food supplies [67,78].

Study Limitations

This study has some limitations. First, publication bias may be present, as studies with significant findings are more likely to be published, potentially underrepresenting negative or null results and skewing risk factor assessments. Second, the lack of formal risk-of-bias assessments may also affect the reliability of findings. In addition, excluding gray literature and non-English studies may have limited the scope, as multilingual and unpublished data could provide further insights. Furthermore, although the review highlights sex-based differences in susceptibility to typhoid fever, the underlying mechanisms remain unclear due to mixed findings, making the

XSL•FO
RenderX

proposed explanation, such as occupational exposure in men versus caregiving roles in women, speculative.

Conclusions

This review combines current knowledge of typhoid fever risk factors and identifies critical areas for targeted intervention. While food and water have been traditionally recognized as the primary transmission pathways for typhoid fever, this review identifies demographic and socioeconomic factors as predominant drivers for transmission. This shift in understanding underscores the need to move beyond conventional mitigation strategies and adopt targeted interventions that address demographic and socioeconomic disparities, which may play a more significant role in typhoid transmission than previously acknowledged. Considering all identified risk factors, mitigation strategies should be prioritized based on regional transmission dynamics and resource availability. In urban Asia, street food regulation should take precedence, while in rural Africa, investment in water infrastructure is equally critical. A combined approach integrating WASH and vaccination programs, particularly in schools and high-risk communities, remains a key priority for long-term disease control in endemic regions. In addition, addressing environmental and climate-related risks, such as flooding and poor waste management, should be incorporated into prevention strategies.

While this review provides a broad synthesis, key knowledge gaps remain. The absence of longitudinal studies limits the understanding of causality and the temporal dynamics of typhoid risk factors. Methodologically, while this review allows a flexible and wide-range synthesis, it lacks the rigor of systematic reviews and meta-analyses, particularly in terms of risk-of-bias assessments and standardized inclusion criteria.

Future studies should focus on longitudinal and case-control methodologies to establish causality in typhoid risk factors, particularly regarding sex, occupation, and disease susceptibility. In addition, structured bias evaluations and quantitative meta-analyses should be incorporated where possible to improve the reliability and comparability of findings. Future research should also investigate the impact of demographic, socioeconomic, and climate variability on typhoid transmission dynamics, given their increasing relevance. Moreover, TCVs are an important tool in reducing *S* Typhi transmission and should be prioritized for introduction in endemic areas to strengthen prevention and control efforts.

By addressing these gaps and priority key areas, future research can strengthen the empirical foundations for typhoid control strategies, enabling policy makers and public health professionals to develop more targeted, evidence-based interventions for effective typhoid fever prevention and control.

Abstract

Background: With hypertension emerging as a global public health concern, taking measures to alleviate its burden is urgently needed. The hypertension management program (HMP) in China is a standardized policy to help people with hypertension to improve their health levels and reduce health inequalities. However, studies focusing on details regarding participation in this program remain scarce.

Objective: This study aims to investigate the participation rates in HMPs in China and examine the health disparities in hypertension management between local residents and internal migrants in Shenzhen.

Methods: This study used the medical record of Shenzhen, Guangdong, China. We included adults with new-onset diagnosis of hypertension after 2017 and focused on patients who have a record in the community health center. We described the basic characteristics of people diagnosed with hypertension, including age, gender, marital status, occupation, education level, and health insurance type. Enrolled rate, follow-up rate, and adherence rate were used to measure the engagement with this program at the city, district, and community levels.

Results: Of the 1,160,214 hypertensive patients, 29.70% (344,526/1,160,214) were local residents, while 70.3% (815,688/1,160,214) were internal migrants. In addition, 55.36% (642,250/1,160,214) were enrolled in the HMP. Of those, 57.52% (369,439/642,25) were followed up. In addition, 62.59% (231,217/369,439) of followed up individuals were adherents. Internal migrants demonstrated a significantly higher participation in the HMP, especially for the enrolled rate (local residents: 156,085/344,526, 45.30% vs internal migrants: 486,165/815,688, 59.60%) and adherence rate (local residents: 44,044/84,635, 52.04% vs internal migrants: 187,173/284,804, 65.72%). Apart from that, local, single, and younger individuals had lower rates compared to their counterparts. There also existed within-district and within-community variation among enrolled, follow-up, and adherence rates.

Conclusions: Based on our research, individuals with different demographic and socioeconomic characteristics and in different regions had different enrolled, follow-up, and adherence rates. Internal migrants in Shenzhen showed a significantly higher participation in the HMP. Given these findings, there exists the potential to enhance the outreach and engagement of local, single, and younger populations through targeted promotional strategies.

Introduction

Background

The United Nations' Sustainable Development Goals are important global issues. The goals focus on promoting health and well-being, as well as reducing inequalities, highlighting the need for all individuals, regardless of their circumstances, to be able to access quality health care and essential services for optimal health outcomes.

Hypertension presents a significant global health challenge, emerging as a primary contributor to the global disease burden. Analysis from the Global Burden of Disease Study reveals that high systolic blood pressure stands as the foremost risk factor for mortality worldwide, accounting for 10.8 million cardiovascular disease deaths and 11.3 million deaths overall in 2021 [1]. The World Health Organization's latest report highlights a surge in hypertension prevalence, with figures doubling from 650 million individuals in 1990 to an alarming 1.3 billion in 2019 [2]. In China, about 270 million people have hypertension, while research showed that, among the 256 million individuals aged 30-79 years with hypertension, only 52% were aware of their condition, 39% were receiving treatment, and a scant 16% had their blood pressure under control [2,3]. In China, hypertension is one of the earliest chronic diseases undergoing widespread public health intervention. The government has bolstered efforts to combat hypertension through initiatives such as the Basic Public Health Services policy, China Medium- and Long-term Plan for the Prevention and Treatment of Chronic Diseases, National Demonstration Areas for Comprehensive Chronic Disease Prevention and Control, and the National Healthy Lifestyle Action. Chinese strategies underscore the inclusion of hypertension management within basic public health services at the grassroots level, ensuring regular dissemination of national guidelines on hypertension management and treatment. These guidelines provide comprehensive details on the management processes and protocols for diagnosed patients and vulnerable individuals [4]. According to the National Standard for Basic Public Health Services [5], the hypertension management program (HMP) is one of most crucial programs within the Basic Public Health Services. It requires community health centers (CHCs) to establish dedicated medical records for hypertensive patients and provide regular follow-up services without additional fees beyond outpatient costs. According to performance assessments, there must be at least 1 follow-up visit record every 3 months.

Significant health inequities exist in the health policy context; health-related behaviors and beliefs; quality of care; utilization of health care services; and health status [6]. Research has highlighted health inequities between local residents and internal migrants in China. Many internal migrants still face significant barriers in accessing local public health services, particularly in establishing health records and receiving health education. This is more common in economically developed eastern regions, where internal migrants use public health services less often than those in central regions, indicating regional disparities [7]. Furthermore, internal migrants often have poorer health compared to local residents due to socioeconomic and cultural factors, with social integration and income inequality being key determinants. In 2017, internal migrants in Qingdao had relatively better health, while those in Shenzhen faced the greatest health challenges [8].

In terms of hypertension management, treatment, and control within the population [9], previous research has explored the potential impacts of multidimensional factors on the health inequity of hypertension and cardiovascular disease [10]; the factors can be summarized as individual, socioeconomic [11,12], and environmental. A nationally representative cross-sectional study in China revealed that age, BMI, and economic status contributed to the inequitable situation of hypertension prevalence [13]. Another study showed that economic status and educational level are associated with socioeconomic inequalities of health services utilization among patients with hypertension in the Pearl River Delta of China [14]. In addition, due to economic status, the hypertension burden appeared higher in rural areas compared to urban regions in China [15].

As China's first Special Economic Zone, Shenzhen has undergone sweeping changes, including a significant demographic shift due to a large influx of internal migrants from other parts of Mainland China. According to The Shenzhen Statistical Yearbook 2022, the total population of Shenzhen was 17,681,600, of which the registered household population was 5,563,900 (31.5%) and the nonregistered population was 12,117,700 (68.5%). Despite this, Shenzhen, similar to many other regions in China, prioritizes the provision of health care services to its local residents [16]. For example, older adults with local household registrations or local medical insurance are prioritized for free influenza vaccination, while internal migrants without local insurance have to pay out of pocket [17]. Local people aged ≥60 years are eligible for free health checks, whereas internal migrants are required to be ≥65 years old [18].

As a survey indicated that the prevalence rate of hypertension among the residents of Shenzhen is 20.74% [5], and the incidence of hypertension in Shenzhen is increasing, the HMP is accessible to all patients regardless of household registration status, with the aim of reducing health disparities; however, as of yet, there has been no research comparing the health inequity in hypertension management between internal migrants and local residents. In the context of an internal migrant–dense city, understanding the unique challenges and needs of both local residents and internal migrants is essential.

This Study

The primary objective of this baseline report was to describe the characteristics of hypertensive patients and those who have received HMP services at a CHC, as well as the current status of the specific services they receive. The secondary objective was to reveal the health inequity for utilization of hypertension management between local residents and internal migrants in Shenzhen.

Methods

Study Design and Data Source

This study used a cross-sectional design. The data of the study were obtained from CHCs and the government-owned hospitals

XSL•FO
RenderX

in Shenzhen, Guangdong, China. All data were extracted with SQL queries from original datasets at the Shenzhen Health Development Research and Data Management Center. The data included the patients' basic information as well as the actual hypertension record and follow-up service record from January 1, 2017, to September 30, 2023. We defined participants without Shenzhen household registration who had been living in Shenzhen for 6 months or more as internal migrants. The HMP is a key component of primary care services for hypertensive patients. Therefore, this study uses the enrollment rate, follow-up rate, and adherence rate of this program to assess the health equity in utilization of primary care services between local residents and internal migrants.

Eligibility Criteria of Resident Records

We included the records of the following residents: (1) those who were documented in either the health information system of a CHC or medical record of government-owned hospitals in Shenzhen, Guangdong, China from January 1, 2017, to September 30 2023; (2) those who were diagnosed with hypertension according to these information systems (patients with gestational hypertension, based on the International Classification of Diseases Tenth Revision code, were excluded); (3) those whose earliest diagnosis date was after January 1, 2017, and (4) those who were aged ≥18 years, which is the age threshold for blood pressure measurements when people visit medical institutions as per the hypertension management policy in Shenzhen.

Sociodemographic Variables

A total of 6 individual-level sociodemographic factors were included in this study: gender (male or female), age (<45 years, 45 - 65 years, and >65 years), marital status (single, married, widowed, or divorced), occupation (technical personnel/office staff, business service industry, agriculture and forestry, industry, other, unemployed), education level (Bachelor's degree or above, college diploma, high school or technical school, junior high school, elementary school or below), and health insurance type (urban employees, urban residents, others, fully self-funded).

Key Variables

The participation in the HMP in this research was assessed using 3 measures. First, "enrollment" in the program was defined as having a hypertensive record, which includes the diagnosis date, blood pressure at the time of diagnosis, lifestyle, specific information about the physicians and institutions providing the services, and patient contact information. This indicates that the patient has visited the CHC and the doctor had the opportunity to interact with them. Enrollment in the HMP is the initial step for doctors when encountering a hypertensive patient for the first time according to the policy. Second, follow-up in this study was defined as patients having at least 2 follow-up records at different times. Third, regular follow-up was defined as patients having an average of more than 4 follow-up visits per year, in accordance with the national policy, which mandates that hypertensive patients should be followed up at least 4 times per year. We used 3 corresponding ratios to evaluate engagement. The enrolled rate refers to the proportion of individuals enrolled out of all patients who have ever been diagnosed with hypertension. The follow-up rate indicates the number of individuals who are followed up out of those enrolled. The adherence rate represents the proportion of individuals who undergo regular follow-up out of the total number of those who are followed up.

Statistical Analysis

Individuals were assessed by household register (internal migrants or local residents). Indicators were estimated for participation in the HMP; for the whole city, this was stratified by sociodemographic factors (resident status, gender, age category, occupation, education level, and insurance type). The city was also stratified by district and community. Categorical variables and prevalence rates were expressed as absolute frequencies and percentages. Missing values were categorized as 1 group for each variable. Logistic regression was used to evaluate the main characteristics associated with participation in the HMP among all patients and internal migrants and local residents as a sensitivity analysis. A 2-sample *z*-test for proportions was used to evaluate whether the observed differences in proportions between internal migrants and local residents were statistically significant. The map figure was drawn using ArcMap 10.8 (Esri) and the other figures were drawn using OriginPro (version 2020b; OriginLab). Statistical analyses were conducted using R Studio (version 4.2.2; Posit).

Ethical Considerations

The data used in this study were anonymized and encrypted, ensuring no access to personally identifiable information. Our data access was authorized through an agreement with government departments. In addition, our study is 1 component of a larger study that was approved by The Tsinghua University Science and Technology Ethics Committee (20230065).

Results

Demographic Characteristics

The total number of diagnosed individuals recorded in the electronic health record was 1,160,214, with 344,526 local residents (29.7%) and 815,688 internal migrants (70.3%). In the overall population, 58.24% (n=675,692) were male and 41.76% (n=484,522) were female. More demographic characteristics of the diagnosed population are detailed in Table 1. Males constituted a higher proportion across all age groups and resident categories, with a noticeable decline in older age groups. Higher educational attainment was more prevalent in younger age groups. Internal migrants had higher proportions of individuals with lower educational levels (elementary school or below). Insurance coverage varied, with urban employee insurance being more common in younger and middle-aged groups, while urban resident insurance was more prevalent in the oldest age group.

City-Level HMP Participants

In Total

Among all diagnosed individuals, 55.36% (n=642,250) were enrolled in the HMP. We found that 57.52% (n=369,429) of those followed up. Furthermore, 62.59% (n=231,217) of the individuals who were followed up demonstrated adherence. Compared to local residents, internal migrants have a significantly higher participation rate (P<.001) in the HMP, as shown in Figure 1 (Table S1 in Multimedia Appendix 1).

Figure 1. City-level hypertension management program participants by household registration.

Enrollment Rate

Among all diagnosed individuals (n=1,160,214), 58.1% (n=642,250) were enrolled in the HMP. As is shown in Table 2, the enrollment rates were similar between different sexes, with males at 55.27% (n=373,452) and females at 55.48% (n=268,798). For internal residents, the enrollment rate was higher for females, with a rate of 60.15% (202,115/335,997) for females and 59.22% (284,050/479,691) for males. The opposite was seen for local migrants. Industrial workers had the highest enrollment rate, followed by those in agriculture and forestry, then the unemployed, with the lowest rate among those in the “other” category, and technical and administrative personnel just above that. For the local population, the business service industry was above the “other” group. The lower the educational level, the higher the enrollment rate. Older individuals had higher enrollment rates; the enrollment rate was only 39.27% (n=109,623) among those aged 18 - 44 years, but it increased to 64.14% (n=174,335) among those older than 65 years. Divorced and widowed individuals represented the

XSL•FO
RenderX

smallest proportion of the diagnosed population, but they had the highest enrollment rate at 67.52% (n=11,405), followed by married individuals at 59.16% (n=610,208), with single individuals having the lowest rate at 18.41% (n=20,018). The trends in enrolled rates across different age groups, marital statuses, and educational levels were similar between local residents and internal migrants. The logistic regression results indicated that all the research variables examined were significant factors influencing the enrollment rate (Table S2 in Multimedia Appendix 2).

[a]All percentages are calculated in relation to a broader population. For instance, the proportion of males within the enrolled individuals stands at 55.27% and is calculated as n/N × 100. Here, "n" represents the number of males within the enrolled individuals subset, while "N" denotes the number of males within the entire population. For N values, please refer to the corresponding "subtotal" columns in Table 1.

Follow-Up Rate

Of patients who have been enrolled in the hypertension program, about 57.52% (369,439/642,250) were followed up. As is shown in Table 2, the follow-up rate was higher among internal migrants (284,804/486,165, 58.58%), while it was 54.22% (84,635/156,085) among the local population. The proportions of those who follow up were higher among men (male: 220,066/373,452, 58.93%; female: 149,373/268,798, 55.57%) and industrial workers (88,760/134,668, 65.91%). For other characteristics, there were significant differences in follow-up rates between local residents and internal migrants. For the local population, follow-up rates increased with age: 50.93% (9565/18,782) for those aged 18‐44 years and 55.73% (29,939/53,723) for those over 65 years. However, for internal migrants, the trend was the opposite: the follow-up rate for those aged 18‐44 years was 61.78% (56,120/90,841), while it was 55.61% (67,069/120,612) for those over 65 years. Among local residents, the highest follow-up rate was observed among divorced and widowed individuals, at 58.65% (2001/3412). Conversely, for internal migrants, married individuals had the highest follow-up rate, at 58.89% (272,661/463,006). Single individuals exhibited the lowest follow-up rates in both populations, with 46.34% (2428/5240) of local residents and 51.62% (7629/14,778) of internal migrants following up. Among local residents, the highest follow-up rate was observed in individuals with an educational level of elementary school or below and those with urban resident insurance. Conversely, among internal migrants, the highest follow-up rate was found in individuals with a junior high school education and those with urban employee insurance. The logistic regression results indicated that all the research variables examined were significant factors influencing the follow-up rate (Table S2 in Multimedia Appendix 2).

Adherence Rate

A total of 62.59% (231,217/369,439) of patients who followed up continued to do so at least 4 times per year. As is shown in Table 2, similar to the enrolled rate and follow-up rate, the adherence rate was higher among internal migrants (187,173/284,804, 65.72%) compared to local residents (44,044/84,635, 52.04%). Among the followed-up patients, men (140,515/220,066, 63.85%), single individuals (7166/10,057, 71.25%), and people aged 18‐44 years (45,436/65,685, 69.17%) had the highest adherence rates. Individuals with urban employee and urban resident insurance did not have the highest adherence rates. These trends were consistent between both local and internal migrants. However, among local residents, those engaged in commercial and industrial occupations had the highest adherence rates, at 52.74% (9998/18,956) and 52.65% (2405/4568), respectively. Conversely, in the internal migrants group, the unemployed and those classified under other categories had the highest adherence rates, at 67.14% (66,344/98,816) and 66.47% (8136/12,241), respectively. Regarding educational level, among local residents, those with a junior high school level of education had the highest adherence rate at 53.28% (7776/14,595), whereas among internal migrants, those with an educational level of elementary school or below had the highest adherence rate. The logistic regression results indicated that all the research variables examined were significant factors influencing the adherence rate (Table S2 in Multimedia Appendix 2).

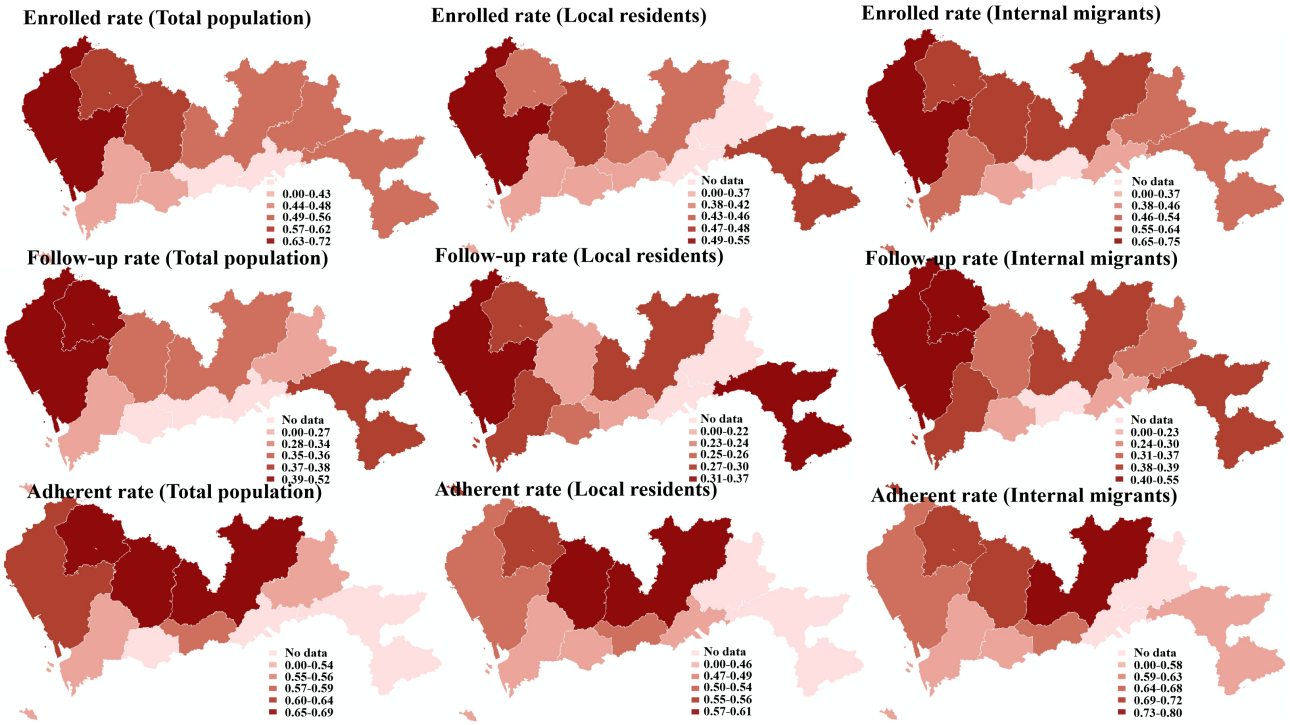
RenderX



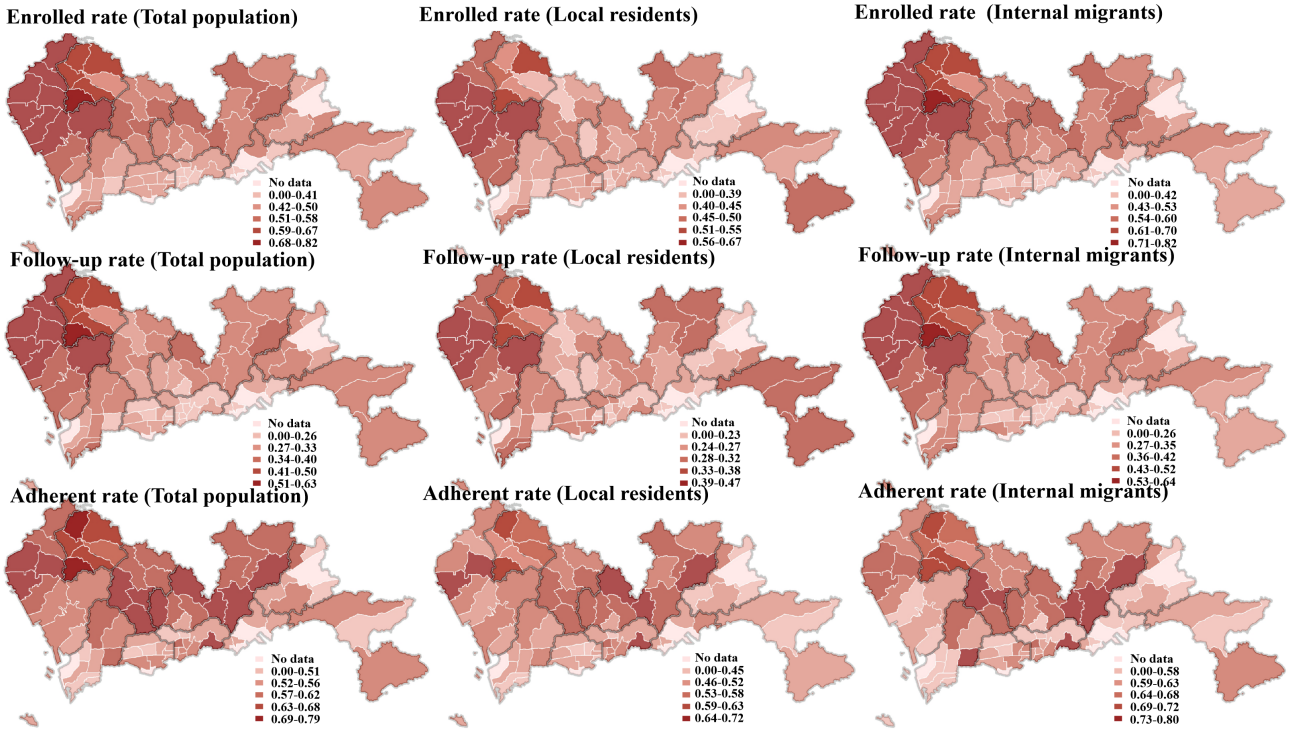
District-Level Hypertension Management

As shown in Figure 2, the highest enrolled rate was detected in Baoan district (180,301/250,036, 72.11%), Guangming district (33,308/54,063, 61.61%), and Longhua district (74,115/124,878, 59.35%), while the lowest enrolled rate was found in Luohu district (52,413/132,023, 39.70%), Yantian district (8609/19,924, 43.21%), and Futian district (59,962/132,337, 45.31%). It is worth noting that, apart from Luohu district, the enrolled rate of internal migrants was higher than that of local residents.

Regarding follow up rate, Baoan district, Guangming district, and Dapeng New Area showed the highest rates, which were 52.21% (131,171/251,237), 45.86% (24,915/54,328), and 36.72% (4301/11,713), while the lowest rate was found in the same places as the enrolled rate. The enrolled rate of internal migrants was higher than that of local residents in all districts.

Considering the adherence rate, Longhua district (31,779/45,917, 69.21%), Longgang district (54,088/79,965, 67.64%), and Guangming district (17,949/26,658, 67.33%) were ranked as the first 3. Similarly, the adherence rate of internal migrants was higher than that of local residents in all districts.

Figure 2. District-level hypertension management.



Community-Level Hypertension Management

There was considerable within-city and within-district variation in the community level of hypertension management. Generally speaking, the community-level enrolled rate, follow-up rate, and adherence rate were descending from east to west and from north to south. Although only the adherence rate was slightly different, some communities in the southern region showed a high rate, as shown in Figure 3.

XSL•FO
RenderX

Figure 3. Community-level hypertension management.

There also exists within-district variation such that a 24.30% gap between different communities was found in the enrollment rate of Guangming district. A 23.59% gap was detected in the follow-up rate of Baoan district. Similarly, a 23.59% gap was found in the adherence rate in Luohu district. In addition, rates of internal migrants were much higher than those of local residents in all districts.

Discussion

Principal Results

Regarding the crucial role of health service supply from primary health centers in achieving health equity in the domain of hypertension prevention, we summarized the enrolled rate, follow-up rate, and adherence rate of the Shenzhen population that participated in the HMP based on the data collected from CHCs. Among all diagnosed individuals, 55.36% (642,250/1,160,214) were enrolled in the HMP. Of those, 57.52% (369,439/642,250) followed up, and 62.59% (231,217/369,439) were adherents. Furthermore, we compared the health inequity in hypertension between internal migrants and local residents in Shenzhen.

Comparison With Prior Work

Overall, the data revealed that men exhibited higher rates of both follow-up and adherence compared to women, which is not consistent with the conclusion of some studies [19,20] related to hypertension treatment adherence. However, the medication adherence rates of men and women taking one medication were 61.04% and 55.86% in Beijing, respectively [21]. Despite the fact that the majority of individuals over the age of 65 years were enrolled in the program, this age group demonstrated the lowest rates of follow-up and adherence, although the rates were relatively high in Beijing and Shanghai [22]. Conversely, individuals aged between 18 and 44 years, who have the lowest enrollment rate, showed the highest rates of follow-up and adherence. It is not similar to common research results in which the oldest patients are the most adherent [19,20]. This phenomenon may be related to the fact that older individuals often have more complex health conditions, which CHCs cannot address well at present, leading them to generally prefer seeking treatment at higher-level medical institutions [23,24]. The observed low initial engagement of younger individuals with primary health care facilities may be attributed to a general mistrust or lower acceptance of these services among this demographic; the result is similar to that of a study conducted in Hong Kong [25]. Despite the low proportion of young patients who initially seek care at primary health centers following a hypertension diagnosis, those who do engage exhibit the highest follow-up and regular follow-up rates across all age groups. This indicates a high level of acceptance and satisfaction with primary health care management among younger patients once they have accessed these services.

Regarding marital status, the enrollment rate among widowed and divorced individuals was the highest, exceeding that of single individuals by more than 3 times. It is possible that this group, having experienced significant life events, became more concerned about their health. However, without a partner to provide encouragement and support [26], they may find it difficult to maintain consistent health behaviors and this group had higher mortality [27]. As a result, despite their high enrollment rates, their adherence tended to be relatively low. Interestingly, however, single individuals had the highest adherence rate. Perhaps this is because single individuals who enrolled in the HMP tend to pay more attention to their own health and are more likely to take action to keep healthy, leading to higher adherence; this is similar to a finding in the United States that never-married individuals reported better health habits and had higher rates of protective factors compared to

XSL•FO
RenderX

married or divorced/separated individuals [28]. Previous studies showed that, in general, blue-collar employees appeared less likely to participate in health promotion programs compared to white-collar workers [29], and they may not have enough time to participate in the program [30,31]. Conversely, in our research, industrial workers stood out with the highest rates of enrollment, follow-up, and adherence across all categories; this may be related to the fact that in Shenzhen, many primary health care centers operate until 9 PM, providing this group with sufficient time to access the programs. Furthermore, the data indicated that, regardless of age, individuals with lower educational levels tended to have higher rates for all 3 metrics. Previous research has also found that individuals with higher education levels may be less likely to participate in cancer screening or achieve favorable screening outcomes [32], suggesting the impact of education on health behaviors is complex.

Importantly, internal migrants demonstrated a significantly higher participation in the HMP, especially in terms of project inclusion and regular follow-up. The participation rate of internal migrants was more than 10% higher than that of local residents. This result is inconsistent with previous global and national studies on the health service utilization of internal migrants. Previous research has indicated that internal migrants face long-standing disadvantages due to various institutional, social, cultural, and other exclusionary factors [33]. These disadvantages often extend to health and health care access, limiting their access to health resources [34,35]. A review focusing on migrants' and refugees' health status and health care in Europe highlighted the issue of underuse of primary health care services among these populations [36]. A study [37] based on the 2017 National Migrants Dynamic Monitoring Special Survey in China revealed that, compared to the registered population, the floating population is at a disadvantage in utilizing basic public health services. Most studies [38,39] focusing on hypertension management in China showed that the rate of hypertension management at primary health care centers among the floating population was less than 30% and as low as 2.3% in Hunan province [40], but our study showed that this situation does not exist in Shenzhen. In fact, among the hypertensive population in Shenzhen, on the contrary, internal migrants are better able to utilize primary health care services than locals. The Shenzhen municipal government has invested significantly in ensuring that all residents can access health care services within a 15-minute radius, making it highly convenient for the entire population. Additionally, the city provides free blood pressure screening at CHCs for all individuals aged ≥18 years, which promotes accessibility and equity in hypertension management services [41]. Certain districts in Shenzhen supply free medication to hypertensive patients enrolled in the program [42]. For most internal migrants, free health care services hold strong appeal due to their economic constraints. Some internal migrants came to Shenzhen to help their son/daughter look after children [43], so they or their son/daughter may care more about their health and they usually have enough time to go to a CHC. Insurance is considered an important factor for the utilization of health services for internal migrants and immediate reimbursement of medical insurance can significantly increase inpatient utilization, promoting health [44]. The statistical model showed that insurance type is an important factor influencing the 3 hypertension management rates studied. However, there were notable differences between local residents and internal migrants. For local residents, those with urban resident insurance were more likely to participate in the HMP compared to those with urban employee insurance. In contrast, for internal migrants, those with other insurance types were less likely to participate compared to those with urban employee insurance. It takes less money to get treatment and medicine in CHCs compared with upper health care facilities, especially for people who do not have native health insurance or cannot get immediate reimbursement.

Our analysis revealed several intriguing trends regarding HMP engagement among different demographic groups in Shenzhen. Previous studies conducted in Beijing and Shanghai have also found variations in hypertension management across different demographic factors, including age, gender, education level, workload, marital status, residential area, and annual household income [45,46]. Among individuals aged 18 - 44 years, the enrolled rate of internal migrants was nearly 18% higher than that of local residents. This discrepancy may be attributed to the comparatively better economic conditions of local residents, who do not face the housing issues often encountered by migrants [47,48]. They may just go to upper hospitals when they think necessary, while internal migrants are more likely to utilize CHCs as the first choice for their routine health problems [49,50]. Additionally, the presence of their parents may lead locals to prioritize their own health less than migrants, who often lack familial support [51] and thus might be more vigilant about their health. Interestingly, in the divorced or widowed demographic, the follow-up rate among local residents surpassed that of internal migrants. Moreover, among local residents, the follow-up rate for this group was higher than that of married individuals. This finding contrasts with conventional research, which typically suggests that marriage promotes greater health awareness and engagement with health care services while the effects of bereavement usually lead to less health care utilization [52]. For married migrant individuals, having a spouse provides them with companionship [53] and significant support from their partner, whereas local residents can receive support from other relatives. This may cause internal migrants, compared to local residents, to have a more limited support system, making the protective effects of marriage on their health more pronounced. In contrast, local residents who are divorced or widowed may have access to a broader range of social support. The adherence rate showed an increasing divergence between local residents and internal migrants as age groups progress. Internal migrants tended to exhibit greater concern for their health after relocating to a new environment, which may explain this trend. Despite the fact that, among those with an undergraduate education or higher, the enrolled rate and follow-up rate for local residents were higher than those for internal migrants, the adherence rate for local residents remained lower than that of internal migrants. This suggests that, while highly educated local residents may initially engage with health care services, they may not maintain the same level of adherence as their migrant counterparts.

Some research showed that there exists vast disparities in health insurance coverage and health service utilization between floating populations and local residents; most of the floating population has no timely access to primary or some other kinds of health care service [39], which cause the poor control of chronic diseases. In our study, it appears that health insurance played a less significant role in the disparity of participation in the HMP between local residents and internal migrants.

From a district and community level, hypertensive patients were experiencing health inequity in hypertension treatment and prevention. The potential reasons included population, economic reasons, and policy differences. The populations of Longgang, Longhua, and Nanshan in Shenzhen are large and concentrated; in addition, the health care services are mature and systematic. Hence, the HMP is better than in other regions such as Yantian and Pingshan districts. Similarly, the wealthy regions had higher enrolled, follow-up, and adherence rates compared to the relatively poor regions, namely Yantian and Pingshan districts. These finding were consistent with previous research. A large national survey during 2004‐2018 found a provincial difference in awareness, treatment, and control is partly correlated with per capita gross domestic product [54]. Richer provinces are more successful in controlling hypertension. Globally, the proportions of hypertension awareness, treatment, and blood pressure control are low [55], particularly in low- and middle-income countries, and few comprehensive assessments of the economic impact of hypertension exist [56,57]. In terms of policy differences, the hypertensive patients who participate in the HMPs of CHCs could get free prescription medicines, blood pressure measurement services, and blood glucose measurement services once per quarter. The policy is different in different districts in Shenzhen, which may have caused the observed difference in enrolled, follow-up, and adherence rate. Furthermore, when it comes to health equity between internal migrants and native citizens in Shenzhen, the difference in enrolled, follow-up, and adherence rates within internal migrants was higher than that within local residents. This may be caused by different health care service supply situations toward internal migrants within different districts and communities [58]. The same problems were found in Ireland, Portugal, Spain, and the United States [59].

Limitations and Strengths

This study represents a pioneering effort to examine the participation of internal migrants and local residents in HMPs, thereby highlighting the equity of internal migrants' utilization of primary health care services under current Chinese hypertension management policies. By focusing on the specific involvement of diagnosed hypertension patients in HMPs, this research offers valuable insights into the accessibility and fairness of these services for internal migrants. The data utilized in this study were derived entirely from the primary health care system, ensuring its authenticity and reliability. However, this study has several limitations. It exclusively addressed the participation of hypertension patients in primary HMPs, which means that it did not account for patients who may receive regular treatment at other medical institutions without ever visiting CHCs. Consequently, the findings may not fully represent the hypertension management engagement of all patients citywide. Furthermore, the study was centered on participation rates within the HMP and did not capture the ultimate blood pressure control outcomes of the subjects. As a result, it is not possible to ascertain the differences in blood pressure control outcomes that may arise from varying levels of management participation.

Future research should consider integrating data from multiple health care providers and tracking long-term health outcomes to provide a more comprehensive understanding of hypertension management across diverse patient populations.

Conclusions

Based on our research, of the 1,160,214 hypertensive patients, 642,250 were enrolled in the HMP, 48,848 were included in the followed up population, and 34,186 were adherents. Notably, internal migrants demonstrated a significantly higher participation in the HMP. Furthermore, populations with different demographic and socioeconomic characteristics and in different regions showed different rates. Given these findings, there is the potential to enhance the outreach and engagement of native, younger, and single populations through targeted promotional strategies.

Acknowledgments

This project was supported by the Sanming Project of Medicine in Shenzhen (grant SZSM202111001). We would like to express our gratitude to the Shenzhen Government and the Shenzhen Health Development Research and Data Management Center for their invaluable support in providing data, funding, and an enabling environment for this project. We acknowledge the use of generative ChatGPT for grammatical checks.

Data Availability

The datasets generated during and/or analyzed during this study are not publicly available due to restrictions imposed by the local government. The data originate from the medical system and are managed by the local government. Access to the encrypted data stored on the cloud platform is limited to research institutions that have established formal collaborations with the local government.

Abstract

Background: The adoption of eHealth accelerated during the COVID-19 pandemic. Inequalities in the adoption of eHealth during the COVID-19 pandemic have been reported, but there are few such studies among people with impairment.

Objectives: This study aimed to investigate self-reported use and difficulty in the use of eHealth before the COVID-19 pandemic compared to during late social distancing restrictions in Sweden, among people with and without impairment, as well as between different types of impairment.

Methods: A cross-sectional survey was distributed twice by snowball sampling to people with self-reported impairment and a general population matched by age, gender, and county. Use and difficulty in the use of six eHealth services were compared between groups using chi-square test and logistic regression with year interaction terms, reported as odds ratio adjusted (aOR) for gender and age with 95% CI.

Results: The surveys included 1631 (in 2019) and 1410 (in 2021) participants with impairment, and 1084 (in 2019) and 1223 (in 2021) participants without. Participants with impairment, compared to those without impairment, reported less use and more difficulty in booking health care appointments online, digital identification, and the Swedish national web portal for health information and eHealth services (1177.se), both before and during the pandemic (P=.003 or lower). Video health care appointments were the exception to this disability digital divide in eHealth as video appointment adoption was the most likely among participants with attention, executive, and memory impairments (interaction term aOR 2.10, 95% CI 1.30 - 3.39). Nonuse and difficulty in the use of eHealth were consistently associated with language impairments and intellectual impairments. For example, language impairments were inversely associated with use of the logged-in eHealth services in 1177.se in 2021 (aOR 0.49, 95% CI 0.36 - 0.67) and were associated with difficulty in the use of 1177.se in 2019 (aOR 2.24, 95% CI 1.50 - 3.36) and the logged-in eHealth services in 1177.se in 2021 (aOR 1.89, 95% CI 1.32 - 2.70). Intellectual impairments were inversely associated with the use of the logged-in eHealth services in 1177.se in 2021 (aOR 0.19, 95% CI 0.13 - 0.27).

Conclusions: This repeated cross-sectional survey study, including participants with diverse types of impairment and a control group without impairment, reveals persisting disability digital divides, despite an accelerated adoption of eHealth across the pandemic. eHealth services were not accessible to some groups of people who were identified as being at risk of severe disease during the COVID-19 pandemic. This implies that all people could not use eHealth as a measure of infection protection.

Introduction

Adoption of eHealth accelerated during the COVID-19 pandemic [1]. Before the pandemic, we identified a disability digital divide in eHealth, that is, people with impairment reported less use and more difficulty in the use of eHealth, particularly with some types of impairment (language impairments and intellectual impairments) [2]. Sustainable development [3], legislation, and human rights principles [4] demand accessible eHealth for all. During the pandemic, people with impairment have reported less use of COVID-19 digital services than people without impairment [5], and have reported difficulty in the use of eHealth [6]. Likewise, eHealth websites have failed to pass accessibility assessments [7]. Even though there are multiple studies and even reviews of associations between eHealth and other sociodemographic factors or somatic diseases, there are very few studies of how people with impairment perceive using eHealth. The three survey studies conducted prior to ours did not sample psychiatric or intellectual impairments, and they had no comparison to before the pandemic [5,6,8]. Further, the two of them that investigated the eHealth modality telehealth reported aggregated results of video health care appointments with telephone contacts.

The emergency phase of the COVID-19 pandemic in the spring of 2020 was characterized by uncertainty [9], and exceptional episodes of social distancing restrictions, including rapid digitalization [1]. Reprioritizing was a necessity, in order to provide acute health care in severe cases of COVID-19, triage with health care guidance, and public health assignments. Like the rest of the general population, health care workers were instructed to self-quarantine when having respiratory tract symptoms, which also limited health care availability [10]. To provide health care services in a social distancing manner, health care facilities were reorganized, separating dedicated areas for suspected COVID-19 cases [11] and the population was encouraged to redirect contacts to eHealth instead of face-to-face contacts [1]. Groups at risk for severe COVID-19 were identified and were recommended intensified social distancing restrictions [12], which included people with intellectual impairments, Down's syndrome, schizophrenia, bipolar disorder, and stroke. The Swedish restrictions were reimposed in a second wave from autumn 2020 to summer 2021 and a third wave from January 2022 to September 2022. This was a time of realization and concern about prolonged postpandemic scenarios [9].

This study aimed to investigate self-reported use and difficulty in the use of eHealth before the COVID-19 pandemic compared to during late social distancing restrictions in Sweden among people with and without impairment, as well as between different types of impairment.

Methods

Study Design

This study had a repeated cross-sectional comparative design, using data from the "Swedes with impairment and the internet 2019" (SMFOI19) survey and the "Swedes with impairment and the internet 2021" (SMFOI21) survey, to people with diverse types of impairment and matched controls.

Study Setting

The publicly financed Swedish national web portal for health information and eHealth services (1177.se) is open to the whole population and is the most commonly used eHealth service in Sweden [13]. To access the personal eHealth services in 1177.se, it is required that the user have digital identification. Digital identification is also needed to access other private eHealth services. In the past decade, private eHealth services that provide video health care appointments have been launched [14]. Subsequently, this has encouraged the public health care regions to also provide video health care appointments.

Participants

Participants were people with self-reported impairment and people from the general population matched to the sample of people with impairment by gender, age, and county of residence. Impairment status was self-reported by one questionnaire item with 43 checkboxes of diagnoses and activity limitations and a free-text response option for reporting "Other impairment" (Multimedia Appendix 1). Participants who received the survey as matched controls, but responded that they had impairment, were reallocated to be analyzed as participants with impairment.

Procedures

The first version of this survey was developed in 2017 to mirror two nationwide Swedish surveys [15,16], out of which the latter is connected to Eurostat [17]. In the SMFOI19 survey, questions on eHealth services were added [2], and SMFOI21 also included questions on video health care appointments. SMFOI19 comprised 47 questions and SMFOI21 comprised 43 questions, on information and communication technology, impairments, and background characteristics. The wording of the questionnaires was developed in collaboration with the Begripsam group, all of whom have lived experience of impairment [18]. Several response modalities were provided (web, pen, phone, or on-site interview) and adaptations were provided upon request (sign language, reading support, speech therapist, or pictograms). Snowball sampling was undertaken from June to October 2019 (SMFOI19) and from May to August 2021 (SMFOI21), respectively [19]. The snowball sampling was distributed by disability networks, as well as by the participants themselves. Then, in February 2020 (SMFOI19) and in March 2022 (SMFOI21), the surveys were posted to six randomly selected matched controls per participant with impairment. Addresses were provided by the Swedish state personal address register [20].

Data Collection

This study used SMFOI19 and SMFOI21 questionnaire items on eHealth, impairments, and background characteristics.

Outcomes

Table 1 provides an overview of outcome variables. In summary, outcomes were measured on the use of eHealth services (ie, whether the services had been used and whether avoiding or preferring use) and difficulty in the use of eHealth services (ie, perceived difficulty or ease of use).

XSL•FO
RenderX

Table . Outcome variables measuring "use of eHealth" and "difficulty in the use of eHealth."

Outcome variable followed by response options	In the SMFOI19[a] survey	In the SMFOI21[b] survey
Use of booking health care appointments online		
Checkbox items		
"I use booking medical appointments online" or "I use booking dental appointments online"	✓	✓
Use of video health care appointments		
Multiple-choice item		
"Yes, I used video health care appointments prior to the COVID-19 pandemic" or "Yes, I used video health care appointments during the COVID-19 pandemic"		✓
Comparisons were made respectively with the response option "No, I have not used video health care appointments," whereas "Do not know" was treated as missing value		
Use of private eHealth services (which are services that primarily provide video health care appointments, chat, and drug prescriptions)		
Checkbox items		
Use of five Swedish private eHealth services or "Other private eHealth service"		✓
Use of the Swedish national web portal for health information and eHealth services (1177.se)		
Checkbox items		
"I use the health information website in the 1177.se"		✓
"I use the logged-in eHealth services in the 1177.se"		✓
Use of digital identification		
Checkbox items		
"I use the digital identification app BankID" or "I use other digital identification than BankID"	✓	✓
Avoid booking health care appointments online		
Multiple-choice item		
"If possible, I avoid booking medical appointments online" or "If possible, I avoid booking dental appointments online"	✓	✓
Comparison was made with the response option "I try to book all appointments online," whereas "Not applicable" was treated as missing value.		
Avoid video health care appointments		
Multiple-choice item		
"If possible, I avoid video health care appointments"		✓
Comparison was made with the response option "I try to get all my appointments as video health care appointments," whereas "Not applicable" was treated as missing value.		
Difficulty in the use of the Swedish national web portal for health information and eHealth services (1177.se)		
Multiple-choice items

Two items in SMFOI21 "The health information website in 1177.se is difficult to use" or		✓
"The logged-in eHealth services in 1177.se is difficult to use." For comparison between SMFOI19 and SMFOI21, they were combined.		✓
One single item in SMFOI19 "The Swedish national web portal for health information and eHealth services (1177.se) is difficult to use"	✓	
Comparison was made with the response option "It is easy to use," whereas "Not applicable" was treated as missing value.		
Difficulty in the use of digital identification		
Multiple-choice item		
"It is difficult to use the digital identification app Mobile BankID" or "It is difficult to use other digital identification than BankID"	✓	✓
Comparison was made with the response option "It is easy to use," whereas "Not applicable" was treated as missing value.		

[a]SMFOI19: Swedes with impairment and the internet 2019.

[b]SMFOI21: Swedes with impairment and the internet 2021.

Data on the use of eHealth were collected in both SMFOI19 and SMFOI21 on booking health care appointments online and digital identification. In SMFOI21, use of eHealth was also collected on video health care appointments "before the pandemic" and "during the pandemic," private eHealth services, and the Swedish national web portal for health information and eHealth services (1177.se).

Data on the use of eHealth were also collected by questions on whether the respondents "Avoided" or "Preferred" booking health care appointments online in both SMFOI19 and SMFOI21, and video health care appointments in SMFOI21.

Data on difficulties in the use of eHealth were collected in both SMFOI19 and SMFOI21, on the use of the 1177.se and use of digital identification.

Independent Variables

Age and gender were selected to be confounding variables based on empirical studies of known demographic associations with the study outcomes [21,22]. Gender was analyzed as "female" and "male" whereas the response options "Other gender" and "Prefer not to answer" were handled as missing values in the analysis. Age was categorized for analysis into four categories: 16 - 29, 30 - 44, 45 - 69, and 70 years of age and older.

Data on impairment were collected by one question with 43 checkbox multiple response options on activity limitations (eg, difficulties in understanding) and diagnoses (eg, intellectual disability), and a free-text option for "Other impairment" (Multimedia Appendix 1). For the analysis, we applied a conceptual model of purposeful subgrouping of impairments, which we had developed in a previous study [2]. The categorization of types of impairment was based on our competence in human-computer interaction, digital accessibility, and medical science, and with the International Classification of Functioning, Disability, and Health (ICF)-classification as a framework [23], as well as empirical knowledge of comorbidity and functioning [24]. The grouping of impairments was done independently by three of the researchers (LP, SJ, and CG). There was almost complete interrater agreement and consensus in a conceptual model. Our conceptual model comprises 11 types of impairments by merging ICF-Body functions and ICF-Activities, as well as the 7 global and 11 specific ICF-Cognitive functions. The robustness of the conceptual model was assessed in a cluster analysis [25] using SPSS (version 26.0; IBM Corp).

Background Characteristics

Data on participant characteristics were collected to describe the study samples in regard to educational level, native language, occupation, income, urban or rural status, accommodation, cohabitant status, professional support in everyday life, and access to digital devices.

Data Analysis

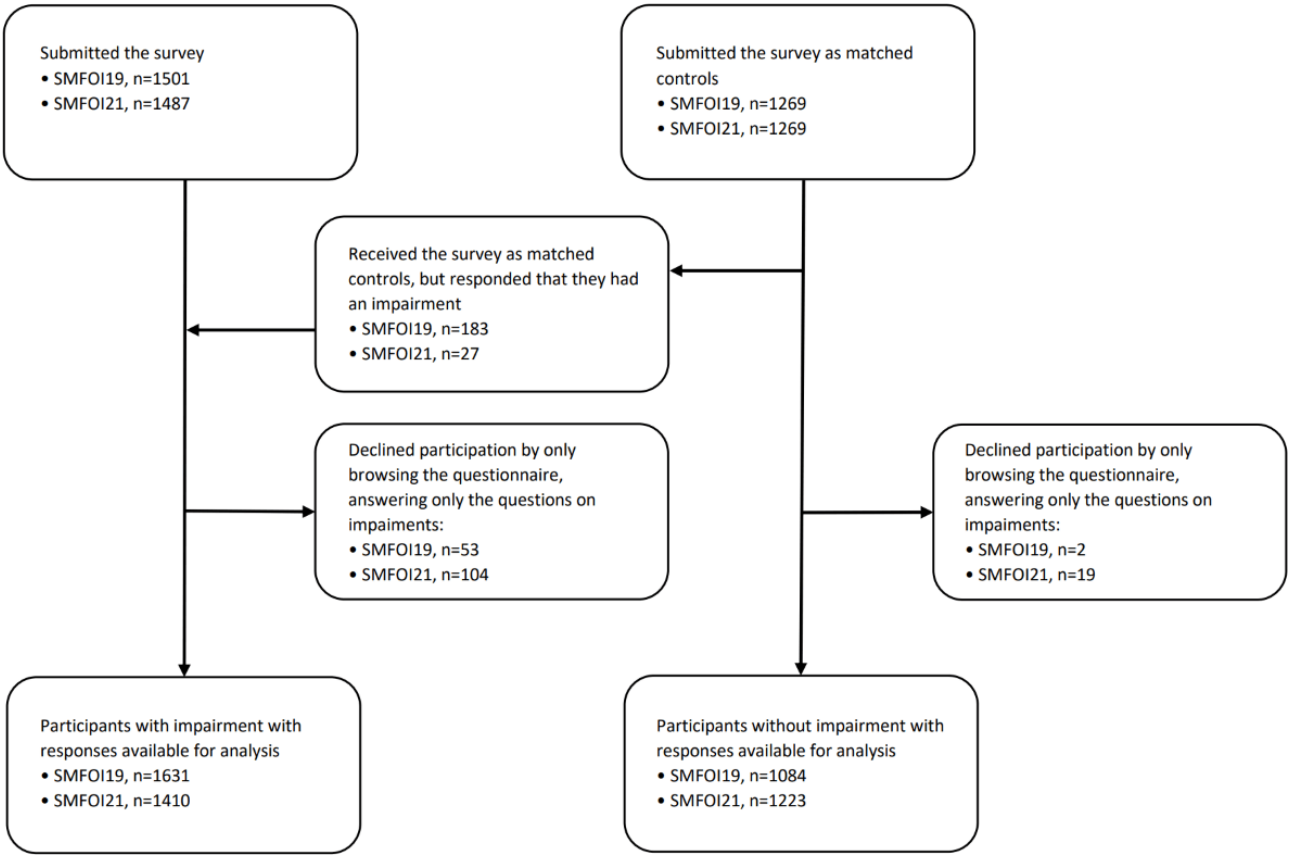
We compared 11 outcomes between participants with and without impairment, as well as between different types of impairment. Six of the outcomes were compared between the survey years (2021 and 2019; Table 1). The statistical software R (version 4.0.3; R Core Team) was used for the analyses. Pair-wise deletion was applied. The significance level was set to ≤.05. Chi-square test and logistic regression with robust standard errors (Huber-White) adjusted for gender and age were used. Multicollinearity was assessed in relation to a predetermined cut-off. Sensitivity analyses indicated the robustness of the estimates, that is, models were fitted with and without independent variables with wide CIs. Results from the following analyses are visualized in figures and presented as numeric values in Multimedia Appendix 2. Among all participants overall, SMFOI21 was compared to SMFOI19, by

XSL•FO
RenderX

logistic regression models, adjusted for types of impairment, in addition to adjusting for confounders. Comparisons between participants with impairment to those without were made by chi-square test. To identify types of impairment associated with nonuse and difficulty in the use of eHealth, year-stratified confounder-adjusted logistic regression was used. Comparisons between types of impairment in SMFOI21 to SMFOI19 were performed by the input of multiplicative interaction terms of types of impairment with survey year [26].

Ethical Considerations

This study was approved by the Swedish Ethical Review Authority (registration 2022-00184-01). The participants provided informed consent prior to participation. No compensation was provided for participation. This study used anonymized data.



Results

The flowchart of participation (Figure 1) includes 1631 (in SMFOI19) and 1410 (in SMFOI21) participants with impairment, along with 1084 (in SMFOI19) and 1223 (in SMFOI21) participants without impairment.

Compared to participants without impairment, more of the participants with impairment were educated in a special school, were outside the labor market or not working, had lower income, lived in rental apartments or supported accommodation, were living alone, had professional support in everyday life, and lacked access to digital devices (Table 2).

In both survey years, participants with impairment had a median of 2 (IQR 1-6 in SMFOI19 and 1-5 in SMFOI21) impairments. The types of impairment were distributed in approximately similar proportions in the two survey years (Figure 2).

Figure 1. Flowchart of participation in the SMFOI19 and SMFOI21 surveys. SMFOI19: Swedes with impairment and the internet 2019; SMFOI21: Swedes with impairment and the internet 2021.

[a]SMFOI19: Swedes with impairment and the internet 2019.

[b]SMFOI21: Swedes with impairment and the internet 2021.

Figure 2. Description of participants' types of impairment (subgrouped in the inner circle and disaggregated to the level of the questionnaire in the outer circle). The labels are followed by number and proportion of all participants with impairment, n (%). Adds up to over 100% as multiple responses were allowed. The impairment question construction covered both activity limitations (eg, reading difficulties) and diagnoses (eg, dyslexia; Multimedia Appendix 1). *Free-text "other impairments" were in falling frequency: pain, genetic syndromes, paresis, and posttraumatic stress disorder, followed by infrequent responses. ADD: attention deficit disorder; ADHD: attention-deficit/hyperactivity disorder; SMFOI19: Swedes with impairment and the internet 2019; SMFOI21: Swedes with impairment and the internet 2021.

Comparisons of use between the survey years, as well as between participants with and without impairment, are reported in Figures 3a and 4a. Among all participants, all eHealth services were used by more participants in SMFOI21 compared to SMFOI19: booking health care appointments online (adjusted odds ratio [aOR] 2.73, 95% CI 2.39 - 3.10), video health care appointments (aOR 3.34, 95% CI 2.81 - 3.96), and digital identification (aOR 1.74, 95% CI 1.43 - 2.10; Figures 3a and 4a). In both survey years, all but two of the eHealth services were used by fewer participants with impairment compared to participants without impairment: booking health care appointments online (P<.001), the information pages in 1177.se (P<.001), the logged-in eHealth services in 1177.se (P<.001), and digital identification (P<.001; Figures 3a and 4a). The exceptions were video health care appointments, which were used by 9% in both groups (P=.93) before the pandemic, and 29% with impairment versus 19% without impairment (P<.001) during the pandemic, and private eHealth services (P=.10; Figure 3a).

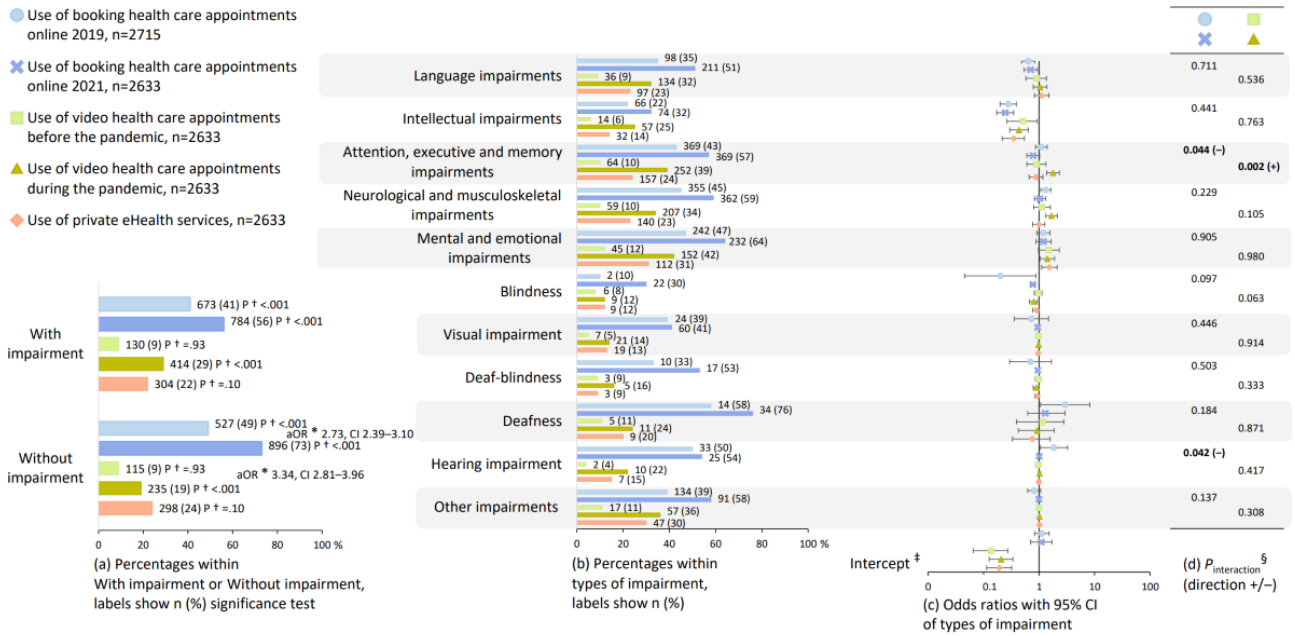
Figure 3. Use of booking health care appointments online, video health care appointments, and private eHealth services. The group with impairment (a) is disaggregated into the subgrouped types of impairment from Figure 2 (b-d). The numeric values visualized in this figure are presented in Tables S1 and S3-S5 in Multimedia Appendix 2. *aOR: adjusted odds ratio from logistic regression comparing use of eHealth among all participants overall between before and during the pandemic (reference group is before the pandemic), adjusted for type of impairment (reference is participants without impairment), gender (reference female), and age (reference <30 years of age); †2-sided *P* value from chi-square test comparing participants with and without impairment. ‡Intercept from year-stratified logistic regression (reference group is participants without impairment), adjusted for gender (reference female), and age (reference <30 years of age). §*P* value from logistic regression interaction terms of year with types of impairment (reference is before the pandemic and participants without impairment), adjusted for gender (reference female), and age (reference <30 years of age).



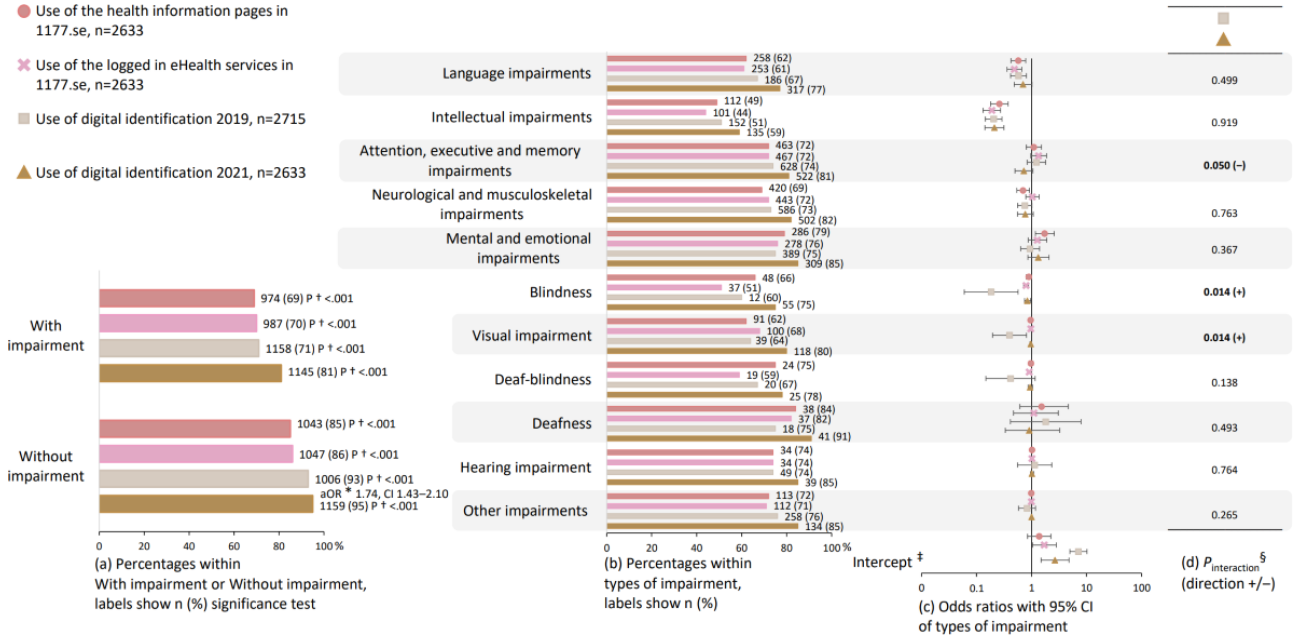


Figure 4. Use of the Swedish national web portal for health information and eHealth services (1177.se) and digital identification. The group with impairment (a) is disaggregated into the subgrouped types of impairment from Figure 2 (b–d). The numeric values visualized in this figure are presented in Tables S1, S6, and S7 in Multimedia Appendix 2. *aOR: adjusted odds ratio from logistic regression comparing use of eHealth among all participants overall between the SMFOI19 and SMFOI21 surveys (reference group is SMFOI19), adjusted for type of impairment (reference is participants without impairment), gender (reference female), and age (reference <30 years of age); †2-sided *P* value from chi-square test comparing participants with and without impairment. ‡Intercept from year-stratified logistic regression (reference group is participants without impairment), adjusted for gender (reference female), and age (reference <30 years of age). §*P* value from logistic regression interaction terms of year with types of impairment (reference is SMFOI19 and participants without impairment), adjusted for gender (reference female), and age (reference <30 years of age). SMFOI19: Swedes with impairment and the internet 2019; SMFOI21: Swedes with impairment and the internet 2021.

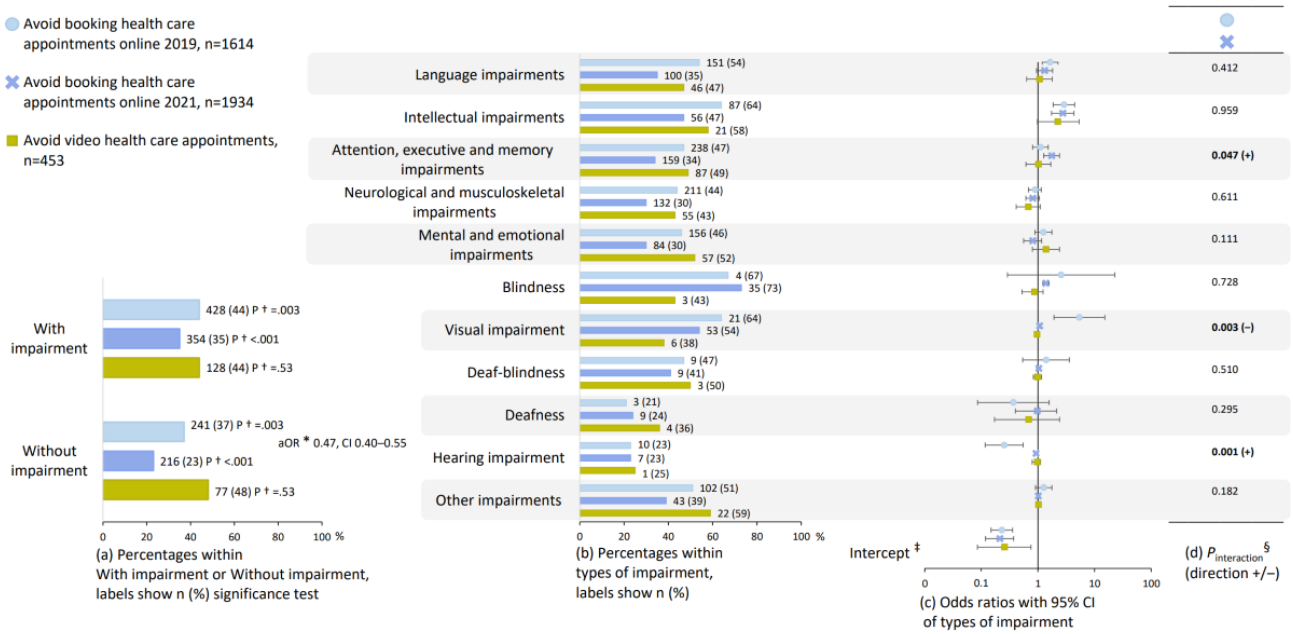
Associations between use and types of impairment are reported in Figures 3b, c, 4b, c, and further, changes in the associations between the survey years are reported in Figures 3d and 4d.

Booking health care appointments online was inversely associated with language impairments in SMFOI19 (aOR 0.64, 95% CI 0.49 - 0.83) and in SMFOI21 (aOR 0.70, 95% CI



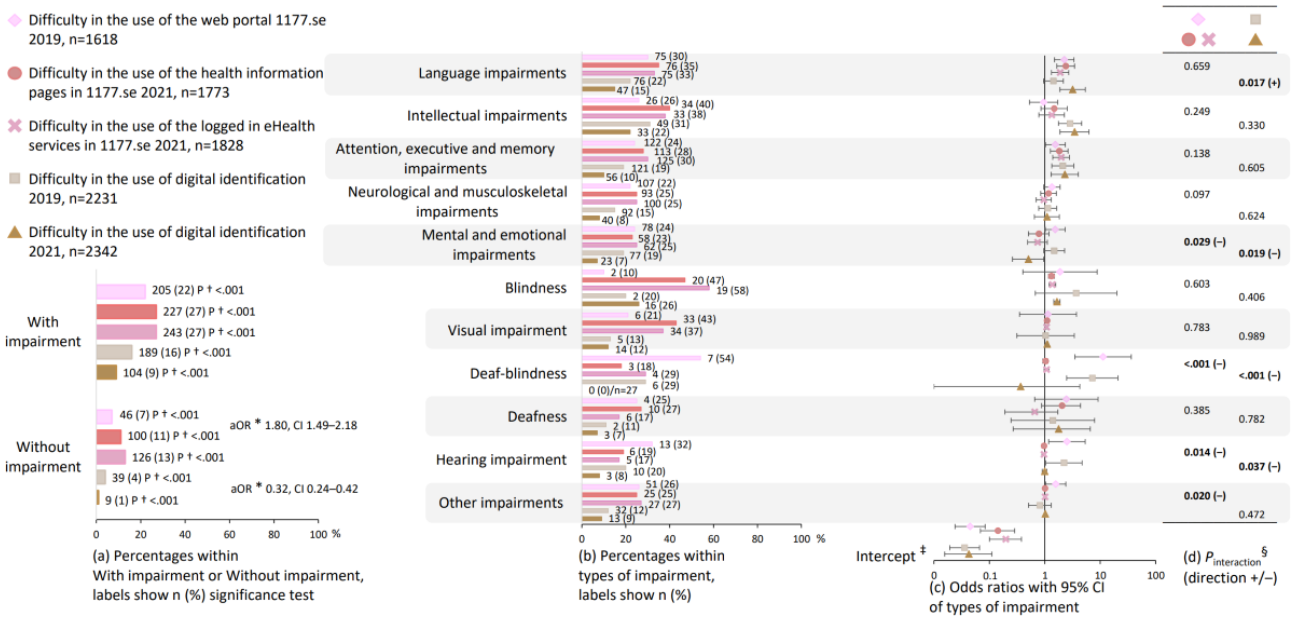
XSL•FO
RenderX

0.54 - 0.93), with intellectual impairments in SMFOI19 (aOR 0.28, 95% CI 0.20 - 0.39) and in SMFOI21 (aOR 0.25, 95% CI 0.17 - 0.35), and with blindness in SMFOI19 (aOR 0.20, 95% CI 0.05 - 0.88) and in SMFOI21 (aOR 0.78, 95% CI 0.70 - 0.86; Figure 3c). The use of video health care appointments was inversely associated with intellectual impairments before the pandemic (aOR 0.51, 95% CI 0.26 - 0.93) and during the pandemic (aOR 0.44, 95% CI 0.30 - 0.64; Figure 3c). Comparing during the pandemic to before, the use of video health care appointments was the most likely to increase among participants with attention, executive, and memory impairments (interaction term aOR 2.10, 95% CI 1.30 - 3.39; Figure 3d). The use of private eHealth services was associated with mental and emotional impairments (aOR 1.53, 95% CI 1.11 - 2.11) and inversely associated with intellectual impairments (aOR 0.35, 95% CI 0.22 - 0.55; Figure 3c). Use of the 1177.se was inversely associated with three types of impairments: language impairments (aOR 0.58, 95% CI 0.43 - 0.78 and aOR 0.49, 95% CI 0.36 - 0.67), intellectual impairments (aOR 0.26, 95% CI 0.18 - 0.38 and aOR 0.19, 95% CI 0.13 - 0.27), and blindness (aOR 0.89, 95% CI 0.80 - 1.00 and aOR 0.80, 95% 0.72 - 0.88; Figure 4c). The use of digital identification was inversely associated with intellectual impairments in SMFOI19 (aOR 0.21, 95% CI 0.15 - 0.29), and in SMFOI21 (aOR 0.21, 95% CI 0.14 - 0.32), and blindness in SMFOI19 (aOR 0.19, 95% CI 0.06 - 0.57) and SMFOI21 (aOR 0.84, 95% CI 0.75 - 0.96; Figure 4c).

Comparisons of avoiding use between the survey years, as well as between participants with and without impairment, are reported in Figure 5a. Among all participants, avoiding booking health care appointments online was less frequent in SMFOI21 compared to SMFOI19 (aOR 0.47, 95% CI 0.40 - 0.55). Booking health care appointments online was avoided by more participants with impairment compared to participants without impairment in SMFOI19 (44% vs 37%; *P*=.003) and SMFOI21 (35% vs 23%; *P*<.001; Figure 5a). Regarding avoiding video health care appointments, no difference was found between participants with and without impairment (44% vs 48%; *P*=.53; Figure 5).

Associations between avoiding use and types of impairment are reported in Figure 5b,c, and further, changes in the associations between the survey years are reported in Figure 5d. Avoiding booking health care appointments online was associated with intellectual impairments in SMFOI19 (aOR 2.88, 95% CI 1.86 - 4.45) and SMFOI21 (aOR 2.74, 95% CI 1.74 - 4.33), and visual impairment in SMFOI19 (aOR 5.40, 95% CI 1.92 - 15.18) and SMFOI21 (aOR 1.07, 95% CI 1.04 - 1.10; Figure 5c). Regarding avoiding video health care appointments, no associations were found with types of impairment (Figure 5c).

Figure 5. Avoid booking health care appointments online and video health care appointments. The group with impairment (a) is disaggregated into the subgrouped types of impairment from Figure 2 (b-d). The numeric values visualized in this figure are presented in Tables S2, S8, and S9 in Multimedia Appendix 2. *aOR: adjusted odds ratio from logistic regression comparing avoidance of eHealth among all participants overall between the SMFOI19 and SMFOI21 surveys (reference group is 2019), adjusted for type of impairment (reference is participants without impairment), gender (reference female), and age (reference <30 years of age); †2-sided *P* value from chi-square test comparing participants with and without impairment. ‡Intercept from year-stratified logistic regression (reference group is participants without impairment), adjusted for gender (reference female), and age (reference <30 years of age). §*P* value from logistic regression interaction terms of year with types of impairment (reference is SMFOI19 and participants without impairment), adjusted for gender (reference female), and age (reference <30 years of age). SMFOI19: Swedes with impairment and the internet 2019; SMFOI21: Swedes with impairment and the internet 2021.



Comparisons of difficulty in the use of eHealth services between the survey years, as well as between participants with and without impairment, are reported in Figure 6a. Among all participants, difficulty in the use of the 1177.se was more frequent in SMFOI21 compared to SMFOI19 (aOR 1.80, 95% CI 1.49 - 2.18; Figure 6a). Difficulty in the use of digital identification was less frequent in SMFOI21 compared to SMFOI19 (aOR 0.32, 95% CI 0.24 - 0.42; Figure 6a). More

XSL•FO
RenderX

participants with impairment than participants without impairment reported difficulty in the use of the 1177.se in SMFOI19 (22% vs 7%; *P*<.001), the information pages in 1177.se in SMFOI21 (27% vs 11%; *P*<.001), the logged-in eHealth services in 1177.se in SMFOI21 (27% vs 13%; *P*<.001), and digital identification in SMFOI19 (16% vs 4%; *P*<.001), and in SMFOI21 (9% vs 1%; *P*<.001; Figure 6a).

Figure 6. Difficulty in the use of the Swedish national web portal for health information and eHealth services (1177.se) and digital identification. The group with impairment (a) is disaggregated into the subgrouped types of impairment from Figure 2 (b–d). The numeric values visualized in this figure are presented in Tables S2, S10, and S11 in Multimedia Appendix 2. *aOR: adjusted odds ratio from logistic regression comparing difficulty in the use of eHealth among all participants overall between the SMFOI19 and SMFOI21 surveys (reference group is 2019), adjusted for type of impairment (reference is participants without impairment), gender (reference female) and age (reference <30 years of age); †2-sided *P* value from chi-square test comparing participants with and without impairment. ‡Intercept from year-stratified logistic regression (reference group is participants without impairment), adjusted for gender (reference female) and age (reference <30 years of age). §*P* value from logistic regression interaction terms of year with types of impairment (reference is SMFOI19 and participants without impairment), adjusted for gender (reference female) and age (reference <30 years of age). SMFOI19: Swedes with impairment and the internet 2019; SMFOI21: Swedes with impairment and the internet 2021.

Associations between difficulty in the use of eHealth services and types of impairment are reported in Figure 6b,c, and further, changes in the associations between the survey years are reported in Figure 6d. Difficulty in the use of the 1177.se was associated with two types of impairments: language impairments and attention, executive, and memory impairments (Figure 6c). Language impairments were associated with difficulty in the use of the 1177.se in SMFOI19 (aOR 2.24, 95% CI 1.50 - 3.36), the 1177.se information pages (aOR 2.39, 95% CI 1.65 - 3.44), and the logged-in eHealth services (aOR 1.89, 95% CI 1.32 - 2.70) in SMFOI21. Attention, executive, and memory impairments were associated with difficulty in the use of the 1177.se in SMFOI19 (aOR 1.55, 95% CI 1.03 - 2.34), the 1177.se information pages (aOR 1.82, 95% CI 1.26 - 2.62), and the logged-in eHealth services (aOR 1.97, 95% CI 1.39 - 2.78) in SMFOI21. Difficulty in the use of digital identification was associated with intellectual impairments in SMFOI19 (aOR 2.86, 95% CI 1.77 - 4.62) and in SMFOI21 (aOR 3.44, 95% CI 1.87 - 6.26), and attention, executive, and memory impairments in SMFOI19 (aOR 2.11, 95% CI 1.33 - 3.34) and in SMFOI21 (aOR 2.30, 95% CI 1.30 - 4.02; Figure 6c).

Discussion

Principal Findings

In a rapid digitalization in health care, this first comparison across the COVID-19 pandemic revealed disability digital divides in eHealth that remained proportional. In this comparison of people with and without impairment, the former were disfavored in regard to eHealth. Namely, they reported less use of booking health care appointments online, the 1177.se and digital identification, which is in line with most studies before the pandemic as discussed in our previous article [2] and one during the pandemic [5]. Further, they reported substantial difficulty in the use of eHealth, which is in agreement with a survey conducted during the pandemic [6]. Nonuse and difficulty in the use of eHealth were consistently associated with language impairments and intellectual impairments. Our findings show that the highest adoption of video health care appointments was among participants with attention, executive, and memory impairments, which is in line with other surveys during the pandemic [8,27]. The latter of the cited studies concluded that video health care appointments increased among mental health service users when contacts were redirected to eHealth instead of face-to-face [27]. Accordingly, it is plausible that the adoption of video health care appointments among participants with attention, executive, and memory impairments in this study was due to disrupted face-to-face health care provision.

The Swedish national web portal for health information and eHealth services, 1177.se, was more frequently reported as difficult to use in SMFOI21 than in SMFOI19, both among participants with and without impairment, despite an accelerated adoption of eHealth across the pandemic. This may be

XSL•FO
RenderX

interpreted as a sign of forced digitalization, which implies that eHealth followed a previously shown societal pattern of nonaccessible social distancing restrictions [28]. People with intellectual impairments were afflicted on two fronts. They were distinguished as a risk group for severe COVID-19 [12] and thereby recommended intensified social distancing restrictions, which meant that they were encouraged to redirect contacts to eHealth instead of face-to-face contacts with health care if possible, while at the same time, they were facing substantial difficulties in the use of eHealth. Cognitive accessibility is insufficiently covered in eHealth studies [29,30] and guidelines [30]. Known adaptations for cognitive accessibility are intuitive structure, important elements before page scroll, large icons, visualizations, and third-party participation [31,32]. However, there is a lack of conformance to what is known about accessibility [7]. Moreover, in this study, people with language impairments were particularly afflicted by difficulties in the use of digital services, which has previously been shown by multiple studies [10,33], but not all [5]. Text and numerical tasks can be adapted by standards for understandable text, autocorrect, data import, speech recognition, audio, and enabling enough duration [31,32]. Barriers to the use of video appointments can be due to reduced nonverbal communication [10] and natural pauses [33].

Implications

Until this disability digital divide in eHealth is bridged, practitioners should provide eHealth integrated with staff support, or maintain conventional services as alternatives to digitalized options. In line with policy [34], we underscore that research and development must conform to legislated accessibility standards [4,31,32,35]. But in addition, we suggest that user participation in the design of eHealth [36] and adherence to principles for universal design [37] can bring additional benefits, beyond the accessibility standards. Such benefits exceed accessibility, by, for instance, readability, clarity, interoperability, and assistive functions, which improve usability for all users [32,35].

Strengths and Limitations

This is, to our knowledge, the first study comparing the accessibility of eHealth across the COVID-19 pandemic among people with diverse types of impairment relevant to the risk of disablement by poorly designed digital services. The pandemic provoked exceptional conditions, which can provide insights for developing resilient health care systems, in which people with high health care needs are included. This comparison between two cross-sectional surveys was deemed a suitable study design to study an unanticipated historical event, in the absence of an available cohort study.

Snowball sampling [19] is a major reason for achieving representation of seldom-heard populations. However, it is plausible that this sampling method engaged more people with higher digital literacy to respond to the survey. Further, self-assessment of digital literacy can be associated with overestimation of skills [38]. Thus, in summation, while this study did demonstrate the disability digital divide in eHealth, it may have underestimated its magnitude. In the two study samples, participants' characteristics and types of impairment demonstrate similar proportions, which makes it plausible that misclassification did not obstruct drawing inferences on comparisons between samples. To allow representation of individuals with multimorbidity in the analysis, we assessed that multicollinearity did not exceed the predetermined cut-off, and that outcomes were not associated with the number of reported impairments. The SMFOI21 survey sampled more participants in the oldest group (70 years or older) and less participants of 45 - 69 years of age, as compared to the SMFOI19 survey. This was handled as we adjusted for age in the statistical analysis. While we adjusted for gender and age, there were socioeconomic differences between people with and without impairment, for which we did not control. The dependent variables were investigated by different types of response options "I use"; "I avoid" or "I prefer"; as well as "is difficult to use" or "is easy to use" in order to capture different aspects of the phenomenon. We consider that avoiding is a dimension of using, in that it measures a type of "not using." However, it is possible that avoidance also can be associated with difficulty of use, but may also be influenced by other mechanisms, for example, self-efficacy, normative beliefs, or social support. This study focused on the association between types of impairment and eHealth services for patient-provider contact, meaning that other types of eHealth and other factors plausibly mediating the use of eHealth were not investigated, that is, eHealth literacy, socioeconomic factors, or lacking access to digital devices.

Conclusions

Despite an accelerated adoption of eHealth across the COVID-19 pandemic, our results show no relevant difference in the disability digital divide in eHealth between the survey years. In both before and during the pandemic, there were substantial nonuse and difficulty in the use of eHealth among people with impairment. Nonuse and difficulty in the use of eHealth were consistently associated with language impairments and intellectual impairments. This implies that groups recognized as being at risk of severe COVID-19 could not use eHealth, while emphasis was put on eHealth as a measure of infection protection in the social distancing policy. Accessibility standards can improve services. Until then, our results indicate that eHealth in its current state should be provided with optional support, or only be provided as a complement to conventional contacts.

Acknowledgments

Our research partners, the Begripsam group, all of whom have lived experience of impairment, contributed to the study design and development of the questionnaire of the first SMFOI survey (2017) and participated in further elaboration and refinement of the following surveys. Riccardo Lo Martire, statistician at the Center for Clinical Research Dalarna Sweden, provided consultation.

Abstract

Background: People with opioid use disorder (OUD) have the highest rates of hepatitis C virus (HCV) infection. Despite the availability of curative HCV medication, people with OUD have limited health care access largely due to stigma. In a recent, pragmatic, randomized controlled trial (RCT), we compared a facilitated telemedicine intervention for HCV treatment integrated into opioid treatment programs (OTPs) with off-site referral. Facilitated telemedicine is bidirectional videoconferencing between a remote provider and a patient, supported by a case manager who facilitates the telemedicine encounter. The case manager schedules telemedicine visits, provides appointment reminders, and operates the digital equipment. Among 602 participants in the RCT, 90% (n=262) were cured through facilitated telemedicine and 39% (n=123) were cured through off-site referral. In this work, a multidisciplinary group of investigators, who directed the RCT, conducted a workshop, "Advancing Viral Hepatitis Screening and Treatment in Opioid Treatment Settings – Models & Resources," at the American Association for Treatment of Opioid Dependence Conference in May 2024 to disseminate knowledge of facilitated telemedicine, including implementation considerations. We highlighted facilitated telemedicine as a patient-centered, sociotechnical, pragmatic health care delivery model for underserved populations.

Objective: This study aimed to identify lessons learned to successfully overcome challenges of facilitated telemedicine implementation for HCV treatment integrated into OTPs.

Methods: We partnered with the National Alliance of State and Territorial AIDS Directors in planning the workshop. The workshop consisted of 7 presentations on topics related to facilitated telemedicine implementation. The workshop was recorded and transcribed by Zoom (Zoom Communications). The transcripts served as data for the thematic analysis. The transcripts were interpreted to elucidate patterns of meanings and nuances derived from each presentation. In an iterative process, preliminary findings were compared and coalesced into themes. Verbatim quotes from the workshop were highlighted to support the themes.

Results: We developed 3 themes. First, patient-centered care promotes HCV treatment for underserved populations through facilitated telemedicine. Case managers leveraged the destigmatizing environment of the OTP to build trust with patients, promoting an HCV cure through facilitated telemedicine. Second, sociotechnical approaches expand health care access for people with OUD. To be effective, facilitated telemedicine integrates 2 necessary components, a social aspect and a technical aspect. Third, facilitated telemedicine supports pragmatic research emphasizing people with OUD. Pragmatic research of facilitated telemedicine is needed to assess sustainability and scaling considerations beyond OTPs. Overall, we found that facilitated telemedicine overcame the digital divide, promoting access to digital technology, internet provision, and digital literacy.

XSL•FO
RenderX

Conclusions: Facilitated telemedicine incorporates both a technical and a social component. The technical component largely addresses geographical challenges, while the social component addresses temporal (ie, care coordination) issues, promotes trust, and largely assuages patients' concerns related to HCV treatment. The patient-centered, sociotechnical intervention can address the digital divide, thereby increasing health care access.

Trial Registration: ClinicalTrials.gov NCT02933970; https://clinicaltrials.gov/study/NCT02933970

KEYWORDS

telemedicine; patient-centered; sociotechnical; hepatitis; opioid; health equity; digital divide; underserved; pragmatic.

Introduction

People with opioid use disorder (OUD) have the highest hepatitis C virus (HCV) incidence and prevalence due to viral transmission through injection drug use [1]. If left untreated, HCV infection can lead to cirrhosis, liver failure, and death. The development of almost ubiquitously curative, direct-acting antivirals (DAAs) for HCV in 2 to 3 months with minimal side effects has profoundly changed the therapeutic landscape since 2013 [2]. Unfortunately, however, people with OUD have had limited access to DAAs, largely due to stigma in conventional health care settings, competing priorities, unawareness of their HCV status, and service unavailability [3,4]. A recent United States nationwide study documented that only 35% of eligible individuals received DAAs from 2013 to 2022 [5]. In addition, almost 40% of people with HCV are unaware of their infection status [6]. Nonetheless, HCV treatment is a health equity priority [7]. Thus, an HCV therapeutic divide exists with insufficient penetration of highly curative DAAs among the population most in need. Furthermore, people with OUD suffer from a digital divide, defined as the unequal access to digital technology, internet provision, and gaps in digital literacy [8].

Opioid treatment programs (OTPs) provide medical and behavioral treatment for OUD in a destigmatizing, supportive, and trusting environment [9]. Integrating HCV treatment into the OTP environment can promote therapeutic interactions, patient engagement, and retention in health care. To potentially overcome the HCV therapeutic divide among people with OUD, we developed a facilitated telemedicine intervention fully integrated into OTPs using the sociotechnical system framework [10]. Recently published facilitated telemedicine results demonstrated an HCV cure in almost all treated individuals, accompanied by high patient satisfaction with health care delivery [11-13] (details of facilitated telemedicine procedures and effectiveness results are provided in Multimedia Appendix 1). Facilitated telemedicine is bidirectional videoconferencing between a remote provider and patient, supported by a case manager. The case manager established trusting relationships with patients to promote personalized HCV care approaches. The intervention can overcome geographical and temporal challenges, as well as the therapeutic and digital divides. Since facilitated telemedicine encounters are embedded in OTPs facilitated by a case manager, patients had access to digital technology, internet provision, and assistance with digital literacy. Facilitated telemedicine not only increases DAA access among people with OUD, but it can also improve service provision by OTPs.

We obtained input from a variety of stakeholders involved in the implementation and conduct of facilitated telemedicine in OTPs. We conducted a workshop entitled "Advancing Viral Hepatitis Screening and Treatment in Opioid Treatment Settings – Models & Resources." The objective of the workshop was to disseminate successful approaches that overcame facilitated telemedicine implementation challenges. We also desired to inform workshop participants how facilitated telemedicine promotes patient-centered health care delivery for HCV treatment integrated into OTPs. We highlighted facilitated telemedicine implementation considerations that addressed the digital divide. We also highlighted specific considerations when conducting pragmatic trials, emphasizing underserved populations. We anticipate that the lessons learned could be beneficial in the expansion of facilitated telemedicine to address HCV-OUD treatment integration and health equity among people with OUD.

Methods

Study Design, Setting, and Sampling

We conducted a thematic analysis of the transcripts of a 3.5-hour workshop that addressed facilitated telemedicine implementation challenges. Our study's aim was to identify facilitated telemedicine considerations that overcame implementation challenges to promote the delivery of patient-centered HCV care. The primary study outcome was the results derived from the thematic analysis. The workshop transcripts served as data for the thematic analysis.

The workshop was sponsored by the University at Buffalo (UB) and took place as a preconference workshop at the 2024 American Association for the Treatment of Opioid Dependence (AATOD) Conference [14]. The workshop occurred on May 19, 2024, in Las Vegas, Nevada. Planning for the workshop began in 2018 when 3 of the workshop speakers attended the AATOD annual meeting; the workshop planning followed an iterative process (Figure 1). The data analysis occurred in July and August 2024.

XSL•FO

Figure 1. Workshop development flow diagram. The objective of the workshop was to disseminate knowledge of facilitated telemedicine for hepatitis C virus infection treatment integrated into opioid treatment programs to attendees of the 2024 American Association for the Treatment of Opioid Dependence conference. AATOD: American Association for the Treatment of Opioid Dependence; NASTAD: National Alliance of State & Territorial AIDS Directors; Q&A: question and answer.

XSL•FO
RenderX

AATOD works with federal and state agencies to promote the growth and development of opioid treatment services. The association has a long history of promoting approaches to increase HCV management within OTPs, and the workshop concept originated at the 2018 annual meeting, where 3 workshop participants attended. Our workshop aligned with the AATOD conference theme of "Treating Opioid Use Disorder: So Much More Than Medication" [15]. In alignment with the conference objectives, we disseminated the outcomes of facilitated telemedicine among people with OUD. Our workshop attendees included OTP providers, OTP administrators, patient representatives, front-line staff, and state officials involved in the treatment of OUD.

Study Intervention

The workshop activities were approved by the UB Institutional Review Board. The principal investigator (AHT) of the facilitated telemedicine trial established a collaboration with the National Alliance of State and Territorial AIDS Directors (NASTAD) in planning the workshop. The focus of the alliance is to advance the health of people impacted by HIV, viral hepatitis, and intersecting epidemics through public health advocacy, capacity building, and social justice [16]. NASTAD represents public health officials who administer HIV and viral hepatitis programs in all 50 states. NASTAD representatives participated in developing the workshop's objectives and maintaining the relevance of the workshop through partnering with state and territorial health departments.

Workshop Speakers

The planning committee invited workshop speakers based on their roles and a high degree of engagement in the trial. The workshop was hosted by 2 planners, 1 moderator, and 7 speakers. The planners were AHT (also a speaker) and BN-R. AHT is a physician-scientist with more than 20 years of experience in treating HCV, especially among people with OUD. He is a Professor of Medicine at UB and the principal investigator on the randomized controlled trial entitled "Integrated Hepatitis C–Opioid Use Disorder Care Through Facilitated Telemedicine A Randomized Trial" [13]. AHT serves on the New York State HCV Elimination Task Force and its HCV Guidelines Committee. BN-R is the Senior Director of Syndemic Approaches at NASTAD. She leads the integration of HIV, viral hepatitis, and harm reduction. The moderator was ZG, Senior Hepatitis Manager at NASTAD. She supports prevention and surveillance capacity building through NASTAD's technical assistance center for viral hepatitis.

The speakers were AHT, EJH, MM, LSB, KEB, AD, and RM. EJH is a Program Director at Research Triangle Institute. Previously, she was an Associate Director at the Patient-Centered Outcomes Research Institute (PCORI) and the trial's program officer. PCORI is an independent, nonprofit organization that funds patient-centered comparative clinical effectiveness research with emphasis on stakeholder engagement, and dissemination and implementation of successful interventions. MM is a Distinguished Professor of the State University of New York and Associate Chair for Research and Healthcare Informatics, Department of Biostatistics at UB. She was the lead biostatistician for the trial. LSB is the former chief executive officer at START Treatment & Recovery Centers, treating patients with substance use and co-occurring medical and mental health disorders. Founded in 1969, START is the oldest and largest minority-run substance use treatment program in the United States, serving over 3000 patients through 7 medication-assisted programs in New York City. KEB is the former program administrator at Drug Abuse Research and Treatment of the Community Action Organization of Western New York. Founded in 1971, Drug Abuse Research and Treatment is a free-standing community organization that provides integrated services to people with OUD throughout Western New York. KEB was also an administrative surveyor for the Commission on Accreditation of Rehabilitation Facilities. AD is a physician and the Director of Liver Services at UB. RM is a research assistant in MM's laboratory group and a doctoral student in computational and data-enabled sciences and engineering at UB.

Workshop Presentations Overview

The workshop was developed through planning meetings between AHT, AD, and NASTAD's representative, BN-R. The planning committee developed an agenda with topics related to facilitated telemedicine and invited stakeholders who participated in the study by email. We used purposive sampling to select speakers who were the most appropriate to discuss each topic, as illustrated in Table 1. Furthermore, 2 individuals, representing an expert in substance use disorder and a patient-participant with lived experience, were unable to participate. These topics were represented by LSB, who has 40 years of experience in substance use treatment, and AD, who has served as a patient representative and program director during the trial. We used investigator and data source triangulation to understand when we had achieved sample saturation [17]. The workshop consisted of 7 presentations, and all invited speakers shared their presentations before the workshop. The dissemination of the trial's findings to an AATOD audience permitted scalability opportunities to a national and international audience substantially larger than New York State, where the trial occurred.

Research	
Facilitated telemedicine	AHT (MD, MPH)
Substance use	EJH (PhD)
Social determinants of health	MM (PhD)
Data acquisition and the use of large language models	MM (PhD) and RM (MS)[a]
Perspectives and experiences	
Patients	AD (MD)
OTP[b] leadership	LSB (MD, MPH)
OTP administration	KEB (BS)
Stakeholders	
Public health advocacy	BN-R (JD, MPH) and ZG (MPH)
Experience with OUD[c]	AATOD[d] audience

[a]Speaker.

[b]OTP: opioid treatment program.

[c]OUD: opioid use disorder.

[d]AATOD: American Association for Treatment of Opioid Dependence.

AHT opened with an overview of the trial, "Facilitated Telemedicine for Underserved Populations: A Stepped Wedge Trial of Hepatitis C Treatment." AHT discussed the background of HCV treatment access and health care delivery. He introduced the facilitated telemedicine model, the trial design, primary and secondary outcomes, and the trial's strengths, limitations, and lessons learned.

EJH followed with "Funding Projects in People with OUD." EJH explained that comparative effectiveness research funded by PCORI must be patient-centered, stakeholder-driven, and pragmatic, and that the facilitated telemedicine trial met all 3 criteria. She described the recent increase in patient-centered approaches for people with OUD. EJH highlighted several patient-centered parts of the final rule of the Substance Abuse and Mental Health Services Administration that was released in April 2024 [18]. The Substance Abuse and Mental Health Services Administration final rule expands treatment access by permitting telehealth evaluation, replacing stringent dosing requirements with clinical judgment, removing daily visit requirements, and meeting OUD diagnostic criteria. EJH cautioned that critical barriers remain, such as internet access in rural and underserved areas and for those with limited digital literacy.

MM presented on "Improvements in Substance Use and Social Determinants of Health (SDOH)." She discussed how substance use and SDOH can be evaluated as predictors for HCV treatment initiation and cure. MM explained that integrated HCV and OUD treatment resulted in improvements in substance use, education, employment, and criminal justice status. However, since treatment for HCV and OUD is not well-integrated into health care systems, managing these conditions will require addressing social and structural inequalities.

LSB discussed "Drivers for HCV-Related Telemedicine Research." He described the critical relationship between public policy and clinical care as he was originally from a neighborhood in which substance use was, and unfortunately still is, part of the landscape. LSB provided an overview of START Treatment and Recovery Centers in New York City. He explained that facilitated telemedicine aligned very closely with START's corporate philosophy of participating in medical and behavioral research and advocacy to address unmet patient needs.

KEB presented "The Evolution of Incorporating Facilitated Telemedicine in an Opioid Treatment Program: An Administrator's Perspective." KEB defined the notions of the "phenomenon of the OTP" and "full-service garage." He described the "phenomenon of the OTP" as a natural incubator of trust because the OTP provided structure, purpose, a safe environment, and socialization to people with OUD. The "full-service garage" implies that the OTP offers a panoply of health care and social services beyond medication-assisted treatment. KEB emphasized the interactions of facilitated telemedicine with both concepts.

AD discussed "Facilitated Telemedicine: Overcoming Challenges for Hepatitis C Treatment." He presented patient testimonials of facilitated telemedicine derived from qualitative interviews [3]. Patients were enthusiastic about health care delivery through facilitated telemedicine, and an HCV cure promoted self-confidence and improved whole health. AD also reviewed the CREATE (Culture, Respect, Educate, Advantage, Trust, Endorse) framework, an engagement approach for facilitated telemedicine [9].

RM concluded the workshop with "From Words to Wellness: Large Language Models Applied to the Identification of SDOH." He explained that SDOH data are limited in people with HCV,

XSL•FO
RenderX

and he described approaches used to derive SDOH data from trial participants [19]. RM concluded his presentation with a discussion of issues of quality and the application of models for the identification of SDOH derived from people with OUD.

Once the speakers had agreed to present at the workshop, they worked iteratively with the planning committee to obtain feedback on the presentations. When the presentations were finalized, each speaker uploaded the presentation to the AATOD website. Workshop speakers met in person before the workshop to review the presentations' content and to promote cohesiveness and flow. Speakers reviewed logistical considerations immediately before the workshop, including timing, recording, and moderation by NASTAD staff. Furthermore, 2 question-and-answer sessions were held during the workshop that were moderated by ZG. During the introductory remarks, the moderator discussed the objectives of the conference, the context of HCV with a special emphasis on the importance of HCV elimination, and specific areas of discussion for the audience. To minimize recollection bias, the question-and-answer sessions occurred immediately after the workshop presentations. As the workshop presenters had extensive experience working collaboratively to achieve the trial's goals, respondent bias was minimized. On the other hand, however, the moderator was not previously known to the workshop presenters and represented a public health advocacy perspective, which encouraged discussion of a diverse array of perspectives. To ensure question comprehension, the moderator repeated the question before eliciting a response. The moderator also sought responses from multiple workshop presenters as appropriate. After completion of the workshop, the planning committee met to discuss topics for manuscript development. The primary focus of the planning committee was the thematic analysis of the workshop presentation transcripts.

Thematic Analysis

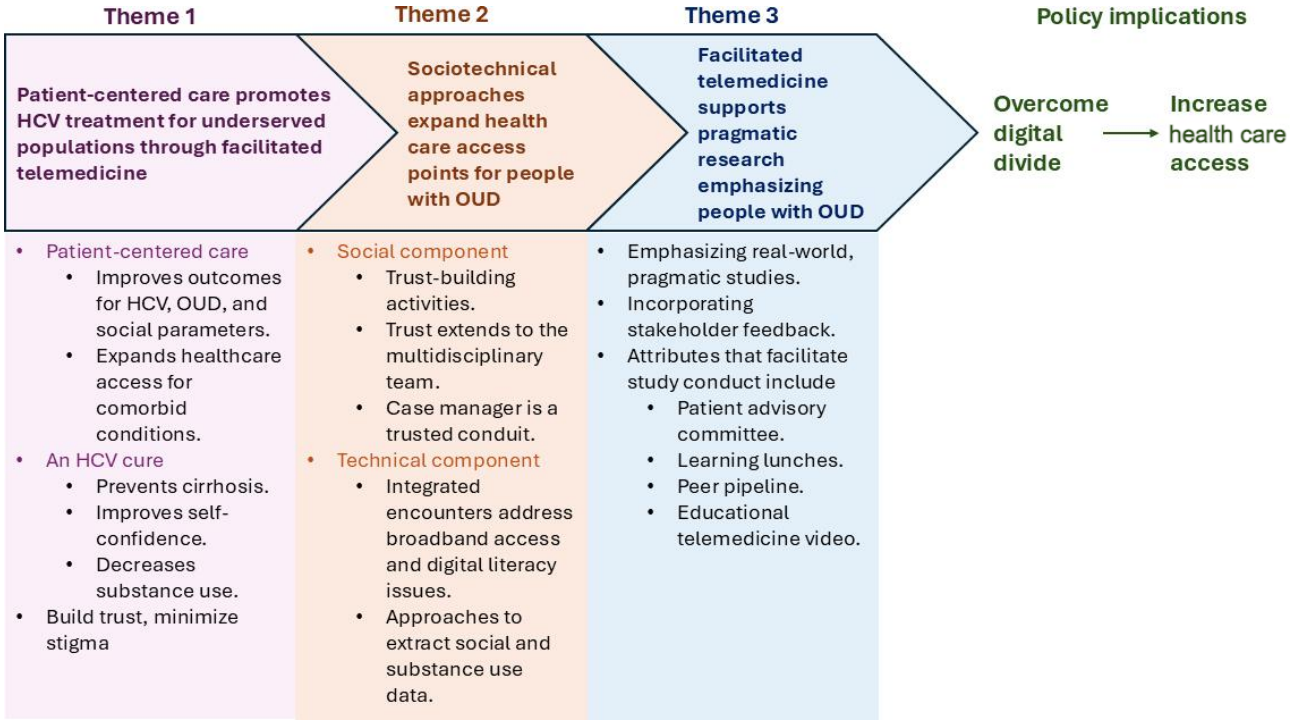
The 3.5-hour workshop was recorded and transcribed by Zoom (Zoom Communications). All workshop speakers disseminated their successful approaches that overcame facilitated telemedicine implementation challenges. After the final set of transcripts was obtained, they were reviewed for completeness independently by 2 investigators (AHT and AD), with inconsistencies verified by listening to the recordings. While the transcripts did have identifiable quotations, those that were used in the analysis were deidentified. The workshop transcripts served as the raw data and the primary source for the thematic analysis. Since all workshop presenters had worked collaboratively for 8 years on evidence generation as part of the trial, the workshop adhered to the principle of investigator triangulation. The development of multiple manuscripts covering a variety of different perspectives from the trial adhered to the use of data triangulation [17].

Using a constructivist paradigm, we performed a thematic analysis to identify facilitated telemedicine considerations that overcame implementation challenges and delivered patient-centered care. In total, 2 investigators, AD and AHT, followed the 6-step framework for thematic analysis described by Braun and Clarke [20,21]. AD and AHT have published several qualitative studies in Q1 journals [3,9,22-27] and are well-versed in the approaches to minimize bias in qualitative research. They became familiar with the data by independently reviewing the transcripts for accuracy and formatting. They independently and inductively coded the transcript data based on its relevance to facilitated telemedicine considerations that overcame implementation challenges and delivered patient-centered care. Subsequently, they independently grouped the initial codes into general categories. In a recursive process, they discussed code generation to identify and interpret repeated patterns of meaning and nuances derived from each presentation. They met frequently to discuss these patterns of meaning until a consensus was reached and lower-level themes were developed with supporting quotations [28]. In the case of disagreements in the textual interpretations, they reviewed the transcripts until a consensus was reached.

Once a draft of concepts had been derived and agreed upon, the lower-level themes were discussed and reviewed with all coauthors in a series of meetings. Using a consensus and iterative approach, lower-level themes were defined and evolved into higher-level themes. Verbatim quotes from the workshop presentations were highlighted to support the themes. All coauthors reviewed the final themes and supporting quotes for agreement. All coauthors were active participants in the data-driven thematic analysis. We acknowledge that the experiences and interactions of the coauthors may have influenced the thematic analysis in this constructivist paradigm. As a concise report of qualitative analytical methods used, the Consolidated Criteria for Reporting Qualitative Research (COREQ) checklist is provided (Multimedia Appendix 1).

Because of time constraints, several aspects related to care delivery through facilitated telemedicine could not be addressed at the workshop and are discussed in detail in separate papers. Specifically, the aspects that led to successful case management are discussed in a study by Talal et al [27]. The considerations for effective case conferencing at the patient and system levels are discussed in [22,29], respectively. Finally, the issues related to care delivery in studies by Ventuneac et al [23], Dickerson et al [24], and Talal et al [unpublished data, 2025] describe the considerations for scaling and maintaining facilitated telemedicine, the characteristics that led to full integration of facilitated telemedicine into OTP workflows,, and implementation characteristics required for effective treatment outcomes and high levels of patient satisfaction, respectively. In addition, the issues of data ownership, sharing, and privacy were not discussed at the conference, as these topics had been outlined in the trial protocol approved by the institutional review board.

Ethical Considerations



The study was approved by the Institutional Review Board at UB (MODCR00009273) (Multimedia Appendix 2). All workshop speakers consented to participate. All quotations were deidentified. Confidentiality concerns prohibit us from sharing data transcripts. We provided reimbursement for travel, lodging, and meals. Artificial intelligence was not used in any portion of this study.

XSL•FO
RenderX

Results

We developed 3 themes from the textual analysis of the workshop presentations (Figure 2).

Figure 2. Three themes and important attributes identified through thematic analysis of workshop presentations at the 2024 American Association for Treatment of Opioid Dependence Conference. The objective of the workshop was to disseminate knowledge of facilitated telemedicine for hepatitis C virus treatment. We highlighted facilitated telemedicine as a patient-centered, sociotechnical, pragmatic health care delivery model for underserved populations. We found that facilitated telemedicine integrated into opioid treatment programs overcame the digital divide. HCV: hepatitis C virus; OUD: opioid use disorder.

Theme 1: Patient-Centered Care Promotes Hepatitis C Treatment for Underserved Populations Through Facilitated Telemedicine

Patient-centered care for HCV and OUD promotes improvements not only in medical conditions but also in social factors. Patient-centered care emphasizes promoting individual health care choices and empowering patients to actively participate in health care decision-making [30] and is delivered by a multidisciplinary team.

> *[The] approach is to treat the whole person, and not just their substance use disorder… They have co-occurring alcohol use disorder… HIV, hepatitis C, diabetes, hypertension, and psychiatric disorders.*
>
> *[HCV and OUD treatment] promotes improvements in substance use and social functioning, [specifically] education, employment, and involvement with the legal system.*
>
> *The patients were actually helped to go back to school and complete whatever degrees they had [to complete].*

Consistent with the strong potential benefits of integrated OUD and HCV care, an OTP administrator cited his desire for participation in facilitated telemedicine as the "full-service garage" concept, providing essential medical care within the OTP for a large repertoire of comorbidities.

> *The full-service garage sentiment is the leverage of the trust equity and utilizing facilitated telemedicine provided a hub and spoke… If OTPs reach out to community providers, it becomes the home base for consumers and facilitated telemedicine becomes the opportunity to engage in essential services without having to leave the clinic.*

The value of integrated care was illustrated through obtaining an HCV cure, which represented a major achievement for people with OUD.

> *For patients that successfully completed [HCV treatment], it was the first major win for them. They realized that they had an active role in their recovery… Having a personal win that they could own was profound and had long term effects.*

An HCV cure removed the risk of cirrhosis and improved substance use.

> *He [trial PI] would actually use 'cure', and that's a 4-letter word we don't use in the [methadone] program.*
>
> *The message to take home is that once the patient initiates the treatment, you have a high probability that the patient is actually going to stick with it and obtain an HCV cure.*
>
> *Patients valued the HCV cure because it promoted self-confidence, and it enabled them to improve their health and lives.*

XSL•FO
RenderX

Among cured participants, we observed significant decreases in substance use, as assessed through the drug abuse screening test [31], with minimal HCV reinfections [13]. An HCV cure enabled the treatment team to reinforce adherence to OUD treatment.

> *When the patients progress through the study, the counselors and the treatment team will often utilize that [HCV cure] as a pivot with the patient… It was a wonderful tool that the treatment team used to support a patient's recovery.*

To engage people with OUD in research, we pursued approaches to build trust, such as integrating facilitated telemedicine encounters into the supportive, destigmatizing, and trusting environment of the OTP [32,33]. The foundation of facilitated telemedicine is patient-centeredness. Patients endorsed facilitated telemedicine because they realized the profound effects of an HCV cure.

> *The OTP became an extension of their family… A place of trust.*

People with OUD frequently encounter stigma [34] and feel ostracized in conventional health care settings. Stigma is a major impediment to health care access.

> *They describe themselves as addicts, dirty or clean. Patients blame themselves for contracting a lethal disease [i.e., HCV]. They face stigma in conventional healthcare settings outside of the OTP.*
>
> *We had tried multiple attempts to refer out [for HCV]… It was really met dismally. For some, it was logistics. They had a hard time getting to the other location. But for a lot of them, it was stigma.*

The approaches we used to maintain patient-centeredness are described in Multimedia Appendix 1. The growth of patient-centeredness in the treatment of substance use disorders has been gaining considerable momentum [35].

> *The vision of the agency [OTP] is dedicated to transforming the perception of addiction and behavioral health disorders by bringing dignity and respect to the lives, families, and communities we serve.*

Theme 2: Sociotechnical Approaches Expand Health Care Access for People With OUD

The sociotechnical system framework, which we used to evaluate the facilitated telemedicine intervention, is specifically designed to address challenges in telemedicine implementation in adaptive, complex health care systems, such as OTPs [29]. The facilitation aspect is the social component of facilitated telemedicine and was critical when designing digital health solutions for people with OUD.

> *[We had] to think about cultural and trust issues that may diminish its [telemedicine's] acceptability.*
>
> *Case managers were communicating information about the study, enrollment, retention, and all things hepatitis C beyond the study.*
>
> *[We had to] gain trust in the OTP to participate in patient-centered telemedicine encounters.*

An OTP leader explained the benefits of facilitated telemedicine and his reason for pursuing the intervention. He described the 4 pillars that guided his leadership strategy.

> *Our corporate philosophy is recognizing and overcoming OTP-related challenges like continuing relationships and addressing patient needs.*
>
> *Patient care, education, advocacy, and research... Telemedicine offers a number of opportunities to enhance value-based clinical care.*

The social structure within the OTP promoted trial enrollment and retention. Trust extended to the multidisciplinary team.

> *Early on, the treatment team did a lot of priming of the pump regarding recruitment… I thought it was important to provide education about the study to everyone because the trust equity that the patients have certainly was to the doctors, nurses, and counselors. But sometimes, their strongest relationships were with security staff or a business office person that they saw every day.*

During the question-and-answer periods, several audience members asked about the requirements to replicate the facilitated telemedicine intervention, including social parameters.

> *Remember the eligibility requirements [for the trial]. You had to be in [OUD] treatment for some period of time [6 months] so that means that there was a relationship that was developed between that patient and their counselor, as well as the employees of our program, who are related to the study. There was a relationship that had started to flourish at the time prior to [trial] enrollment.*

The other aspect of facilitated telemedicine is the technical component. We mitigated digital divide issues, such as technology access, digital health literacy, and broadband access, by fully embedding telemedicine encounters into the OTP. During the COVID-19 pandemic and lockdown, facilitated telemedicine became an approach to maintain patient engagement.

> *If one is thinking about adding a telehealth solution, one needs to consider the digital divide. Specific concerns would be access to the internet, digital health literacy, and medical-behavioral integration with virtual care.*
>
> *COVID-19 tethered the consumer away from the clinic… Telemedicine became the umbilicus; it brought the patient back.*

We developed workflows to extract patient-level data on social factors to support facilitated telemedicine implementation as well as for identifying social factors that might be associated with HCV treatment uptake and cure. These tools enabled cross-domain collaboration as well as played crucial roles in ensuring reproducibility and in optimizing clinical and social data acquisition and their integration [19]. An interest in the

XSL•FO
RenderX

use of artificial intelligence as a component of OTP operations was discussed during the question-and-answer period.

> *Recently, large language models have shown the capacity to process vast amounts of data to generate insights... We are interested in how these models can aid in the identification of social factors… to explore relationships between social factors and pursuit of HCV [treatment].*

These approaches are permissive for the direct inclusion of social factors and substance use variables in the patient's treatment plan.

> *[The analytical goal is] to emphasize social factors that can be integrated into the treatment approach.*

Facilitated telemedicine successfully manages the digital divide by addressing both social and technical challenges faced by people with OUD, as substantiated in Table 2.

Table . Sociotechnical system framework for facilitated telemedicine supported by workshop examples. Table adopted from study by Talal et al [29].

Sociotechnical system framework constructs	Definition	Workshop examples	Sociotechnical component
People	Clinicians, patients, administrators, researchers, or software developers.	"Case managers were communicating information about the study, enrollment, retention, and all things hepatitis C beyond the study."	Social
		"[We had to] gain trust in the OTP[a] to participate in patient-centered telemedicine encounters."	
Internal organizational features	Internal organizational policies, procedures, and institutional culture	"Our corporate philosophy is recognizing and overcoming OTP-related challenges like continuing relationships and addressing patient needs... Telemedicine offers a number of opportunities to enhance value-based clinical care."	Social
Hardware and software computing infrastructure	Technical requirements, (eg, hardware, equipment, devices, broadband)	"If one is thinking about adding a telehealth solution, one needs to consider the digital divide."	Technical
Human-computer interface	Comfort level and overall user-friendliness of the interface	"COVID-19 tethered the consumer away from the clinic… Telemedicine became the umbilicus; it brought the patient back."	Sociotechnical
Workflow and communication	Logistics surrounding the proper functioning of the system and ensuring cohesive communication	"I thought it was important to provide education about the study to everyone because the trust equity that the patients have certainly was to the doctors, nurses, and counselors."	Sociotechnical

Theme 3: Facilitated Telemedicine Supports Pragmatic Research Emphasizing People With OUD

The tremendous efficacy of DAAs promoted support for pragmatic effectiveness studies for HCV. Simultaneously, the trial sponsor emphasized pragmatism in research.

> *There was real interest in hepatitis C treatment and that opened the channels for funding OUD studies.*
>
> *The studies had to be done in the real world, and they had to include the people who are implementing the treatment and the patient-centered aspects of telehealth.*

Simultaneously, however, various stakeholders voiced concerns about engaging people with OUD in research.

> *The concerns regarding funding studies in people with OUD very much reflected the ones that payers and providers had… Grave concerns about treating this particular population because of its reputation for being unstable, that they would not complete treatment, would get reinfected, or would disappear.*

Historically, clinical research was largely focused on academia and was considered complete when the study results were published.

> *Studies were developed by researchers and then evaluated by other researchers… The problem with academic research was that if there was nobody who wanted to implement what was found effective, then nothing happened with it.*

Pragmatic studies achieve their full potential when they have long-lasting impact. In our case, 4 of 8 sites have continued to use facilitated telemedicine for evaluation of complex cases.

We used a variety of techniques, including the patient advisory committee, peer pipeline, and learning lunches, to understand and address facilitated telemedicine implementation challenges

XSL•FO
RenderX

within the OTP. The patient advisory committee facilitated participant understanding of facilitated telemedicine through recommendations to augment digital literacy. For example, we developed an educational video explaining facilitated telemedicine that we showed to participants during recruitment discussions.

> *We had a patient advisory committee that… formed a very cohesive bond and served as a mechanism for discussion and feedback on study-related interventions even before we implemented them.*

Alongside the patient advisory committee, there was a peer pipeline where patients had the opportunity to endorse trial participation to their peers.

> *We had a peer pipeline… Patients spoke to other patients that promoted subsequent engagement and maintained retention.*
>
> *They [patients] became the strongest advocates for enrollment into the study.*

We discovered that learning lunches were a particularly important mechanism to provide staff education, to facilitate OTP staff and research team interactions, and to receive feedback for potential course correction of trial procedures [9].

> *Learning lunches were open for the entire multidisciplinary team… Patient care providers, billing department and our security staff because many of them were seeing the patients every day… Having that opportunity to work through some of those knots was very instrumental to the [trial's] success.*

In addition to OTP leadership, patients, and trial sponsors, stakeholder engagement extended to the clinical and nonclinical staff. It was important to regularly communicate with OTP staff as they managed OTP workflows. Ongoing stakeholder engagement, combined with program funding, was synergistic toward facilitated telemedicine implementation, as explained by OTP leadership.

> *I've come to appreciate the need to have continuing relationships… Those relationships are not just research, but they are also economic. When you can get funding from a research institute to support what you do, it makes a big difference in day-to-day operations.*

HCV treatment access is a health equity priority [7]. Therefore, funding and policy should be evidence-based. Future research funding should focus on the scaling and sustainability of facilitated telemedicine to promote health care access.

> *Public policy is not always driven by science or clinical practice.*
>
> *What we need are some creative solutions to the access problem. Telehealth takes care of part of it, but we also need to think about where telehealth doesn't work… We still have the great digital divide. There are people who have no access to the internet... You have to have some familiarity with the technology… Not everybody has digital literacy.*

Discussion

Principal Results

Facilitated telemedicine, through its transcendence of geographical and temporal boundaries, resulted in remarkably high HCV cure rates when integrated into 12 OTPs throughout New York State. Implementing the intervention, however, required convincing stakeholders of the benefits of facilitated telemedicine. We conducted a pragmatic randomized controlled trial in people with OUD that satisfactorily addressed the digital divide in an underserved population and that successfully implemented a novel health care delivery modality using a complex design. We found that open and honest stakeholder discussions were usually sufficient to overcome initial resistance regarding integrating facilitated telemedicine into OTPs. Conducting clinical research in OTPs and recruiting people with OUD were novel concepts when the trial was proposed because neither typically participated in research. An initial challenge was convincing stakeholders to endorse a trial directed toward the setting and population. An additional challenge was whether true uncertainty (ie, equipoise) existed between the interventions being tested in the clinical trial. Since it was difficult to establish whether true uncertainty existed, we used the stepped wedge design [36]. The concept of using the stepped wedge design was also considered a potential complexity given its stringent enrollment and timing requirements. Patient engagement in a trusting and destigmatizing environment by staff, who had the patients' best interests as their priority, mitigated several of these concerns. From these perspectives, the OTP environment enabled us to fully integrate HCV treatment through facilitated telemedicine into its workflows. After the trial's conclusion, we have continued facilitated telemedicine for evaluation of complex cases in 4 sites. In 8 sites, facilitated telemedicine served as a bridge to onsite HCV treatment by OTP staff. From our investigation, we have learned that facilitated telemedicine can increase health care access using a value-based care approach.

Digital Divide

The digital divide remains a challenge to the scalability of facilitated telemedicine. The digital divide refers to the unequal access to digital technology, internet provision, and digital literacy that worsens inequality around access to information and resources [8]. In the design of facilitated telemedicine, we considered social and technical aspects, which were facilitated by a case manager. During telemedicine encounters and videoconferencing for patient advisory committee meetings, the case manager facilitated equipment operation. The case manager also addressed patients' questions and concerns and was an information conduit for any HCV-related issues. The importance of considering the social aspects of digital connectivity was demonstrated most poignantly during the COVID-19 pandemic and lockdown, when patient advisory committee meetings occurred weekly (instead of quarterly) through videoconferencing. The committee meetings became an extremely important approach to maintain patient engagement. In resource-limited settings, OTP staff can assume the role of HCV champion. Therefore, facilitated telemedicine has the potential to reach underserved populations (ie, migrants,

XSL•FO
RenderX

incarcerated individuals, and the homeless) and address the digital divide through specific approaches as illustrated (Table 3). The importance of the social aspects when increasing digital health care access to underserved populations has been investigated among people who use drugs in Athens, Greece [26,37]. Participants emphasized the importance of trust-building, including several suggestions to enhance trust through digital means, during focus group discussions. More importantly, social interaction and relationship building (ie, empathy, trust, support, and transparency) contributed to the patient-centeredness of facilitated telemedicine. Therefore, telemedicine without the "facilitation" aspect would be devoid of the social component that is crucial for high-quality, patient-centered care [24], especially for populations that often experience stigma from various sources. In this context, the social component was largely delivered by the case managers who facilitated the telemedicine encounters, educated patients, and served as patient advocates. Other facilitated telemedicine approaches have employed staff or peers to facilitate the telemedicine encounters [38-40]. The sociotechnical approach also has the potential to present the OTP as a "full-service garage" that can address OUD-related infectious diseases, mental health issues, common comorbidities, and social factors. The novelty of facilitated telemedicine remains the integration of the social and technical aspects for underserved populations.

Table . Lessons learned through the implementation of facilitated telemedicine to overcome the digital divide.

Topic	Lessons learned and recommendations
Medical	• Integrate HCV[a] and opioid use disorder treatment • Address medical comorbidities
Social	• Minimize stigma against underserved populations • Maintain patient-centeredness • Promote trust • Address competing priorities • Provide patient education • Employ case manager as patient advocate and patient navigator
Technical	• Facilitate telemedicine encounters • Promote access to technology • Ensure sufficient broadband strength • Negate digital literacy challenges
Lessons for pragmatic research	• Promote learning lunches and establish patient advisory committees • Reinforce the importance of HCV cure by OTP[b] staff • Disseminate information through peer pipeline • Engage stakeholders • Emphasize underserved population • Consider telemedicine sustainability through reimbursement

[a]HCV: hepatitis C virus.

[b]OTP: opioid treatment program.

Pragmatic research related to facilitated telemedicine implementation, conventionally conducted as explanatory clinical trials, sought to evaluate an intervention while controlling for multiple factors [41]. Within the past decade, increasing value has been placed on pragmatic research, including stakeholder engagement, implementation evaluation in real-world settings, and sustainability of effective interventions following study completion (Table 4).

XSL•FO
RenderX

Table . Comparison between explanatory and pragmatic research related to facilitated telemedicine implementation. Table adopted from studies by Le-Rademacher et al [41] and Krist et al [42].

Domain	Explanatory research	Pragmatic research	Facilitated telemedicine examples
Impact	To gain scientific knowledge	To make real-world changes	Facilitated telemedicine overcoming digital divide
Patient relevance	Patients are typically solely research participants	Usually patient-centered research matters to patients and caregivers; patient involvement in all study phases	Patients readily view the advantages of facilitated telemedicine
Stakeholder involvement	Largely investigator focused	Multiple stakeholders engaged in all study phases	OTP[a] staff referred patients for facilitated telemedicine
Research design	Extensive exclusion and inclusion criteria often lead to homogenous populations and settings	Real-world settings, populations, contextual assessments; usually parallel or stepped-wedge design usually with a high degree of heterogeneity.	Research in opioid treatment programs with usual workflows, development of a statewide telemedicine network.
Measures	Validated measures that minimize bias; focus on internal consistency	Practical to real-world and low-resource settings; matter to patients	HCV[b] cure, satisfaction with healthcare delivery through telemedicine
Costs	Infrequently collected	Assess cost of intervention	Telemedicine reimbursement
Data sources	Data collection from patients as part of the trial.	Data collected at patient and site level; can use existing datasets (ie, health records, administrative data, and patient lists)	Remote access to electronic health records, case managers faxing laboratory reports
Analyses	Can be per protocol	Intention-to-treat, relevant to multiple stakeholders; goal is understanding implementation process	Patient satisfaction with health care delivery through facilitated telemedicine.
Intervention adherence and follow-up requirements	Close monitoring and follow-up	Can be as usual care	Case managers ensured adherence to study and clinical procedures.
Sustainability	Emphasis on efficacy under ideal circumstances	Emphasis on effectiveness in real-world settings	HCV management of complex cases through telemedicine at 4 sites, on-site HCV treatment at 8 sites after study completion.

[a]OTP: opioid treatment program.

[b]HCV: hepatitis C virus.

Health care delivery approaches, such as facilitated telemedicine, are most effectively investigated through pragmatic as opposed to explanatory trials. The typical goal of explanatory research is to evaluate the efficacy of an intervention in a controlled setting, whereas pragmatic research evaluates its effectiveness in routine clinical practice settings to maximize applicability, generalizability, and transferability [43]. Explanatory research typically measures clinical symptoms or biological markers, whereas pragmatic research focuses on multiple outcomes, many of which are patient-centered. Pragmatic research emphasizes stakeholder involvement, real-world settings and populations, and outcomes that are relevant to patients and stakeholders. Therefore, data collection is typically more laborious and is required from patients, sites, and communities [41]. In addition, since sites where pragmatic studies are conducted are often part of a health care system, they typically share personnel, policies, and resources. Thus, the assumption that study sites are independent of each other, typically observed in explanatory studies, may be violated in pragmatic trials. Proper analysis of pragmatic trial data may require complex statistical models that can account for correlated responses between clusters. In the trial, we were fortunate to have a negligible correlation between our study sites [36]. Furthermore, we developed a comprehensive dataset that permitted the analysis of substance use and social factors in relation to HCV treatment initiation and cure [44].

Strengths and Limitations

Strengths of the workshop include multidisciplinary speakers who directed a multiyear trial of facilitated telemedicine. The presentations have been substantiated with extensive staff and patient interviews [3,22-24]. Another strength was partnering with national organizations (ie, AATOD, NASTAD, and PCORI) that represent patients with HCV and OUD and their caregivers. The workshop provided the opportunity to disseminate the findings of the trial to a national audience that specializes in OUD care. A minor limitation is the nonrecognition of all spoken words by the recording and transcription program; less than approximately 1% of spoken words were not picked up by the recording. In addition, a patient-participant was unable to attend the workshop. Fortunately, the patient's voice was communicated through a presentation about patient perspectives derived from a recent publication [3]. Given that the age of 18 years or older was a

XSL•FO
RenderX

trial inclusion criterion, we are unable to generalize the findings from this investigation to younger-aged individuals.

Conclusions

We developed facilitated telemedicine as a patient-centered intervention designed to expand DAA access among people with OUD. Because people with OUD may have difficulty crossing the digital divide, we used facilitated telemedicine to engage and retain the population in HCV care. A multidisciplinary group of investigators hosted a workshop to disseminate knowledge of facilitated telemedicine for HCV care integrated into OTPs. From the workshop presentations, we identified 3 themes. First, patient-centered care promotes HCV treatment for underserved populations through facilitated telemedicine (theme 1). Second, sociotechnical approaches expand health care access for people with OUD (theme 2). While the technical aspect of facilitated telemedicine was conducive to overcoming geographical and temporal obstacles, we had to consider the social aspect in the delivery of HCV care through digital approaches to people with OUD. These were primarily addressed by integrating HCV telemedicine encounters into the destigmatizing, supportive, and trusting OTP environment and by facilitation through a case manager.

Third, facilitated telemedicine supports pragmatic research emphasizing people with OUD (theme 3). Initial resistance of OTP leadership and frontline staff regarding facilitated telemedicine was effectively mitigated through engagement of a patient advisory committee, a peer pipeline operating within the OTP, and learning lunches. These approaches facilitated participant and OTP staff input on approaches to improve facilitated telemedicine. Addressing the digital divide requires developing patient-centered, sociotechnical innovations for health care delivery and equity directed toward underserved populations.

Acknowledgments

We would like to acknowledge the American Association for the Treatment of Opioid Dependence, its 2024 conference contributors and participants. We would like to thank Michael E Cain, MD, for his review of the manuscript.

This work was supported by a Patient-Centered Outcomes Research Institute (PCORI) Award (IHS-1507- - 31640) and partially supported by the Troup Fund of the Kaleida Health Foundation (to AHT). The statements in this work are solely the responsibility of the authors and do not necessarily represent the views of PCORI, its Board of Governors or Methodology Committee. Abstract

Background: Varicella is a prevalent respiratory infectious disease. Continuous monitoring is essential to understand evolving epidemiological patterns, particularly given the impact of vaccination and recent nonpharmacological interventions.

Objective: This study aims to monitor the epidemiological characteristics of varicella and the changes in breakthrough cases to inform adjustments in immunization strategies and enhance prevention efforts.

Methods: From 2010 to 2023, varicella incidence was monitored using active (2010-2011) and passive (2012-2023) surveillance methods. Data were obtained from the Chinese Center for Disease Prevention and Control's information system and Ningbo's Immunization Information System. The study period was divided into four intervals to analyze trends. A birth cohort (2009-2013) was established to examine breakthrough cases. A recurrent neural network model was constructed for deep learning analysis of incidence trends and the impact of nonpharmaceutical interventions.

Results: Between 2010 and 2023, a total of 70,163 varicella cases were reported in Ningbo. Seasonal distribution indicated two incidence troughs before 2020 and only one from 2020 to 2023. The predominant age of onset was 10 - 14 years, accounting for 23.93% (16,795/70,163) of cases. From 2010 to 2013, the highest incidence was among children aged 5 - 9 years; from 2014 to 2019, it shifted to those aged 10 - 14 years; and from 2020 to 2023, it was primarily among individuals aged 15 - 19 years. Following the introduction of a second vaccine dose (2014 - 2019), incidence among children younger than 10 years of age decreased, notably by 59.54% in those aged 1 - 4 years. Conversely, incidence among individuals aged 10 years and older increased, particularly by 123.78% in the 15 - 19 years age group, with a significant upward trend (P_{trend}<.001). From 2020 to 2023, although incidence rates increased across age groups 15 years and older, the rise was modest. The average annual incidence rate of breakthrough cases after one vaccine dose was 83.40/100,000 (range, 51.21 - 119.50/100,000), significantly higher than the 24.80/100,000 (range, 17.67 - 32.90/100,000) observed after two doses. However, the incidence of breakthrough cases after the first dose declined following the implementation of the 2-dose program. The median time from vaccination to breakthrough case occurrence was 27 (IQR 17.50 - 48) months. The recurrent neural network model demonstrated high accuracy (mean squared error, 49.96) and indicated that implementation of emergency response and community lockdown measures in early 2020 correlated with a divergence between predicted and actual case numbers, suggesting an impact of nonpharmaceutical interventions on varicella transmission.

Conclusions: The significant shifts in varicella epidemiology between 2010 and 2023 highlight the importance of continuous monitoring and proactive immunization adjustments. We recommend enhanced varicella surveillance focusing on adult populations, and a targeted increase in 2-dose vaccine coverage, particularly in high-risk environments such as high schools and universities.

varicella; breakthrough case; epidemiology; disease surveillance; infectious; monitoring; vaccine; nonpharmacological interventions; machine learning

Introduction

Varicella, a highly contagious disease caused by the varicella-zoster virus, is primarily transmitted through direct contact with the rash of varicella or herpes zoster, as well as by inhaling aerosolized droplets from the respiratory secretions of patients with varicella [1]. While varicella is typically mild and self-limiting in healthy children, it can be life-threatening for immunosuppressed patients, pregnant women, and older people. In high-risk groups, varicella infection may result in severe complications such as pneumonia, encephalitis, hepatitis, organ failure, and acute cerebellar ataxia [2]. According to the World

XSL•FO
RenderX

Health Organization, the annual global burden of varicella is estimated at around 140 million cases, leading to 4,200,000 harsh complications necessitating hospitalization, and resulting in 4200 deaths [3]. Notably, China reported a total of 3,047,715 varicella cases between 2016 and 2019, with an average annual incidence rate of 55.05 per 100,000 [4]. The incidence rate significantly increased from 35.50 per 100,000 in 2016 to 70.14 per 100,000 in 2019, surpassing other legally notifiable infectious diseases like measles and rubella. Since varicella is not a notifiable infectious disease in China, the actual incidence rate is probably higher than the reported rate. This underscores the pressing need for effective prevention strategies to tackle the significant public health impact of varicella infection.

The introduction of the varicella vaccine has been crucial in disease control, significantly reducing the incidence, hospitalizations, and mortality rates associated with varicella [5,6]. The vaccine was first licensed for use in the United States in 1995. In 2006, a 2-dose schedule was recommended for children, with the first dose given at 12 - 15 months and the second dose between 4 and 6 years of age [6]. This immunization strategy has also been adopted by Germany, Australia, and Canada. In contrast, China introduced the varicella vaccine in 1998 but did not include it in the national immunization program, opting for a single-dose strategy targeting children aged 12 - 18 months. Starting in 2014, Ningbo implemented a 2-dose vaccination strategy, with the first dose administered at 12 - 15 months and the second dose at age 3 years and older. Vaccination in Ningbo is voluntary and self-funded, achieving a vaccination rate exceeding 90% for one dose and over 70% for two doses [7,8]. The use of the varicella vaccine in children has led to changes in the epidemiological characteristics of varicella, including a shift toward older age groups [3]. Nonpharmaceutical preventive measures for COVID-19 may also impact the epidemiological features of varicella. Studies indicated that the effectiveness of a single varicella vaccine dose diminishes over time, contrasting with the sustained effectiveness of the 2-dose vaccine [9]. Even if vaccinated, breakthrough cases of varicella can still occur. Although usually less severe, these cases can contribute to the spread of varicella within a community.

The World Health Organization emphasizes the need for thorough varicella surveillance to understand the disease's spread and to guide public health efforts in prevention and control. Since 2009, targeted surveillance efforts have been implemented, establishing specific varicella surveillance points in Ningbo, China, to monitor disease incidence and spread. In 2012, the Ningbo Municipal Bureau of Health required all health care facilities to report varicella cases to the China Information System for Disease Control and Prevention (CISDCP) within 24 hours, and this measure enhanced the accuracy and promptness of data collection. This study aims to use both active and passive surveillance data to analyze the epidemiological features of varicella and breakthrough cases.

Methods

Setting

Ningbo, a subprovincial city in Zhejiang province, East China, is one of the five state-planning cities in the country. Before 2016, Ningbo comprised 6 urban districts (Haishu, Jiangbei, Jiangdong, Zhenhai, Beilun, and Yinzhou), 3 satellite county-level cities (Fenghua, Yuyao, and Cixi), and 2 rural counties (Ninghai and Xiangshan). Following a regional restructuring in 2016, Ningbo now includes 6 urban districts: Haishu, Jiangbei, Zhenhai, Beilun, Yinzhou, and Fenghua; 2 county-level cities: Yuyao and Cixi; and 2 counties: Ninghai and Xiangshan. The city spans 9816.2 km² of land and 8355.8 km² of sea. As of the end of 2022, Ningbo had a population of 9.618 million permanent residents. Since 2005, the Ningbo Center for Disease Control and Prevention has operated the Ningbo Immunization Information System, a computerized system that maintains immunization data and demographic information on vaccines for the Ningbo region [10].

Active Monitoring Only, 2010-2011

The varicella active surveillance project [10] was conducted in Yuyao City, Yinzhou District, and Ninghai County during 2010 and 2011, through a collaboration between the Yuyao Center for Disease Prevention and Control (CDC), Yinzhou CDC, Ninghai CDC, and Ningbo CDC. Yuyao City is located in the western part of Ningbo, on the southern bank of the Yangtze River Delta. Yinzhou is a central district of Ningbo, covering an area of 1380 square kilometers. Ninghai County is situated to the south of Ningbo and spans approximately 1931 square kilometers. The populations of Yuyao, Yinzhou, and Ninghai County were 830,000, 730,000, and 580,000, respectively.

Since mid-2009, local health providers and physicians in the varicella surveillance areas have been required to electronically report any diagnosed varicella case to CISDCP within 24 hours. The epidemiologic information recorded for each case includes age, gender, current home address, household registration, date of symptoms onset, date of diagnosis, vaccine history, and other relevant details. Public health doctors in the surveillance area were also responsible for actively identifying varicella cases in hospitals, community health service centers, schools, and kindergartens on a weekly basis. If an unreported varicella case was found, public health doctors would report it through CISDCP.

Passive Surveillance, 2012-2023

Since 2012, under the requirement of the health administration department in Ningbo City, all medical institutions in the city have been required to report varicella cases through CISDCP. The CDC conducted quarterly investigations on underreporting to improve the quality of reporting.

Varicella Vaccine Immunization Strategy Adjustment in 2014

Ningbo City implemented a 2-dose varicella immunization strategy. Children receive voluntary and self-paid varicella vaccination. The recommended timing for the first dose is at 1

XSL•FO
RenderX

year of age, and the recommended timing for the second dose is between 3 and 4 years of age.

Nonpharmaceutical Intervention Measures

Starting from 2020, various nonpharmaceutical intervention (NPI) measures have been implemented by the government to control the COVID-19 epidemic. These measures include maintaining social distancing, wearing masks, school closures, and community lockdowns, which have had a significant impact on the transmission of other respiratory infectious diseases.

Diagnosis of Varicella and Breakthrough Cases

Varicella diagnostic criteria [11] are characterized by typical clinical manifestations, namely the presence of characteristic rashes that progress from macules to papules and then to vesicles before crusting. It is usually accompanied by fever and systemic symptoms such as malaise. If there are no typical clinical manifestations, the diagnosis needs to be made in conjunction with epidemiological history. The incidence of varicella in Ningbo is determined by dividing the number of reported cases by the corresponding population size. Population data for each age group is sourced from the Ningbo Municipal Public Security Bureau.

A birth cohort was established for children born between 2009 and 2013 who received one dose of varicella vaccine at the surveillance sites. Their varicella incidence was monitored through CISDCP. Varicella vaccine administration information was obtained through Ningbo's Immunization Information System.

Breakthrough varicella is defined as the occurrence of clinically diagnosed varicella in individuals who present with characteristic symptoms or have a documented epidemiological exposure history (as previously described), with symptom onset occurring more than 42 days after vaccination [12]. Furthermore, the rate of breakthrough infections has been delineated as the ratio of breakthrough infections occurring in children who have undergone varicella vaccination.

Data Extraction and Analysis

The varicella cases recorded between the years 2010 and 2023 were sourced from the comprehensive infectious disease surveillance and CISDCP. According to the temporal onset of illness, the cases were stratified into four phases for the purposes of descriptive analysis: 2010 - 2011, 2012 - 2013, 2014 - 2019, and 2020 - 2023. In the context of regional distribution analysis, and owing to specific regional modifications in Ningbo, the interval from 2014 to 2019 was further subdivided into two distinct phases: 2014 - 2015 and 2016 - 2019. Chi-square statistical tests were used to examine the variations in age and gender across the different phases, while trend chi-square tests were used to assess the evolving trends of various age cohorts within each phase.

To evaluate the impact of NPIs on the incidence of chickenpox, we developed an advanced deep-learning framework using recurrent neural networks. The model was trained on a dataset of chickenpox cases recorded between January 1, 2012, and December 31, 2018, and validated using data from January 1, 2019, to December 31, 2019. Predictions generated by the model were compared with actual incidence data from January 1 to June 30, corresponding to the implementation of Level 1 Emergency Response on January 22 and community lockdown measures introduced on February 2. The training process used a sliding window technique to forecast future case numbers, and model performance on the validation dataset was evaluated using metrics such as mean squared error, root mean squared error, and mean absolute error. The final model was then used to predict chickenpox incidence for the period from January 1, 2020, to June 30, 2020. These predictions were analyzed to assess the influence of NPIs by comparing the forecasted incidence with the observed data for the same timeframe.

The Python programming language facilitated the processes of data cleansing, analytical procedures, and data visualization. The 2-sided *P* values were documented, adhering to a significance threshold of $P<.05$. All analytical procedures were conducted using Python software (version 3.10; Python Software Foundation) [13].

Ethical Considerations

This study used secondary surveillance data on varicella cases obtained from the CISDCP. The study protocol was reviewed and approved by the Biological and Medical Ethics Committee of Ningbo Center for Disease Control and Prevention (approval: 202312), ensuring adherence to ethical guidelines for public health research. The original data collection involved informed consent procedures as per national regulations; the Ningbo CDC Ethics Committee specifically granted approval for this secondary analysis without requiring additional consent from individual patients. All data were fully anonymized and deidentified prior to access and analysis, protecting patient privacy and confidentiality. No personal identifiers were present in the dataset provided to the researchers. No compensation was provided to participants as this study involved the analysis of routinely collected surveillance data. The manuscript and supplementary materials do not contain any images of individual participants. We confirm that all data handling and analysis were conducted in compliance with relevant ethical standards and regulations for public health surveillance.

Results

Pathogenesis Overview

Between 2010 and 2023, a total of 70,163 varicella cases were documented in Ningbo. Within the designated monitoring region, 4753 cases were reported during 2010 - 2011. In the birth cohort from 2009 to 2013, there were 1404 varicella cases, including 912 classified as breakthrough cases. The overall incidence rate for breakthrough cases was 47,149 per 100,000 individuals. The frequency of breakthrough cases increased over time postvaccination, peaking in 2022 at 6307 per 100,000. The annual incidence of varicella rose from 63.89 per 100,000 in 2010 to 98.42 per 100,000 in 2013. It remained relatively stable between 2014 and 2017, ranging from 85.58 to 99.60 per 100,000, before increasing to 121.75 per 100,000 in 2018. A significant decline began in 2020, with the incidence rate dropping from 71.79 per 100,000 to 6389 per 100,000 (Table 1).

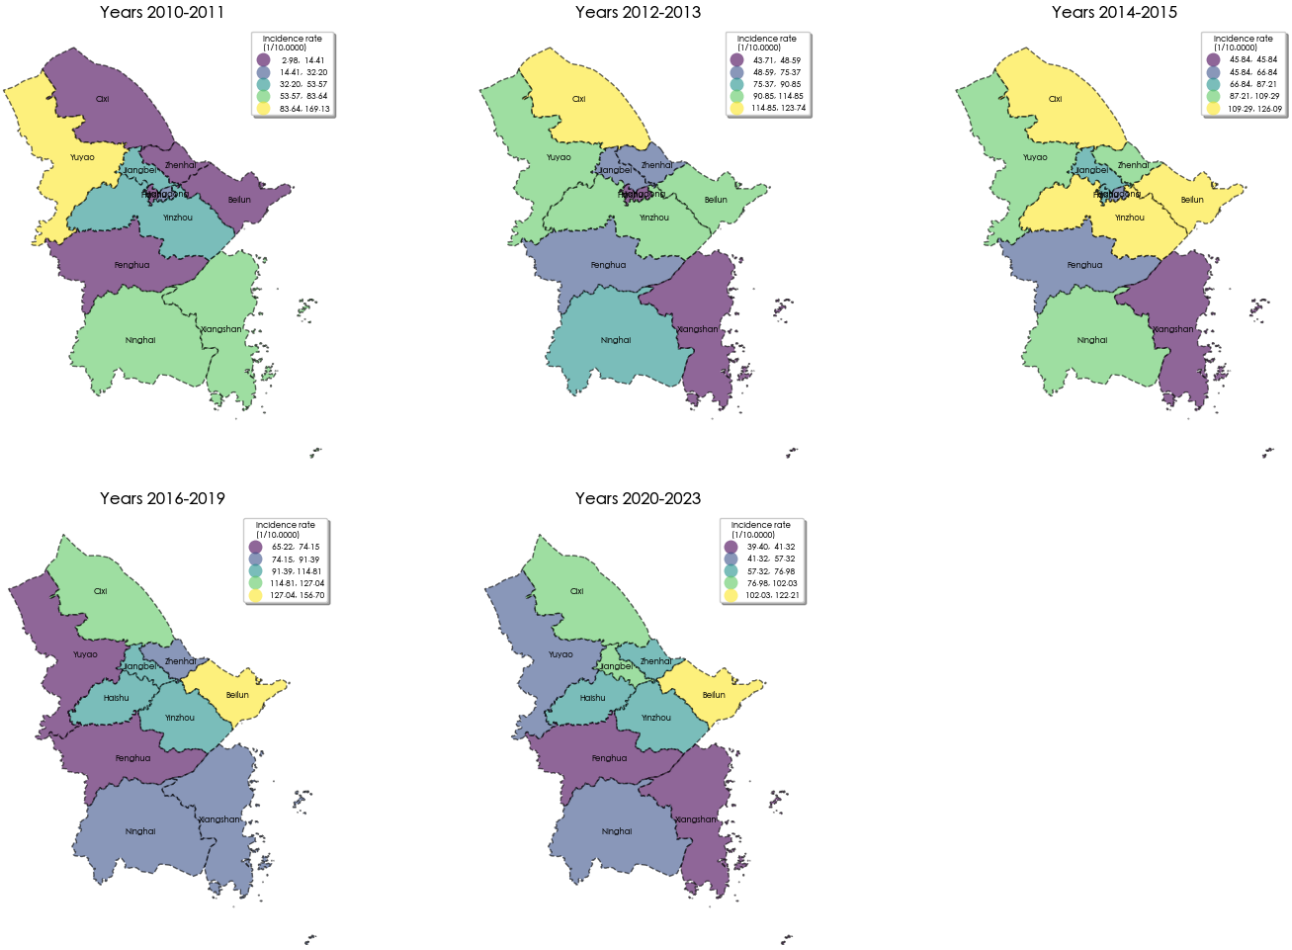
2023	3932	63.89	33.32



[a]BVR: breakthrough varicella incidence rate.

Spatial Distribution

Between 2010 and 2023, the municipalities with the highest average annual incidence rates of varicella were Beilun District, Yinzhou District, and Cixi City, with rates of 113.44, 105.95, and 99.70 per 100,000, respectively. Figure 1 illustrates the trajectory of these rates across each county and city district. During the active surveillance period, Yuyao City recorded the highest average annual incidence rate of 169.13 per 100,000 in 2010 - 2011. In the subsequent periods of 2012 - 2013 and 2014 - 2015, Cixi City reported the highest rates at 123.73 and 126.09 per 100,000, respectively. From 2016 to 2019 and 2020 to 2023, Beilun District had the highest rates at 156.70 and 122.21 per 100,000, respectively.

XSL•FO
RenderX

Figure 1. The spatial distribution of varicella in Ningbo, 2010 - 2023.

Temporal Distribution

Between the years 2010 and 2023, there were documented instances of varicella cases on a monthly basis in the city of Ningbo. Table 2 illustrates that during the periods 2010 - 2011, 2012 - 2013, and 2014 - 2019, two significant peaks in cases occurred: from May to July and from October to January of the following year. The incidence rates for May to July were 29.84% (1867/6257), 22.38% (2371/10,595), and 25.27% (9108/36,048), while the rates for October to January were 47.16% (2951/6257), 47.16% (2951/6257), and 45.51% (16,406/36,048), respectively. The months with the lowest incidence rates were February and September, with September accounting for 4.12% (258/6257), 4.95% (524/10,595), and 4.49% (1620/36,048), and February accounting for 2.70% (169/6257), 4.91% (520/10,595), and 5.90% (2127/36,048) across the respective years. From 2020 to 2023, the incidence rates in August and September showed no significant variation, while the number of cases from October to January remained high, comprising 45.32% (7823/17,263) of the total cases.

Population Distribution

From 2010 to 2023, the age groups with the highest number of cases were primarily 10 - 14, 5 - 9, and 15 - 19 years, comprising 23.93% (16,795/70,163), 20.86% (14,639/70,163), and 17.42% (12,224/70,163) of the total cases, respectively. Notably, between 2010 and 2011, the 5 - 9 age group had the highest proportion, accounting for 40.10% (2509/6257) and 37.31% (3953/10,595) of the total cases, respectively. In contrast, from 2014 to 2019, the 10 - 14 age group had the highest proportion, reaching 29.34% (10,577/36,048). From 2020 to 2023, the 15 - 19 age group had the highest proportion, accounting for 26.97% (4656/17,263) of the total cases (Figure 2A).

Figure 2. The age distribution of varicella in Ningbo. (A) The composition ratio of age by the phases. (B) The incidence rates by age during the phases.

XSL•FO
RenderX

From an analytical perspective on incidence rates, the age groups younger than 1 year and 5 - 9 years demonstrated a declining trend from 2012 - 2013 to 2020 - 2023, with reductions of 31.70% and 80.96%, respectively. In contrast, the 10 - 14 year age group experienced a significant increase of 72.68% from 2012 - 2013 to 2014 - 2019, followed by a decrease of 29.97% by 2020 - 2023. The age groups 15 - 19 years, 20 - 24 years, 25 - 29 years, and 30 years and older showed consistent upward trends from 2010 - 2011 to 2020 - 2023, with increases of 312.99%, 278.79%, 327.99%, and 575.62%, respectively. These trends were statistically significant, as determined by the trend chi-square test (all P<.001; and Table 3) (Figure 2B).

Table . The incidence rates of varicella by age and gender in Ningbo.

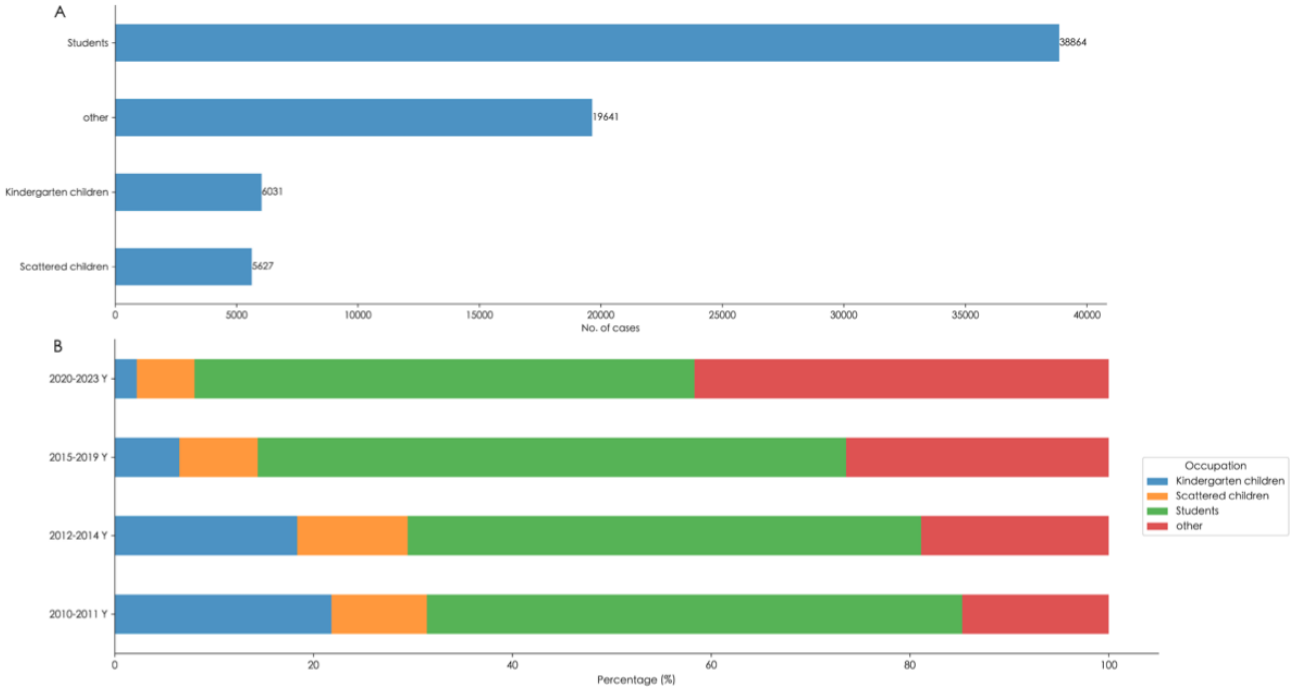
[a]Chi-square test for trend: <.001.



Among the total cases, male participants constituted 54.90% (38,519/70,163), while female participants accounted for 45.10% (31,644/70,163), resulting in a male-to-female ratio of 1.22:1. From 2010 - 2011 to 2020 - 2023, the incidence rate for male increased by 146.72%, whereas the rate for female rose by 169.37% (Table 3).

Occupational Distribution

Among the cases, there were 38,864 students (comprising 55.39%), 6031 children in childcare (representing 8.60%), 5627 children in disparate circumstances (accounting for 8.02%), and 19,641 instances classified as other nonchildren or students, which collectively constituted 28%. Figure 3 shows the distribution of cases by occupational classification. The proportion of children in childcare significantly declined (P<.001), from 21.80% in 2010 - 2011 to 2.21% in 2020 - 2023. Similarly, the percentage of children in disparate circumstances decreased from 9.61% in 2010 - 2011 to 5.82% in 2023 (P<.001). In contrast, the proportion of students remained relatively stable, with percentages of 53.84%, 51.67%, 59.19%, and 50.30% during the periods 2010 - 2011, 2012 - 2013, 2014 - 2019, and 2020 - 2023, respectively. Conversely, the proportion of other nonchildren or students increased significantly, from 14.75% in 2010 - 2011 to 41.67% in 2023 (P<.001).

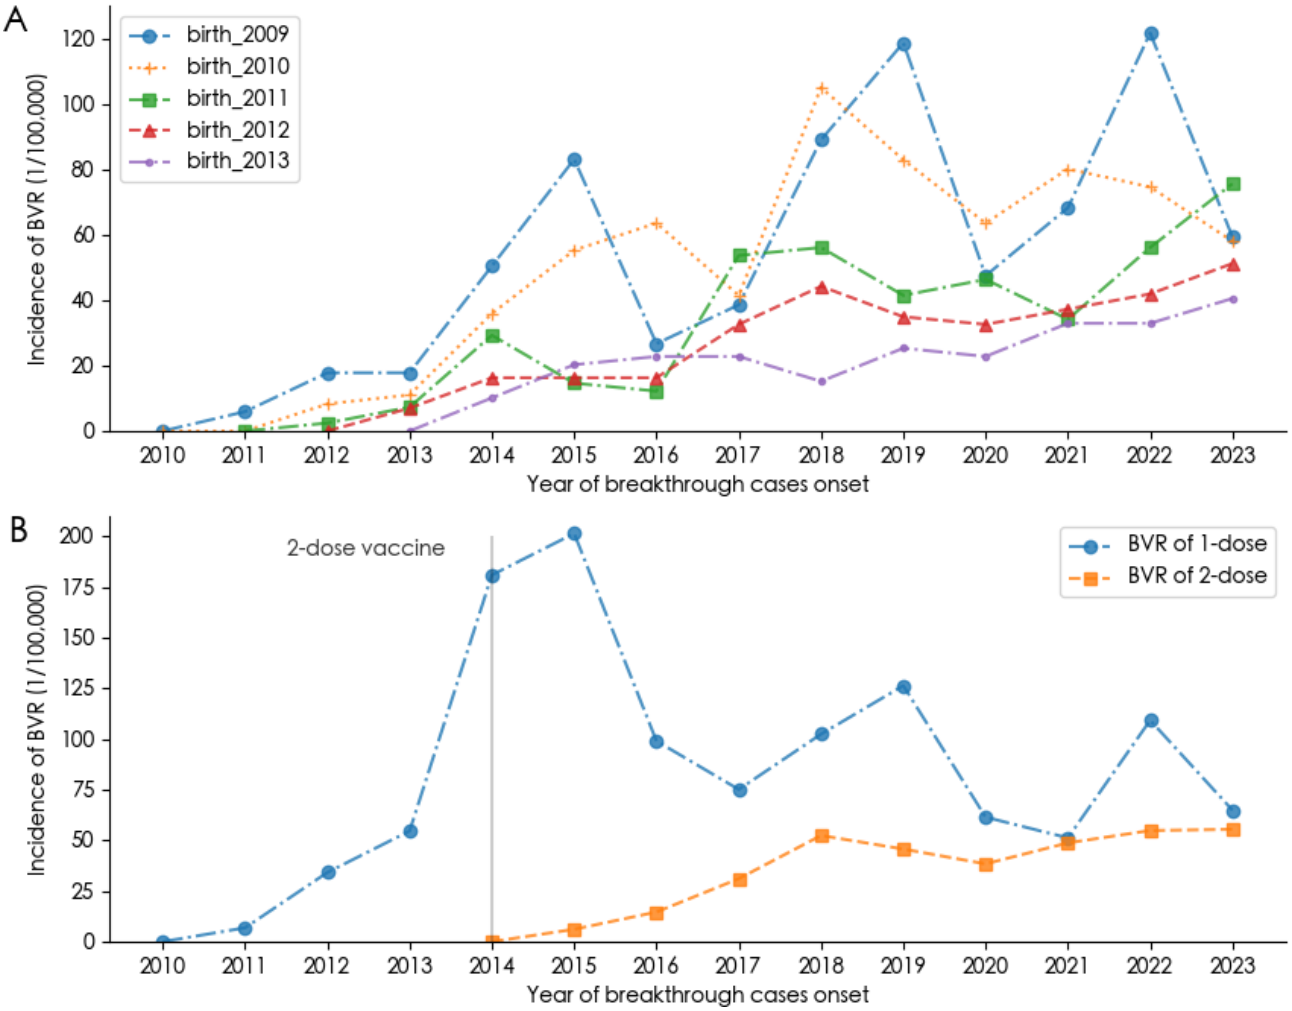
Figure 3. The occupational distribution of varicella by the phases in Ningbo.



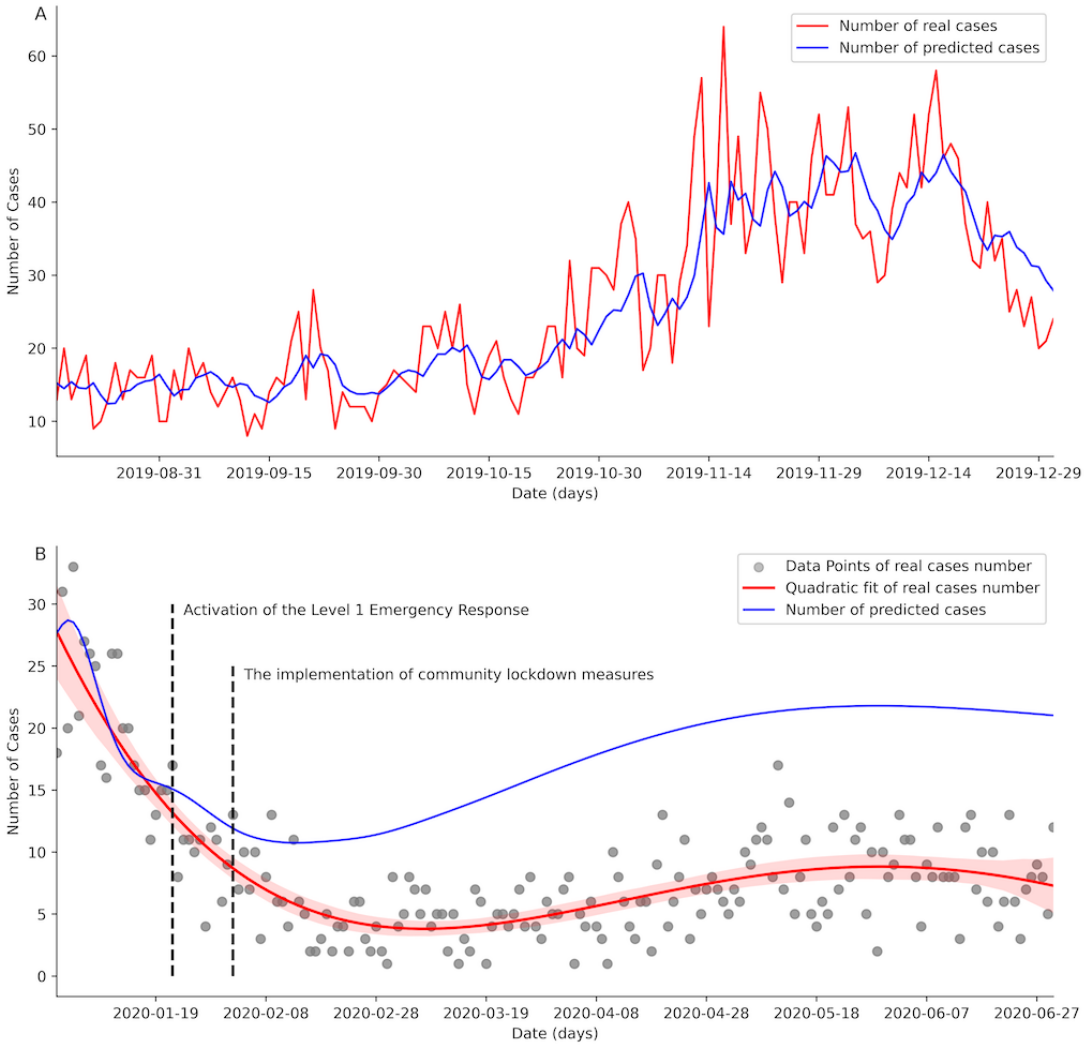
The Incidence and Number of Varicella Breakthrough Cases

Figure 4A presents the annual incidence of breakthrough varicella infection among different birth cohorts from 2009 to 2013, spanning the years 2010 to 2023. The mean annual breakthrough varicella incidence rate has shown a downward trend in cohorts with more recent birth years compared to those with earlier birth years. Specifically, the breakthrough varicella incidence rate was 53.16 per 100,000 individuals (range, 29.66 - 80.07 per 100,000) in 2009, 48.52 per 100,000 (range, 27.62 - 71.80 per 100,000) in 2010, 30.64 per 100,000 (range, 14.63 - 48.76 per 100,000) in 2011, 23.60 per 100,000 (range, 9.31 - 39.56 per 100,000) in 2012, and 17.53 per 100,000 (range, 5.06 - 32.91 per 100,000) in 2013.

XSL•FO
RenderX

Figure 4. The incidence and number of varicella breakthrough cases in Ningbo. (A) The annual incidence of breakthrough cases by birth cohorts. (B) The annual incidence of breakthrough cases by 1-dose and 2-dose varicella vaccination.

The average annual incidence of breakthrough cases following a single dose of the varicella vaccine was 83.40 per 100,000 (range, 51.21 - 119.50 per 100,000), significantly higher than the incidence after two doses, which was 24.80 per 100,000 (range, 17.67 - 32.90 per 100,000). Notably, after the implementation of the 2-dose immunization protocol, the incidence rate of breakthrough cases following the first dose showed a downward trend (Figure 4B).



The median time from vaccination to the occurrence of breakthrough cases was 27 (IQR 17.50 - 48) months. For individuals who received a single dose, the median interval was 23 (IQR 17.25 - 31.50) months, whereas for those who received two doses, it was 46 (IQR 18 - 66) months.

Impact of NPIs

To further analyze the impact of NPIs on the incidence of varicella, we constructed a recurrent neural network model for deep learning. This model features a three-layer neural network architecture with a total of 469,633 trainable parameters. Figure 5A illustrates the comparison between the actual and predicted case numbers in the validation dataset, demonstrating the model's effectiveness and accuracy in identifying varicella incidence trends. The model achieved a mean squared error of 49.96, a root mean squared error of 7.07, and a mean absolute error of 5.36. Figure 5B presents a comparison of the predicted and actual varicella case numbers from January 1 to June 30, 2020. The results indicate that after the implementation of the Level 1 Emergency Response on January 22, the predicted case numbers gradually exceeded the actual case numbers. Following the implementation of community lockdown measures on February 2, the discrepancy between predicted and actual case numbers significantly increased.

RenderX

Figure 5. Using recurrent neural network to analyze the impact of nonpharmacological interventions on varicella incidence. (A) The comparison between the actual and predicted case numbers in the validation dataset. (B) The comparison of the predicted and actual varicella case numbers from January 1 to June 30, 2020.

Discussion

Principal Findings

In China, varicella is not a legally regulated infectious disease, and the varicella vaccine, as the most effective control measure, is administered voluntarily and at personal expense. Varicella monitoring sites were established to conduct proactive monitoring in Ningbo City. Subsequently, health authorities required web-based direct reporting according to the requirements for reporting Class C infectious diseases. Compared to other studies based largely on voluntary case reporting [14-16], this method can more accurately reflect epidemiological characteristics. This study examined the epidemiological characteristics of varicella from 2010 to 2023, revealing significant changes. The administration of two doses of the varicella vaccine and NPIs had a substantial impact on the epidemiological characteristics.

Previous studies have consistently demonstrated a decline in varicella incidence following the introduction of the varicella vaccine [17-19]. However, our research presents a contrasting trend, revealing an overall increase in varicella incidence from 2010 to 2019. This observation, mirrored by the rising incidence reported in Anhui province from 2012 to 2019 [15], suggests that vaccine impact can be complex and influenced by local epidemiological factors. While our data show a 15% increase in varicella incidence following the implementation of a 2-dose immunization strategy, this overall trend masks important age-specific effects. Notably, we observed a significant decrease in varicella incidence among children younger than 9 years of age, with the most substantial decline (59.54%) in the 1 to 4

XSL•FO
RenderX

age group. This finding aligns with reports from Shi et al [17], who documented a similar reduction in incidence among children aged 0 - 4 years in Minhang District, Shanghai, and supports the efficacy of the vaccine in this young age group. However, the contrasting trend of increasing incidence among individuals aged 10 years and older warrants further investigation. This divergence from the findings of Marin et al [18], who reported declines across all groups, highlights the potential for waning immunity or incomplete vaccine coverage in older populations. Shi et al's [17] report of a 54.09% reduction in incidence among children aged 5 - 19 years further underscores the age-specific nature of vaccine effectiveness. Several factors may explain these discrepancies. The timing of 2-dose vaccination programs differs considerably between regions. The United States implemented a routine 2-dose program in 2007, with the second dose administered relatively early at ages 4 - 6 years, while this study area implemented the program in 2014. Shanghai's program, beginning in 2017 and integrated into the local immunization plan by August 2018 with over 80% coverage for the second dose [17], demonstrates the importance of both program timing and achieving high vaccination rates. Our continued observation of increasing incidence among those aged 10 - 19 years suggests that lower overall varicella vaccination rates in this cohort may be a key driver.

The optimal timing of the second dose also remains a point of discussion. While the United States and Shanghai recommend it at age 4, Ningbo City administers it at age 3. Sero-epidemiological studies offer conflicting insights: Sun et al [20] suggest a 3-year interval between doses maximizes antibody concentration, while Zhang et al [21] indicate higher seropositivity rates with earlier administration (ages 3 - 6). These findings emphasize the need for further research to refine immunization strategies and tailor them to local epidemiological contexts. Ultimately, understanding these nuanced interactions between vaccination programs, age-specific immunity, and population-level factors is crucial for optimizing varicella control and preventing future outbreaks.

During the COVID-19 pandemic, NPIs have demonstrated significant efficacy in controlling varicella outbreaks [22,23]. Originally intended to contain COVID-19, these interventions inadvertently reduced the incidence of other respiratory infectious diseases, such as varicella, due to similar transmission pathways [23]. Measures such as social distancing, mask-wearing, and enhanced hygiene practices led to a notable decline in varicella cases, underscoring their effectiveness in managing respiratory infections. In Xi'an, China, the incidence of varicella decreased by 43.18% in 2020 compared to 2019, attributed to the implementation of COVID-19 NPIs [14]. A European study also suggests that these infection control measures during the pandemic may have curtailed the spread of varicella [24]. Research by Wang et al [25] indicated that the actual number of varicella cases was 93.37% lower than expected, as predicted by the autoregressive integrated moving average model, highlighting a significant reduction in varicella activity due to COVID-19 NPIs. This study revealed that the incidence of chickenpox decreased by an average of 32.64% during the COVID-19 pandemic. Among individuals aged 15 years and older, the rate of increase in chickenpox cases continues to rise; however, this rate is significantly lower compared to the trends observed between 2014 and 2019. Additionally, predictions generated using the long short-term memory (LSTM) model demonstrated that prior to the implementation of COVID-19 prevention and control measures, the predicted number of chickenpox cases closely aligned with the actual reported cases. Following the adoption of these measures, the predicted case numbers consistently exceeded the actual reported cases. Notably, after the introduction of community closure management, the discrepancy between predicted and actual case numbers widened further. These findings suggest that NPIs implemented to curb the spread of COVID-19 also contributed to the prevention and control of chickenpox. Additionally, between 2020 and 2023, the low incidence of varicella from August to September was not significant. This finding aligns with the results of Sabale et al [24], indicating that infection control measures during the pandemic may have altered the seasonal transmission patterns of varicella and reduced its incidence rate.

This study reveals a notable shift in the age distribution of varicella incidence. While consistent with previous reports demonstrating a significant decline in cases among young children [19,26,27], we observed a gradual increase in varicella among individuals aged 10 - 14 years between 2010 and 2019, followed by a subsequent rise in cases among those aged 15 - 19 years between 2020 and 2023. This contrasts with findings from studies conducted in largely vaccinated populations [28], which have not reported a similar shift toward older age groups. The 95.5% decrease in incidence among children younger than 10 years of age reported by Moek and Siedler [19] highlights the effectiveness of childhood vaccination programs but also underscores the potential for a displacement of incidence to older, unvaccinated or incompletely vaccinated populations. Our finding of increasing incidence among adults aged 20 years and older further supports this hypothesis. The observed epidemiological pattern, with students representing the primary incidence group and a decline in cases among children in childcare, suggests that the implementation of the 2-dose vaccination strategy for children aged 3 years and older is successfully shifting the primary locus of transmission away from early childhood settings like kindergartens. This pattern is consistent with the concept of "herd immunity" waning in older, unvaccinated cohorts, leading to increased susceptibility and transmission within these groups. Further research is needed to investigate the long-term implications of this age-related shift and to inform targeted vaccination strategies for adolescents and adults.

Our initial observations, supported by extensive literature, indicate that the 2-dose varicella vaccine provides substantial epidemiological protection [8,10,29-31] and generally achieves a high vaccination rate. However, breakthrough cases of varicella continue to occur. Liu et al [32] reported that among 6961 varicella cases in Qingyang, China, 28.4% were breakthrough cases. Similarly, Zhu et al [33] documented an increase in the proportion of breakthrough cases during outbreaks, rising from 21.5% in 2008 to 86.1% in 2014, indicating an upward trend. Our findings also demonstrate an

XSL•FO
RenderX

increasing incidence of breakthrough cases over time following vaccination. Notably, the incidence of breakthrough cases with the 2-dose vaccine is lower than with a single dose. Furthermore, the implementation of a 2-dose immunization strategy significantly reduced the incidence of breakthrough cases associated with a single dose. The median interval between breakthrough cases was 23 months after a single dose and 46 months after two doses. This suggests that while breakthrough cases still occur after 2 doses, the 2-dose regimen is more effective than a single dose. It not only extends the duration of immune protection but also plays a crucial role in mass immunization efforts.

While the 2-dose varicella vaccine demonstrably provides substantial epidemiological protection and achieves high vaccination rates [8,10,29-31], recent data highlight the ongoing occurrence of breakthrough cases, a phenomenon increasingly recognized in the postvaccination era. Studies from China such as those by Liu et al [32] (28.4% breakthrough rate among 6961 cases) and Zhu et al [33] (increasing from 21.5% in 2008 to 86.1% in 2014) corroborate a growing trend of breakthrough infections, potentially linked to factors such as waning immunity or the emergence of vaccine-escape viral strains. Our findings align with this trend, demonstrating an increasing incidence of breakthrough cases over time following vaccination. Importantly, our data confirm the superior protection offered by the 2-dose regimen compared to a single dose, a finding consistent with established immunological principles regarding vaccine-induced immunity and memory cell development [34]. The significant reduction in breakthrough cases associated with the 2-dose strategy underscores its critical role in sustaining population immunity. The observed median interval of 23 months postsingle dose versus 46 months posttwo doses suggests that the second dose not only enhances initial protection but also extends the duration of immunity, a key consideration for long-term public health strategies. Further research is needed to investigate the factors contributing to breakthrough infections, including viral genetics, host immune responses, and the potential need for booster doses to maintain robust protection.

Limitations

This study has certain limitations. First, the identification of chickenpox cases in Ningbo primarily relies on clinical assessments. Cases with atypical presentations require evaluation in conjunction with epidemiological histories. However, when cases lack both characteristic clinical features and relevant epidemiological context, accurate identification becomes challenging. As vaccination coverage increases, breakthrough chickenpox cases often present with mild symptoms. Without comprehensive epidemiological investigations, such cases are likely to be overlooked. Furthermore, since 2012, chickenpox surveillance in Ningbo has predominantly relied on passive monitoring. This approach depends on health care providers voluntarily reporting diseases, symptoms, or health events, and it involves compiling data from existing medical records and self-reports from the public. Passive surveillance may lead to diagnostic inaccuracies, such as misclassifying nonchickenpox cases as chickenpox [35]. Additionally, it may result in underreporting, thereby underestimating the true incidence rate. The shift from active to passive monitoring introduces potential biases, particularly in terms of the completeness and representativeness of reports, which can obscure temporal trends and geographic distribution patterns in the data. Active monitoring, while more comprehensive, requires significant labor and time resources, making its consistent implementation across the city challenging. As a result, passive monitoring is widely adopted as a cost-effective alternative for tracking the epidemiological characteristics of infectious diseases over extended periods. To address the limitations of passive monitoring, implementing quality improvement measures is essential. For example, since 2012, Ningbo has integrated chickenpox case reporting into the management framework for Class C statutory infectious diseases. Disease control agencies at various levels are required to conduct regular audits to identify underreporting and provide feedback to improve surveillance accuracy. Based on monitoring outcomes, the system has not indicated significant underreporting of chickenpox cases. Third, LSTMs have demonstrated clear advantages in predicting long-term trends, but they remain unable to accurately model the overall spread of chickenpox during the COVID-19 pandemic. Consequently, the LSTM method is insufficient for evaluating the long-term impact of NPIs on chickenpox incidence when vaccine effects are excluded.

Conclusions

Through extensive longitudinal surveillance of varicella, we have identified significant changes in its epidemiological characteristics. These include the elimination of the seasonal incidence trough, a shift in the age of onset, and an increasing trend in adult morbidity. These findings highlight the critical need for ongoing epidemiological monitoring and underscore the importance of adapting vaccination strategies to address evolving epidemiological patterns, particularly in the context of postpandemic public health measures. Our investigation further revealed that the incidence of breakthrough cases was markedly lower among individuals who received the 2-dose varicella vaccination regimen compared to those who received only 1 dose. This emphasizes the importance of completing the full vaccination series to achieve higher levels of individual protection and herd immunity. Additionally, the application of machine learning algorithms has demonstrated significant potential in predicting chickenpox incidence. These algorithms enable more effective analysis of the impact of NPIs on disease incidence, providing evidence that NPIs have substantially reduced the burden of chickenpox. The growing use of machine learning in disease surveillance allows researchers to identify previously undetectable patterns and trends, improve predictive accuracy, and facilitate timely interventions. This, in turn, supports the development of more effective disease control measures. In summary, continuous epidemiological surveillance remains essential. We recommend enhanced monitoring of varicella in adults, increased vaccine coverage among individuals aged 15 years and older, and the implementation of 2-dose vaccination programs in high-risk settings such as high schools and universities. For individuals who have received only 1 dose, it is strongly advised to complete the second dose promptly to ensure optimal protection.

Abstract

Background: Hepatitis B is an important public health challenge facing China. Understanding the long-term epidemiological trends and evolving spatial distribution patterns is critical for optimizing prevention strategies and achieving the World Health Organization's 2030 hepatitis elimination targets.

Objective: This study aimed to explore the epidemic trends and spatial distribution characteristics of hepatitis B in China from 2004 to 2020.

Methods: This study used data on hepatitis B incidence from 2004 to 2020 from the China Public Health Science Data Center to analyze the time trend of hepatitis B incidence by joinpoint regression. The age-period-cohort model was used to analyze the age, period, and cohort effects of hepatitis B onset. Spatial autocorrelation analysis was used to explore the spatial distribution characteristics of hepatitis B in China.

Results: From 2004 to 2020, China reported a total of 17,449,842 cases of hepatitis B, with an average annual incidence rate of 76.30/100,000. The incidence of hepatitis B in China showed an increasing trend from 2004 to 2007, with an average annual percentage change (AAPC) of 9.49 (95% CI 2.12-17.39), and a decreasing trend from 2007 to 2014, with an AAPC of −3.77 (95% CI −5.93 to −1.55). The incidence of hepatitis B in China tended to be stable from 2014 to 2020, with an AAPC of −0.46 (95% CI −2.86 to 2.01). Age, period, and cohort effect significantly affect the incidence of hepatitis B. The age effect showed that the incidence rate of hepatitis B reached its peak at the age of 22 years, with an average incidence rate of 176.173/100,000. The period effect showed that the highest level during the study period occurred during 2004 - 2006. The cohort effect showed that the risk of hepatitis B increased first and then decreased, with the turning point of 1924 - 1974. The incidence of hepatitis B varies significantly among regions. The incidence in the northeast and northwest regions has decreased, that in the south and southwest regions has increased, and that in other regions has remained stable.

Conclusions: China has achieved remarkable results in the prevention and control of hepatitis B, but there are still differences in the incidence rate among different age groups and regions. These results suggest the need to further strengthen the identification and screening of high-risk populations and promote supplementary adult hepatitis B vaccination. Future intervention strategies should fully consider regional differences, implement precise intervention measures based on the epidemic trends and spatial distribution characteristics of each region, optimize resource allocation, and enhance the overall effectiveness of hepatitis B prevention and control.

KEYWORDS

hepatitis B; joinpoint regression analysis; APC model; spatial epidemiology; public health; vaccination

Introduction

Hepatitis B is a chronic infectious disease caused by hepatitis B virus (HBV) infection. Its onset is hidden and it is difficult to cure. Many infected people have no obvious symptoms in the early stage, and delayed treatment may lead to serious complications [1]. Hepatitis B is still an important public health problem in the world. According to the World Health

XSL•FO
RenderX

Organization, by 2022, a total of 254 million people worldwide were infected with chronic hepatitis B, with 1.2 million new infections and 1.1 million deaths; the main causes of death were cirrhosis and hepatocellular carcinoma (HCC) [2]. HCC is the sixth most common cancer and the third leading cause of cancer death worldwide [3]. HCC is also the fourth most common cancer and the third leading cause of cancer death in China [4]. In China, about 85% of patients with HCC have a history of HBV infection. HBV can induce HCC in various ways, and it is the most common and important factor in induced HCC [5]. HBV infection and its complications have brought a heavy economic burden to patients' families and society [6]. Therefore, understanding the epidemic characteristics of hepatitis B is helpful to provide a key basis for the optimization and precise implementation of hepatitis B prevention and control strategies.

Since China introduced the hepatitis B vaccine into the neonatal immunization program in 1992, the spread of hepatitis B has been controlled to some extent. The positive rate of hepatitis B surface antigen (HBsAg) in children under 5 years old has decreased from 9.9% in 1992 to 0.3% in 2014 [7]. However, due to China's large population base, HBV infection is still serious, and China's achievement of the global goal of eliminating hepatitis by 2030 is still hampered [8,9]. It is estimated that 90 million people are enduring chronic HBV infection in China, accounting for about 7% of the national population, and 330,000 people die of HBV-related cancer every year [10]. Although China has made some progress in hepatitis B control, it is still the country with the largest burden of HBV infection in the world. A series of health problems caused by HBV still pose a serious challenge to public health, and it is still necessary to continue to pay attention to high-risk regions and high-risk groups [11]. Therefore, gaining a comprehensive understanding of the epidemic trends and spatial distribution characteristics of hepatitis B incidence in China holds utmost significance for devising scientific, precise, and effective intervention strategies. It is pivotal for further optimizing China's hepatitis B prevention and control system, as well as driving deeper advancements in prevention and control efforts.

Current research on hepatitis B transmission, both domestically and internationally, predominantly concentrates on maternal-fetal prevention strategies and immunization programs. However, there remains a paucity of studies investigating the age-period-cohort effects on hepatitis B risk stratification. Furthermore, existing epidemiological investigations are largely confined to localized regions, specific demographic cohorts, or short-term observational periods, lacking systematic assessment of spatiotemporal dynamics and nationwide epidemiological patterns of hepatitis B in China. However, the spread of infectious diseases may vary greatly due to different spatial distributions, which makes the spatial distribution characteristics important factors to consider when formulating the response measures for infectious disease outbreaks [12]. For this reason, researchers use geographic information systems to examine the spatial distribution of various infectious diseases. Spatial autocorrelation analysis is a common method to analyze the spatial distribution characteristics of diseases and is widely used in the field of public health, especially the spatial cluster analysis of infectious diseases. This approach enables the identification of disease clusters, visualization of incidence and clustering trends over time and space, and clarification of geographical distribution patterns and risk levels across different regions [13].

In this study, the joinpoint regression model was used to analyze the long-term trend of the incidence of hepatitis B in Chinese residents from 2004 to 2020. The age-period-cohort model was used to estimate the effect of age, period, and birth cohort on the risk of hepatitis B. The spatial autocorrelation analysis was applied to visualize and spatially aggregate the incidence of hepatitis B in China from 2004 to 2020, and analyze the distribution characteristics of hepatitis B in different regions of China. This study aims to understand the spatiotemporal trends of hepatitis B in different regions of China and the impact of age, period, and birth cohort effect on the risk of hepatitis B, to provide a basis for clarifying the risk of hepatitis B in China and implementing accurate and effective prevention and control strategies. The results of this study will provide key evidence for the optimization of the hepatitis B prevention and control system in China, provide a scientific reference for the rational allocation of medical and health resources, and also contribute methodology and practical experience for the global realization of the World Health Organization's 2030 goal.

Methods

Data Source

Hepatitis B–related data in this study were sourced from the public database of the Public Health Science Data Center, which is hosted by the Chinese Center for Disease Control and Prevention [14]. The database is China's official authoritative public health data platform. Relevant data are collected based on China's notifiable infectious diseases reporting system, which requires medical institutions at all levels to confirm and report hepatitis B cases by the diagnostic criteria and management principles stipulated by the National Health Commission of the People's Republic of China. The dataset contains the hepatitis B data of 31 provinces, autonomous regions, and municipalities directly under the central government from 2004 to 2020 (excluding Hong Kong, Macao, and Taiwan). The data include the annual incidence and number of cases of hepatitis B in different regions and age groups in China, ensuring the comprehensiveness and representativeness of the study. The demographic data of China and its provinces in the same period (from 2004 to 2020) were obtained from the China Statistical Yearbook [15]. China's provincial vector maps are sourced from the National Basic Geographic Information System of China.

Joinpoint Regression Analysis

The Joinpoint regression software (version 5.0.2), developed by the National Cancer Institute, was used to analyze the temporal trend of hepatitis B incidence in China from 2004 to 2020. Joinpoint regression software uses the default grid search method to construct the model and uses the Monte Carlo permutation test method for model optimization. The Bayesian information criterion served as the criterion for evaluating the quality of model fit. Joinpoint regression analysis segments the study period into various intervals by identifying multiple connection points, fits and optimizes trends within each interval,

XSL•FO
RenderX

and thereby assesses the characteristics of hepatitis B incidence changes across different intervals. The number, location, and *P* value of the connection points were determined through a Monte Carlo permutation test (α=.05, 2-sided test). The average annual percentage changes (AAPCs) of the incidence rate of hepatitis B from 2004 to 2020, along with 95% CIs, were calculated. When AAPC>0 (*P*<.05), it indicates an increasing trend in incidence; when AAPC<0 (*P*<.05), it suggests a decreasing trend; and when *P*≥.05, it suggests a stable trend. The AAPC calculation formula is as follows:

(1)n(y|x)=b0+b1x

(2)AAPC={exp(wibiwi)−1}×100%

x represents the year, y denotes the incidence rate, b_0 signifies the intercept, b_i represents the regression coefficient, which is the slope coefficient of each line segment, and w_i indicates the number of years encompassed in each time segment.

Based on China's geographical characteristics and administrative divisions, this study divided China into 7 regions: the northern region (including Beijing, Tianjin, Hebei, Shanxi, and Inner Mongolia), the northeast region (including Heilongjiang, Jilin, and Liaoning), the northwest region (including Shaanxi, Gansu, Qinghai, Ningxia, and the Xinjiang), the eastern region (including Shanghai, Jiangsu, Zhejiang, Fujian, Shandong, Anhui, and Jiangxi), the central region (including Henan, Hubei, and Hunan), the southern region (including Guangdong, Hainan, and Guangxi), and the southwest region (including Chongqing, Sichuan, Guizhou, Yunnan, and the Xizang). It also analyzed the trend of hepatitis B incidence rate across these 7 regions.

Age-Period-Cohort Model

The age-period-cohort-model (APC model) is widely used to analyze incidence trends in epidemiology. Among them, the age effect reflects the difference in the risk of disease in different age groups. The period effect reflects the overall change in the incidence risk of all age groups at a specific time point. The cohort effect reflects the change in the risk of morbidity in people with the same birth year. This study used the online network analysis tool developed by Rosenberg, Check, and others to construct the APC model [16].

Due to the scarcity of cases among individuals aged 84 years and older, as well as the challenges in determining birth cohorts, this study adopted a 5-year age interval, dividing the age range of 0 - 84 years into 17 age groups. The data from 2004 to 2020 were divided into 5 groups: 2004 to 2008, 2009 to 2013, 2014 to 2018, and 2019 to 2020, to construct the APC model.

The model uses the Poisson log-linear model and uses the Akaike Information Criterion for a comprehensive evaluation of the model's goodness of fit. The formula for this model is expressed as:

(3)log(Eij)=log(Pij)+μ+αi+βi+γk

In this formula, E_{ij} and P_{ij} represent the total number of individuals who developed the disease in the ith age group during the jth period group, respectively. μ denotes the intercept term of the incidence rate. α_i signifies the regression coefficient for the ith age group, while β_i indicates the regression coefficient for the jth period group. γ_k stands for the regression coefficient of the kth birth cohort group.

Spatial Autocorrelation Analysis

In this study, ArcGIS 10.8 (Esri) software was used to describe the spatial distribution of hepatitis B in China from 2004 to 2020 through global spatial autocorrelation analysis. In addition, Moran's *I*, a global spatial autocorrelation coefficient, was used to assess the spatial distribution pattern of hepatitis B across various regions in China. Moran's *I* values range from −1 to 1. A positive value indicates spatial clustering, with a larger value indicating stronger spatial clustering. Negative values indicate spatial dispersion, with a smaller value indicating stronger spatial dispersion. A value of 0 indicates no spatial autocorrelation. The formula for calculating the Moran's *I* is as follows:

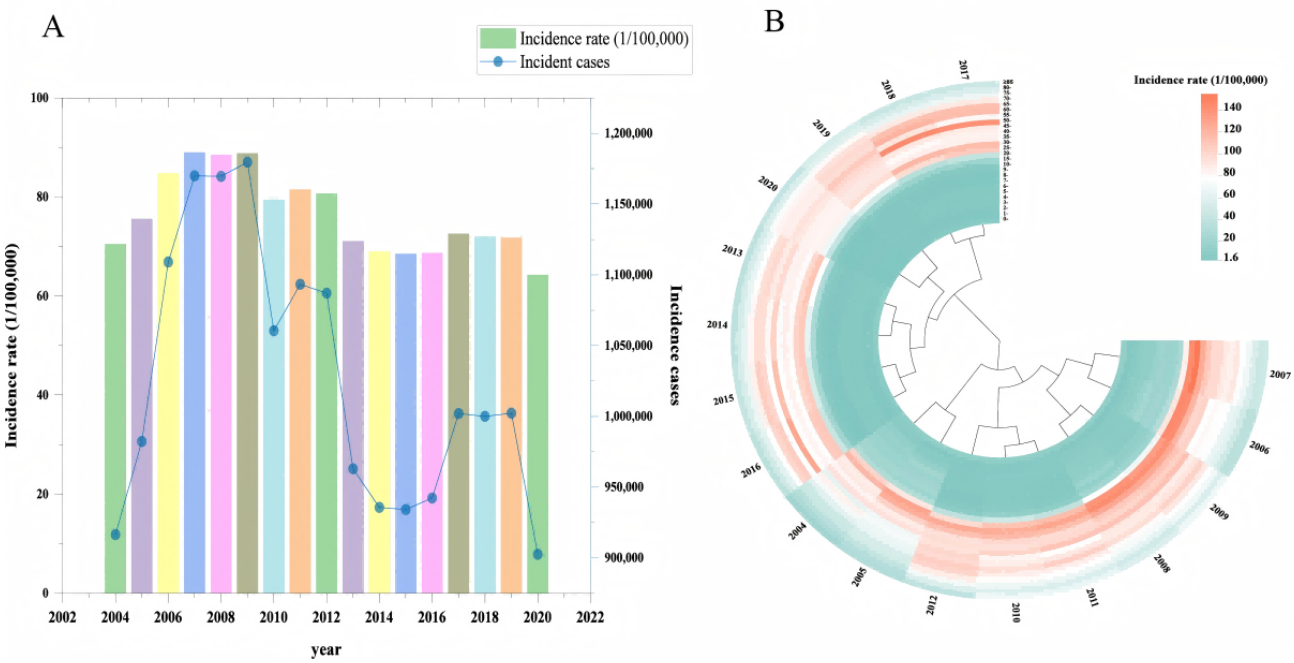
(4)I=n∑i=1n∑j=1nwij(xi−x^)(xj−x^)(∑i=1n∑j=1nwij)∑i=1n(xi−x^)2

In this formula, the incidence rate is represented by λ, the average incidence rate is represented by X, and the matrix of spatial weights is denoted as W_{ij}, representing the proximity relationship between region i and region j.

Local Moran's *I* was used to conduct a local analysis of the distribution of hepatitis B cases in each region, and the local autocorrelation type was determined by visualizing the local autocorrelation map. The aggregation types can be categorized into the following four types: "high-high," "high-low," "low-high," and "low-low."

Ethical Considerations

The data of this study were obtained from the public database authorized by the public health science data center of the Chinese Center for Disease Control and Prevention. According to the relevant provisions of the international code of Biomedical Research Ethics, this study meets the exemption conditions for ethical review, mainly for the following 3 reasons: (1) the research data are completely anonymized public information and do not contain any personally identifiable information; (2) this study did not involve any form of intervention, nor did it collect or use human biological samples; and (3) the processing and publication of the research results will not have any impact on the clinical diagnosis and treatment plan of the original data provider.



Results

Overall Description of Hepatitis B in China From 2004 to 2020

From 2004 to 2020, China reported a total of 17,449,842 cases of hepatitis B, with an average annual incidence rate of 76.3/100,000. The incidence rate fluctuated but exhibited an overall decreasing trend, decreasing from 70.5/100,000 in 2004 to 64.29/100,000 in 2020 (Figure 1A). From 2004 to 2020, the majority of hepatitis B cases occurred in the adult population, with 70.77% of cases falling within the age range of 20 - 50 years (Figure 1B).

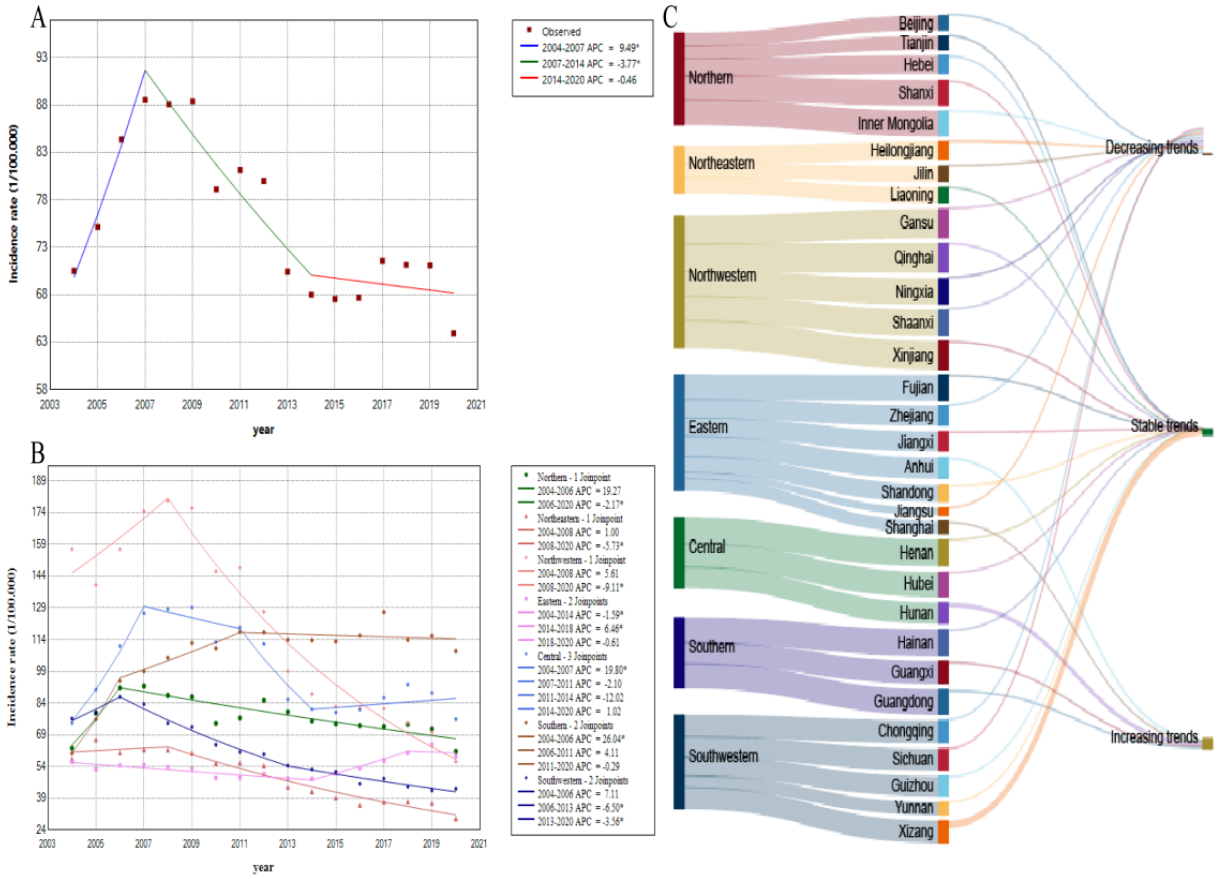
RenderX

Figure 1. Incidence of hepatitis B in China from 2004 to 2020. (A) Several cases and incidence rate of hepatitis B in China from 2004 to 2020. (B) Heat map of age-specific incidence rates of hepatitis B in China from 2004 to 2020.



Temporal Trends of Hepatitis B Incidence Rate in China From 2004 to 2020

The incidence rate of hepatitis B in China increased from 70.5/100,000 in 2004 to 89/100,000 in 2007 (AAPC=9.49, 95% CI 2.12 to 17.39). Subsequently, it decreased from 2007 to 69.05/100,000 in 2014 (AAPC=–3.77, 95% CI −5.93 to −1.55). From 2014 to 2020, the incidence rate of hepatitis B in China exhibited a stabilizing trend (AAPC=−0.46, 95% CI −2.86 to 2.01) (Figure 2A).

XSL•FO
RenderX

Figure 2. Temporal trends of hepatitis B incidence rate in China from 2004 to 2020: (A) temporal trends in the incidence rate of hepatitis B in China, (B) temporal trends in the incidence rate of hepatitis B across 7 regions in China, and (C) temporal trends in the incidence rate of hepatitis B across 31 regions in China. APC: annual percentage change.

From 2004 to 2020, the incidence rate of hepatitis B decreased in Northeast China (AAPC=−4.09, 95% CI –5.60 to −2.56) and Northwest China (AAPC=−5.64, 95% CI −7.48 to −3.75). Conversely, the incidence rate of hepatitis B increased in Southern China (AAPC=4.07, 95% CI 1.41-6.80) and Southwest China (AAPC=3.60, 95% CI −4.86 to −2.33). However, the incidence of hepatitis B remained stable in the northern, eastern, and central regions (both *P*>.05; Figure 2B).

From 2004 to 2020, among all provinces, Xizang (AAPC=16.93, 95%CI 14.31-19.60) and Hunan (AAPC=10.52, 95% CI 7.91-13.20) experienced the most significant increases in hepatitis B incidence rates. Shaanxi (AAPC=−9.23, 95% CI −10.96 to −7.48), Chongqing (AAPC=−9.23, 95% CI −11.15 to −7.28), Beijing (AAPC=−9.05, 95% CI −15.36 to −2.26), Ningxia (AAPC=−9.84, 95% CI −11.37 to −8.28), Gansu (AAP=−8.31, 95% CI −12.63 to −3.77), and Zhejiang (AAPC=−8.43, 95% CI −11.25 to −5.52) saw a rapid decrease in hepatitis B incidence rates. The incidence rates of hepatitis B in other regions exhibited a stable trend (Figure 2C and Table 1).

Age-Period-Cohort Model

Age Effect

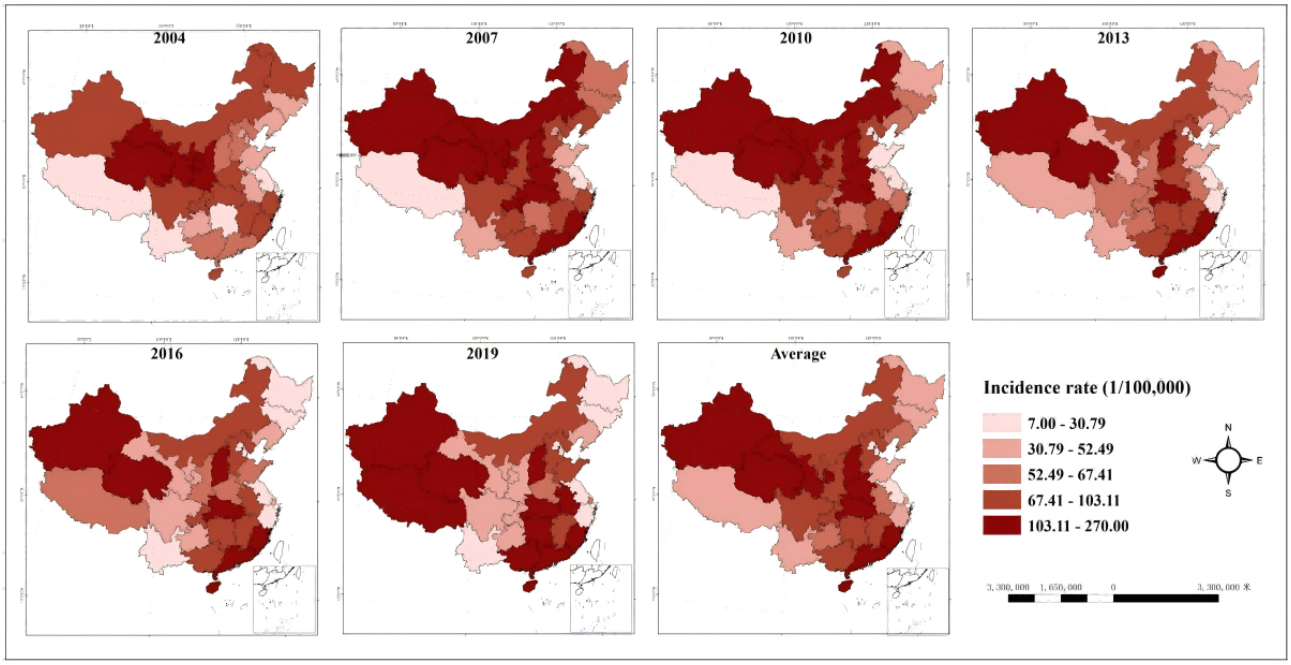
APC model analysis indicates that the majority of hepatitis B cases occur in adults, with the incidence rate exhibiting fluctuations across different age groups. The incidence rate increased from childhood to adolescence. At the age of 22 years, the incidence rate of hepatitis B reached its peak, with an average incidence rate of 176.173/100,000. Subsequently, it began to decline, remained relatively stable in middle age, and slightly increased in old age (Figure 3A).

Figure 3. Average annual percentage change model of hepatitis B incidence rate in China from 2004 to 2020: (A) longitudinal age curve; (B) period rate ratio; (C) cohort rate ratio. RR: relative risk.

XSL•FO
RenderX

Period Effect

After adjusting for age and cohort effects, the relative risk (RR) value for the period effect of hepatitis B incidence rate from 2004 to 2020 exhibited a trend of initially decreasing and then increasing. Using 2011 as the reference period (RR=1), the peak incidence rate of hepatitis B was observed between 2004 and 2006, with an RR value of 1.14 (95% CI 1.03-1.25). Subsequently, the RR value for the period effect on the incidence rate of hepatitis B exhibited a decreasing trend, with the RR value for the incidence rate of hepatitis B during the period from 2011 to 2016 being 0.81 (95% CI 0.74-0.9). The RR value of hepatitis B incidence from 2016 to 2020 was 0.84 (95% CI 0.76-0.93), indicating a slight increase compared with the previous period (Figure 3B).



Cohort Effect

After adjusting for age and period effects, the cohort born in 1969 was set as the reference cohort (RR=1). From 1924 to 1974, the RR value of the cohort effect for hepatitis B in China exhibited an increasing trend, reaching its peak in 1974 with an RR value of 1.04 (95% CI 0.9-1.21). The RR value of the cohort effect for hepatitis B in China decreased after 1974, reaching its nadir in the 2019 cohort, with an RR value of 0.03 (95% CI 0.01-0.13; Figure 3C).

Spatial Distribution Characteristics of Hepatitis B in China From 2004 to 2020

Between 2004 and 2020, China witnessed significant regional disparities in the incidence rate of hepatitis B. The high-incidence regions of hepatitis B are primarily located in the northwest and central regions, while the incidence in the southwest and some parts of the eastern regions is gradually increasing over time. Among them, Qinghai (216.86/100,000), Xinjiang (170.21/100,000), and Gansu (130.23/100,000) exhibited the highest average incidence rate, whereas Jiangsu (18.56/100,000), Beijing (20.68/100,000), and Tianjin (23.54/100,000) had lower average incidence rate (Figure 4).

Figure 4. Spatial distribution characteristics of hepatitis B in China from 2004 to 2020.

Spatial Autocorrelation Analysis of Hepatitis B in China From 2004 to 2020

The global spatial autocorrelation analysis of hepatitis B incidence in 31 regions of China spanning from 2004 to 2020 revealed that the overall Moran's *I* values for the periods of 2004 to 2011 and 2020 were greater than 0, ranging from 0.1089 to 0.2084 (all $P<.05$), indicating a positive spatial autocorrelation. No significant spatial autocorrelation was observed from 2012 to 2019 (all $P>.05$; Table 2).

2018	0.1009	−0.0333	0.0058	1.7582	.079
2019	0.0999	−0.0333	0.0058	1.7432	.081
2020	0.1308	−0.0333	0.0058	2.1482	.032

The results of local spatial autocorrelation analysis indicate that low-low cluster regions are primarily located in Jilin and Liaoning in Northeast China, as well as Shandong in the eastern region. The high-low cluster regions have shifted from Xinjiang in the northwest to northern regions such as Inner Mongolia and Hebei. From 2004 to 2007, high-high cluster regions were primarily located in the northwest and southwest regions, specifically in Qinghai, Gansu, Ningxia, Sichuan, and Chongqing. After 2007, the high-high cluster regions phenomenon gradually dissipated in the northwestern region of China, except Ningxia. In 2013, Ningxia transformed from a high-high cluster region to a high-low cluster region, ultimately evolving into a region with no significant spatial clustering. Since 2015, Guangdong Province has transformed from a region with no significant spatial clustering to a high-high cluster region, whereas Xizang has shifted from a high-low cluster region to a high-high cluster region (Figure 5).

Discussion

Principal Findings

Using joinpoint regression analysis, the APC model, and spatial autocorrelation analysis, this study delves into the epidemic characteristics and spatial distribution patterns of hepatitis B in China from 2004 to 2020. The findings offer valuable data support and theoretical insights for comprehending the evolving epidemic trends of hepatitis B among Chinese residents and formulating targeted prevention and control strategies accordingly.

The study findings revealed that the overall incidence rate of hepatitis B in China exhibited a decreasing trend between 2004 and 2020, with a decrease from 70.5/100,000 in 2004 to 64.29/100,000 in 2020. This indicated that the prevention and control measures for hepatitis B in China from 2004 to 2020 had yielded certain positive outcomes, which align with the findings of other studies [17]. According to the results of joinpoint regression analysis, the incidence rate of hepatitis B in China exhibited an increasing trend between 2004 and 2007, subsequently experienced a decreasing trend, and ultimately stabilized after 2014. Since 2007, the incidence rate of hepatitis B decreased, primarily attributed to the neonatal hepatitis B vaccination program that was launched in China in 1992 [18,19]. Furthermore, China has been offering free hepatitis B vaccinations to newborns since 2002, significantly reducing the risk of hepatitis B infection among newborns. A study revealed that the hepatitis B vaccination coverage among individuals aged 1 to 59 in China increased significantly, escalating from 54.1% to 78.9% between 2006 and 2024 [20]. According to a study on the global burden of disease, the positive rate of HBsAg in China has undergone a significant decrease, decreasing from 11.9% in 1990 to 8.4% in 2015, and further decreasing to 7.8% in 2019 [7]. These data provide further evidence of China's significant advancements in the prevention and control of hepatitis B.

The APC model-based analysis of age effects revealed that the risk of hepatitis B is relatively low in childhood, rises during adolescence, peaks at age 22, and exhibits a decreasing trend in older adulthood. The increased incidence rate among young adults may be attributed to high-risk sexual behaviors (such as unprotected sex and multiple sexual partners), unhealthy lifestyles (including excessive stress, staying up late, alcohol abuse, and smoking), and specific occupational exposures [21,22]. The increased risk of hepatitis B in the elderly is significantly influenced by the low coverage of hepatitis B vaccination in this population. A study exploring the factors influencing hepatitis B vaccination coverage highlighted a negative correlation between vaccination coverage and age, which is likely linked to the national hepatitis B immunization program for newborns and infants instituted by the Chinese government in 1992 [23]. In addition, the decrease in immune function among the elderly further heightens their susceptibility to hepatitis B infection [24]. In terms of period effects, the highest hepatitis B incidence rate in China during 2004 - 2020 was observed between 2004 and 2006. Cohort analysis indicated that individuals born between 1924 and 1974 exhibited an increased trend in hepatitis B incidence risk, whereas a decreased trend was observed among those born after 1974. These shifts in period and cohort effects can be attributed to factors such as the widespread adoption of hepatitis B vaccines, advancements in medical technology, increased public awareness of hepatitis B prevention, and changes in lifestyle habits [25]. Therefore, an in-depth discussion of the age, period, and birth cohort effect of hepatitis B can not only help to locate the high-risk population of hepatitis B, but also provide important references for the formulation of public health policies in the future, to more effectively control the spread and risk of hepatitis B.

The overall incidence rate of hepatitis B in China exhibited a decreasing trend from 2004 to 2020, albeit with regional variations in its trajectory. Specifically, the northeastern and northwestern regions observed a decrease in hepatitis B incidence. Notably, the northwestern region experienced a steeper decrease in hepatitis B incidence rate compared with the northeastern region. However, the northwestern region consistently maintained a relatively high incidence rate, particularly in Qinghai, Xinjiang, and Gansu, where the average incidence rate from 2004 to 2020 ranked among the highest nationwide. This high incidence rate can be attributed to various factors such as geographical conditions, sluggish economic development, scarcity of medical resources, and varying levels of health literacy among residents [12]. Contrastingly, the southern and southwestern regions witnessed an increased trend in hepatitis B incidence. This increasing trend in the southern region is likely associated with factors like frequent population movements, uneven distribution of health care resources, and geographical considerations. Given the dense and mobile population in the southern region, disparities in health literacy, access to health care resources, and vaccination coverage among the mobile population may contribute to the widespread transmission of the HBV in this region. In addition, the humid and hot climate prevalent in the southern region may facilitate the easier spread of hepatitis B [26]. In addition, Liang et al [27] showed that some alleles are closely related to HBV infection. There are obvious differences in genotype distribution between southern and Northern Chinese populations. The difference in genetic background may be a potential factor for Southern Chinese populations to be more susceptible to hepatitis B. Simultaneously, the increasing incidence rate in Southern China in recent years can also be partially attributed to the enhanced quality of hepatitis B case reporting, which has significantly reduced previously overlooked cases [12,28]. The swift increase trend observed in Southwest China is primarily attributed to the rapid incidence rate in Xizang. Located on the southwestern border of China, the Xizang, owing to its vast territory, sparse population distribution, and inconvenient transportation, lags behind other provinces in immunization planning. Consequently, Xizang has consistently been identified as a high-prevalence area for hepatitis B [29].

Through global spatial autocorrelation analysis, this study revealed the spatial distribution characteristics and evolving trends of hepatitis B incidence in 31 regions of China from 2004 to 2020. The findings of the global spatial autocorrelation analysis indicated that there was a significant clustering of

XSL•FO
RenderX

hepatitis B incidence rate in China during the periods of 2004 - 2011 and 2020. These cluster regions could potentially be attributed to socioeconomic disparities, the distribution of medical resources, varying health conditions, and the implementation of preventive measures across different regions [30]. Based on the data from 2012 to 2019, no significant spatial autocorrelation was evident, indicating a more randomized geographical distribution of hepatitis B during this period and a narrowing of incidence rate disparities among regions. These changes may be attributed to the full implementation of "China's viral hepatitis prevention and control plan (2012 - 2020)" for gradually reducing the differences in hepatitis B prevalence between regions, as indicated by the high overall hepatitis B vaccination rate for newborns, which has been maintained at >90%; the popularization of hepatitis B prevention and control knowledge among the population; and the effective construction of the population immune barrier.[31].

Local spatial autocorrelation analysis has further illuminated the clustering patterns of hepatitis B incidence rates across diverse regions. Specifically, certain regions in the eastern part of the northeast exhibit low-low cluster regions, whereas regions in the northwest demonstrate high-low cluster regions. According to the findings of Ren et al [32] on the allocation of medical and health resources in China's provinces from 2010 to 2021, there has been an increasing trend in medical and health resources, and the allocation has essentially achieved parity in terms of quantity. However, high-quality medical and health resources in China are heavily concentrated in the eastern region, which may further explain the disparities in the spatial pattern of hepatitis B incidence among regions. Between 2004 and 2007, northwest and southwest regions, including Qinghai, Gansu, Ningxia, Sichuan, and Chongqing, exhibited high-high cluster regions. Nevertheless, this spatial aggregation gradually dissipated in 2007. This shift could be attributed to significant progress made in hepatitis B prevention and control efforts in these regions, leading to changes in the spatial clustering pattern of the disease. Since 2015, Guangdong and Xizang have transformed from areas with nonsignificant spatial cluster regions to high-high cluster regions. This transformation is likely linked to population movements, economic development, and improvements in health conditions in these regions. As an economically developed region, Guangdong Province has frequent population mobility, which is an important reason for increasing the risk of hepatitis B transmission [33]. However, due to the improvement of health conditions, the increase of medical resources, and the improvement of diagnostic levels in Xizang, the detection and reporting of hepatitis B is more accurate, thus showing a high-high clustering phenomenon [29].

This study offers fresh perspectives on the epidemic trends and spatial clustering patterns of hepatitis B in China, serving as a scientific foundation for developing targeted prevention and control measures. Future research should delve deeper into the factors influencing the variations in hepatitis B incidence rates across different regions, as well as explore more effective strategies for implementing preventive measures, particularly in regions with high incidence rates or evident increase trends. Concurrently, it is imperative to enhance vaccination and health education efforts targeting adults to mitigate the occurrence of hepatitis B.

This study has several limitations in analyzing hepatitis B surveillance data in China, which are worthy of further discussion. First of all, this study was limited to the analysis of the incidence of hepatitis B in China for 17 years (2004 to 2020) and failed to explore the influencing factors of the incidence of hepatitis B. In the future, a longitudinal research design should be considered to systematically assess the impact of various potential factors on the incidence rate of hepatitis B. Second, due to the limitations of data and methods, this study failed to fully analyze the differences between genders, differences between occupations, differences between urban and rural areas, and other factors that influence the incidence rate of hepatitis B in China. Therefore, future research should further improve the data and conduct a hierarchical analysis of these factors, to identify high-risk groups and develop targeted interventions. In addition, although economic factors, population density, medical service level, and medical resource allocation have an impact on the spatial clustering of hepatitis B, the impact of these factors on the regional incidence level still needs further research.

Conclusions

From 2004 to 2020, China witnessed a decrease in the overall incidence rate of hepatitis B, indicating remarkable progress in its hepatitis B prevention and control efforts. Nevertheless, challenges persist in specific populations and regions. Therefore, it is imperative to maintain vigilance in hepatitis B prevention and treatment, in addition to enhancing health education initiatives. Further, given the disparities in age and geographical distribution, efforts must be intensified to identify and screen high-risk groups and promote supplementary vaccination programs for adults. These comprehensive measures will alleviate the health burden of hepatitis B on the population, enhance the overall standard of healthy living, and establish a robust scientific foundation for the ongoing prevention and control of hepatitis B in China.

Acknowledgments

The authors would like to thank the Chinese Center for Disease Control and Prevention for sharing the valuable data, the fifth National Comprehensive Prevention and Control Demonstration Zone for AIDS (NO. State AIDS Office Letter [(2023) No. 4]), the Key Laboratory for Major Infectious Disease Monitoring in the Northern Xinjiang Area of the Corps (N0.2024PT01), and the Corps Guiding Science and Technology Program Project (N0.2024ZD026).

Abstract

Background: Mortality from external causes is a major public health issue globally, with significant impacts on both lives and economies. In Brazil, external cause mortality has shown spatiotemporal variations across regions, influenced by social, economic, and demographic factors.

Objective: This study aimed to examine the spatiotemporal dynamics of mortality from external causes in Brazil for 23 years (2000 - 2022), identifying patterns across regions and demographic groups and assessing the major contributing causes of death.

Methods: This ecological study used data from the Brazilian Mortality Information System (SIM) and used joinpoint regression to analyze temporal trends, Moran I for spatial analysis, and Poisson scanning statistics for spatiotemporal patterns. A total of 3,240,023 deaths were analyzed, with specific attention given to regional and demographic disparities.

Results: The study found that mortality from external causes remained significant, with men and young adults (20 - 39 years) having the highest rates of death. The main causes of death were assaults (36.61%), transport accidents (26.55%), falls (7.83%), and self-harm (7.43%). Despite an overall decrease in mortality, increases were observed in the North and Northeast regions and among the older adults. High-risk areas were predominantly located in the North, Northeast, and Central-West regions. The mortality trends varied by region, with significant differences in risk across the country.

Conclusions: Although there was a general reduction in mortality from external causes in Brazil, this trend was not uniform across all regions. The North, Northeast, and Central-West regions showed the highest mortality risks, with men and young adults being the most affected demographic groups. These findings emphasize the need for targeted public health interventions that address the regional and demographic disparities in mortality from external causes.

Introduction

Mortality from external causes represents one of the main global public health problems. This phenomenon encompasses both unintentional events, such as traffic accidents, drownings, and falls, as well as intentional events, resulting from injuries caused by different forms of violence, such as suicide, homicide, femicide, and others [1]. Notably, these causes are impactful not only because of the number of lives lost but also due to the high socioeconomic burden they impose on countries and the negative consequences for affected families and health systems [1,2].

According to data from the World Health Organization (WHO), more than 4 million people die annually from external causes worldwide (about 8% of all global deaths) [1,3]. The WHO estimates that 29% of these fatal outcomes result from traffic accidents, 16% from suicides and falls, and 11% from homicides. Furthermore, teenagers and young adults aged 15-29 years are the most affected [3].

In Brazil, external causes constitute a significant issue in national mortality rates and represent substantial challenges to the national health system, being one of the major causes of disability and premature mortality [4,5]. In 2021, deaths from violence and accidents accounted for approximately 8% of all deaths across the country, ranking as the fourth leading cause of mortality, with particular emphasis on homicides and transport accidents, which together were responsible for more than 50% of deaths related to external factors in Brazilian territory [5].

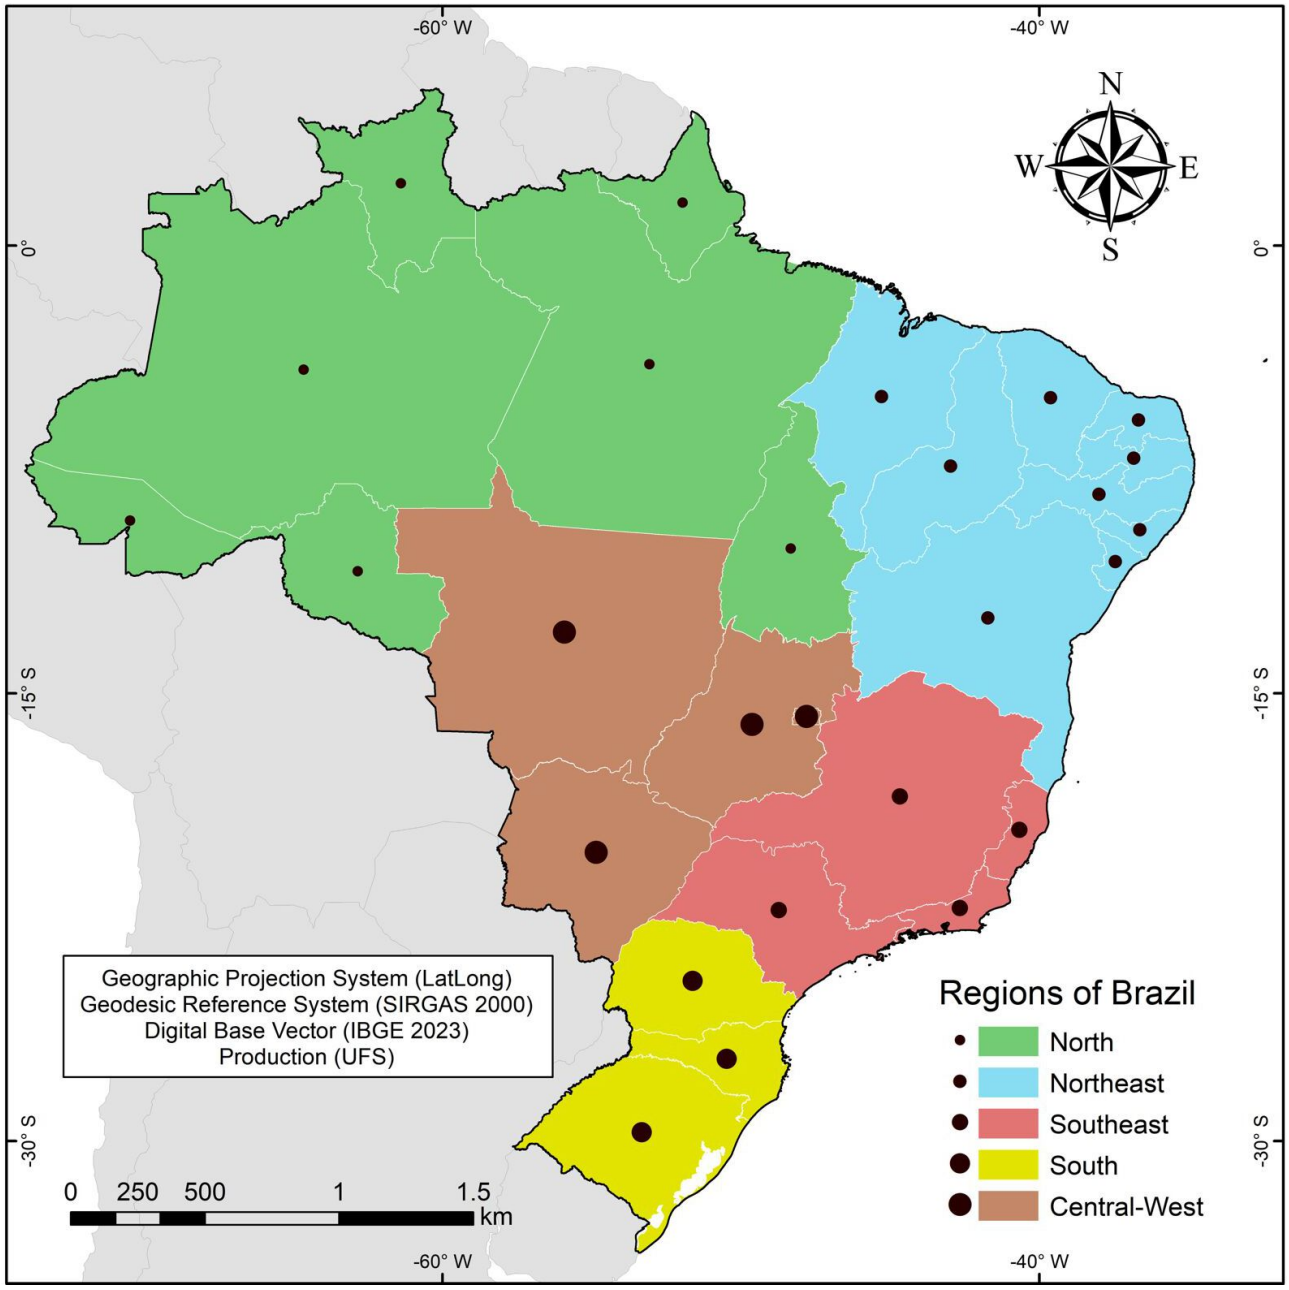
Despite the significant socioeconomic impacts of accidents and violence worldwide, certain population groups and regions are more vulnerable [6,7]. Mortality patterns from external causes can be influenced by social, economic, and demographic determinants, such as income, age structure, the level of socioeconomic inequality, and the presence and efficiency of public policies in the areas of education, health, and safety [1,8]. In this context, deaths from external causes are not evenly distributed across Brazil and may present marked spatial heterogeneity across regions of the country [7,9,10]. This is due to Brazil's complex reality, which is manifested through distinct geographic, cultural, political, and socioeconomic characteristics, creating different mortality patterns throughout the country [11].

Importantly, in 2011, the Brazilian Ministry of Health launched the Strategic Action Plan to Combat Chronic Noncommunicable Diseases (NCDs) (2011 - 2022), with emphasis on effective, integrated, and sustainable strategies for the prevention and control of noncommunicable diseases and their risk factors. Nevertheless, as the plan's end year approached (in 2019), the Brazilian Ministry of Health began preparing a new document that reaffirmed and expanded the established proposals. The DANT Plan (Strategic Action Plan to Combat Chronic Diseases and Non-Communicable Diseases in Brazil, 2021 - 2030) also included external causes of death. This collective effort is part of the health agenda for the next 10 years, in line with the 2020 - 2030 Agenda on Sustainable Development Goals. The goals aim to reduce the mortality rate from traffic injuries by 50%, reduce the homicide mortality rate by one-third, and halt the growth of mortality from suicides and fall-related deaths among older adults in Brazil by 2030 [2].

In this regard, combating deaths from external causes requires a range of approaches that strengthen prevention and control strategies in Brazil. Therefore, spatial analysis techniques using geographic information systems are fundamental tools [12], as they provide a better understanding of the spatial dynamics of violent and accidental incidents, identifying high-mortality areas that require priority investment for effective interventions and public policies that consider the health realities of each region. This study aimed to analyze the spatiotemporal dynamics of mortality from external causes in Brazil and its regions for 23 years.

Methods

Type and Study Design



An ecological and population-based study was conducted using spatiotemporal analysis techniques. The study encompassed all deaths related to external causes in Brazil from 2000 to 2022. This time frame was established because, starting in 1999, Brazil adopted a new version of the Mortality Information System (SIM), which introduced an updated death certificate (DC). This update improved data recording, with more detailed completion of the DC [13]. When the data were collected for this study, the numbers of deaths from external causes were only available up to 2022. The 5 regions of the country and their 5570 municipalities were considered for all analyses.

Study Area

Brazil is located in South America, being the largest country on the continent, with a territorial area of 8,515,767.049 km². The Brazilian population is approximately 203 million inhabitants. The country is politically and administratively divided into 27 federative units (26 states and 1 federal district), with the capital city being Brasília. For political and operational purposes, the federative units are grouped into five regions (North, Northeast, Southeast, South, and Central-West) with distinct geographic, socioeconomic, and cultural characteristics [11] (Figure 1).

IBGE: Instituto Brasileiro de Geografia e Estatística; LatLong: latitude and longitude; SIRGAS: Sistema de Referência Geocêntrico para as Américas; UFS: Universidade Federal de Sergipe.

Data Source

Data regarding deaths from external causes were collected from the Brazilian SIM. The SIM plays a fundamental role in the process of collecting, storing, and managing death records in the country, using the DC as a standard document, which is a form filled out by medical professionals for all deaths occurring in Brazil. It is important to highlight that SIM data are in the public domain and available for access on the website of the Department of Informatics of the Unified Health System. For data acquisition, codes V01 to Y98 from the *ICD-10* (*International Statistical Classification of Diseases and Related Health Problems, Tenth Revision*) were used.

In addition, population data were obtained from the Brazilian Institute of Geography and Statistics, based on information from the Brazilian population censuses conducted in 2000, 2010, and 2022, as well as intercensal population estimates for the years 2001 - 2009 and 2011 - 2019 [12]. The digital cartographic mesh of Brazil (divided by states and regions), based on the Geographic Projection System in shapefile format (Geodesic Reference System, SIRGAS/2000), was extracted from the Brazilian Institute of Geography and Statistics website for the preparation of spatial analysis maps.
