The demographic characteristics included age and geographical region, categorized as Seoul (the capital), other metropolitan cities, and smaller cities or rural areas. Work-related characteristics included hospital size (number of beds); job position (manager or head nurse and charge or staff nurse); and work unit (special unit, general ward, or delivery room).

Psychological Variables

Four scales were used to measure the psychological variables: depression, stress, fatigue, and sleep. Depressive symptoms were measured using a nine-item, 4-point Likert scale from the Patient Health Questionnaire [27]. Possible scores range from 0 to 27, with higher scores indicating more severe depressive symptoms. On the basis of a previous study, a cutoff score of 10 was used for no to mild and moderate to severe symptoms [27]. Its sensitivity and specificity were 88% [27]. In this study, the Cronbach α was 0.892. Stress was measured using the Perceived Stress Scale (PSS)-4 [28], which consists of four 5-point Likert-type items. The possible scores range from 0 to 16, with higher scores indicating higher stress levels. The cutoff scores were determined based on the literature, and the top tertile of the scores (≥11) was categorized as *high stress*, with the other tertiles considered as *low stress* [29]. The PSS-4 has been confirmed to be reliable and valid compared to the original 14-item PSS [28]. Cronbach α was 0.691. Fatigue was measured using the Chalder Fatigue Scale [30], which comprises 11 items rated on a 4-point Likert scale. The possible scores range from 0 to 33, with higher scores indicating higher levels of fatigue. Scores between 0 and 16 were categorized as low, those between 17 and 21 as moderate, and those above 22 as high fatigue [30]. In this study, Cronbach α was 0.918. Sleep disturbance was measured using the Jenkins Sleep Questionnaire [31], which evaluates sleep problems during the preceding 4 weeks. This scale comprises 4 items rated on a 6-point Likert-type scale. Scores range from 0 to 20, with higher scores indicating greater sleep disturbance. On the basis of the cutoff point of 12 or more, which indicates severe sleep problems, participants were classified into groups with little sleep disturbance and those with high frequency of sleep disturbance (<12 and ≥12) [31]. In this study, the Cronbach α was 0.875. The collinearity of the 4 psychological variables was tested using the Pearson correlation coefficient (r<0.4 for all 4 psychological variables).

Survey-Related Characteristics

Survey-related characteristics included 3 items: time spent on survey completion, usability of the survey website, and overall impression of the survey website. Time spent completing the survey was categorized as <15 minutes, 15 to 30 minutes, and ≥30 minutes. Usability and overall impressions of the survey website were assessed using end-of-survey questions, such as "What is your overall impression of this survey website?" and "What was your experience using the survey website?" The responses were categorized as unsatisfactory, neutral, or satisfactory.

Data Analysis

Descriptive statistics were used to examine nonresponse rates and factors. Chi-square tests were used to compare the respondent and nonrespondent groups using initial survey data. A fully adjusted logistic regression model with available variables from the initial survey was used to identify factors associated with nonresponse. Missing data were excluded from analyses involving these variables. SPSS software (version 29; IBM Corp) was used for statistical analysis.

Ethical Considerations

For the initial survey in 2013 and the follow-up surveys until 2015, the institutional review board of the National Institute of Health in Korea reviewed and approved the study (#2013-03CON-03-P, 2014-05EXP-01-1C-A, 2014-08EXP-01-2C-A, and 2015-05-EXP-04-3C-A). For the follow-up surveys conducted in 2016, the Ewha Womans University Institutional Review Board reviewed and approved the study (#117-4, EWURB-17-3.0-20170901, ewha-201904-0012-01, ewha-201904-0012-09, ewha-201904-0012-12, and ewha-201904-0012-15). The Korea Nurses' Health Study survey instrument was meticulously designed by integrating questions from various validated sources to ensure comprehensive coverage of relevant topics. The quality of the survey was ensured through a rigorous pilot testing phase with nurses and expert groups to verify the clarity, relevance, and logical sequence of the questions. This process helped identify and rectify potential issues, such as redundancy and omission of important inquiries. No essential items from the original tools were omitted during the integration of questions from multiple sources. In cases where redundancy was identified, questions were asked only once to streamline the survey without compromising its psychometric properties. The questionnaire construction and refinement of the Korea Nurses' Health Study have been described in greater detail elsewhere [6]. The participants provided informed electronic consent before participating in the baseline and follow-up surveys. The participants were informed of the research purpose, anonymity, and confidentiality. All data were fully deidentified before analysis, with access restricted to authorized investigators through secure servers in compliance with Korea Nurses' Health Study data protection policies. Individual-level information was neither disclosed nor reported. Beverage vouchers were provided as an incentive.

Results

Overview

The nonresponse rates of the participants in the Korea Nurses' Health Study are shown in Table 1. Participants from the baseline survey (N=20,613) were contacted for the follow-up surveys. The nonresponse rate varied between 25.5% (5258/20,613; second survey) and 61.2% (12,620/20,613; sixth

XSL•FO
RenderX

survey), with the sixth survey having the highest nonresponse rate.

Table 1. Nonresponse rate of the Korea Nurses' Health Study participants (first survey: N=20,613)

Survey number	Nonresponding participants, n (%)
2	5258 (25.5)
3	7765 (37.7)
4	9963 (48.3)
5	9086 (44.1)
6	12,620 (61.2)
7	11,955 (58.0)
8	10,360 (50.3)
9	9957 (48.3)
10	10,503 (51)
11	10,357 (47.9)

Comparison of Respondent and Nonrespondent Groups

Differences between the respondent and nonrespondent groups from the second to the eleventh survey were compared based on participant characteristics from the first survey (Multimedia Appendix 1). In the initial survey, most participants were in their 20s (12,059/20,613, 58.5%) with a mean age of 29.4 (SD 5.9) years. All participants worked in hospitals, and 45.2% (9316/20,613) held a bachelor degree [13]. Age, education, stress, and perceived usability of the survey at baseline were found to be statistically different across the follow-up surveys, up to the 11th survey. Overall impressions of the survey website at baseline differed significantly in all follow-up surveys except the second. Nurses dissatisfied with the usability of the survey responded more to the second to fourth surveys than satisfied nurses, and nurses dissatisfied with the overall survey responded more to the third and fourth surveys. Geographical region and fatigue level in the baseline survey differed significantly between the respondent and nonrespondent groups up to the seventh survey. Hospital size at baseline was significantly associated with the response status in the fifth survey. The working units significantly differed until the third survey was conducted.

Factors Affecting Nonresponse

A fully adjusted logistic regression analysis was performed to identify the factors associated with nonresponse in the follow-up surveys (Tables 2 and 3). Age, education level, and perceived usability of the survey website at baseline were significant factors that showed a consistent association with nonresponse throughout the 11th survey. In the third survey, nurses in their 20s were less likely to respond compared to those in their 30s (odds ratio [OR] 0.93, 95% CI 0.87-1.00); this association remained significant in all surveys through the 11th, except the second. In the second survey, nurses with an associate degree were less likely to respond than those with a bachelor degree (OR 0.84, 95% CI 0.79-0.91) or a master degree or higher (OR 0.75, 95% CI 0.64-0.88); this pattern remained significant through the 11th survey. Nurses who reported neutral feelings about the usability of the survey website were more likely not to respond in the second survey compared to those who perceived the survey website to be useful in the second survey (OR 0.90, 95% CI 0.81-0.99), and this association was consistently significant until the 11th survey.

The association between geographical region and hospital size lasted until the fifth and sixth surveys. In the second survey, nurses working in Seoul were more likely to respond compared to those working in metropolitan areas (OR 1.16, 95% CI 1.06-1.27) and other regions (OR 1.17, 95% CI 1.08-1.27). This association remained consistently significant until the sixth survey was conducted. Nurses who worked in hospitals with more than 300 beds were less likely to respond to the second survey compared to their counterparts (OR 1.40, 95% CI 1.29-1.52); this association was consistently significant until the fifth survey.

Age at baseline was a significant factor for nonresponse throughout the follow-up surveys, except for the second survey. Nurses in their 30s were less likely to be nonrespondents than those in their 20s in the third survey (OR 0.93, 95% CI 0.868-0.999), and this was consistently significant up to the 11th survey (OR 0.82, 95% CI 0.764-0.875).

RenderX

Geographical region was significantly related to nonresponse until the seventh survey, and hospital size was significant until the fifth survey. In the second survey, nurses working in metropolitan cities (OR 1.16, 95% CI 1.06-1.27) and other areas (OR 1.17, 95% CI 1.08-1.27) were more likely to be nonrespondents than those working in Seoul. This was consistently significant up to the sixth survey in other areas (OR 1.13, 95% CI 1.04-1.21) and up to the seventh survey in metropolitan cities (OR 1.09, 95% CI 1.01-1.17). Nurses working in hospitals with fewer than 300 beds were more likely to be nonrespondents than their counterparts in the second survey (OR 1.40, 95% CI 1.29-1.52), which was consistently significant up to the fifth survey (OR 1.15, 95% CI 1.07-1.24).

Psychological factors, including fatigue, stress, and sleep disturbance, were significant non–response-related factors in some follow-up surveys, but did not show consistency across follow-up surveys.

Finally, it has been reported that the demographic characteristics of participants, such as gender and ethnicity, may influence their responses to cohort studies [17]. However, the Korea Nurses' Health Study participants comprised only female Korean nurses, leaving little room to explain the influence of gender and ethnicity on nonresponse in community-based cohort studies and future studies.

Discussion

Principal Findings

In this study, we reported the nonresponse rate and associated factors for more than 10 follow-up surveys. Our findings are crucial for informing future research on the factors that should be considered when designing and recruiting cohort studies, especially for women and nurses. Cohort study results should be interpreted carefully, considering random nonresponse factors. Thus, researchers must report nonresponses that occur during the study period when synthesizing studies using quality evaluation to provide a high level of evidence [32].

As of March 2025, the ongoing Korea Nurses' Health Study has conducted more than 10 follow-up surveys, with nonresponse rates ranging from 25% (5258/20,613) to 61% (12,620/20,613) and averaging around 50% (10,306/20,613). Unexpectedly, nonresponse peaked at the sixth survey from September 2017 to September 2019, although there was no change in the recruitment method. This may be attributed to reduced promotional activities following a change in the managing research institution in 2018. After the change in the research institute, we started the seventh survey and focused on promotional activities to increase response rates.

In this study, the age and education level of the nurses and the perceived usability of the survey website from the baseline survey were nonresponse factors throughout the 11th follow-up survey. Fewer nurses in their 20s at the baseline survey responded to the follow-up surveys than those in their 30s. This may be related to career stability and professional confidence, which often increase with experience [33-35]. Conversely, younger nurses may face greater challenges when transitioning from student to professional nurses [36,37], considering that the mean age of newly graduated nurses is 24.7 years in Korea [38], which is much younger than the 29 years in the United States [39]. Notably, nurses aged more than 40 years did not show significantly different nonresponse rates from those in their 20s, indicating that factors other than age, such as career development, leadership roles in the organization, and life-work balance, may influence survey response at follow-up. These findings suggest the need for supportive strategies tailored to different career stages to enhance participation in longitudinal studies.

Consistent with previous studies [25,40-43], educational level was associated with nonresponse. Nurses with associate degrees were less likely to respond to follow-up surveys than those with higher education levels. Targeting more participants with less education may be a strategy for retaining this group in follow-up surveys of cohort studies. Contrary to our findings, 1 longitudinal study that investigated nonresponse to follow-up surveys among an aging population did not report education as a factor related to nonresponse [26]. However, the influence of education may not be applicable to older adults in cohort studies.

In addition, nurses working in hospitals with more than 300 beds and those located in Seoul were more likely to respond to the follow-up surveys through the fifth and sixth rounds, respectively, compared to their counterparts. Most large hospitals are located in Seoul, and university-affiliated hospitals and large corporation-operated hospitals may have more professional and systematic organizational support for nurses [44,45], which might have influenced their value in health research. However, because nurses may change their jobs or relocate, baseline information on location and workplace may not retain its predictive value in later follow-ups.

Although the association between psychological factors, such as depression, stress, fatigue, sleep disturbance, and nonresponse in the follow-up surveys, was not consistent in this study, there is some evidence of psychological factors influencing the follow-up surveys in the literature. Studies have reported that experiencing stressful life events has been shown to result in lower subsequent follow-up responses [40], and respondents reported better subjective health and healthier lifestyle behaviors than nonrespondents [40,46]. Therefore, further systematic research on this topic is required.

Interestingly, the time taken to complete the survey was not a significant factor in nonresponse; rather, the perceived usability of the survey website was related to nonresponse. This suggests that participants were willing to return to the survey regardless of the length of time spent; however, technical issues in completing the surveys might be a barrier to participation in future research. The presentation of survey websites is an important but often overlooked part of data collection, as it can influence not only the response rate but also the measurement error [47]. Researchers who use websites to deliver surveys in cohort studies should carefully consider the wording and display of questions, including question ordering, to increase the response rates [48].

Strategies for participant recruitment and retention in longitudinal research should be specifically developed to minimize the dropout risk. Current suggestions for designing

XSL•FO
RenderX

cohort studies focus on recruiting and maintaining retention while considering the education, age, and psychometric characteristics of registered nurses. Further research on ethnic minority groups [49] is required worldwide. The factors associated with the nonresponse rates in this study should also be considered when designing cohort studies involving women. As nonresponse rates differed according to demographic factors such as age, education, and geographical region, tailored strategies should be developed to lower the nonresponse rate of participants with specific demographic characteristics. Examples of these strategies include posting flyers in certain regions, such as small cities, retrieving participants, and advertising the research through social networking services to gain access to those who are younger and who do not live or work in metropolitan areas.

Limitations

The data were measured only at baseline, which limited the ability to assess the influence of geographical location changes over time, such as participants moving from Seoul to metropolitan or urban areas in subsequent survey waves. Furthermore, the statistical analysis of confounding variables may yield further information regarding nonresponse. We could not identify participants who died during the follow-up period. However, participants who had left the nursing profession were included because this study focused on women's health rather than their professional roles. In addition, 3 to 3.7% of participants could not be reached due to lost contact information.

Conclusions

The nonresponse factors identified by the Korea Nurses' Health Study during the 10-year follow-up survey were age, education, and comprehensive feelings about the survey. We suggest that future research examine the extent of nonresponse bias and its potential impact on the observed associations to further enhance the validity and reliability of the findings. The implementation of weighting methods to account for nonresponse may also be considered in subsequent analyses. Customized strategies that reflect these factors should be developed and tested in future studies to increase follow-up survey response rates.

Acknowledgments

The authors would like to thank all the nurses who completed the survey and made this study possible. This study was funded by the Korea Disease Control and Prevention Agency (grants 2016ER630500, 2016ER630501, and 2022ER0602-01).

Authors' Contributions

YTK conducted statistical analyses and drafted the manuscript. JHS contributed to the methods, results, and discussion sections. CC drafted the manuscript and handled the project administration, supervision, validation, and review. GB contributed to the results and discussion sections. BK was responsible for writing the introduction and methods sections. BMS, JYL, and HYP were involved in the project administration, supervision, validation, and review. All the authors wrote, reviewed, and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Interpersonal violence (IV) has an extensive and profound impact on health, representing a public health concern. Different health outcomes have been identified based on the characteristics of the survivor and the abuser, their relationship, the type of violence perpetrated, and the cumulative effect of multiple violent experiences.

Objective: The main objective of this study was to estimate the likelihood of negative health outcomes, such as substance abuse, mental health, and somatic disorders, occurring in adults presenting a clinical suspicion of IV.

Methods: We performed a retrospective, observational cohort study, using secondary data from electronic health records of adult patients of the Local Health Unit of Matosinhos (ULSM). The control cohort included all patients aged between 18 and 59 years followed at ULSM between January 1, 2008, and May 9, 2024, while the violence cohort included patients within the same age range who were suspected survivors of IV within the same time period. Exposure was defined by the presence of one or more of the IV text expressions or codes in the patient's electronic health record. Data regarding violence suspicion, comorbidities, and health outcomes were obtained by conducting a text search on clinical notes, as well as *ICD-9* (*International Classification of Diseases, Ninth Revision*) and *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision*) and International Classification of Primary Care 2 codes. The follow-up period was 10 years. To estimate the risk of developing health outcomes, we constructed a cohort model using a Cox proportional hazards model adjusted at baseline for age and sex.

Results: The control cohort included 154,145 patients, and the violence cohort included 36,835 patients. Suspected survivors of IV had a higher hazard ratio of developing alcohol abuse (3.05, 95% CI 2.87-3.24), drug abuse (6.03, 95% CI 4.5-8.06), suicidal ideation (5.50, 95% CI 4.78-6.32), major psychiatric disorder (4.46, 95% CI 4.38-4.53), chronic pain (3.70, 95% CI 3.60-3.81), sleep disorders (3.57, 95% CI 3.46-3.68), use of antidepressants (3.57, 95% CI 3.51-3.64), use of anxiolytics (2.98, 95% CI 2.93-3.03), and eating disorder (2.72, 95% CI 2.06-3.59). Regarding somatic health conditions, suspected violence exposure was linked to a higher hazard ratio for metabolic dysfunction–associated steatotic liver disease (6.91, 95% CI 6.37-7.50), chronic immune inflammatory disorder (3.68, 95% CI 3.93-3.44), asthma (2.64, 95% CI 2.53-2.74), chronic kidney disease (2.49, 95% CI 2.39-2.59), hypercholesterolemia (2.16, 95% CI 2.12-2.20), and early heart disease (2.01, 95% CI 1.93-2.10).

XSL•FO
RenderX

Conclusions: Exposure to violence was linked to a higher likelihood of developing adverse events related to substance abuse, mental, and somatic health. Our findings lead to a deeper understanding of the complex burden of violence on health, uncovering new relationships between IV and health outcomes while validating those already explored.

KEYWORDS

interpersonal violence; health outcomes; health risk behaviors; mental health; somatic health conditions; health care diagnosis

Introduction

The World Health Organization (WHO) defines violence as "the intentional use of physical force or power, threatened or current, against oneself, another person, or against a group or community, that either results in or has a high likelihood of resulting in injury, death, psychological harm, maldevelopment, or deprivation." Thus, it includes active and passive behaviors, mostly of a repetitive nature. It is present across every stage of life, regardless of sex, and in different sociocultural contexts and forms [1].

In Portugal, data from the National Institute of Statistics from 2023 shows that 20.1% of people aged between 18 and 74 years have been survivors of physical or sexual violence in adulthood. Women are primarily affected in the context of intimacy, while men are more often survivors of violence from nonpartners [2].

Interpersonal violence (IV) is no longer regarded only as a criminal justice matter. Its impact on health is extensive and profound, and it is recognized as a significant public health problem, which requires the attention of health care providers [1,3]. Overall, IV has short-, medium-, and long-term effects. In fact, they are not limited to immediate physical trauma but include physiological changes, psychological consequences, and coping strategies that may increase the risk of negative health outcomes, years or decades following the primary exposure [4-7]. There are several mechanisms behind these transformations, some happening in the first years of life [5,8-11]: (1) changes in the brain's white and grey matter, its volume and functional connective; (2) altered neurotransmitter metabolism; (3) changes in the neuroendocrine stress response; (4) chronic inflammation; (5) impaired glucose metabolism; (6) changes in the microbiome in response to stress; and (7) epigenetic mechanisms through DNA methylation. Many of these alterations seem related to the hypothalamic-pituitary-adrenal (HPA) axis, which integrates and coordinates the central and peripheral aspects of the mammalian stress response. Thus, violence exposure acts as a trigger and places survivors at high risk for the development of physical and mental health illnesses, as well as latent and genetically programmed diseases [5,7].

Several studies describe different health outcomes according to the survivor's and abuser's personal characteristics and their relationship, as well as the type of violence perpetrated. Intimate partner violence is shown to be related, for example, with mental health disorders (where genetics have a significant preponderance [11]), substance consumption, and somatic diseases, as obesity, metabolic syndrome, type 2 diabetes (T2D; due to increased cortisol levels and suppressed insulin levels [10]), hypertension (as a result of chronic activation of HPA axis, and autonomic nervous system [9]) among others [6,7,9-13]. Bullying and cyberbullying seem to be associated with depression, anxiety, and somatization symptoms [6]. Sexual abuse is found to be mainly related to depression, anxiety, suicide attempts, substance abuse, sleep disorders, gastrointestinal disorders, or nonepileptiform seizures [5,6,14]. Economic abuse is considered associated with increased depression, anxiety, suicidal ideation, and posttraumatic stress disorder [15].

Furthermore, it must be outlined that survivors of IV frequently experience multiple forms of it [6,16]. Experiencing or being exposed to one type of violence increases the risk of becoming a survivor of other types of violence or inflicting harm on others [17,18]. The association of different types of IV or its reiteration may result in different and potentially more severe negative impacts on health consequences [18,19]. This way, to understand the full burden of IV health outcomes, we should look to the cumulative effect of the multiple experiences of violence during the lifespan [18].

Ultimately, there are still associations to be unveiled and better understood that may revolutionize the approach to survivors. The better we understand the possible long-term outcomes of IV, the more capable doctors are to minimize the burden of violence on survivors' development and well-being.

The main objective of this study was to estimate the likelihood of negative health outcomes, such as substance abuse, mental health, and somatic disorders, occurring in adults presenting a clinical suspicion of IV. The study also aimed to establish the incidence of individuals with suspected exposure to violence followed in the Local Health Unit of Matosinhos (Unidade Local de Saúde de Matosinhos [ULSM]) and to characterize this population both demographically and according to prior clinical history.

Methods

Study Design and Setting

A real-world, retrospective, observational, and analytical cohort study was performed using data from electronic health records (EHR) of adult users of ULSM.

ULSM is a health unit that provides primary, secondary, and tertiary health care, being composed of 1 hospital and 14 primary care centers, serving a population of around 176.774 inhabitants.

The study's inclusion criteria for the violence cohort were: (1) patients aged between 18 and 59 years; (2) sought the ULSM service between January 1, 2008, and May 9, 2024; (3) having text expressions (according to predefined keywords, described

XSL•FO
RenderX

in Table 1) related to IV documented in the clinical notes or codes or at least one *ICD-9* (*International Classification of Diseases, Ninth Revision*) or *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision*) or an International Classification of Primary Care 2 (ICPC-2) IV-related code occurring after the age of 18 years (Table 1); and (4) having at least one appointment at ULSM in the 365 days before the index date. This last criterion was established to ensure the capturing of a population regularly followed at ULSM and to exclude sporadic visitors, such as tourists, thus increasing accuracy in the characterization of the local population.

The control cohort consisted of an incident population from ULSM, between 18 and 59 years old, who sought the ULSM service between January 1, 2008, and May 9, 2024, and had at least one appointment at ULSM in the previous 365 days before the index date.

No exclusion criteria were used in this investigation other than not meeting the inclusion criteria. Formal sample size calculations were not conducted, as the sample consisted of all the patients eligible according to the inclusion criteria.

The two study cohorts were not mutually exclusive; therefore, the same patient could enter the two cohorts at different times during the study period.

The index data corresponded to the date when each patient met all the cohort criteria. The patients' medical history, also described as prior outcomes, was evaluated using all records available in the preindex period. The follow-up period was 10 years (3650 days).

[b]ICD-9: International Classification of Diseases, Ninth Revision.

[c]ICD-10: International Statistical Classification of Diseases, Tenth Revision.

[d]ICPC-2: International Classification of Primary Care, 2nd edition.

Exposure and Outcome Definitions

Exposure was defined by the presence of one or more of the IV text-expressions or *ICD-9*, *ICD-10*, or ICPC-2 codes in the patient's EHRs described in Table 1.

Study Variables

The variable categories included in the study were (1) sex, (2) age, (3) health risk behaviors, (4) mental health disorders, and (5) somatic health conditions.

The health risk behaviors category included the following variables: (1) alcohol abuse and (2) drug abuse.

Mental health disorders encompassed (1) major psychiatric disorders, (2) posttraumatic stress disorder, (3) suicidal ideation, (4) chronic pain, (5) headache, (6) sleep disorders, (7) memory disorders, (8) eating disorders, and (9) psychotropic drug use (sedatives, antidepressants, anxiolytics, and antipsychotics).

Within the somatic health conditions category, the included variables were (1) T2D, (2) hypercholesterolemia, (3) metabolic dysfunction–associated steatotic liver disease (MASLD), (4) hypertension, (5) chronic kidney disease, (6) early heart disease, (7) asthma, (8) chronic inflammatory disorder, (9) cancer, and (10) unspecified illness.

All variables described above were used for cohort characterization, using all information available in the preindex period, within study dates.

The events used to estimate hazard ratios (HRs) included all of the health outcomes included in the categories "health risk behaviors," "mental health disorders," or "somatic health conditions" occurring up to 3650 days after the index date.

Statistical Analysis

Analysis was conducted through local execution of analytical programs developed using VERO technology that were compiled for ULSM target data infrastructure built upon Apache Spark Framework version 3.2.1 and source data harmonized according to the OMOP CDM 5.4 standard. The package implements a complete data engineering pipeline to transform the source data into the final dataset, as well as the execution of statistical analysis and the generation of results reports. Continuous variables were described using the average and SD, while categorical variables were expressed by absolute and relative frequencies. Age was analyzed as a continuous and a categorical variable. Patients were stratified into 10-year age categories in order to better characterize the age distribution of the study's population. To estimate the risk of developing health outcomes, we constructed a cohort model using a Cox proportional hazards model adjusted at baseline for age and sex. HRs were calculated with 95% CIs. Time at risk was calculated from the index date until the development of the outcome of interest. Patients were censored in case of leaving the database. Missing data were not imputed for any variables. Analysis was performed using only the available data.

Ethical Considerations

The Health Ethics Committee and Data Protection Officer of ULSM authorized the use of the database for this study, under approval codes 14/CES/JAS of 02-11-2022 and 04/CLPSI/2022 of 03-02-2022. Data processing and analysis were performed using analytical programs developed for this purpose that were sent for execution at ULSM servers. Researchers did not have access to patient-level data. Only aggregated data were shared with the researchers. No data extraction took place in the context of this study. Informed consent was waived by the institution, invoking public health and research interests, following the General Data Protection Regulation. No type of compensation was given to participants.

Results

Baseline Characteristics of Incident Population

The baseline characteristics of the control and suspected IV cohorts are described in Table 2.

The population on both cohorts was mostly female (83,636/154,145, 54.3% in the control and 23,521/36,835, 63.9% in the suspected IV cohort), average age was 32.7 (SD 23.6) in the control and 42.6 (SD 19.6) in the IV cohort.

Regarding patients' clinical history, there was a higher prevalence of both drug and alcohol abuse in the suspected IV cohort. The same was true for the major psychiatric disorders, chronic pain, sleep disorders, and the use of psychotropic drugs.

Regarding somatic health conditions, there was a higher prevalence of all studied conditions in the suspected IV cohort when compared to the control, with the biggest differences concerning cancer (1723/154,145, 1.1% in the control; 5704/36,835, 15.5% in the suspected IV cohort), hypertension (7131/154,145, 4.6% vs 13,343/36,835, 36.2%), and hypercholesterolemia (8401/154,145, 5.5% vs 13,819/36,835, 37.5%).

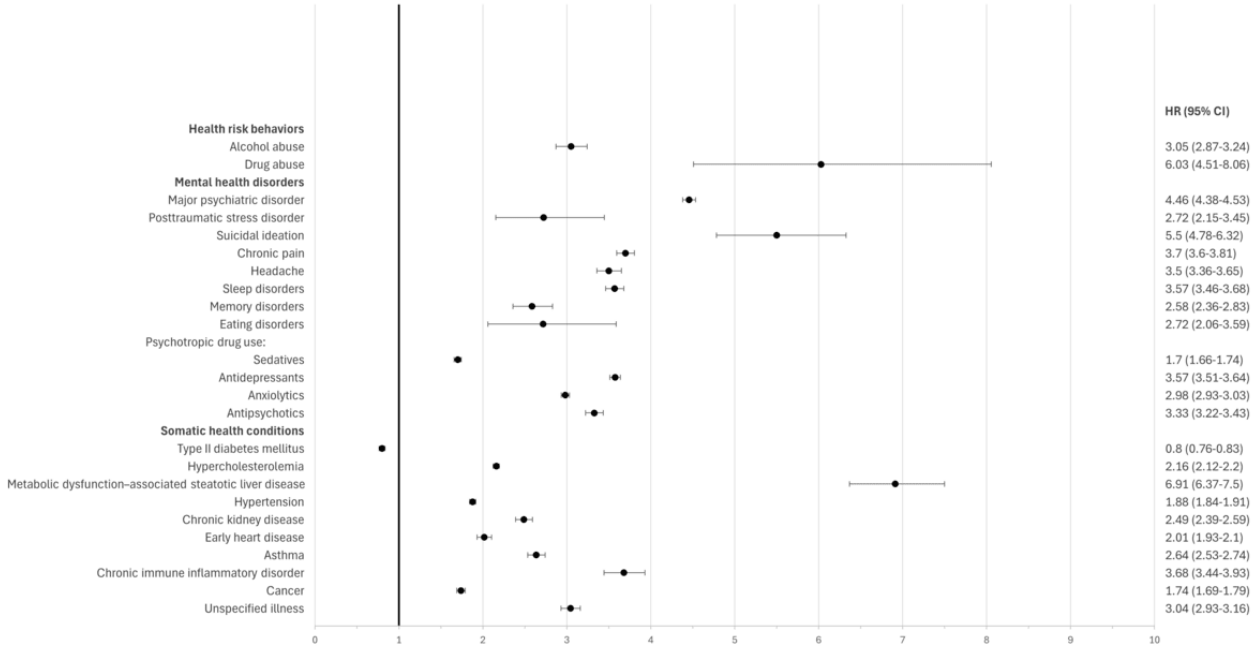
[b]IV: interpersonal violence.

Health Outcomes 10 Years After the Episode of Suspected Violence



The results obtained from the 3650-day follow-up after the index date are represented in Figure 1 and Table 3.

For every outcome studied, the follow-up period for adult survivors of IV was consistently shorter compared to other adults. The shortest follow-up periods were observed for the use of anxiolytics (mean 1064, SD 1151), major psychiatric disorder (mean 1227, SD 1257), and hypercholesterolemia (mean 1241, SD 1171).

Health outcomes did come up earlier in survivors of IV, compared to adults who were not survivors of IV. The shortest times to event occurred in early heart disease (mean 43, SD 127), T2D (mean 123, SD 294), and hypertension (mean 381, SD 532).

The violence cohort had a higher HR of developing the outcomes studied, except for T2D (0.80, 95% CI 0.76-0.83). The outcomes that stood out, as they presented the highest HR values, were fatty liver disease (6.91, 95% CI 6.37-7.50), drug abuse (6.03, 95% CI 4.5-8.06), suicidal ideation (5.50, 95% CI 4.78-6.32), and major psychiatric disorder (4.46, 95% CI 4.38-4.53).

Figure 1. Health outcomes up to 3650 days postindex in the suspected violence cohort. All patients were followed at the Local Health Unit of Matosinhos between January 1, 2008, and May 9, 2024, and were aged between 18 and 59 years.

Discussion

Principal Findings

The analysis of EHR data from adult users of ULSM revealed that patients who were suspected survivors of IV were more likely to develop negative outcomes when compared to the control cohort. This was true for the different health outcomes regarding health risk behaviors, mental health, and somatic conditions studied, except for T2D. In addition to reinforcing existing literature on the subject, we advanced a potential link between the experience of violence and the onset of MASLD.

We found that adult suspected survivors of IV were more likely to develop drug and alcohol abuse, respectively. This goes according to Rivara et al [6], Stubbs and Szoeke [12], Kyle [20], and Colaprico et al [21], which describe a relation between different types of IV and alcohol and substance use. Health risk behaviors, as substance abuse and alcohol abuse, may work as coping mechanisms to violence exposure [6,20,21], but it is important to note that this relationship is bidirectional. Substance abuse and worsened mental health may result in a higher risk of being a survivor of violence or inflicting harm on others [20].

According to WHO, “a mental disorder is characterized by a clinically significant disturbance in an individual’s cognition,

XSL•FO
RenderX

emotional regulation, or behavior" [22]. In this study, adult suspected survivors of IV were more likely to develop each of the mental disorders studied. This goes according to other studies, such as Rivara et al [6], which summarizes the relation between intimate partner violence and depression, posttraumatic stress disorder, suicidal ideation, and chronic mental illness. Kyle [20] and Stubbs and Szoeke [12] describe similar findings, adding anxiety disorders and eating disorders, respectively. In this study, suspected survivors of IV were more likely to develop memory disorders, which is consistent with findings described by Campbell et al [23].

Sexual abuse is also related to depression, anxiety, sleep disorders, suicide, eating disorders, and posttraumatic stress disorders, according to Rivara et al [6]. Bullying and cyberbullying in the youth and children population seem to be linked to depression, anxiety, self-esteem, posttraumatic stress disorder, sleep disturbances, and headache [6]. Colaprico et al [21] described a relation between workplace bullying in adults and disorders as anxiety, depression, suicidal tendencies, and headache.

Another finding of this study was the higher likelihood of the use of psychotropic drugs. This finding seems to be directly related to the type of mental health disorders developed and their comorbidities, as these drugs may be part of a treatment strategy to respond to them.

Literature describes correlations between IV in adults and various health issues, including cardiovascular diseases, hypertension, elevated cortisol levels, cancer, sexually transmitted infections, a higher risk of developing cancer, gastrointestinal disorders, such as irritable bowel syndrome, and asthma [5-7,12].

Lin et al [24] found that children exposed to adverse childhood experiences had higher risks of dyslipidemia, asthma, liver disease, kidney disease, and arthritis, similar to our findings in the adult population.

We found a potential link between adult IV and MASLD. This possible correlation with violence has not yet been described in the literature for the adult population. However, a recent cross-sectional study found a moderate risk in men for specific forms of child maltreatment [25]. Recent studies have focused on the relation between NALFD and mental health disorders. Shea et al [26] described in their systematic review a high prevalence of depression, anxiety, and stress among adults with MASLD. Kang et al [27] concluded that higher perceived stress was independently associated with an increased prevalence of MASLD. Soto-Angona et al [28] have also come to the conclusion that MASLD is part of a complex system of mental and noncommunicable somatic disorders, with a shared underlying pathogenesis. This is based on common lifestyle and environmental risk factors, mediated by dysregulation of inflammation, oxidative stress pathways, and mitochondrial function.

This study found an inverse correlation between the experience of IV and T2D. Some studies have found a link between intimate partner violence and T2D [7,10,12]. Studies performed on adverse childhood experiences also correlate these experiences to the higher prevalence of T2D in childhood [29,30] This way, the lower HR of developing T2D in the IV cohort may be explained by a higher prevalence of the disease in children exposed to violence—a higher baseline prevalence could lead to lower incidence in adulthood as a bigger percentage of the cohort could have developed the disease prior to index date [30]. In this study, 4.9% of the IV cohort had T2D at the index date compared to only 1.9% of the control cohort.

Survivors of violence may be more susceptible to losing follow-up due to instability in their lives, which can result in missed appointments, relocation, or increased mortality, for example.

As previously said, the association between IV and negative health outcomes may be partially explained by the impact of chronic stress on various systems that regulate body homeostasis, particularly the HPA axis [5,8,16,31,32]. Hyperactivation of the HPA axis leads to neuroendocrine and immune disruption and altered systemic cortisol production [5,8,31]. Survivors of violence are at a higher risk of resurvivorization across their lifespan, exposing them to chronic and cumulative stress. This snowball effect may result in the negative outcomes explored in this study [16,32]. In fact, violence may even start before birth (intrauterine violence), in cases of violence against pregnant women, perpetuating through every phase of life, having a cumulative effect with tremendous consequences [16].

Even though it seems clear that violence is deleterious, we are still not able to comprehend the full extent of its consequences. Studies tend to address IV within each subtype of violence or a specific subgroup of the population, overlooking the intricate relation between different forms of violence and recurrent experiences of it. This limits our capacity to draw conclusions and compare patterns across diverse populations. A lot of studies have been done on children, trying to understand the direct impact of violence on health during childhood, but also its long-term consequences through their adult life [4,8,29-31,33-35]. There is also a great amount of literature regarding intimate partner violence, particularly among women [7,12,15,20,23,36-38]. However, there is limited research on other subtypes of IV. The body of research regarding men's health and violence is less robust than that for women [18], creating barriers in understanding the true burden in this sex and whether there are significant differences in response to violence between sexes.

Since multiple experiences of violence across a person's lifespan are common, we will only understand the full impact of IV by considering the co-occurrence and interconnections of the multiple experiences of it. Violence must be conceptualized from a dose-response perspective, considering the accumulation of exposure over time and across multiple domains [19]. Scott-Storey et al [32] propose an approach aligned with this. They developed a cumulative lifetime violence severity scale reflecting dimensions of type, focus (target or perpetrator), timing (childhood or adulthood), context, frequency, and degree of distress. This tool was designed only for men. Similar tools could be developed for both sexes, adjusting to each population,

XSL•FO
RenderX

allowing a profound understanding of violence's negative impact on health.

In this study, we chose to have a global approach to IV in adults, as we could not develop a dose-response perspective or differentiate each type of violence in each patient, due to the poor codification on this matter and the broad vocabulary used to describe it in EHR.

Our results underscore the significant burden of IV, which affects multiple facets of survivors' lives. Health consequences have their own repercussions that substantially diminish survivors' quality of life, affecting other spheres of life, such as job loss and career abandonment, or increased health care costs [1,15]. Violence is therefore conceptualized as a structural determinant of health. Its presence negatively impacts patients' health outcomes and self-development. Moreover, distinct patterns of cumulative lifetime exposure to violence result in varying degrees of symptom severity [13].

Violence screening represents a cost-effective prevention strategy that should be standard practice [39]. Several barriers prevent an effective detection of the cases: (1) survivors may struggle with disclosure due to shame, fear of being judged, of not being believed [40], or of violence escalation; (2) health care practitioners may face challenges such as insufficient time and skills to identify cases, discomfort, confidentiality concerns, or their own experiences with IV [39,40]; and (3) clinical-level factors may include inadequate information, lack of screening protocols, and insufficient support [39,40]. These constraints may lead to a misdiagnosis of cases. Furthermore, due to medical privacy and doubts associated with the case complexity, some situations might only be recorded in confidential registers, which may contribute to an apparent underidentification of IV cases, making it difficult to understand the full extent of the problem.

Since almost all clinicians across their practice will encounter patients who were survivors of IV, they should be trained with the necessary skills to identify and report these situations and respond appropriately, reducing their harmful consequences and preventing reoccurrence [37,39,40]. Public institutions must have a direct role in the prevention of violence, addressing underlying causes, and creating appropriate measures and programs that can give the needed support to survivors and their families.

A deeper understanding of the long-term consequences of IV enables an improvement in the approach to survivors in medical practice. By identifying the negative health outcomes that may arise from exposure to violence, clinicians can develop a proactive and targeted follow-up of survivors. An early detection of these pathologies and an understanding of the complex and multifaceted needs of survivors contribute to a more personalized, preventive, and effective medical care.

Limitations

Omission bias is possible due to certain aspects of this study. Physicians might not document or code all suspected IV cases they detect in the EHR. Additionally, they may choose to record these cases only in confidential health registers.

Given that the identification of suspected cases of IV was done through data from the EHR of adult users, we implemented comprehensive selection criteria and used a dual approach that integrates all relevant ICPC-2, *ICD-9*, and *ICD-10* codes, as well as all relevant clinical notes at every intervention point for any health care professional.

While we tried to include pertinent and broad terminology used by physicians to describe violence scenarios in clinical notes, it is not possible to account for the all variety of possible expressions that may have been used to describe a context of violence; as such, there may be a potential subestimation of violence-exposed patients in the respective cohort.

Furthermore, the variability in coding and terminology used to describe violence between countries and institutions may compromise the comparability and reproducibility of our findings when applied to different clinical settings.

Another potential limitation of this study is the reporting bias that may be associated with patients who are suspected of IV, as health care professionals may have a stronger tendency to report health care outcomes, especially those connected with mental health, regarding these patients.

In addition, given the fact that there is no methodical registration of variables as socioeconomic status, race or ethnicity, and educational level, it was not possible to adjust the data for these possible confounders; therefore, confounding bias may be present.

By including all the patients who met the inclusion criteria, without any additional exclusion criteria, we minimized selection bias and enhanced the detection of patients exposed to violence. Our comprehensive approach, encompassing all the eligible population at ULSM during the study period, resulted in a large and diverse sample, which strengthens the validity and generalizability of our findings.

A validation study of these data should be carried out. We intend to extend the study to other regions of Portugal and collaborate with research groups in other countries, which would allow us to assemble larger cohorts, conduct robust statistical analyses, and gain a deeper understanding of violence to improve prevention, intervention, and treatment. The use of real-world data is recommended as it provides the possibility of analyzing larger patient populations over longer timelines [41]. We also intend to compare the effects of IV between sexes and to develop study designs that incorporate the cumulative impact of violence across multiple domains and stages of life, while characterizing the studied populations with further socioeconomic demographic data such as profession, employment situation, level of education, and family structure.

Conclusions

This research has demonstrated that adults suspected to be survivors of IV are more likely to develop negative health outcomes than the general population. This was true for health risk behaviors, as well as for mental health and somatic conditions. Notably, this study introduces a novel perspective on the matter, suggesting that violence is linked with the development of MASLD.

XSL•FO
RenderX

Furthermore, adults suspected to be survivors of IV developed health outcomes earlier and had a shorter period of follow-up, compared to the adults with no exposure to violence. These findings highlight the complex impact of violence on health, underscoring the urgent need to address this endemic problem in society. Health providers play a crucial role in the early detection of cases, follow-up, and treatment of survivors of IV. Future multicentric research (including international research groups) should focus on validating these findings, trying to have a dose-response perspective. Such efforts will enable more robust statistical analyses and a deeper understanding of violence's consequences, ultimately contributing to improved prevention, detection, and treatment strategies.

Abstract

Background: Condyloma acuminata (CA), the clinical manifestation of infection with low-risk human papillomaviruses 6 and 11, is a common sexually transmitted infection (STI) with recurrent lesions and notable psychosocial and health system burden. Recent evidence indicates a substantial global burden, with prevalence ranging from 0.5% to 33.1% and incidence ranging from 24 to 2940 per 100,000 person-years, varying by age, sex, time, and geography. In South Korea, national insurance data show sustained increases in patients receiving care for CA during 2010 to 2019. Beyond individual behaviors, spatial proximity and contextual factors can produce clustered STI risk. However, the municipal-level spatial distribution of CA in Korea and its contextual correlates remain understudied.

Objective: This study aimed to identify high-risk geographic clusters of CA in South Korea and determine the regional factors associated with its incidence rates.

Methods: We conducted an ecological analysis using 2019 municipal-level data from the National Health Insurance Service of Korea. Spatial autocorrelation of CA incidence rates was evaluated using Moran's I, and clustering was assessed with Getis-Ord Gi* to detect high-risk clusters. We then analyzed potential regional determinants using two Bayesian spatial regression models: the intrinsic conditional autoregressive model and the Besag–York–Mollié model. Key municipal-level variables included health behaviors, socioeconomic indicators, health care access, adult entertainment venue density, and risk of sexual violence. Results are reported as adjusted relative risks (aRRs) with 95% credible intervals (CrIs).

Results: A total of 52,009 CA cases were identified in 2019, 70.03% (36,421/52,009) of which were in men. We found significant positive spatial autocorrelation in CA incidence rates (Moran's I>0, *P*<.001), indicating nonrandom spatial clustering. The Getis-Ord Gi* analysis revealed several high-incidence clusters (*hotspots*) in metropolitan and southeastern regions of South Korea. In the Bayesian spatial models, higher CA incidence rates were associated with a greater share of the municipal budget spent on social welfare (aRR 1.005, 95% CrI 1.001 - 1.009), a higher percentage of single-person households (aRR 1.034, 95% CrI 1.025 - 1.043), and more adult entertainment establishments per 10,000 people (aRR 1.006, 95% CrI 1.001 - 1.012).

Conclusions: We identified significant geographic hotspots of CA and several community-level risk factors driving these patterns in South Korea. These findings highlight the importance of spatial surveillance and targeted public health interventions in high-risk areas. Adapting STI prevention programs to address local social determinants may help reduce the spread of CA in the identified hotspots.

Introduction

Background

Condyloma acuminata (CA), the clinical manifestation of infection with low-risk human papillomaviruses 6 and 11, remains a persistent public health concern due to its high incidence, recurrent course, psychosocial burden, and nontrivial health system costs [1]. Although generally asymptomatic, CA lesions can itch, bleed, and cause irritation or discomfort in the anogenital region [2]. Recent studies indicate that CA remains a substantial global burden, with prevalence ranging from 0.5% to 33.1% and incidence rates ranging from 24 to 2940 per 100,000 person-years, varying by age, sex, time, and geography [3]. In South Korea, population-based analyses using the Korean National Health Insurance Service (KNHIS) data showed sustained increases in patients receiving care for CA during 2010 - 2019 [4]. Earlier Health Insurance Review and Assessment Service in South Korea data (2007 - 2015) also

XSL•FO
RenderX

documented rising prevalence and economic burden at the national level [5].

Several individual-level risk factors for CA have been identified in prior studies. These include early age at first sexual intercourse, engaging in sexual activity with multiple partners, unprotected intercourse [6], a history of other sexually transmitted infections (STIs) [7], and smoking tobacco [8]. However, most of these studies focused on individual behaviors and did not examine how regional or community-level factors contribute to the geographical heterogeneity of CA incidence rates.

Beyond person-to-person transmission, spatial proximity effects can produce geographically clustered STI patterns through several ecological mechanisms. Evidence from large urban settings demonstrated that exposure to high-STI neighborhoods increases infection risk in both geographically proximate and socially connected areas through spillover [9]. Also, municipalities that share contextual determinants such as urbanicity, socioeconomic deprivation, and access to sexual health services tend to exhibit correlated STI risks over space and time. Recent spatial studies of STIs demonstrate these mechanisms across settings, including spatiotemporal clustering of HIV in China with strong associations to urbanization and health-system indicators, and persistent hot spots of curable STIs in subnational analyses [10]. Korean data also showed spatial clustering for STI, underscoring that geographically structured ecological determinants can shape STI risk beyond individual behavior [11]. These mechanisms justify spatial analyses to identify clustered risk and its contextual determinants.

Despite the increasing CA burden, evidence on the municipal-level spatial distribution of CA in South Korea remains limited. Specifically, no study has quantified municipal-level spatial clustering of CA in South Korea and examined how local contextual factors relate to CA incidence rate. Filling this gap is essential for geographically targeted prevention and service planning.

Objectives

We hypothesized that (1) CA incidence rates would cluster spatially (hot spots) and (2) area-level determinants would partially explain this clustering. To address these, we aimed to quantify municipal-level clustering of CA in South Korea and identify which regional characteristics are associated with higher CA incidence rates to inform geographically targeted interventions.

Methods

Study Design and Setting

We conducted a cross-sectional ecological study at the municipal level in South Korea for the year 2019. Reporting followed the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) checklist for cross-sectional studies (Checklist 1). The unit of analysis was the Si-Gun-Gu (municipalities, including cities, counties, and districts), of which there are 250 nationwide. By focusing on area-level data across all municipalities, this design allowed us to assess geographic variations and identify municipal-level risk factors associated with CA incidence rates in a single year.

Data Sources and Variables

This study analyzed nationwide health insurance claims generated from the KNHIS. The KNHIS insures approximately 97% of residents, with the remainder covered by the Medical Aid program [12]. The KNHIS claims constitute almost complete national dataset for epidemiologic research in Korea. The claims files include dates of service, diagnosis and procedure codes, provider type and location, and basic beneficiary characteristics needed for population-level analyses; personally identifiable information is not available to investigators [13]. Because this was a secondary analysis of collected data, there was no clinical recruitment or patient enrollment.

The primary outcome was the incidence rates of CA in each municipality during 2019. CA cases were identified using the *International Classification of Diseases, 10th Revision, Clinical Modification* code A63.0 recorded in the principal or additional diagnosis fields. To define incident cases for 2019, first A63.0-coded claim was selected in 2019 as the index event. To avoid counting follow-up care from the same clinical episode as new incidents, a 30-day reattendance window was applied: any subsequent A63.0-coded claims occurring ≤30 days after the index claim were considered part of the same episode and not counted as additional incident events. The incident events were assigned to the municipality recorded in the claims and aggregated across the 250 municipalities of South Korea for 2019. Annual municipal incidence rates per 100,000 people were computed using midyear resident-registry denominators from Statistics Korea [14].

We assembled a broad set of municipal characteristics as potential risk factors for CA, drawing on multiple data sources. These variables encompassed several domains including health behaviors, welfare-related variables, health conditions, socioeconomic variables, health care accessibility, adult entertainment establishments, and the risk of sexual violence (Table S1 in Multimedia Appendix 1). Additionally, two demographic covariates were included to adjust for population structure: the sex ratio and the median age of the population in each municipality. These adjustments account for differences in the age and gender distribution that might influence CA incidence rates.

All municipal-level variables were obtained from authoritative national data sources for the year 2019 to ensure consistency with the outcome data. Health behavior, health condition, and welfare and socioeconomic indicators were extracted from the 2019 Korean Community Health Survey and the Korean Statistical Information Service databases [14,15]. The number of adult entertainment establishments in each area was gathered from the government's open data portal [16], which provides official public data on local businesses and facilities. The regional risk of sexual violence was derived from a report published by the Korea Institute of Criminology and Justice [17]. By integrating these diverse data sources, we compiled a comprehensive dataset of regional variables hypothesized to be associated with CA incidence rates.

Spatial Autocorrelation

The global Moran's I statistics for the incidence rates of CA across the 250 municipalities were calculated to examine whether the geographic distribution of CA incidence rates exhibited spatial autocorrelation [18]. Moran's I is a measure of global spatial autocorrelation that ranges from –1 to +1, where values close to +1 indicate strong clustering of similar values and values close to –1 indicate spatial dispersion of values. A value near 0 would indicate that CA incidence rates are spatially random. A spatial weights matrix was constructed based on the K-nearest neighboring municipalities for each area (K=4), using great-circle distances between municipality centroids to define neighbors. The K-nearest neighbors approach ensures that every municipality has a consistent number of neighboring areas considered, even for those with no direct geographic borders. Given this weights matrix, Moran's I was computed for the CA incidence rates per 100,000 population, and a permutation test with 999 Monte Carlo simulations was conducted to determine the significance of the observed Moran's I value. The null hypothesis for this test is that CA incidence rates are distributed randomly in space; a significant Moran's I (P<.05) would indicate that spatial autocorrelation is present, justifying the use of spatial modeling techniques in subsequent analyses [19].

Cluster Detection (Hotspot Analysis)

In addition to global autocorrelation, we explored local clusters of high or low CA incidence rates using the Getis-Ord Gi* statistic [20]. The Getis-Ord Gi* is a local spatial statistic that identifies *hotspots* and *coldspots*, meaning areas where the incidence rates are significantly higher or lower than would be expected by chance, given the values in neighboring areas. For each municipality, Gi* considers the value of CA incidence rates in that area and those of its surrounding neighbors (using K=4) and computes a z score. A high positive z score with a significant P value (<.05) indicates a clustering of high incidence rates (a hotspot), whereas a high negative z score indicates a clustering of low incidence rates (a coldspot). Municipalities with a Gi* statistic exceeding the 95% CI bounds were mapped as significant clusters of elevated or reduced CA incidence rates. This hotspot analysis complements the global Moran's I by identifying where spatial clusters occur, providing insight into specific high-risk regions.

Variable Selection and Nonspatial Regression Analysis

Prior to building spatial models, we conducted a nonspatial regression analysis to identify important predictors of CA incidence rates and to ensure that our model would account for overdispersion in the count data [21]. Initially, a Poisson regression framework was considered because the number of CA cases in each municipality is a count outcome. However, we tested for overdispersion in the count data by comparing the variance to the mean and using an overdispersion test statistic [22]. The overdispersion test indicated that the variance of CA cases across municipalities was significantly greater than the mean (P<.05). We therefore chose a negative binomial regression model to account for the overdispersion.

Using the negative binomial framework, bivariate regression analyses were performed for each candidate independent variable. In these models, the outcome was the count of CA cases in the municipality, and the log of the municipality's population was included as an offset term. Each candidate variable was entered individually to assess its crude association with CA incidence rates. A liberal significance criterion of P≤.25 was used to screen for potential predictors [23]. In other words, any variable that showed an association with CA incidence rates at P≤.25 in the bivariate analysis was retained for consideration in the multivariable model. This cutoff is more inclusive than the conventional .05 level and was chosen to avoid prematurely excluding variables that might become significant in a multivariable context [23].

Next, a multivariable negative binomial regression model was used, including all candidate variables that passed the screening threshold. Variance inflation factors were computed for the covariates to check for multicollinearity, with a variance inflation factor >5 used as an indicator of high multicollinearity that could distort the model estimates [24]. If any pair of variables were highly collinear, we planned to remove or combine one of them, favoring the variable with more direct relevance to CA or the one that yielded the better model fit. The final nonspatial model was selected through a backward elimination procedure. Starting with the full set of selected covariates, we iteratively removed the least significant variable one at a time and compared model fit using the Akaike Information Criterion. The final model provided a baseline set of risk factors for CA incidence rates without accounting for spatial effects.

Bayesian Spatial Modeling

We incorporated spatial dependence into our regression modeling using a Bayesian approach because the exploratory spatial analysis revealed evidence of nonrandom spatial clustering in CA incidence rates. A Bayesian hierarchical spatial modeling was adopted because the outcome comprises municipal counts exhibiting overdispersion and residual spatial autocorrelation. Traditional nonhierarchical spatial regression often struggles to accommodate these characteristics in small-area count settings due to the absence of area-level random effects to capture residual dependence [25]. The Bayesian framework enables us to specify a negative binomial likelihood with a population offset, incorporate area-level spatial random effects that borrow strength from neighboring municipalities, and quantify uncertainty with posterior intervals.

Two types of Bayesian spatial regression models were implemented to account for residual spatial autocorrelation in the incidence rates of CA across municipalities. These were the intrinsic conditional autoregressive (ICAR) model and the Besag–York–Mollié (BYM) model [26]. Both models are commonly used in disease mapping to improve estimates by *borrowing strength* from neighboring areas and to control for spatially structured confounding [27]. The ICAR model introduces a spatially structured random effect that assumes nearby areas have similar risk, whereas the BYM model includes two random effect components—one spatially structured and one unstructured—allowing it to capture both localized spatial clustering and independent heterogeneity at the municipal level.

XSL•FO
RenderX

The municipal incidence rates of CA were modeled using a negative binomial likelihood. We let Y_i denote the counts of CA in municipality i (i=1,…,250).

(1)Yi~ NB(r, pi), pi=rr+λi, E(Yi)=λi, Var(Yi)=λi+λi2r

Here, r>0 is the size (overdispersion) parameter and p_i is the success probability. The mean λi is linked to covariates with a population offset:

(2)log λi=α+log Ni+∑kβkXi,k+ηi

where α is the intercept, N_i is the municipal population (offset), $X_{i,k}$ are municipal-level covariates with coefficients βk, and ηi is a spatial random effect. To account for residual spatial autocorrelation, we first specified ηi under an ICAR prior, which imposes spatial smoothing such that neighboring municipalities have similar risk:

(3)ηi=si, s=(s1, …, s250)T~ ICAR (W, σs2)

The spatial weights matrix W was built using K=4 K-nearest neighbors computed from municipal centroids in projected coordinates. We then considered the BYM extension, which augments the ICAR component with an independent, spatially unstructured term to capture residual heterogeneity:

(4)ηi=si+ui,ui~N(0,σu2)

Both ICAR and BYM models are widely used in disease mapping to borrow strength across adjacent areas and to mitigate spatially structured confounding [28,29]. We fitted both ICAR and BYM specifications and compared performance using deviance information criterion (DIC) values with practical and theoretical considerations. For regression outputs, the posterior median of the exponentiated fixed effects was reported as an adjusted relative risk (aRR) with a 95% credible interval (CrI). For clarity, in the Bayesian framework, a 95% CrI denotes the range containing 95% of the posterior probability mass for the parameter, given the model and prior. Covariate effects were considered significant when the 95% CrI for the aRR does not include 1.00.

The posterior marginal distribution of the model parameters was approximated using the integrated nested Laplace approximation [30]. A flat prior distribution was applied to the intercept α and the regression parameters β corresponding to each explanatory variable and covariate. For the variance associated with spatially structured and spatially unstructured terms, a weakly informative prior known as the Penalized Complexity prior was applied [31].

We conducted a sensitivity analysis to examine the robustness of the findings to the choice of spatial neighborhood structure. The primary analysis defined spatial adjacency using each municipality's four nearest neighbors (K=4). For sensitivity testing, the Bayesian spatial model was rerun under two alternative neighbor definitions: first using three nearest neighbors (K=3) and then using five nearest neighbors (K=5) for each municipality. All the results were compared across the different neighbor specifications: spatial autocorrelation statistics, identified hotspots, and key regression coefficients. The sensitivity analysis confirmed that the overall spatial patterns and the identified significant predictors of CA incidence rates remained consistent when using K=3 or K=5, suggesting that our findings are robust to reasonable variations in the spatial neighborhood definition.

All statistical analyses were performed using R version 4.3.1 (R Foundation for Statistical Computing). Spatial autocorrelation and clustering statistics (global Moran's I and Getis-Ord Gi*) were computed with the *spdep* package [32]; all maps were produced with *tmap* [33]; the nonspatial negative binomial baseline model was fitted using *MASS* [34]; overdispersion was evaluated with *AER* [22]; and Bayesian spatial models were estimated with *R-INLA* [30]. The shape file was obtained from the National Spatial Geographic Information Service [35].

Ethical Considerations

This study was conducted using aggregated, deidentified health data and publicly available municipal statistics. The Institutional Review Board of Korea University reviewed and approved this study (IRB approval number: KUIRB-2021-0382-01).

Results

Descriptive Statistics

In 2019, a total of 52,009 cases of CA were recorded across the 250 municipalities, with approximately 70.03% (36,421/52,009) of cases in men. Across municipalities, the mean number of CA cases was 207.3 (SD 179.5) per municipality, and the mean CA incidence rate was 95.8 per 100,000 people (Table 1). The burden of CA varied widely between regions: the number of cases ranged from as low as 3 to as high as 886 in different municipalities, and incidence rates ranged from 1.46 to 184.21 per 100,000 people. This represents more than a 100-fold difference in incidence rates across communities, highlighting substantial geographic disparities in CA occurrence. The coefficient of variation for CA cases was 0.87, reflecting this high relative dispersion. By comparison, the potential regional risk factors examined showed coefficients of variation ranging from 0.01 up to 0.85, indicating that none of these variables exhibited as much regional variability as the incidence rates of CA.

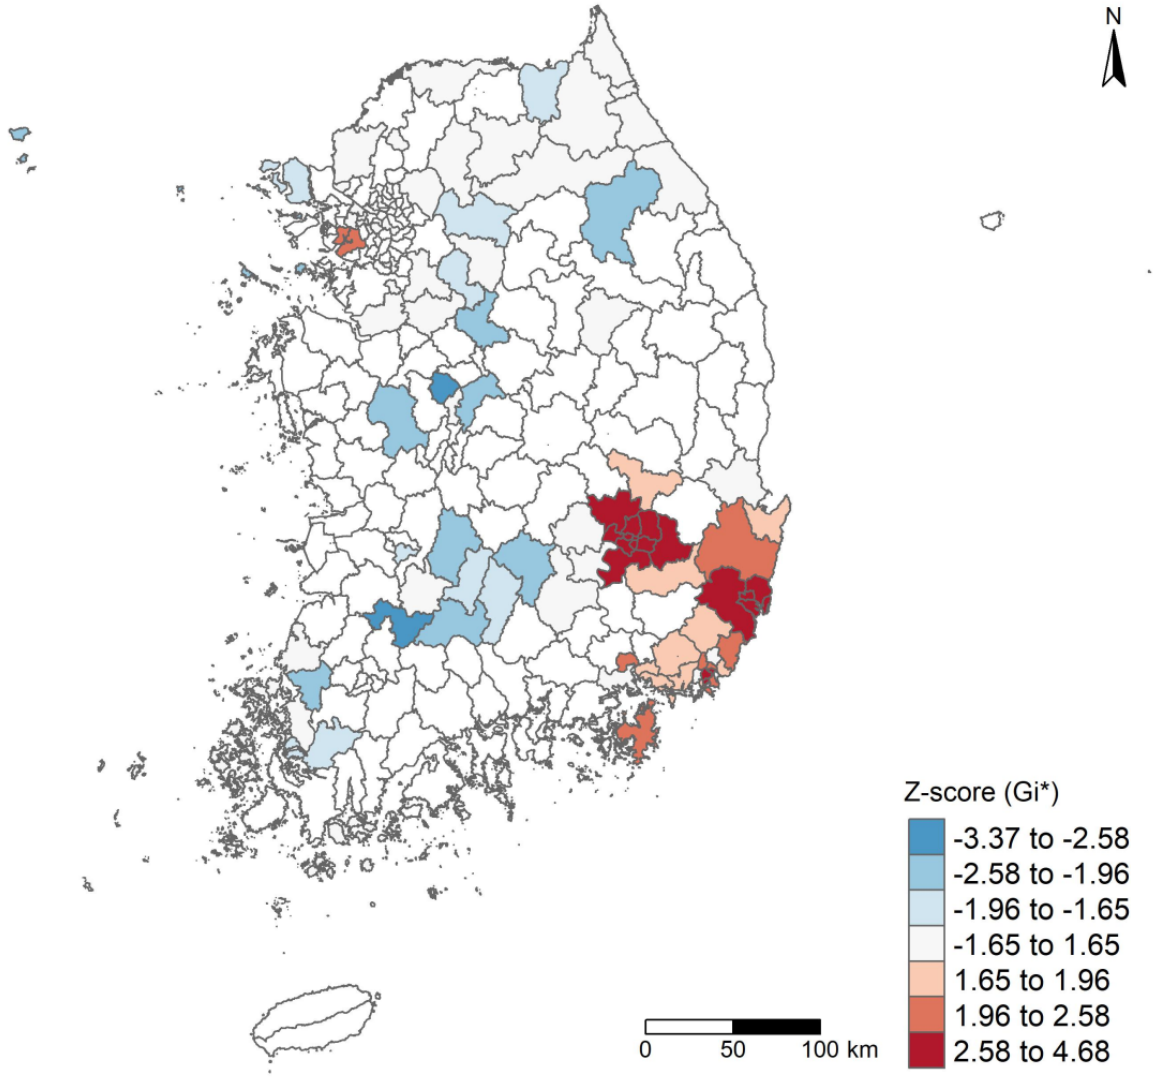
[c]CV: coefficient of variance.

Spatial Clustering

The choropleth map of CA incidence rates (Figure 1; Multimedia Appendix 2) indicated that municipalities in certain metropolitan and southeastern parts of South Korea showed higher incidence rates compared to those in the northeastern and southwestern regions, where rates were lower. Consistent with these visual patterns, the Global Moran's I analysis confirmed significant positive spatial autocorrelation. Specifically, the incidence rates of CA were spatially clustered across municipalities (Moran's I for incidence rates=0.335, $P<.001$), as were the case counts (Moran's I=0.395, $P<.001$). Local cluster detection using the Getis-Ord Gi* statistic further identified specific areas of high and low incidence rates. The Gi* analysis identified several significant hotspots of increased CA incidence rates in the urbanized metropolitan area and the southeastern region (Figure 2).



XSL•FO
RenderX

Figure 1. Geographic distribution of condyloma acuminata (CA; *International Classification of Diseases, 10th Revision, Clinical Modification* A63.0) incidence rates per 100,000, by municipality (n=250), in this nationwide cross-sectional ecological study of South Korea (2019). Incident CA cases were aggregated to the municipality of residence; denominators are midyear resident registry populations. The choropleth shades each municipality by CA incidence rates. Lighter to darker tones indicate lower to higher incidence rates.

XSL•FO
RenderX

Figure 2. Hotspot and coldspot clustering of condyloma acuminata (CA; *International Classification of Diseases, 10th Revision, Clinical Modification* A63.0) incidence rates per 100,000 based on the Getis–Ord Gi* analysis at the municipality (n=250) level for South Korea (2019). Spatial weights were defined by K-nearest neighborhood contiguity (K=4). Municipalities are colored by Gi* *z* score: statistically significant hotspots are shown in red tones (clusters of high incidence rates), and statistically significant coldspots are shown in blue tones (clusters of low incidence rates); nonsignificant areas are shown in white. Significance thresholds are $|z|\geq1.96$ ($P<.05$) and $|z|\geq2.58$ ($P<.01$).

Regression Modeling

After the preliminary nonspatial analysis and variable selection procedure, five candidate variables were selected for the spatial regression modeling: social welfare facilities per 100,000 people, share of municipal budget on social welfare (%), percentage of single-person households, prevalence of hypertension (%), and number of adult entertainment establishments per 10,000 people. In addition, two demographic covariates, median age and sex ratio, were included in the models to adjust for population structure. Model fit was similar for the ICAR and BYM specifications (ICAR: DIC 2422.38; BYM: DIC 2421.36), with ΔDIC=1.02. While the DIC difference was minimal, we selected the BYM model for theoretical reasons. The BYM model accounts for both structured spatial dependence and unstructured spatial heterogeneity, providing a more comprehensive representation of spatial effects. The BYM model decomposed the total spatial variance into structured (precision=101.48, 95% CI 34.84 - 250.05) and unstructured components (precision=17,485.45, 95% CI 202.07 - 119,072.66), indicating the presence of both spatial clustering and municipality-specific variation. Therefore, we present the results from the BYM model as the final spatial regression model (Table 2). The ICAR model yielded nearly identical fixed effect estimates, with magnitudes of fixed effect, directions, and statistical significance remaining consistent across both models, demonstrating that our findings are robust to spatial model specification.

The Bayesian spatial regression identified three key regional factors that were significantly associated with higher CA incidence rates after adjusting for covariates and spatial effects. First, the share of the municipal budget devoted to social welfare showed a positive association: for each 1% increase in welfare budget share, the aRR of CA increased to 1.004 (95% CrI

XSL•FO
RenderX

1.001 - 1.008), suggesting a small but significant increase in risk. Second, the proportion of single-person households in a municipality was strongly associated with CA incidence rates: each 1% increase in single-person households corresponded to the aRR of 1.033 (95% CrI 1.024 - 1.041). Third, the density of adult entertainment establishments was linked to higher CA incidence rates: for each additional adult entertainment establishment per 10,000 population, the aRR was 1.006 (95% CrI 1.001 - 1.012).

Sensitivity analyses confirmed the robustness of the spatial regression findings. We refit the Bayesian models using alternative spatial neighborhood definitions. The model fit remained best when using K=4 neighbors, as evidenced by the lowest DIC at K=4 compared to K=3 or K=5. Importantly, the direction and magnitude of the associations for the identified risk factors were consistent across these different spatial weights (Table S2 in Multimedia Appendix 1).

Discussion

Principal Findings

This study revealed geographic disparities in the incidence rates of CA across South Korea. A total of 52,009 CA cases were analyzed, and the municipal-level incidence rates ranged from as low as 1.46 to 184.21 per 100,000 people—over a 100-fold difference between the lowest and highest areas (Table 1). Such variation indicates substantial spatial heterogeneity in CA burden. Indeed, we found significant positive global spatial autocorrelation (Moran's I=0.33, *P*<.001), confirming that municipalities with high CA incidence rates tended to cluster near each other. The choropleth map of CA incidence rates (Figure 1) and the Getis-Ord Gi* hotspot analysis (Figure 2) consistently identified distinct high-risk clusters in the urbanized metropolitan regions and the southeastern part of the country. These hotspots emphasize that the transmission of CA is not

XSL•FO
RenderX

distributed evenly but rather concentrated in certain communities at an increased risk. In addition to mapping clusters, our analysis identified key regional factors associated with the spatial distribution of CA. Using Bayesian spatial regression modeling, we found three significant municipal-level risk factors that remained positively associated with higher CA incidence rates after adjusting for demographic covariates and spatial autocorrelation (Table 2). First, municipalities that spent a higher share of their budget on social welfare programs had a higher relative risk of CA. Second, areas with a higher proportion of single-person households showed increased CA incidence rates. Third, municipalities with more adult entertainment establishments per 10,000 people had higher CA rates. The Bayesian model that included both spatially structured and unstructured random effects—the BYM model—provided a better fit than the purely spatial ICAR model, indicating that accounting for local heterogeneity in addition to broad spatial trends improved the explanation of CA incidence rates patterns.

Our findings of spatial clustering of CA incidence rates are consistent with patterns observed in other settings. The spatial autocorrelation observed in CA incidence rates does not result from direct person-to-person transmission between neighboring individuals but rather from the geographic clustering of municipal-level risk factors that create similar high-risk environments in spatially proximate areas. Previous geographic studies have also identified localized hotspots for STIs. For example, mapping of STIs in Portugal found distinct high-rate clusters in certain regions [36], and a cross-sectional analysis reported that per-capita STI incidence rates tended to increase systematically with urban population size [37]. Likewise, cross-setting analyses report nonrandom spatial clustering of STIs that aligns with contextual determinants such as urbanicity, socioeconomic conditions, and access to sexual health services [9,38]. In our study, municipalities with higher proportions of single-person households and greater density of adult entertainment establishments exhibited a higher incidence of CA, suggesting that local sexual market structures and alcohol-related social environments may influence opportunities for risky behavior [39]. Furthermore, the highest CA incidence rates were found in densely populated urban and southeastern areas, which is consistent with other studies and suggests that large urban centers often serve as hubs for STI transmission. This aligns with the concept of core transmission areas, where densely interconnected sexual networks facilitate wider spread of infection [40]. Our results support this concept, as the identified metropolitan clusters may act as reservoirs that support wider disease spread. A similar spatial concentration of STIs has been demonstrated in the United States, where county-level analyses using hotspot methods have identified significant clusters of increased STI prevalence [41]. Both our study and prior research suggest that geographic context, especially urbanicity and regional connectivity, plays a central role in STI dynamics.

The positive association we observed between the prevalence of single-person households and CA incidence rates is supported by epidemiological data on sexual behavior. Single individuals are more likely to have multiple sexual partners compared to married or cohabiting individuals [42], and having multiple partners is a well-established risk factor for acquiring CA and other STIs [43]. A Turkish study similarly noted that unmarried status was linked to higher risk of human papillomavirus infection [44]. Thus, areas with many one-person households may inherently have higher levels of casual or transient sexual partnering in the population, contributing to greater CA transmission. Our findings tentatively extend this individual-level evidence to the community level, indicating that municipalities with a higher proportion of single-person households also tend to have higher incidence rates of CA.

The finding that municipalities with more adult entertainment establishments have higher CA incidence rates is also consistent with previous research. Such establishments may foster networks of high-risk sexual contacts. Studies in the United States have documented that individuals working in or around the adult entertainment industry have a higher STI prevalence and engage in riskier sexual behaviors than the general population [45,46]. These studies, combined with our findings, point to adult entertainment establishments as important sites of STI transmission. They likely attract or employ core groups with higher numbers of sexual encounters, thereby amplifying the spread of infection in the surrounding community. Our findings reinforce the need for targeted public health intervention in such areas to reduce local transmission of CA.

In contrast, the positive association we found between higher social welfare expenditure and CA incidence rates appears to be a novel observation with no direct precedent in the literature. This counterintuitive finding should be interpreted with caution. One plausible explanation is reverse causation or confounding: municipalities facing a high burden of CA may allocate a higher share of their budget to social services and public health, including STI management and prevention programs. In other words, increased welfare spending may be a response to the existing public health needs rather than a causal driver of infection. Alternatively, this association may reflect underlying social deprivation regions with need for welfare support could simultaneously have higher STI rates, as suggested by broader public health studies linking low socioeconomic status to increased STI prevalence [47]. CA is a condition requiring long-term management with a tendency for recurrence [48]. Communities heavily impacted by recurrent CA cases may incur higher health care and social support costs, prompting larger welfare budgets. Since no prior study, to our knowledge, has examined this factor in relation to CA, our result highlights a new avenue for research. Further studies are needed to disentangle whether higher social welfare spending is a marker of underlying social determinants that facilitate CA spread or whether it reflects an intensified local response to control an ongoing epidemic [49].

Limitations

This study has limitations. First, the analysis was conducted at the municipal level using an ecological design. All data, including CA cases and risk factors, were aggregated by municipality; individual-level exposures and behaviors could not be assessed. Consequently, the associations we identified do not necessarily imply causation at the individual level, and they may be susceptible to the ecological fallacy. Second, the

XSL•FO
RenderX

cross-sectional nature of our study limits our ability to infer temporal trends or causality. We captured a one-year snapshot of CA incidence rates and regional characteristics, but the situation may evolve over time. Third, our reliance on the NHIS records for CA cases means the data are subject to any inconsistencies in diagnosis or reporting. Genital warts carry social stigma [50], which could lead to underdiagnosis or underreporting in certain areas. For instance, individuals might avoid seeking treatment for an STI due to shame, or clinicians might use nonspecific diagnostic codes to spare patient discomfort. Such variability in health care–seeking behavior and diagnostic practices across municipalities could introduce measurement bias in the recorded incidence rates. Fourth, while we included a wide range of regional covariates, it is possible that unmeasured confounders also influence the spatial distribution of CA. Finally, the spatial resolution of our analysis was at the municipality level; intra-municipal variation or clustering at a finer neighborhood scale could not be examined with the available data. Despite these limitations, this study provides a foundation for addressing CA incidence rates through evidence-based strategies, focusing on identified hotspots and regional risk factors.

Conclusions

In summary, our nationwide spatial analysis of CA in South Korea revealed significant geographic clustering, with hotspots concentrated in the metropolitan and southeastern regions, and demonstrated that area-level factors, particularly a higher prevalence of single-person households and greater density of adult entertainment establishments, are associated with increased incidence rates of CA. These findings highlight the value of integrating spatial epidemiology into routine surveillance to identify communities at greatest risk and to guide the efficient allocation of targeted interventions. Moreover, the observed association with social welfare expenditure suggests that policymakers should consider how recurrent STI burdens strain local resources and ensure that funding for prevention and care is targeted to the most affected areas. Future research should explore the causal pathways linking these regional characteristics to CA transmission and evaluate the impact of geographically targeted public health interventions over time.

This work was supported by the Korea Disease Control and Prevention Agency (grant number 2021-07-010). The funder of the study had no role in the study design, data collection, data analysis, data interpretation, or writing of the manuscript.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to restrictions imposed by the Korean National Health Insurance Service (KNHIS). The KNHIS data can only be accessed and analyzed within a restricted secure network environment, and only aggregated results can be exported from this system. Researchers interested in accessing similar data should apply directly to the KNHIS Data Sharing Service [51], following their established protocols for data access approval. The corresponding author can provide the study's variable list and guidance on the KNHIS application process upon reasonable request.

Authors' Contributions

JJ and BCC conceptualized and designed the study. JJ and SP obtained data. JJ performed the analysis and BCC validated the results. JJ and BCC drafted the manuscript. JJ, SP, and BCC critically revised the intellectual content of the manuscript. All the authors contributed to the reading, provided feedback, and approved the final version of the manuscript.

Conflicts of Interest

Abstract

Background: Hypertension is a significant global public health concern, with particular concern in China due to its widespread prevalence. The spatial distribution of hypertension varies significantly, revealing important regional disparities that may impact public health strategies and interventions.

Objective: This study aimed to investigate the temporal trends and spatial distribution characteristics of hypertension prevalence among individuals lifted out of poverty in China, covering the period from 2018 to 2023.

Methods: We used data from the National Health Poverty Alleviation Dynamic Management System to analyze hypertension prevalence among people lifted out of poverty from 2018 to 2023. Long-term trends were assessed using the Joinpoint regression model. Spatial distribution characteristics were examined through global and local spatial autocorrelation, cluster and outlier analyses, and trend surface analyses. These methods provided insights into the spatial aggregation and variability of hypertension prevalence across different regions.

Results: From 2018 to 2023, the prevalence of hypertension among people lifted out of poverty in China increased from 2.71% to 7.29%. The highest rates were observed in the northeast, with Jilin Province ranking first for 3 consecutive years (2020 - 2023), reaching 27.19% in 2023. Linxi County in Inner Mongolia had prevalence rates exceeding 40% for 5 years (2019 - 2023), peaking at 47.99% in 2022. Among the 22 provinces containing poverty-stricken counties, 9 showed significant annual increases, with Guangxi having the highest annual percentage change at 27.9018% (95% CI 7.4095% - 52.3038%). Spatial analysis identified high-high clusters in northern provinces such as Hebei, Jilin, and Inner Mongolia, and low-low clusters in southwestern provinces such as Yunnan and Guizhou. Trend surface analysis revealed a distinct spatial gradient, with the northeast highest and the southwest lowest.

Conclusions: The study revealed a generally increasing trend in hypertension prevalence among people lifted out of poverty in China from 2018 to 2023. The highest prevalence rates were concentrated in northeastern poverty-alleviated counties, while southwestern counties exhibited the lowest prevalence rates.

Introduction

Hypertension is a global public health issue that poses a significant threat to human health and contributes substantially to the disease burden worldwide [1-3]. According to a global pooled analysis, the prevalence of hypertension has steadily increased over the past three decades, especially in low- and middle-income countries, including China [4]. In 2019, China had one of the highest numbers of people with hypertension globally, with substantial disparities across sex, region, and socioeconomic groups [5]. According to a nationwide survey of 298,438 individuals across 31 provinces conducted from 2020 to 2022, the prevalence among residents aged 18 years or older was 31.6%, with males (36.8%) having a higher prevalence than females (26.3%), and rural areas (33.7%) having a higher

XSL•FO
RenderX

prevalence than urban areas (29.1%) [6]. Although prevention and control programs have expanded, the control rate of hypertension remains unsatisfactory in key populations [7,8]. While there is no cure for hypertension, medication can typically maintain blood pressure at a safe level in most patients, effectively reducing the prevalence and mortality rates of cardiovascular disease, stroke, and kidney disease [9,10]. However, structural disparities in health care access persist, particularly in under-resourced regions [11].

People lifted out of poverty are those who, through policy support and their own efforts, have succeeded in escaping poverty and reaching the minimum standard of living set by the state. According to China's current poverty standards, those lifted out of poverty must meet the following conditions: an average annual per capita household income of more than 2300 yuan (at constant 2010 prices) and the realization of the principle of "two no worries, three guarantees," which refers to not worrying about food or clothing, as well as guarantees for compulsory education, basic medical care, and housing security. Among this population, as an important target of precision poverty alleviation, the "established card households" are those poor families that have been included in the national poverty alleviation information system and dynamically managed throughout the poverty alleviation process. By the end of 2020, all 832 poverty-alleviated counties had met the criteria, resulting in a total of 98.99 million rural poor people being lifted out of poverty according to the current standards. This historic achievement significantly reduced absolute poverty in China and yielded profound social benefits. However, the health status of people in these counties still lags behind the national average. To address this, policies such as chronic disease subsidies, family doctor programs, and enhanced medical insurance have been implemented to promote equitable health care [12-14]. Nonetheless, research shows that individuals in poverty-alleviated counties remain disproportionately affected by chronic diseases, including hypertension [15].

Many scholars have studied the knowledge, treatment, and control of hypertension [16,17], but only a few have focused on hypertension prevalence among people lifted out of poverty. Despite the remarkable success of China's efforts to combat poverty, these individuals still face certain vulnerabilities, especially in terms of their generally poor health status. Due to long-term poverty, they have experienced a relative lack of health management and medical resources, which has led to a higher prevalence of some chronic diseases. In this context, our research focused on analyzing hypertension prevalence among people lifted out of poverty, specifically examining its characteristics across temporal and spatial dimensions. This study aimed to provide a scientific basis for developing more targeted health interventions to further improve the quality of life and health of those who have been lifted out of poverty.

Methods

Data Sources

Hypertension prevalence data for people lifted out of poverty in the 832 poverty-alleviated counties nationwide were obtained from the National Health Poverty Alleviation Dynamic Management System. This system provides comprehensive information on people lifted out of poverty, including details on literacy levels, health status, family types, and ethnicity. Specific data include the number of patients, the number of people receiving assistance, the number of times assistance was provided, and reimbursement ratios. National county-level vector maps were obtained from China's National Basic Geographic Information System.

Descriptive Statistics

We described the temporal trends and regional distribution characteristics of hypertension prevalence among people lifted out of poverty from 2018 to 2023. Using the data on the number of patients and the number of people registered in each county, we analyzed the overall temporal trends in hypertension prevalence among this population nationwide. The 832 poverty-alleviated counties were spread across 22 provinces, and we conducted a statistical analysis of hypertension prevalence in the population lifted out of poverty in each province. In addition to the statistical analysis, we also analyzed the spatial distribution characteristics of hypertension prevalence in each county. Hypertension prevalence was calculated using the following formula:

$$Pi=NiTi*100\%$$

$$Ppi=NpiTpi*100\%$$

$$Pci=NciTci*100\%$$

Where i ($2018\leq i\leq 2023$) denotes the six different years, *Pi* denotes the national prevalence of hypertension among people lifted out of poverty in each year, *Ni* denotes the number of people with hypertension among this population nationwide each year, and *Ti* denotes the total number of people lifted out of poverty nationwide each year. p($1\leq p\leq 22$) denotes the 22 provinces, *Ppi* denotes hypertension prevalence among people lifted out of poverty in each province each year, and *Npi* denotes the number of people with hypertension among people lifted out of poverty in each province each year. *Tpi* denotes the total number of people lifted out of poverty in each province each year. c($1\leq c\leq 832$) denotes the 832 counties, *Pci* denotes hypertension prevalence among people lifted out of poverty in each county each year, *Nci* denotes the number of patients with hypertension among those lifted out of poverty in each county each year, and *Tci* denotes the total number of people lifted out of poverty in each county each year.

Time Series Analysis

We used the Joinpoint regression model [18] to analyze temporal trends in hypertension prevalence among people lifted out of poverty across 22 provinces from 2018 to 2023. The model detects statistically significant trend change points (inflection points) through segmented regression and calculates the annual percentage change (APC) for each period to assess how the trend is changing. In contrast to the autoregressive integrated moving average (ARIMA) model and exponential smoothing, Joinpoint allows data to show different trends over time.

The Joinpoint regression model relies on several key assumptions. First, it assumes that the error terms are independent and identically distributed. To address potential autocorrelation in the data, we examined the residuals for any

XSL•FO
RenderX

signs of serial correlation and applied appropriate adjustments if necessary. Second, the model assumes homoscedasticity, meaning that the variance of the error terms is constant over time. In cases where heteroscedasticity was detected, we used weighted least squares to account for varying error variances. Finally, the model assumes that the trend changes are continuous at the joinpoints, ensuring smooth transitions between different linear segments. For our study, the log-transformed independent variable for prevalence was time (year), and the dependent variable was prevalence. We used the observation series (i_1, Ppi_1), ...(i_n, Ppi_n), ($i_1 \leq ... \leq i_n$), where n is the study period, and the regression equation for the log-linear model is:

$$E[Ppi|i]=e\beta 0+\beta 1i+\delta 1(i-\tau 1)++\ldots+\delta k(i-\tau k)+$$

where e is the base of the natural logarithm, k denotes the number of turning points, β_0 is the intercept parameter, β_1 is the regression coefficient for the trend, and δk denotes the regression coefficient for segment k. When $(i-\tau_k)>0$, then $(i-\tau_k)^+)=i-\tau_k$; otherwise, $(i-\tau_k)^+)=0$.

We used the APC as well as the 95% CI to describe the change in each line segment, the change between inflection points, and the change over the entire period. The formula used is as follows:

$$APC=(e\beta 1-1)\times 100\%$$

Spatial Analysis

In our study, we used both global and local spatial autocorrelation analyses to explore the spatial distribution characteristics of hypertension prevalence among people lifted out of poverty. For global spatial autocorrelation, we applied Moran I [19] to assess the spatial correlation between data points across the study area. Moran I ranges from −1 to 1. Positive values indicate positive autocorrelation (spatial clustering); negative values indicate negative autocorrelation (spatial dispersion); and a value of 0 indicates no spatial autocorrelation. The formula for calculating Moran I is as follows:

$$I=cW\cdot\sum k=1c\ \sum j=1c\ wkj(Pck-Pc-)(Pcj-Pc-)\sum k=1c\ (Pck-Pc-)2$$

where c is the sample size, that is, the number of counties in the study area, W is the sum of the spatial weight matrix, that is, $W=\sum k=1c\ \sum j=1c\ wkj$, Pc_k, and Pc_j are the prevalence rates of hypertension in the kth and jth counties, respectively, and Pc- is the mean of the prevalence rates of hypertension in counties that have escaped poverty. w_{kj} is an element in the spatial weight matrix, which denotes the spatial relationship between kth and jth counties (which can usually be a neighborhood weight or a distance weight).

In this study, we used the method of clustering and outlier analysis (Anselin Local Moran I) to examine the local spatial autocorrelation, which can effectively identify local autocorrelation patterns in spatial data and help reveal intrinsic patterns and anomalous features of spatial phenomena. Based on the calculated Local Moran I and the results of the significance tests, four types of spatial clusters and outliers, namely high-high, low-low, high-low, and low-high, were identified. The formula for clustering and outlier analysis is as follows:

$$Ik=(Pck-Pc-)m2\sum j=1c\ wkj(Pcj-Pc-)$$
$$m2=1c\sum k\ (Pck-Pc-)2$$

where I_k is the local Moran I value for the kth county and $m2$ is the variance of the prevalence rate across the 832 poverty-alleviated counties.

In spatial analysis, z values and P values are two key indicators used to assess statistical significance. The z value represents the standardized value of Moran I and measures the deviation of the observed value from the expected value. A larger (positive) z value indicates that clusters of higher values are more significant, while a smaller (negative) z value indicates that clusters of lower values are more significant. The P values indicate the probability of the observed outcome occurring by chance, reflecting the statistical significance of the result.

Trend Surface Analysis

Trend surface analysis [20] is a spatial data analysis technique used to describe the overall trend in spatial data by fitting a mathematical model. We used a second-order polynomial trend surface model to analyze the spatial distribution of hypertension prevalence among people lifted out of poverty. The coefficient of determination (R^2) of the model was 0.569, and the root-mean-square error was 3.541, indicating that the model could reveal the spatial trend better, but there is still room for improvement. Comparing with first-order and higher-order polynomials, the first-order model was unable to capture nonlinear variations, and the higher-order model was prone to overfitting and did not significantly improve the goodness-of-fit. We used the geographic coordinates (longitude and latitude) of each province as the independent variables (x-axis and y-axis) and the prevalence rate as the dependent variable (z-axis). In this setup, the x-axis increases from left to right, representing longitude from low to high (west to east); the y-axis increases from bottom to top, representing latitude from low to high (south to north); and the z-axis increases from low to high, indicating higher prevalence rates. In the 3D spatial trend surface analysis graphs, the xy plane indicates the distribution of people lifted out of poverty across different latitude and longitude locations. The xz plane illustrates the trend of hypertension prevalence relative to longitude, and the yz plane indicates the trend of hypertension prevalence relative to latitude.

Ethical Considerations

The original data were collected through a national platform established and managed by the National Health Commission of China. In accordance with national regulations, data collection activities conducted under the Commission's authority are subject to institutional review board (IRB) approval. This study involved a secondary analysis of deidentified, aggregate county-level data, with no individual identifiers or biospecimens, and therefore did not require additional IRB review. According to International and National Ethical Guidelines (eg, 45 CFR 46.104[d] [4] and Article 23 of China's Ethical Review Guidelines), such secondary analyses of anonymized data are exempt from further IRB approval. The authors have obtained

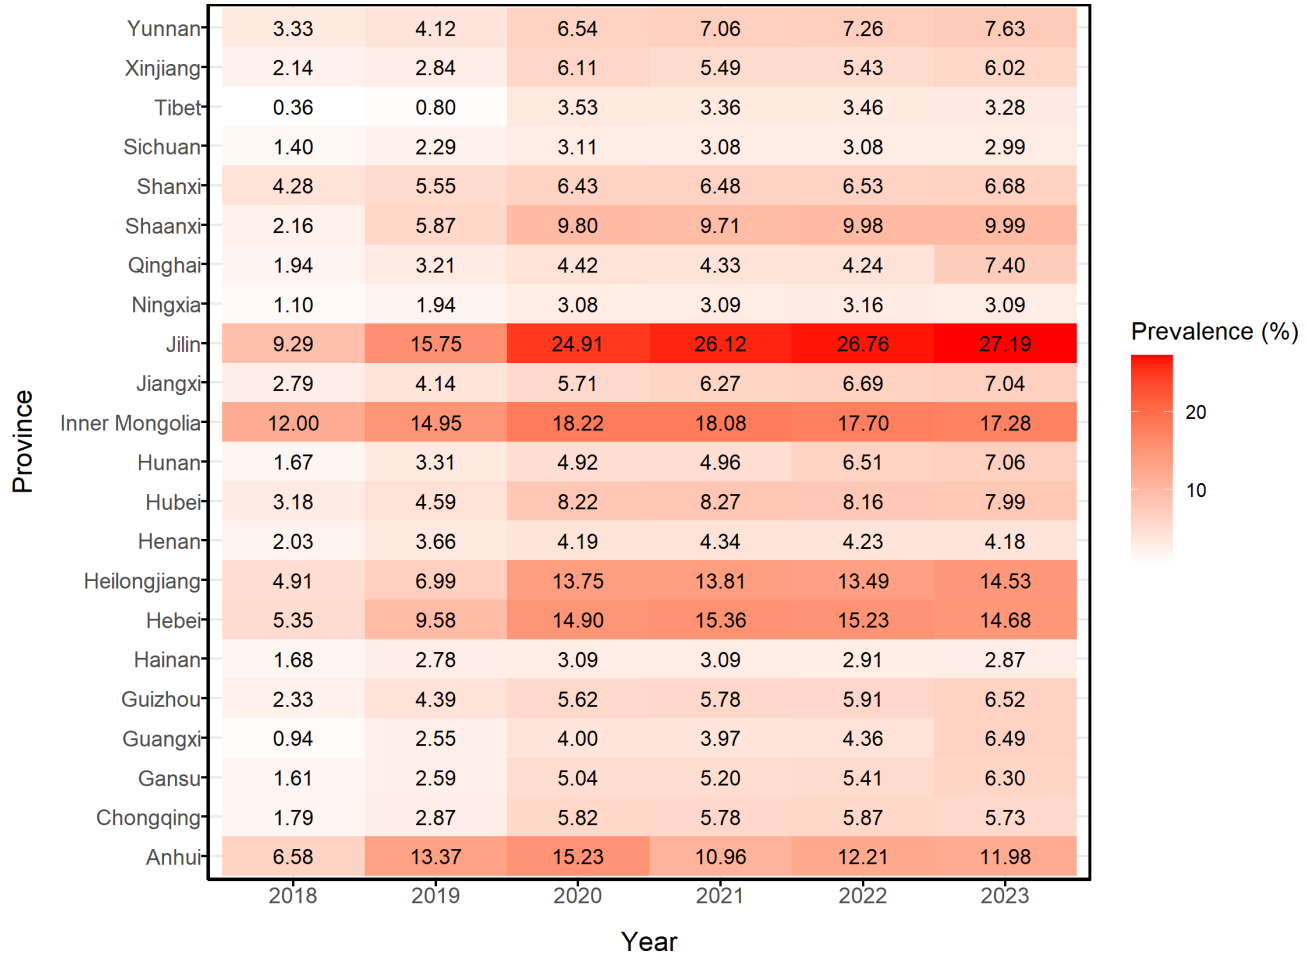
formal permission to access and use the data for academic research purposes.

Results

Epidemiological Characteristics



Between 2018 and 2023, hypertension prevalence among people lifted out of poverty showed an overall increasing trend. As shown in Figure 1, the most significant rise occurred between 2018 and 2020, with the prevalence increasing from approximately 2.71% in 2018 to approximately 6.62% in 2020. There was a slight decrease in prevalence from 2020 to 2021, but the overall trend remained relatively stable. From 2021 onward, the prevalence rate began to rise again gradually, reaching a 6-year peak of approximately 7.29% in 2023. We analyzed the annual trend of hypertension prevalence among people lifted out of poverty across the 22 provinces containing poverty-alleviated counties. As shown in Figure 2, hypertension prevalence varied across provinces from 2018 to 2023. Four provinces—Jilin, Heilongjiang, Inner Mongolia Autonomous Region, and Hebei—exhibited the highest prevalence rates. Notably, Jilin Province had the highest prevalence across all 6 years, peaking at approximately 27.19% in 2023. In addition, we analyzed hypertension prevalence in each of the 832 poverty-alleviated counties. As shown in Figure 3, most counties with high hypertension prevalence among people lifted out of poverty were located in the northeast, followed by the northwest and southwest regions, with consistent regional distribution over the 6 years. Analysis revealed that in 2023, the 17 counties with the highest prevalence were distributed across four regions: Jilin Province (n=5), Heilongjiang Province (n=2), Inner Mongolia Autonomous Region (n=2), and Hebei Province (n=8), as illustrated in Figure 4. Notably, Linxi County in the Inner Mongolia Autonomous Region had a prevalence rate exceeding 40% from 2019 to 2023, peaking at 47.99% in 2022. In parallel, Longjing City in Jilin Province showed a continuous increase in prevalence, with an average annual increase of about 3%.

Temporal Distribution

We analyzed the time trend of hypertension prevalence among people lifted out of poverty across 22 provinces, as shown in Figure 5. Statistically significant APC values were found in only 9 provinces: Yunnan, Shanxi, Qinghai, Jiangxi, Hunan, Hebei, Guizhou, Guangxi, and Gansu. In these provinces, hypertension prevalence showed a consistent year-by-year increase. Guangxi Province had the highest APC value at 27.9018% (95% CI 7.4095% - 52.3038%), followed by Hebei Province with an APC value of 26.4411% (95% CI 0.5839% - 58.9456%), and Hunan Province with the third highest APC value of 24.4372% (95% CI 9.1285% - 41.8933%), as shown in Table 1.

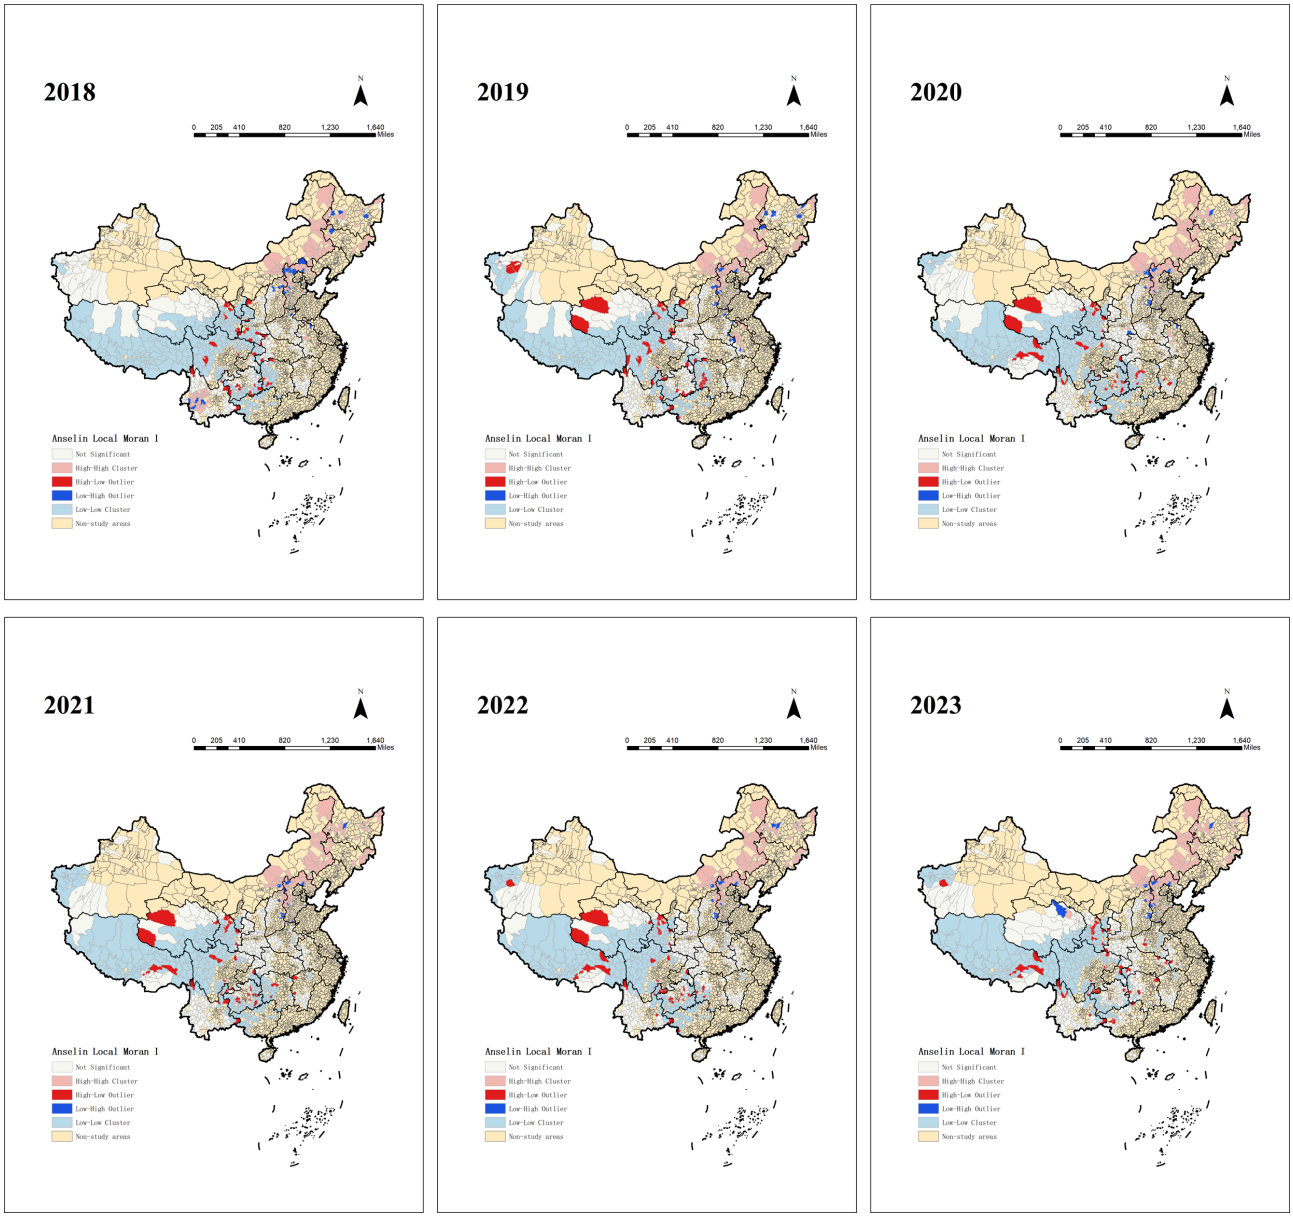
Gansu	22.4657[b] (2.7094 to 46.0222)	3.1983 (5)	.03
Chongqing	17.8208 (−5.5987 to 47.0505)	2.0546 (5)	.11
Anhui	4.4920 (−13.2676 to 25.8881)	0.6549 (5)	.55

[a]APC: annual percentage change.

[b]Indicates that the annual percent change is significantly different from zero at the α=.05 level.

Spatial Distribution



As shown in Table 2, the global spatial autocorrelation analysis revealed that from 2018 to 2023, both Moran I and *z* values were positive. This indicates a significant positive spatial autocorrelation in the distribution of hypertension prevalence among people lifted out of poverty at the county level, reflecting notable spatial clustering. Except for 2020, the variance in the remaining years was 0.000073. This small variance suggests that Moran I showed minimal volatility, indicating stable spatial autocorrelation and limited spatial change trends. As shown in Figure 6, we performed clustering and outlier analysis on hypertension prevalence among people lifted out of poverty in the 832 poverty-alleviated counties. The results showed that the spatial distribution of hypertension prevalence from 2018 to 2023 presents four types of clustering. The high-high clustered areas were mainly distributed in Hebei, Shanxi, Inner Mongolia Autonomous Region, Jilin, Heilongjiang, and Anhui Provinces, where hypertension prevalence was significantly higher than that of the neighboring regions and showed persistent clustering, which may reflect a heavier disease burden in those areas. The identification of high-high aggregation areas is crucial for developing targeted disease prevention and control strategies; therefore, we further identified a county-level list of high-high aggregation areas with high prevalence of hypertension in 2018 - 2023 (refer to Multimedia Appendix 1 for details). The low-low aggregation areas were concentrated in Hunan, Guangxi Zhuang Autonomous Region, Chongqing, Sichuan, Guizhou, Yunnan, Tibet Autonomous Region, Shaanxi, Gansu, Qinghai, Ningxia Hui Autonomous Region, and Xinjiang Uygur Autonomous Region, where hypertension prevalence was significantly lower than that of neighboring regions. High-low aggregation areas were mainly distributed in Hunan, Sichuan, Yunnan, Guizhou, and Gansu Provinces, where hypertension prevalence was relatively high, while neighboring regions had lower rates, possibly reflecting localized disease hotspots. Low-high clusters were mainly located in Hebei, Shanxi, and Heilongjiang Provinces, where hypertension prevalence was lower in these regions but higher in neighboring areas, possibly representing a transitional area of disease spread.

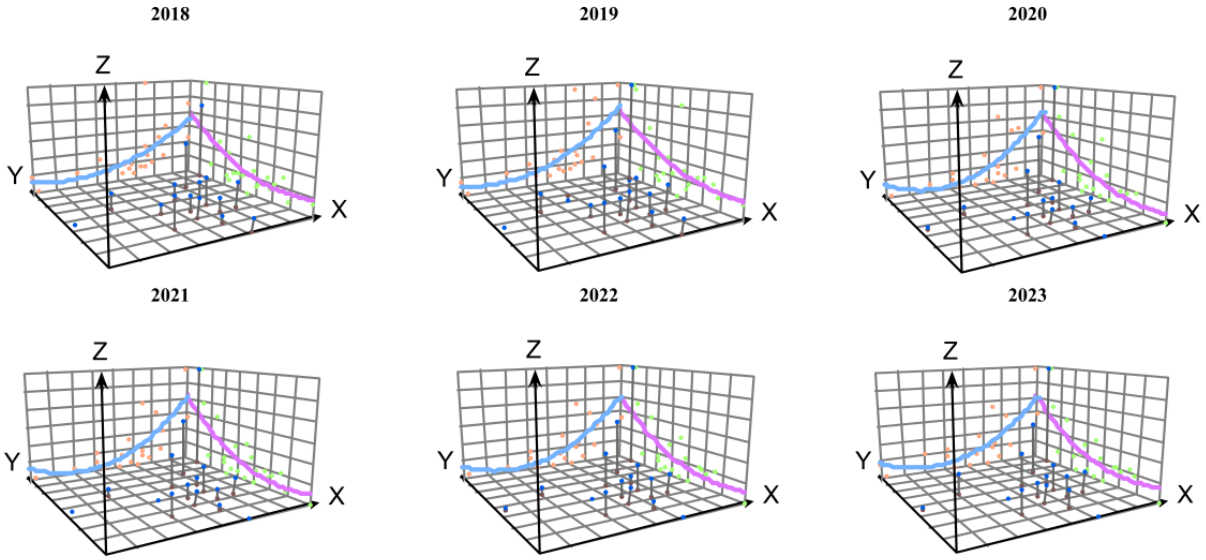
Table . Global spatial autocorrelation analysis of hypertension prevalence among people lifted out of poverty in China (2018-2023).

Year	Moran I	Expected I	Variance	Z value	*P* value	Result
2018	0.256240	−0.001215	0.000073	30.189126	<.001	Clustered
2019	0.272386	−0.001215	0.000073	31.981011	<.001	Clustered
2020	0.319228	−0.001215	0.000074	37.365603	<.001	Clustered
2021	0.329789	−0.001215	0.000073	38.626703	<.001	Clustered
2022	0.315589	−0.001215	0.000073	36.961519	<.001	Clustered
2023	0.282911	−0.001215	0.000073	33.155462	<.001	Clustered

Figure 6. Local spatial clustering of hypertension prevalence among poverty-alleviated counties in China (2018-2023).



Trend Surface Analysis

As shown in Figure 7, there was a clear spatial heterogeneity in hypertension prevalence among people lifted out of poverty at the provincial level. From 2018 to 2023, hypertension prevalence initially decreased with increasing longitude but then increased again at a faster rate. This indicates that the eastern part of the country generally had a higher prevalence than the western part, with the prevalence being lowest in the central and western regions. In 2018, 2021, and 2023, hypertension prevalence among people lifted out of poverty first decreased and then increased with increasing latitude. In contrast, in the remaining years, the prevalence increased with latitude. Overall, the northern regions exhibited significantly higher prevalence rates than the southern, with the southern and south-central provinces having the lowest prevalence. Therefore,

XSL•FO
RenderX

we conclude that the northeastern region generally has the highest prevalence of hypertension among people lifted out of poverty.

Figure 7. Trend surface analysis of hypertension prevalence among people lifted out of poverty in 22 provinces in China (2018 - 2023).

Discussion

Principal Findings

From 1990 to 2019, the number of people with hypertension doubled globally [4]. In our study, hypertension prevalence among people lifted out of poverty in China increased consistently from 2018 to 2023, with a rise of approximately 4.59% in 2023 compared to the level in 2018. The APC values for all provinces were also positive, indicating a general upward trend. This increase in hypertension prevalence in China is likely attributable to rising life expectancy and lifestyle changes [21]. There are four potential factors contributing to the overall increase in hypertension prevalence. First, the Scientific Research Report on Dietary Guidelines for Chinese Residents, issued in 2021, highlights changes in dietary structure. Specifically, there has been an increase in the consumption of high-calorie, high-fat, high-sugar, and high-salt foods. In addition, the rates of overweight and obesity in rural areas have risen more significantly than in urban areas. Obesity is a major risk factor for hypertension [22]. Second, inadequate sleep and poor sleep quality are associated with an increased risk of hypertension [23]. Insufficient sleep can lead to cognitive decline and poor mental health, while high-pressure environments, mental overstimulation, and anxiety can trigger hypertension [24,25]. Third, population aging significantly contributes to the rising prevalence of hypertension. As Chinese society ages, the proportion of older individuals is increasing, and this age group is particularly susceptible to chronic diseases, such as hypertension [26]. Fourth, the increased prevalence of hypertension is not only closely related to environmental factors and lifestyle but is also significantly influenced by hereditary factors. Studies have shown that individuals with a family history of hypertension have a significantly increased risk of developing the condition. This is because certain genetic variants and genes can affect blood pressure regulatory mechanisms, making individuals with genetic susceptibility more prone to developing hypertension [27,28].

According to the spatial autocorrelation analysis, the high-high aggregation area is mainly distributed in the three northeastern provinces and northern China. The low-high aggregation area is distributed at the junction of northern China and northeastern China, and the high-low aggregation and low-low aggregation areas are mainly located in the west. Trend surface analysis shows that hypertension prevalence is higher in the east than in the west, and in the north than in the south. As early as 1994, a study found that hypertension prevalence was higher in northern China than in southern regions [29].

The spatial heterogeneity in hypertension prevalence among people lifted out of poverty may be explained by the following three factors: First, some studies have shown that high-altitude areas may experience abnormal blood pressure regulation due to hypoxia, which can increase the risk of hypertension [30-32]. The lower prevalence of hypertension in Tibet and Qinghai Provinces may be because residents have been exposed to low oxygen levels from birth and have developed adaptations to better cope with high-altitude conditions [33]. In addition, the diversity of physiological changes may result in different adaptations among high-altitude populations. For instance, research has shown that Tibetan populations exhibit better adaptation than non-Tibetan populations due to higher capillary density and greater oxygen delivery [34]. Experimental studies have also indicated that in Tibetan populations, hypertension prevalence increases by 1.2% for every 100-meter increase in altitude, a phenomenon not observed in all high-altitude populations [35]. In non-Tibetan populations, there is no significant correlation between increased altitude and changes in blood pressure [36]. Second, temperature changes can also impact blood pressure. A study conducted in northwest China found a significant negative correlation between outdoor temperature and blood pressure, with blood pressure

XSL•FO
RenderX

demonstrating notable seasonal variations [37]. This seasonal variation in blood pressure is likely due to changes in ambient temperature, as another study showed that the seasonal variation disappeared after adjusting for temperature [38]. Larger differences in blood pressure between colder and warmer months may increase hypertension prevalence, potentially elevating cardiovascular risk, especially among individuals at high cardiovascular risk and older individuals [39]. Third, dietary differences between the northern and southern regions of China also play a significant role. Regular consumption of high-sodium diets, energy-dense foods, fats, refined carbohydrates, added sugars, and low amounts of fruits and vegetables increases the risk of hypertension and cardiovascular disease. According to the Chinese Guidelines for Adults with Hypertension, issued in 2023, the diet in northeastern China is characterized by stews with a heavy taste, while in central China, food processing methods, such as pickling and curing, are popular, also resulting in heavily seasoned dishes. Meanwhile, southwestern China is known for its preference for spicy food. These guidelines emphasize the need to control oil and salt use across all regions. The Dietary Approaches to Stop Hypertension (DASH) diet was introduced in the United States in 1997 as a dietary pattern to prevent and manage hypertension. This diet focuses on reducing fats and oils while ensuring adequate intake of vegetables, fruits, and low-fat dairy products to maintain optimal levels of potassium, magnesium, and calcium, all of which significantly reduce blood pressure [40-42]. In addition, the Chinese heart-healthy diet and its Sichuan cuisine version, tailored for the Chinese population, have shown significant positive effects in reducing the risk of developing hypertension [43,44].

High-high aggregation areas should be used as key intervention areas to strengthen screening and early intervention, optimize medical resource allocation, and promote low-salt and low-fat diets and moderate exercise through health education. Although the current burden of disease in low-low aggregation areas is low, continuous monitoring is needed. High-low aggregation areas may reflect localized disease hotspots, requiring special attention to the distribution of health care resources, increased investment in primary care, and the development of personalized prevention and control strategies. Low-high aggregation areas may be transitional areas for the spread of the disease, and monitoring and regional joint prevention and control should be strengthened to prevent the spread of hypertension from areas of high prevalence to areas of low prevalence.

Uncontrolled hypertension can result in severe health issues, including stroke, cardiovascular diseases, and kidney diseases, leading to unnecessary human burden and premature death. Despite significant investments by the state in poverty alleviation and rural revitalization [45], the health service system remains inadequate. The prevention and control of chronic diseases, such as hypertension, still face considerable challenges due to limited medical resources and a lack of widespread health education [46]. Both national and local governments should enhance interregional collaborative efforts to address the regional differences and clustering patterns in hypertension prevalence [47]. Establishing cross-regional collaboration mechanisms for hypertension prevention and control, information sharing, resource complementation, and joint efforts can enhance the overall effectiveness of these initiatives. In addition, increased investment in medical resources in impoverished areas has optimized the allocation of these resources. The capacity to prevent and control hypertension in these regions has been strengthened through the development of primary health care institutions, training of primary health care personnel, and the promotion of telemedicine. Nurses can make significant contributions to national hypertension control efforts by leveraging evidence-based practices for the prevention, diagnosis, treatment, and management of hypertension [48]. Furthermore, strengthening health education and public awareness initiatives is crucial for promoting healthy lifestyles and dietary habits. Raising public awareness about hypertension and its prevention involves disseminating knowledge through health promotion activities and educational interventions. Providing targeted education to patients with hypertension can encourage the adoption of healthy behaviors and improve overall health outcomes [49].

Limitations

There are some limitations to this study. First, using the total recorded population in each county that has escaped poverty as the county's total population may introduce statistical errors, as this figure may include mobile populations. Second, the study did not account for seasonal changes, which affect both temperature and dietary patterns and can influence hypertension prevalence. Finally, while this study analyzed the spatial and temporal prevalence of hypertension, further research is needed to examine the underlying factors affecting hypertension prevalence to develop more targeted and effective prevention guidelines.

Conclusions

In this study, we determined the temporal trends and spatial distribution of hypertension prevalence among Chinese individuals lifted out of poverty from 2018 to 2023. Our findings reveal an overall increasing trend in hypertension prevalence year by year. High-prevalence areas were notably concentrated in the northeastern poverty-alleviated counties, while low-prevalence areas were found primarily in the southwestern counties.

Abstract

Background: Scrub typhus (ST), also known as tsutsugamushi disease, is a common febrile vector-borne illness in South Korea, transmitted by trombiculid mites infected with *Orientia tsutsugamushi*, with rodents serving as the main hosts. Although vector-borne diseases like ST require both a One Health approach and a spatiotemporal perspective to fully understand their complex dynamics, previous studies have often lacked integrated analyses that simultaneously address disease dynamics, vectors, and environmental shifts.

Objective: We aimed to explore spatiotemporal trends, high-risk areas, and risk factors of ST by simultaneously incorporating host and environmental information.

Methods: ST cases were extracted from the 2013 - 2019 Korea National Health Insurance Service data at 250 municipal levels and by epidemiological weeks (*International Classification of Diseases, Tenth Revision, Clinical Modification code*: A75.3). Data on potential risk factors, including the maximum probability of rodent presence, area of dry field farming, forest coverage, woman farmer population, and financial independence, were obtained from publicly available sources. In particular, the maximum rodent presence probability was estimated using a maximum entropy model incorporating ecological and climate variables. Spatial autocorrelation was assessed using Global Moran *I* statistics with 999 Monte Carlo permutations. Spatial and temporal clusters were identified using Getis-Ord Gi* and hot and cold spot trend analyses. Bayesian hurdle models with a spatiotemporal interaction term, accounting for zero-inflated Poisson distribution, were used to identify associations between ST incidence and regional factors. Stratification analyses by gender and age group (0 - 39, 40 - 59, 60 - 79, and ≥80 years) were performed.

Results: Between 2013 and 2019, 95,601 ST patients were reported. ST incidence had positive spatial autocorrelation (*I*=0.600; *P*=.01), with spatial expansion from southwestern to northeastern regions. Spatiotemporal models demonstrated better fit compared with spatial and temporal models, as indicated by lower Watanabe-Akaike information criterion (WAIC) values. Municipalities with higher rodent suitability (β coefficient=0.618; 95% credible interval [CrI] 0.425 - 0.812) and lower financial independence from central government (β coefficient=−0.304; 95% CrI −0.445 to −0.163) had higher likelihoods of increased ST incidence, even after adjusting for spatiotemporal autocorrelation. However, risk factors varied by age group: among individuals aged 40 years or older, ST incidence was positively associated with rodent suitability, while patients in the 0 - 39 years age group showed no association with rodent suitability (β coefficient=0.028; 95% CrI −0.072 to 0.126), and ST incidence was negatively associated with the women farmer population (β coefficient=-0.115; 95% Crl=−0.223 to −0.006).

Conclusions: This is the first study to investigate ST in South Korea using a spatiotemporal framework grounded in a holistic One Health perspective. We elucidated the critical role of spatiotemporal dynamics in ST distribution, highlighting rodent suitability and economic independence as key drivers of disease distribution. Our findings lay the groundwork for evidence-based, region-specific intervention strategies and may inform targeted public health strategies in South Korea and other settings with similar ecological conditions.

Introduction

Scrub typhus (ST), also known as tsutsugamushi disease, is a vector-borne illness transmitted by trombiculid mites infected with *Orientia tsutsugamushi* [1]. It is a common cause of acute febrile illness across the Asia-Pacific region, including South Korea [1]. Clinical manifestations range from acute fever, headache, rash, and skin eschars at mite bite sites to severe conditions such as acute respiratory distress syndrome, kidney failure, and multiorgan failure, particularly in the absence of timely antibiotic treatment [1,2]. Despite advances in diagnostics and treatment for decades, no effective vaccine exists [2]. The disease primarily occurs during the chigger mite breeding season, typically with an autumn peak in South Korea [3], a seasonal pattern also observed in leptospirosis and hemorrhagic fever with renal syndrome, with rodents as the primary host [4,5].

Analyzing ST requires a holistic approach that considers individual attributes, vectors, and environmental factors, aligned with the One Health perspective [6]. The One Health perspective can improve our understanding of the disease and help identify risk factors by addressing various factors simultaneously, enabling more effective prevention and interventions in person, time, and place [7,8]. In South Korea, *Apodemus agrarius*, the most common rodent species, has been identified as an important reservoir of zoonotic pathogens, including *Orienta tsutsugamushi*, highlighting the need to integrate host surveillance within a One Health framework to support comprehensive public health strategies [9]. However, previous studies have limitations in simultaneously addressing various factors. Most surveys focused primarily on individual experiences [10,11], and ecological studies have addressed environmental factors without considering the distribution of vectors and rodents [12-15]. Previous studies exploring the association between vector distribution and ST infections have overlooked the information environment and human behavior [16], such that they had limitations in suggesting robust risk factors.

Studies on vector-borne diseases have mandated integrated spatiotemporal analyses that encompass disease dynamics, vectors, and environmental shifts. Spatiotemporal methods can help identify high-risk areas [17,18], understand disease transmission [19], monitor disease trends [19], and assess the impact of environmental factors [17,19]. Although previous studies considered both the spatial and temporal axes simultaneously, the studies had limitations in pursuing the One Health approach [12,13,20].

Therefore, we aimed to investigate the spatiotemporal trends, high-risk areas, and risk factors of ST by integrating hosts and environmental information, and spatiotemporal dynamics. These findings are expected to provide a robust foundation for evidence-based policies to alleviate the disease burden, with particular emphasis on rodent distribution as a central determinant of ST risk.

Methods

Data

Scrub Typhus Data

Data on ST cases from 2013 to 2019 were extracted from the National Health Insurance Service (NHIS) of South Korea. We used the NHIS claims data, which cover the entire Korean population under the country's universal health insurance system. Unlike data from the national infectious disease surveillance system, which may be affected by periodic changes in reporting criteria, NHIS data are stable and structured, making them suitable for long-term trend analysis [21]. Therefore, although surveillance reporting criteria were revised in 2019, their impact on NHIS data were limited, and we retained the study period to 2013 - 2019 to ensure sufficient temporal coverage.

ST was defined according to the *International Classification of Diseases, Tenth Revision*, Clinical Modification code (ICD-10-CM code) of A75.3. The data were extracted in 250 municipal-level administrative boundaries on the spatial axis and were extracted in epidemiological week, commonly referred to as Morbidity and Mortality Weekly Report weeks [22], and calendar month on temporal axis. In South Korea, administrative divisions are organized into 4 levels: National, State (Sido), Municipal (Si [cities], Gun [counties], Gu [districts]), Town (Eup-Myun-Dong). The data included information on residential address coded by municipality, gender (men and women), and age group, which were extracted in 20-year interval category (0 - 39 years, 40 - 59 years, 60 - 79 years, and ≥80 years of age) because of privacy-related data extraction regulations of the data provider. Patients with complete data were included in the analyses.

As the standard analysis unit, municipal-level administrative boundaries in 2019 and epidemiological weeks were used to ensure comparability across years. For spatial analysis, a municipal-level shapefile was obtained from the publicly accessible Statistical Geographic Information Service [23]. Population data to calculate incidence per 100,000 population for descriptive analysis was extracted from Statistics Korea [24].

Potential Risk Factors

The maximum probability of rodent presence by municipality was selected as a potential risk factor of ST to consider reservoir distribution, aligned with the One Health perspective [6]. Based on previous studies, information on the maximum probability of the presence of rodents was made using the maximum entropy model (MaxEnt) [25], with point data of rodent existence, human population density [26], and various environmental raster data: 2014 - 2018 average enhanced vegetation index (EVI) [27], land surface temperature (LST) data [27], and a digital elevation model (DEM) [27]. Rodent existence point data were extracted from the 2014 - 2018 National Ecosystem Survey data from the Ministry of Environment [28] regardless of the rodent species and deleted the redundant points. The raster data of human population density in 1×1 km resolution was extracted from "The spatial distribution of population density in 2018,

XSL•FO
RenderX

South Korea" in WorldPop hub [29]. The raster data of EVI and LST were extracted from moderate-resolution imaging spectroradiometer (MODIS) remote sensing data using *MODIStsp* package [30] in R software (version 4.2.1 R Foundation for Statistical Computing). Monthly EVI raster at 1×1 km resolution and daily daytime and nighttime LST at 1×1 km were averaged. The DEM raster at 90×90 m was extracted from the National Spatial Data Infrastructure Portal of the Ministry of Land, Infrastructure, and Transport [31]. The study area of MaxEnt was set outside of a 10 km buffer from rodent existence points for the model to study various environmental areas beyond the point where rodents were discovered. The results of the MaxEnt model showed a better prediction than the random model, with an area under the curve of 0.690. The maximum rodent suitability by municipality was then extracted from the results of the MaxEnt model.

Besides maximum rodent suitability, area of dry field farming [10,11,32,33], forest coverage [32], woman farmer population [11,33], and financial independence as a socio-economic status of the municipality [34] were included based on previous studies and relevance to ST transmission (Table 1). The woman farmer population was defined as the number of females formally engaged in farming activities per municipality and year and used as an ecological indicator of agricultural exposure of women. This variable was selected based on the higher burden of ST among women in Korea and previous findings suggesting strong associations between agricultural activity and ST incidence in women [11,33]. Information on each variable was extracted in year and municipality level. In addition, the population of women and men farmers was extracted from Korean statistical information service at the year and state level to compare the gender ratio in farming population by year and state as supplementary information. Although other potential predictors such as meteorological factors were considered, relevant environmental conditions were already incorporated into rodent suitability construction. Variables were selected considering epidemiological plausibility, municipal-level data availability, and efforts to reduce collinearity among predictors. The shapefile was obtained from the National Spatial Data Infrastructure Portal [31].

Table . Description and data sources of outcome and potential risk factors for scrub typhus incidence in South Korea, 2013-2019.

Variables	Description	Sources
Scrub typhus		
Cases (n)	Cumulative scrub typhus cases by municipality and epidemiological week	NHIS[a]
Potential risk factors		
Maximum rodent suitability	Maximum possibility of rodent presence made by maximum entropy model using point data of rodent existence and various environmental raster data, per municipality (range: 0.0 - 1.0)	NESD[b], WorldPop hub, MODIS[c], NSDIP[d]
Financial independence (%)	Total earned income over total expense, per municipality and year	KOSIS[e]
Forest area (m^2)	Land that forms forests and fields, per municipality and year	KOSIS[e]
Dry field farming area (m^2)	Land that mainly grow plants that do not apply water, per municipality and year	KOSIS[e]
Woman farmer population (n)	Population of women farmers, per municipality and year	KOSIS[e]
Offset		
Population (n)	Human population based on the resident registry in, per municipality	KOSIS[e]

Statistical Analysis

Descriptive Analysis

The frequency and incidence of ST were analyzed with respect to calendar year, gender, and age group, similar to the approach used in a previous study [21]. Descriptive statistics, including mean, SD, minimum, median, first quartile, third quartile, maximum, and coefficient of variation, were used to summarize the baseline information for the variables. As the dataset overlaps with that in the previous study [21], relevant findings were referenced. However, this study introduces spatiotemporal analysis methods and adopts more suitable age groupings, offering a refined understanding of ST dynamics over time and space.

XSL•FO
RenderX

To examine the spatiotemporal distribution of ST incidence, choropleth maps depicting ST incidence per 100,000 population with quintile intervals were created, stratified by calendar year, gender, and age group. Since maps only visualize data and cannot provide definitive conclusions due to various sources of uncertainty, Global Moran's *I* statistics were used with 999 Monte Carlo permutations ($P<.05$) to quantify the annual spatial autocorrelation in ST incidence. The Moran's *I* index ranges from −1 to 1, with a positive value signifying a positive spatial autocorrelation. This implies that regions with high variable values are likely to be close to each other. The significant results of Global Moran's *I* statistics could provide verification to consider spatial autocorrelation for further analysis. Subgroup analyses were conducted based on gender and age group.

Furthermore, a Getis-Ord Gi* analysis stratified by calendar year, gender, and age group was performed to identify municipal-level clusters within each stratum. Municipalities with high positive *z* scores, resulting from the Getis-Ord Gi* analysis, indicated "hot spots," signifying spatial clustering of high values. Conversely, "cold spots" were characterized by low negative *z* scores, indicating spatial clustering of low values surrounded by other low-value municipalities. The results of Getis-Ord Gi* analysis provide information on locations with either high or low value of ST incidence that are statistically significantly clustered.

The hot and cold spot trend (HCT) analysis was performed, which is the visualization of a space-time cube in 2 dimensions. The HCT depicts increasing and decreasing *z* scores resulting from Mann–Kendall statistics, classified as "up trend," "down trend," or "no significant trend" with confidence levels of 90%, 95%, and 99%, respectively. Thus, while Getis-Ord Gi* analysis tests clustering on spatial axis, HCT analysis examines statistical trends across both spatial and temporal axes. The results could test whether the ST clusters expand in spatial and temporal perspectives. The three-dimensional space-time cube (x, y, and t) was generated using the "Create Space Time Cube From Defined Locations" tool, with 250 municipal polygons as spatial units and one calendar month as temporal units, resulting in 21,000 bins (250 spatial units×84 temporal units). Missing values in each bin were replaced with zeros. Spatial analyses, including mapping, assessment of spatial autocorrelation, and cluster identification, were performed using R version 4.2.1 [35], and HCT analysis was conducted using ArcGIS Pro version 3.3.1 (Esri) [36].

Modeling

Modeling was performed to explore the association between ST incidence and each potential risk factor after adjusting the effect of space and time trend. For modeling, continuous predictors, including rodent suitability, were standardized due to varying units. Age-standardized ST incidence per 100,000 population was summarized using population data from Population and Housing Census in 2015 [37]. Univariable linear regression was conducted for each variable using age-standardized ST incidence as dependent variable. Variables with a *P* value ≥.25 [38] were identified for exclusion in the multivariable regression (Table S1 in Multimedia Appendix 1). Multicollinearity was assessed using a variance inflation factors threshold of 10 in the multivariable regression (Table S2 in Multimedia Appendix 1).

The primary analytical method used was the Bayesian hurdle Poisson spatiotemporal analysis using the Integrated Nested Laplace Approximation (INLA) approach [39,40], a computationally efficient alternative to the frequently used Markov Chain Monte Carlo simulations [40]. INLA delivers precise and fast results for latent Gaussian models [40] and is widely applied in spatiotemporal models to handle model complexity and vast database dimensions [41,42].

The zero-inflated Poisson distribution was managed using the hurdle Poisson model due to the excessive zeroes in the ST incidence data [39,43]. A hurdle model outperforms a zero-inflated model when covariates have the possibility of zero deflation when using excess zero data [43]. Thus, a hurdle model was constructed with 2 likelihoods (Bernoulli and truncated Poisson) in the INLA [39,44]. The Bernoulli distribution, implemented as "binomial" in the R-INLA, modeled the probability of any case occurrence [40,44], while the zero-truncated Poisson distribution, specified as "poisson," captured the incidence when cases occurred [44]. The age-standardized incidence of ST per municipality, ii=1,…,250 and epiweek, tt=1,…,365 can be represented as Yit, using a hurdle Poisson model as follows:

$$P(Yit=y|p,\mu)=\{p \quad yit=0,(1-p)e-\mu\mu y/y!1-e-\mu \quad yit>0$$

where p denotes the probability that a participant belongs to the zero component. First, to examine the necessity of spatiotemporal interaction term compared to each spatial and temporal term, three base models were constructed as follows:

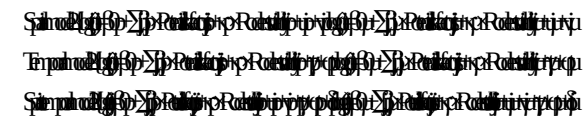
$$\text{Spatial model 0 } \{\log it(pit)=\beta 0p+uip+vip\log(\mu it)=\beta 0\mu+uiμ+viμ$$

$$\text{Temporal model 0 } \{\log it(pit)=\beta 0p+\gamma tp+\varphi tp\log(\mu it)=\beta 0\mu+\gamma t\mu+\varphi t\mu$$

$$\text{Spatiotemporal model0}\{\log(\beta 0)+uip+vip+\gamma tp+\varphi tp+\delta itp\log(\mu it)=\beta 0\mu+uiμ+viμ+\gamma tμ+\varphi tμ+\delta iμ$$

where μit denotes the exponential value of ST incidence for municipality i and epiweek t, β0 denotes intercept [45]. The model contains ui as an intrinsic conditional auto-regressive (iCAR) term, vi as a spatially unstructured term, γt as a temporally structured effect using an autoregressive model of order 1, and φt that has been specified as φt~Normal0,1τφ [46]. The term δit is an interaction term of spatial and temporal structured effect [46]. The spatial weight matrix, which determines the iCAR term, represents a neighboring relationship among the 250 municipalities. The neighbor matrix was constructed using k-nearest neighborhood, with k as 3. Priors followed the default options of R-INLA.

In addition, to assess the effect of potential risk factors other than maximum rodent suitability on ST incidence, a term for these factors was added to each model. When βj denotes regression parameters of each potential risk factor excluding the maximum possibility of rodent presence, the model was constructed as follows:



$$\text{Spatial model}\{\log(\beta 0)+\sum\beta j\times\text{Covariate}jp+uip+vip\log(\mu it)=\beta 0\mu+\sum\beta j\times\text{Covariate}j\mu+uiμ+viμ$$

$$\text{Temporal model}\{\log(\beta 0)+\sum\beta j\times\text{Covariate}jp+\gamma tp+\varphi tp\log(\mu it)=\beta 0\mu+\sum\beta j\times\text{Covariate}j\mu+\gamma tμ+\varphi tμ$$

$$\text{Spatiotemporal model}\{\log(\beta 0)+\sum\beta j\times\text{Covariate}jp+uip+vip+\gamma tp+\varphi tp+\delta itp\log(\mu it)=\beta 0\mu+\sum\beta j\times\text{Covariate}j\mu+uiμ+viμ+\gamma tμ+\varphi tμ+\delta iμ$$

XSL•FO
RenderX

Finally, to assess the risk of rodent suitability on ST incidence after accounting for other potential risk factors, and vice versa, a term of rodent suitability was added to each model, where κ denotes the coefficient for rodent suitability, as follows:

To compare the fit of the models, the Watanabe-Akaike information criterion (WAIC) was used. WAIC offers the advantage of averaging over the posterior distribution instead of relying on a single-point estimate, making it particularly valuable for models with hierarchical or mixed structures where point estimates may not be meaningful, even in cases involving singular models [47]. In general, a model with smaller WAIC value was better supported by data [47]. In this study, final model selection considered both WAIC values and the scientific relevance of covariates. Specifically, we prioritized models that allowed evaluation of our primary hypothesis regarding habitat suitability as a risk factor for scrub typhus incidence. Posterior means and 95% credible intervals (CrI) were reported, and model fit was evaluated spatially and temporally by plotting the fitted and predicted values of ST incidence.

Subgroup analyses by sex and age groups (0 - 39, 40 - 59, 60 - 79, and ≥80 years of age) were conducted using ST case counts as the outcome and the log-transformed population as an offset. Information on woman farmer population was excluded when performing subgroup analysis according to gender, to avoid the possibility of overcorrection. Modeling was performed using R software (version 4.2.1; R Foundation for Statistical Computing) [35] (Multimedia Appendix 2).

Sensitivity Analysis

Sensitivity analysis was performed using a different spatial weight matrix constructed through a k-nearest neighbor approach, with k set at 5, to assess the robustness of the results. In addition, another sensitivity analysis was conducted using the number of ST cases as the outcome and log-transformed population as an offset.

Ethical Considerations

This study received an exemption from the Institutional Review Board (IRB) of Korea University (IRB exemption number: KUIRB-2021-0237-02) as the data used in this study were fully anonymized and contained no personally identifiable information. The requirement for obtaining informed consent was waived as the study was observational in design. As the analysis used secondary data, no compensation was provided.

Results

Descriptive Analysis

A total of 95,627 ST cases were extracted between December 30, 2012, and December 31, 2019 from the NHIS data at the municipal level. For the descriptive analysis, 95,601 patients with ST were considered, and for the modeling, 95,582 patients with cases that corresponded to the epiweek-based study period (from the first epiweek of 2013 to the 52nd epiweek of 2019) were included (Figure 1).

XSL•FO
RenderX

Between 2013 - 2019, ST cases (18,822 in 2013; 7770 in 2019) and incidence per 100,000 population (36.8 in 2013; 15.0 in 2019) decreased (Table S3 in Multimedia Appendix 1, [21]). Although a marginal increase was observed in 2016 (cases: 17,086; incidence: 33.1), the cases decreased by around 58.7% between 2013 - 2019, with a 59.02% decrease in incidence over the same period. The ST incidence per 100,000 population was consistently higher in women than in men between 2013 - 2019 (men: 22.0, women: 30.9). The ≥80 years of age group had the highest incidence (94.6), followed by the 60 - 79 (79.4), 40 - 59 (24.1), and 0 - 39 age group (4.96; Table S4 in Multimedia Appendix 1) [21].

Baseline information for each variable is provided in Table 2. The average number of ST cases in 2013 - 2019 at the municipal level and epiweek was 1.0 (SD 3.5) and the coefficient of variance (CV) was 3.4, suggesting regional and temporal variations. The CV of potential risk factors ranged from 0.2 to 1.1, indicating lower regional and temporal variation than ST incidence per 100,000 population (CV=4.2).

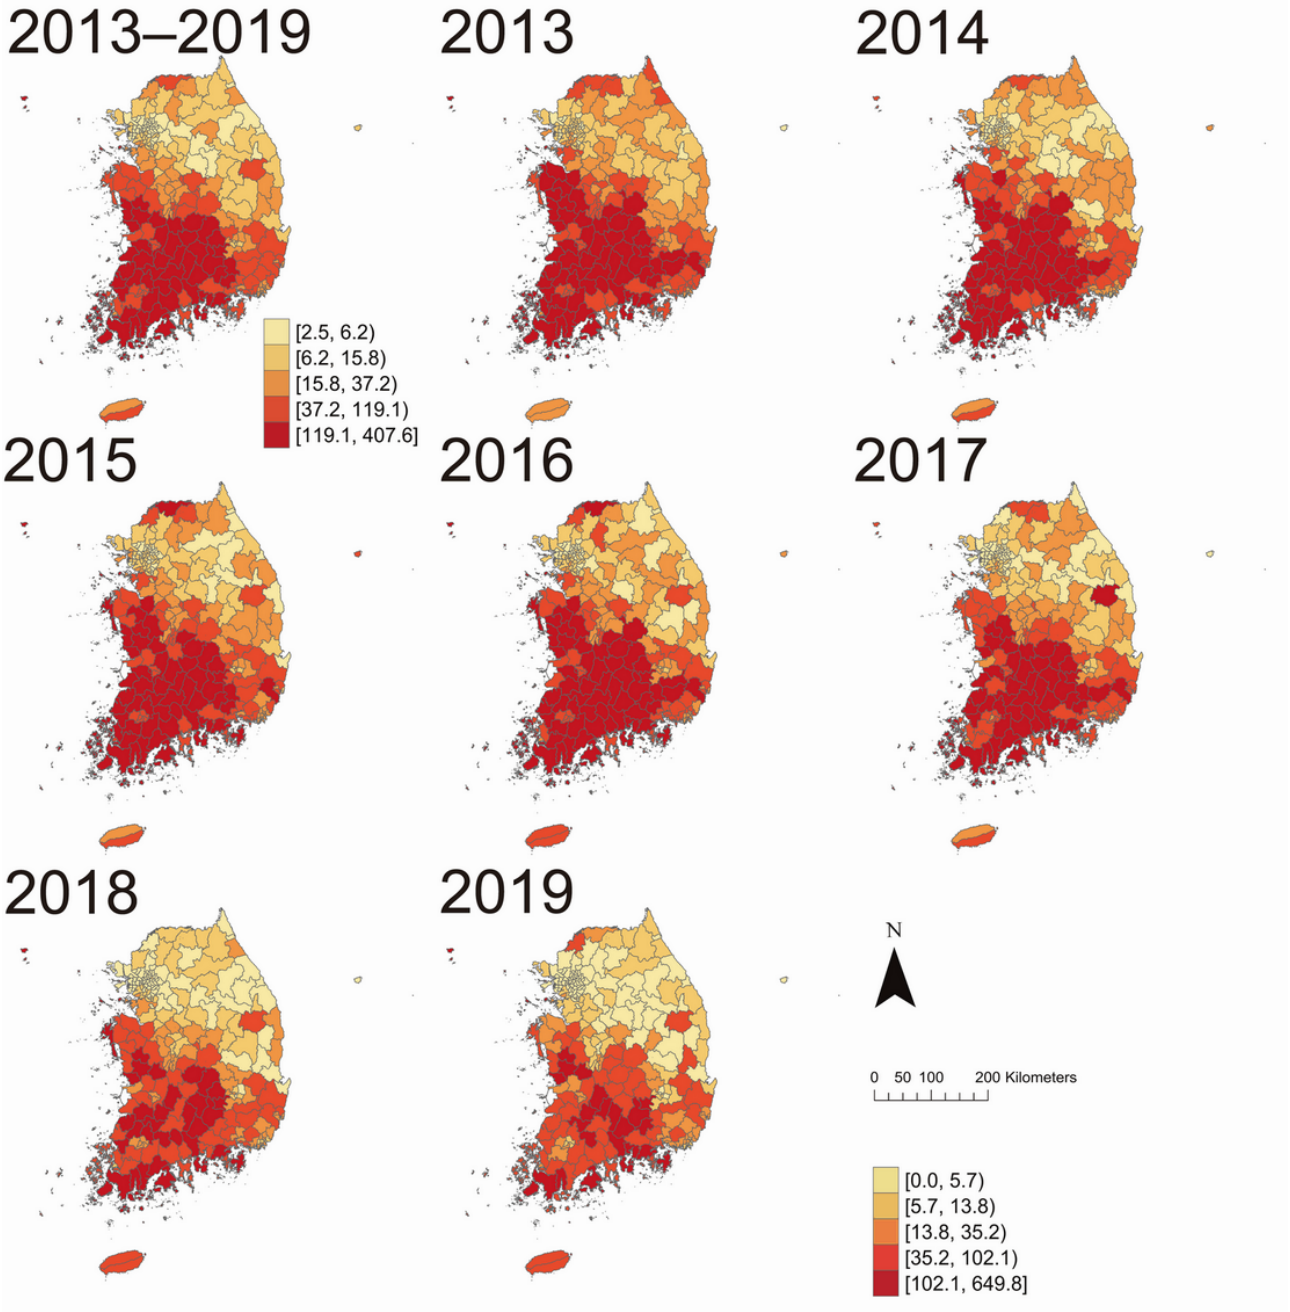

Table . Summary statistics of scrub typhus incidence and potential risk factors by municipality and epidemiological week in South Korea, 2013-2019.

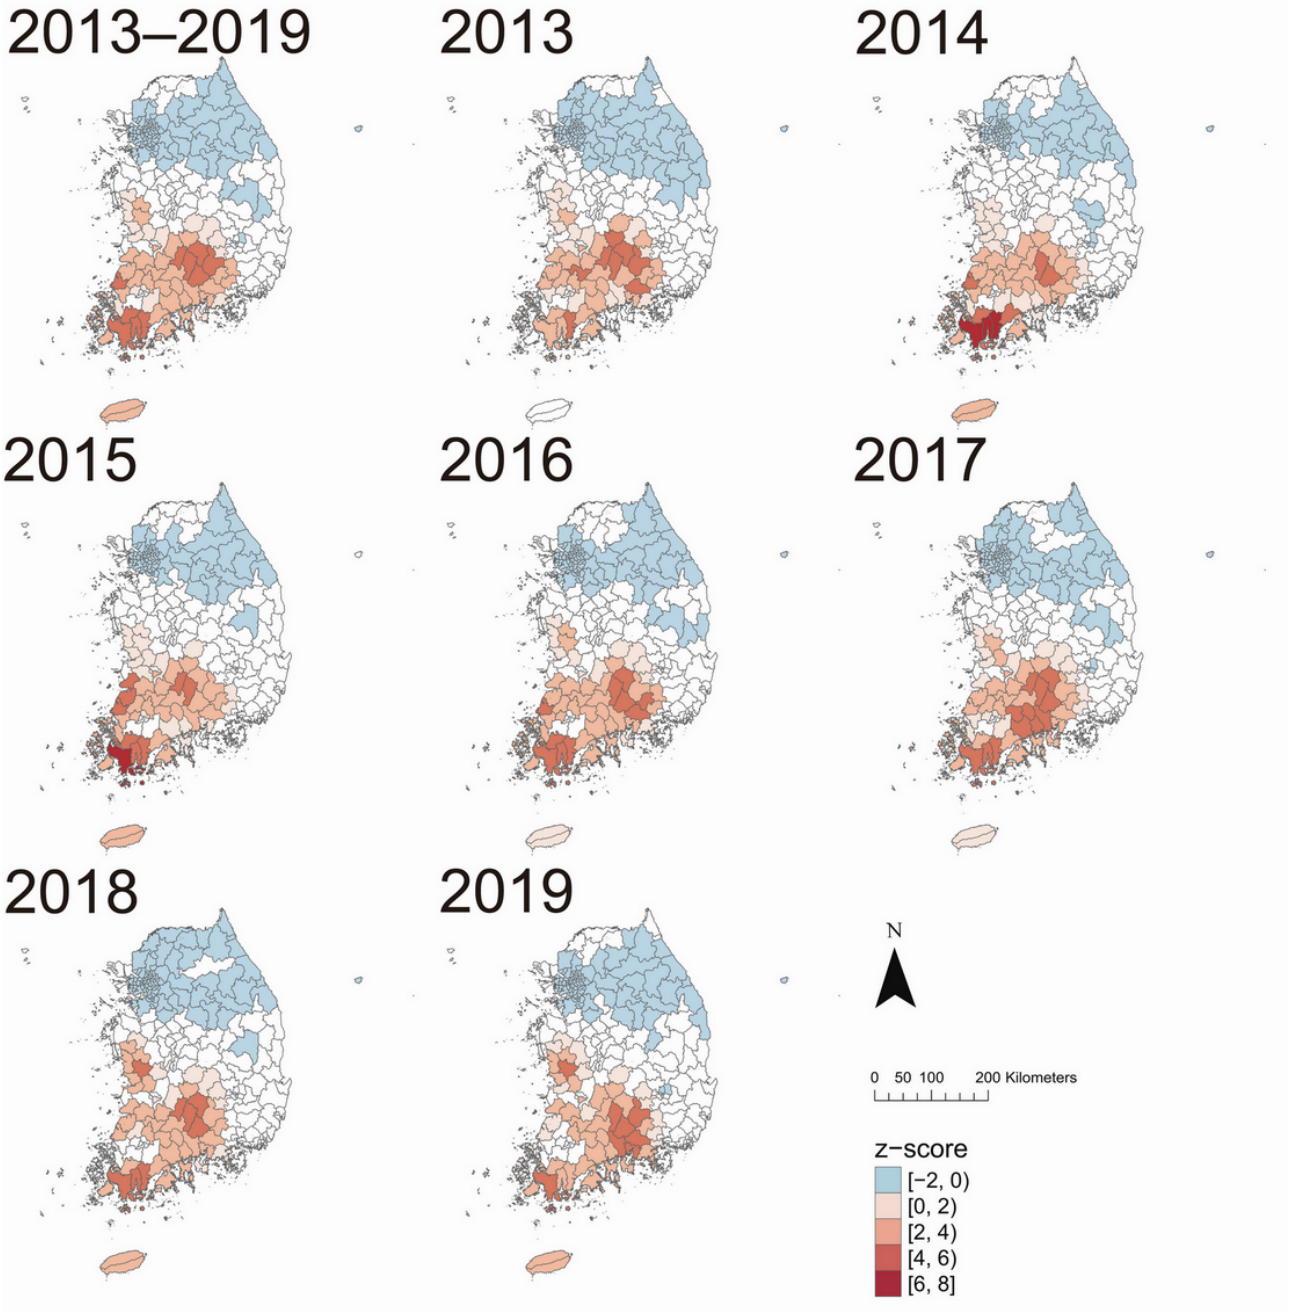
Variables	Mean (SD)	Minimum	Median (Q1-Q3)	Maximum	Coefficient of variance
Scrub typhus					
Cases (n)	1.0 (3.5)	0.0	0.0 (0.0-1.0)	81.0	3.4
Incidence per 100,000 population	1.0 (4.1)	0.0	0.0 (0.0-0.3)	105.7	4.2
Potential risk factors					
Maximum rodent suitability	0.8 (0.2)	0.1	0.8 (0.7-0.9)	1.0	0.2
Financial independence (%)	28.6 (14.9)	7.3	24.2 (16.3-38.9)	75.9	0.5
Forest area (m^2)	255,633,212.9 (287,531,335.5)	0.0	178,314,785.4 (18,240,087.4-405,361,824.9)	1,532,013,213.1	1.1
Dry field farming area (m^2)	30,624,701.2 (32,395,574.9)	0.0	23,566,365.5 (2,706,313.0-52,257,727.8)	210,272,858.0	1.1
Woman farmer population (n)	5,153.8 (4,617.4)	147.0	4286.0 (1068.0-7939.0)	32,932.0	0.9
Offset					
Population (n)	206,370.1 (162,965.9)	9617.0	175,277.0 (59,061.0-314,110.0)	863,720.0	0.8

According to the regional distribution map of ST incidence per 100,000 population in 2013 - 2019, the southwestern parts of South Korea had higher ST incidence (119.1 - 407.6 incidence per 100,000 population) than northeastern parts (Figure 2). Regardless of the year, the ST incidence was the highest in the southwestern region of South Korea. This trend was consistent, regardless of gender (Figure S1 in Multimedia Appendix 1) or age group (Figure S2 in Multimedia Appendix 1). However, over time, the number of municipalities with the highest ST incidence quintile (102.1 - 649.8 incidence per 100,000 population) decreased.

XSL•FO
RenderX

Figure 2. Annual incidence of scrub typhus per 100,000 population in 250 municipalities across South Korea from 2013 to 2019. Each panel represents a specific year, with the top-left panel showing the cumulative incidence from 2013 to 2019. Colors represent incidence rate ranges, where darker red indicates higher incidence and light yellow indicates lower incidence.



Among all the study participants, the results of the Global Moran's *I* statistics indicated that ST incidence had a positive spatial autocorrelation (*I*=0.600; *P*=.01, Table S5 in Multimedia Appendix 1). Positive spatial autocorrelation was consistently reported in 2013 - 2019, with 2015 having the strongest index value (*I*=0.594; *P*=.01). Positive spatial autocorrelation was consistently reported regardless of gender (men, *I*=0.600, *P*=.01; women, *I*=0.590, *P*=.01) and age group (age 0 - 39 years, *I*=0.564, *P*=.01; age 40 - 59 years, *I*=0.630, *P*=.01; age 60 - 79 years, *I*=0.649, *P*=.01; age≥80 years, *I*=0.622, *P*=.01).

The Getis-Ord Gi* analysis on ST incidence per 100,000 population consistently detected hot and cold spots in the southwestern and northeastern parts of South Korea, respectively, between 2013 - 2019 (Figure 3). The trend persisted, regardless of gender (Figure S1 in Multimedia Appendix 1) and age group (Figure S2 in Multimedia Appendix 1).

XSL•FO
RenderX

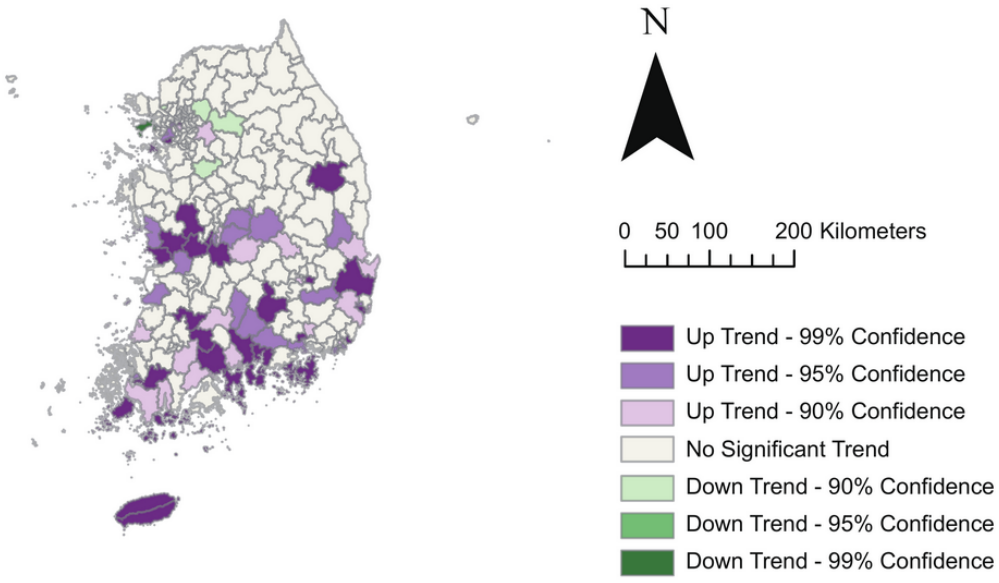


Figure 3. Spatial clusters of scrub typhus incidence per 100,000 population identified using Getis-Ord Gi* analysis across 250 municipalities in South Korea, annually from 2013 to 2019 and for the overall period. Red shades indicate hot spots (high positive *z* score), and blue shades indicate cold spots (low negative *z* score). Color intensity reflects the magnitude of the *z* score resulted from Getis-Ord Gi* analysis.

The HCT results for the total population indicated increasing trends in municipalities across the southern and mid regions of South Korea Figure 4. Municipalities showing increasing trends were also observed in the northwestern part, specifically around the capital region. This pattern was consistent for both genders (Figure S1 in Multimedia Appendix 1), with the southern island of Jeju-do consistently exhibiting an upward trend, regardless of gender and age group. However, the trend varied according to the age group (Figure S2 in Multimedia Appendix 1). Specifically, in the 0 - 39 years age group, municipalities with increasing trends were scattered throughout the country, but the upward trend was more clearly observed in the capital region compared with other age groups. For the 40 - 59, 60 - 79, and ≥80 years age groups, municipalities with increasing trends were more concentrated in the southern and mid regions.

Figure 4. Hot and cold spot trends of scrub typhus incidence per 100,000 population across 250 municipalities in South Korea, from 2013 to 2019, visualized using a 2-dimensional representation of a space-time cube. Purple shades represent up trends (hot spot trends), and green shades indicate down trends (cold spot trends), each categorized by 90%, 95%, and 99% confidence levels. White areas indicate no significant trend.

Modeling

The results of multivariable Bayesian models on ST incidence are presented in Table 3 and Table S6 in Multimedia Appendix 1. Overall, spatiotemporal models demonstrated better fit compared with spatial and temporal models, with lower WAIC values. Among the spatiotemporal models, model 0 had the lowest WAIC value (75,014.8), followed by model 1 (75,019.1), and model 2 (75,037.2). However, given its ability to incorporate relevant covariates and test the primary hypothesis, spatiotemporal model 2 was retained as the model of interest, despite having a slightly higher WAIC than model 0. Sensitivity analysis results also showed that the spatiotemporal model had lower WAIC than spatial and temporal models (Table S7 in Multimedia Appendix 1). By comparing the maps (Figure S3 in Multimedia Appendix 1) and time-series plot (Figure S4 in Multimedia Appendix 1) between the observed and predicted ST incidences using spatiotemporal model 2, the distributions had similarities.

Table . Results of multivariable Bayesian models for age-standardized scrub typhus incidence in South Korea, 2013 to 2019, presented as β coefficients (95% credible intervals).

Model fit metric and variables	Spatial model 2[a]	Temporal model 2[b]	Spatiotemporal model 2[c]
WAIC[d]	211,792.6	115,177.7	75,037.2
Maximum rodent suitability, β coefficient (95% CrI[e])	0.320 (0.075-0.564)	0.493 (0.477-0.509)	0.618 (0.425-0.812)
Financial independence (%), β coefficient (95% CrI)	−0.486 (−0.553 to −0.419)	−0.722 (−0.736 to −0.709)	−0.304 (−0.445 to −0.163)
Forest area (m^2), β coefficient (95% CrI)	0.604 (0.289-0.930)	0.086 (0.074-0.099)	0.171 (−0.076 to 0.421)
Dry field farming area (m^2), β coefficient (95% CrI)	−0.719 (−1.009 to −0.423)	−0.184 (−0.199 to −0.169)	0.040 (−0.228 to 0.311)
Woman farmer population (n), β coefficient (95% CrI)	1.582 (1.525-1.640)	0.272 (0.258-0.287)	0.081 (−0.104 to −0.266)

RenderX

According to the results of spatiotemporal model 2, maximum rodent suitability (β coefficient=0.618, 95% credible interval [CrI] 0.425 - 0.812) was positively associated with ST incidence, while financial independence was negatively associated with ST incidence (β coefficient=−0.304, 95% CrI −0.445 to −0.163).

The subgroup analysis results by gender followed the trends of main analyses, except for forest area having a positive association (Table S8 in Multimedia Appendix 1). The results of the Bayesian spatiotemporal model differed by age group. Table 4 presented the results of the spatiotemporal models by age group. Regardless of age group, financial independence had negative and forest area had positive association with ST incidence. However, the incidence of the 40 - 59, 60 - 79, and ≥80 years of age group had positive association with maximum rodent suitability, while the incidence of 0 - 39 years of age did not have a significant association with rodent suitability (β coefficient=0.028, 95% CrI −0.072 to 0.126). Only the incidence of the 0 - 39 years of age group had a negative association with the women farmer population (β coefficient=−0.115, 95% CrI −0.223 to −0.006). The sensitivity analysis results followed the trends of main analyses, while forest area had significant association (Tables S7 and S9 in Multimedia Appendix 1) and women farmer population did not have significant association with ST incidence in the 0 - 39 year age group like main analysis results (Table S9 in Multimedia Appendix 1).

Table . Results of multivariable Bayesian spatiotemporal models for scrub typhus incidence stratified by age group in South Korea, 2013 to 2019.

Model fit metric and variables	Age group (years)			
	0 - 39	40-59	60 - 79	≥80
Participants, n (%)	8438 (8.8)	28,930 (30.3)	48,129 (50.3)	10,104 (10.6)
WAIC[a]	15,647.3	39,939.7	54,357.4	17,180.7
Maximum rodent suitability, β coefficient (95% CrI[b])	0.028 (−0.072 - 0.126)	0.149 (0.052 - 0.246)	0.223 (0.127 - 0.319)	0.099 (0.017 - 0.180)
Financial independence (%), β coefficient (95% CrI)	−0.350 (−0.431 to −0.268)	−0.262 (−0.329 to −0.194)	−0.206 (−0.269 to −0.143)	−0.136 (−0.199 to −0.072)
Forest area (m^2), β coefficient (95% CrI)	0.472 (0.332 - 0.613)	0.308 (0.180 - 0.436)	0.177 (0.052 - 0.302)	0.174 (0.080 - 0.268)
Dry field farming area (m^2), β coefficient (95% CrI)	0.011 (−0.139 to 0.161)	−0.037 (−0.174 to 0.101)	−0.034 (−0.168 to 0.103)	−0.012 (−0.115 to 0.091)
Woman farmer population (n), β coefficient (95% CrI)	−0.115 (−0.223 to −0.006)	0.036 (−0.046 to 0.118)	0.066 (−0.011 to 0.143)	−0.077 (−0.164 to 0.009)

[b]CrI: credible interval.

Discussion

Principal Findings

This study examined the demographic, spatial, and temporal distributions of the incidence of ST. Notably, ST incidence consistently exhibited spatial hotspots in the southwestern region of South Korea, regardless of year, sex, or age. This pattern aligns with previous findings and can be attributed to the ecological characteristics of the southwestern region, which is characterized by fertile lands conducive for rodent and mite habitats [48].

Moreover, HCT analysis revealed a consistent increasing trend in the southern and mid regions, despite a declining trend in incidence. A similar spatial expansion of ST cases from the southwestern to northeastern regions was noted between 2001 - 2006 [48], which was likely attributed to the effects of climate change, particularly rising temperatures that enhanced vector survival, expanded their geographic range, and accelerated pathogen growth [49]. However, variations in ST trends were observed when age groups were considered. The younger age group (0 - 39 years) exhibited scattered municipalities with increasing trends across the country, whereas older age groups (40 - 59, 60 - 79, and ≥80 years) displayed more concentrated increases in the southern and mid regions. This suggests that age-specific factors play a role in ST transmission dynamics and necessitate tailored prevention strategies based on specific demographic segments.

The current analysis further revealed the importance of incorporating both spatial and temporal dimensions in understanding the epidemiology of ST. Based on the WAIC, models with spatiotemporal interaction term (Spatiotemporal model 0, WAIC=75,014.8; Spatiotemporal model 1, WAIC=75,019.1; Spatiotemporal model 2, WAIC=75,037.2, Table 3, Table S7 in Multimedia Appendix 1) demonstrated a better fit than those with only spatial or temporal terms, regardless of including potential risk factors. This pattern was consistent in a sensitivity analysis using the number of ST cases as the outcome and log-transformed population as an offset (Table S7 in Multimedia Appendix 1), further confirming the benefit of modeling spatiotemporal interaction. This underscores the need for a comprehensive approach that considers both the spatial and temporal dimensions when investigating ST patterns. In particular, the ST data showed distinct temporal patterns in

XSL•FO
RenderX

each area that were inconsistent with those in other regions, and the spatial patterns exhibited considerable variability (Figure S5 in Multimedia Appendix 1). This supports the necessity of including a space-time perspective in the analysis. However, as shown in another sensitivity analysis using a more complex spatial structure, convergence issues occurred in the INLA-based model (Table S9 in Multimedia Appendix 1). This highlights the choice of spatial weight matrix that can affect model convergence in complex Bayesian settings.

We revealed a significant association between ST incidence and specific factors. Our findings quantitatively investigated that municipalities with high rodent suitability were more likely to experience higher ST incidence, supporting previous studies [50-53]. High rodent density, particularly in areas with abundant hosts, contributes significantly to the transmission of *Orientia tsutsugamushi* [52]. In addition, climate variability and rodent abundance jointly influence scrub typhus transmission [53]. The nonsignificant but positive point coefficient observed in the 0‐39 years age group might be due to the smaller number of ST cases and reduced exposure to rodents at home or work. However, as rodent suitability is determined by environmental potential for rodent habitation than actual numbers, future studies should focus on monitoring rodent distribution across the nation and disseminating this information to the public. Additionally, research exploring the relationship between ST cases and the distribution of natural hosts based on this data is needed. Managing human-rodent interaction, as proposed by Sharma et al [54], could be a key strategy for reducing scrub typhus transmission, particularly through rodent habitat control and improved hygiene practices.

Furthermore, this study highlighted the impact of municipality financial status on ST incidence. Municipalities with lower financial independence were more likely to have higher ST incidence, which may reflect the characteristics of rural areas where agricultural and forest environments are common [55,56]. Although these regions may receive targeted support from central government programs, their ecological and occupational conditions likely contribute to the elevated risk.

Following the results of previous studies [8,57], our findings indicated that municipalities with more forest coverage had higher ST incidence in age- and gender–stratified models. Occupational exposure to forest environments, particularly among forestry workers, significantly elevates risk [57]. In addition, Zangpo et al [8] identified activities like cardamom harvesting and living near forests as key risk factors, highlighting the importance of forest proximity in ST transmission. Therefore, implementing targeted preventive strategies, including regular monitoring and enhanced protective education for forestry workers and residents near forested areas, is essential to mitigate future ST cases.

The association between the population of women farmers and ST incidence was mainly observed in the 0‐39 years age group, where women farmer population appeared to have a protective effect on ST incidence at the municipal level. This reflects contrasting trends of increasing ST incidence among men and the decline in the population of women farmers within this age group. From 2003 to 2019, ST incidence became more male-dominant in the 0‐39 years age group, reducing the gender disparity in ST incidence [21]. This age group exhibited a marked increase in ST incidence in the surrounding capital area (Figure S2 in Multimedia Appendix 1), where farming is less prevalent and the proportion of women farmers sharply declined (Figure S6 in Multimedia Appendix 1). Since women farmers have been the main target of ST prevention efforts due to their risk from agricultural work habits during harvest seasons [1,58,59], these findings may indicate a gap in preventive outreach to other at-risk populations, such as younger individuals engaging in nonfarming outdoor activities [60,61]. Considering the changing demographics in both farming populations and ST cases, updated mitigation strategies, such as redefining target populations in nontraditional rural areas, are necessary.

Although previous studies have suggested that dry field farming is associated with outdoor exposure and ST risk [10,33], no statistically significant association was observed in our models. This reflects regional variation in land use, ecological conditions, or population-level exposure, which warrants further investigation.

Strengths and Limitations

To the best of our knowledge, this study is the first to investigate the spatiotemporal dynamics and risk factors of ST in South Korea in a One Health perspective. The considerable diversity observed in the municipal-level epidemic dynamics of ST underscores the necessity for a regional comprehension of the ST infection pattern. This understanding is crucial for the effective implementation of prevention and control strategies tailored to the burden of ST and its determinants at the municipal level. Furthermore, incorporating specific determinants of ST infection into these localized strategies or developing targeted group interventions is warranted. However, this study has some limitations. This study was an ecological study conducted at the municipal level, so the results should not be applied at the individual level. While ecological fallacy and unmeasured confounders may exist, a key advantage of our study is that the results can be directly translated into municipal-level ST interventions. Although our multivariable model enabled simultaneous assessment of multiple risk factors, it may not fully account for variable-specific causal pathways, including distinct confounders and effect modification. Nevertheless, the approach remains valuable insights into overall patterns and supports future hypothesis-driven research. Moreover, the NHIS data provided only municipal residential codes and lacked information on the bite site. As a result, spatial patterns, particularly among younger or more mobile populations, should be interpreted with caution. Further studies that incorporate bite-site information and target the entire nation are required. Although leisure activities such as hiking or camping may contribute to ST risk in younger populations [60], relevant municipal-level indicators were not available. Moreover, ST incidence remains the highest in older adults (Figure 4), despite increasing trends in recreational activity, which suggests that limited explanatory power of leisure exposure. Some popular recreational areas, including mountainous regions and forested areas like Gangwon-do, also showed low incidence (Figures 2 and 3), possibly due to ecological factors such as climate and latitude affecting vector habits [3,8]. In addition, direct

XSL•FO
RenderX

information on mite distribution across the country is unavailable. While vector surveillance programs such as Vector-net could serve as alternatives, their data were not publicly accessible. Therefore, partial compensation has been attempted by using information on rodent suitability, considering that rodents serve as natural hosts of mites and rodent density has been shown to be related to chigger mite distribution [62]. The construction of maximum rodent suitability also incorporated environmental factors, aligning with a One Health approach. Despite these limitations, these findings are expected to provide a foundation for addressing ST through evidence-based strategies based on examined hot spots and risk factors, grounded in a holistic approach that encompasses both One Health and spatiotemporal aspects.

Conclusions

This study provides a detailed analysis of the spatiotemporal dynamics and risk factors of ST in South Korea from 2013 to 2019, emphasizing the importance of incorporating spatiotemporal aspects. The findings indicated positive spatial autocorrelation, with ST expanding from the southwest to the northeast regions. Municipalities with higher rodent suitability, greater forest coverage, and lower financial independence were more likely to experience increased ST incidence, with risk factors varying by age group. This study underscores the value of a holistic, spatiotemporal approach, highlighting the roles of rodent suitability, forest area, and socioeconomic factors in shaping ST dynamics. These findings may inform targeted public health intervention in Korea and provide broader insights applicable to other regions where similar ecological conditions and socioeconomic contexts exist. These insights provide a foundation for developing targeted public health interventions grounded in a One Health perspective to more effectively manage ST in South Korea and similar global settings.

Abstract

Background: Incident HIV infection is a critical indicator of an ongoing epidemic, particularly in high-burden regions such as Liangshan Yi Autonomous Prefecture in China, where HIV prevalence exceeds 1% in 4 key counties (Butuo, Zhaojue, Meigu, and Yuexi). Identifying spatial clusters and drivers of recent infections is essential for implementing targeted interventions. Despite advancements in geospatial analyses of HIV prevalence, studies identifying drivers of incident HIV clustering remain limited, especially in low-resource settings.

Objective: This study aims to identify spatial clusters of recent HIV infections and investigate potential driving factors in 4 key counties of the Liangshan Yi Autonomous Prefecture to inform targeted intervention strategies.

Methods: From November 2017 to June 2018, we identified 246 (4.42%) recent HIV infection cases from 5555 newly diagnosed cases through expanded testing of the whole population in 4 key counties of Liangshan Yi Autonomous Prefecture. Recent infection cases were confirmed using limiting antigen avidity enzyme immunoassays or documented seroconversion within 6 months. The spatial distribution of incident HIV infection cases was analyzed using kernel density. Potential drivers, including population density, HIV prevalence, elevation, nighttime light index, urban proximity, and antiretroviral therapy (ART) coverage, were analyzed. The spatial lag regression model was used to identify factors associated with clustering of recent infection cases. The Geodetector *q*-statistic was used to quantify nonlinear interactive effects among these factors.

Results: Significant spatial autocorrelation was observed in the distribution of recent HIV cases (Moran I=0.11; P<.01). Six spatial clusters were identified, and all were located near urban centers or major roads. Furthermore, 5 factors were identified by the spatial lag regression model as being significantly correlated with the clustering of recent HIV infection cases, including population density (β=0.59; P<.001), HIV prevalence (β=0.02; P<.001), distance to local urban area (β=–3.10; P=.01), SD of

XSL•FO
RenderX

elevation (β=–0.15; *P*=.02), and ART coverage rate (β=183.80; *P*<.01). Geodetector analysis revealed strong interactive effects among these 5 factors, with population density and HIV prevalence exhibiting the largest interactive effect (*q*=0.69).

Conclusions: This study reveals that besides HIV prevalence, urbanization-related factors (population density and proximity to urban area) and transportation accessibility drive incident HIV clustering in Liangshan Yi Autonomous Prefecture. Paradoxically, higher ART coverage was associated with increased transmission, suggesting the need for integrated prevention strategies beyond ART expansion. Furthermore, the township-level geospatial approach provides a valuable model for pinpointing transmission hot spots and tailoring interventions in high-burden regions globally.

Introduction

Background

Incident HIV infection is a direct indicator of an ongoing epidemic. Collecting detailed information on new infection cases has been advocated by the World Health Organization and the Joint United Nations Programme on HIV/AIDS, especially in high-burden areas, to inform trends of HIV transmission. Several laboratory-based assays, such as limiting antigen avidity enzyme immunoassay, have been developed to identify recent HIV infection from newly diagnosed cases and have been proven valid with good credibility [1,2]. The applications of assays for recent HIV infection include providing national estimates of incidence, monitoring HIV incidence in key or sentinel populations, assessing the impact of interventions, and identifying clusters and populations of current epidemics [3-7].

An emerging application of recent HIV infection testing is its integration with geospatial analysis to detect geographic clusters of new transmission, thereby supporting targeted interventions. In Malawi, 3 hot spots of recent infection cases were identified with facility-based HIV testing data [8]. The cluster also indicated service delivery gaps and required an immediate public health response [9]. In several provinces of China, recent infection testing was performed among newly diagnosed HIV cases, and spatial autocorrelation and spatial scan statistics were used to detect hot spots [10-13]. Moreover, in a border prefecture of China, a Bayesian spatiotemporal model was used to estimate the dynamic spatial relative risk of recent infections [14]. Most existing studies focused on describing the spatial distribution, estimating the relative risks, and detecting the hot spots of recent infection cases. However, studies specifically analyzing the potential driving factors of the spatial clustering of incident HIV infection cases remain limited, particularly in low- and middle-income settings and regions with high HIV burden.

Liangshan Yi Autonomous Prefecture, located in Sichuan province in the southwest of China, is one region that has been severely affected by HIV [15,16]. The HIV infection rate among residents in Liangshan Yi Autonomous Prefecture was 0.84% in 2019, with the HIV infection rate in 4 key counties of Butuo, Zhaojue, Meigu, and Yuexi in Liangshan Yi Autonomous Prefecture exceeding 1% [17]. The key to controlling the HIV epidemic in this region is to reveal critical driving factors affecting HIV transmission and implement targeted interventions.

This Study

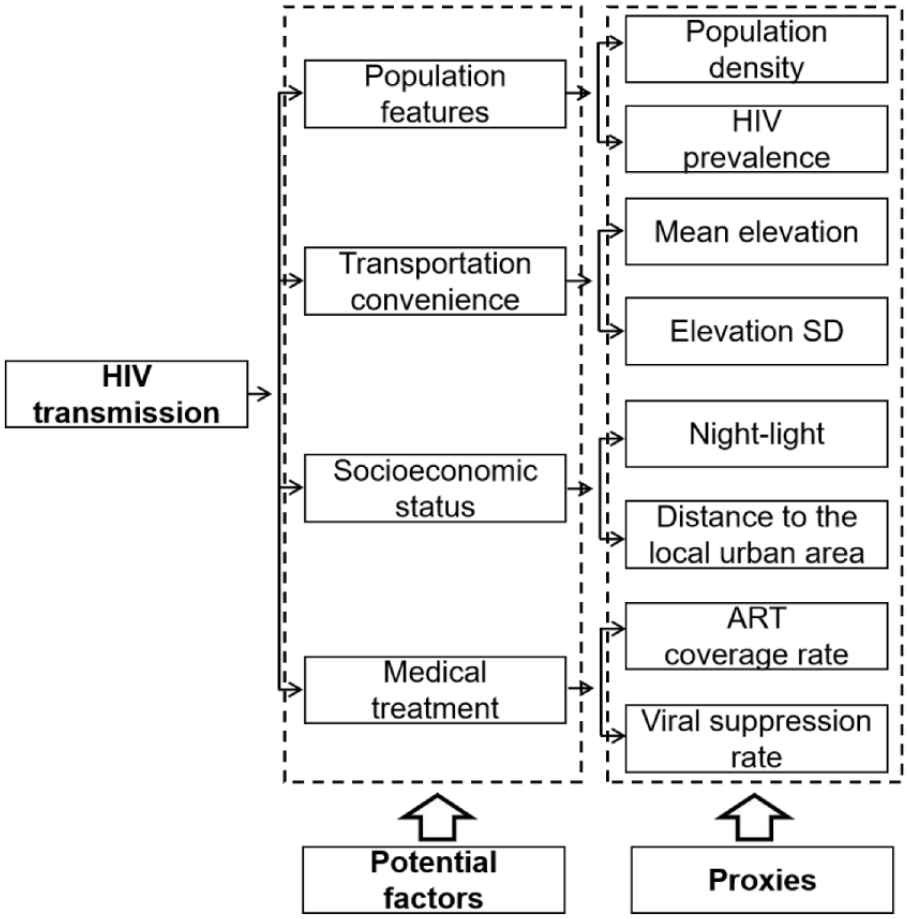
In this study, we tried to focus on 246 recent HIV infection cases identified from 5555 newly diagnosed HIV cases through an expanded HIV testing from November 2017 to June 2018 in the general population in the 4 key counties. Furthermore, we retrospectively conducted multiple geospatial analyses to identify clusters and high-risk areas of recent HIV infection, aiming at revealing potential factors driving the clustering of incident HIV infection cases in this region and consequently informing targeted interventions to effectively curb the local epidemic.

Methods

Study Scheme

The newly diagnosed HIV cases in this study were identified through expanded HIV testing in residents of the 4 key counties of Butuo, Zhaojue, Yuexi, and Meigu in Liangshan Yi Autonomous Prefecture from November 2017 to June 2018; the testing was incorporated into a physical examination provided as a public health service covering more than 95% of the residents. Participating individuals were informed of HIV testing and could choose to reject the test without impacting other parts of the physical examination service. The individuals signed a physical examination form to approve all testing. For individuals who agreed to HIV testing, a rapid test for detecting HIV specific IgM and IgG (Wondfo) antibodies was performed. Individuals with positive screening results were asked to undergo a confirmatory immunoblot test (MP Biomedicals), and the individuals with positive immunoblot test results were registered in the national HIV database.

Identification of Recent HIV Infection Cases



Among newly diagnosed HIV cases, recent HIV infection cases were identified in 2 ways. Most (196/246, 79.7%) of the recent HIV infection cases were identified by a limiting antigen avidity enzyme immunoassay (Beijing Kinghawk Pharmaceutical Co, Ltd). According to the manufacturer's instructions, the mean duration of recent infection of this assay was 130 days. Recent HIV infection cases were also identified through HIV testing history of newly diagnosed HIV cases as having a known negative HIV testing result within 6 months before a positive HIV testing result during the survey period.

RenderX

Sources of Data

In this study, we analyzed potential factors related to the spatial clustering of recent infection cases. On the basis of previous studies [18,19] and local contextual relevance, we categorized these factors into four aspects: (1) population features, (2) transportation convenience, (3) socioeconomic status, and (4) medical treatment (Figure 1).

Figure 1. Potential driving factors and their proxy factors of HIV transmission. Population features, transportation convenience, socioeconomic status, and medical treatment are 4 potential driving factors of HIV transmission. Population density, HIV prevalence, mean elevation, elevation SD, night-light, distance to local urban center, antiretroviral therapy (ART) coverage rate, and viral suppression rate serve as proxy variables of potential driving factors.

The first aspect was population features. Population density (persons/km²) and HIV prevalence were included to reflect the level of population aggregation and the underlying burden of infection, respectively. Information for calculating population density in the township was obtained from the local statistics bureau. HIV prevalence data were provided by the prefecture center for disease control and prevention.

The second aspect was transportation convenience. Previous studies have shown that transportation accessibility can influence HIV transmission and outcomes [20,21]. Given the mountainous terrain in Liangshan Yi Autonomous Prefecture, variations in elevation may lead to disparities in transportation infrastructure and accessibility. Geographic information on elevation was obtained from the National Catalogue Service for Geographic Information. The mean and SD of elevation were calculated using ArcGIS software (Esri) as proxy variables of transportation convenience.

The third aspect was socioeconomic status. Due to data unavailability, we included the nighttime light index and distance to the local urban area as proxies for socioeconomic status. Nighttime light data were sourced from a platform developed by the Chinese Academy of Sciences, and township-level distances to local urban centers were calculated using ArcGIS software.

The fourth aspect was medical treatment. HIV antiretroviral therapy (ART) coverage and viral suppression are 2 important indicators of HIV treatment. These indicators reflect the availability and effectiveness of HIV treatment services. Data on ART coverage and viral suppression rates were obtained from the local ART quality control center.

Furthermore, demographic and location information of recent HIV infection cases were collected from the national HIV/ AIDS database. Recent HIV infection cases were mapped using village midpoint coordinates extracted from resident address information.

Geographic and Statistical Analyses

All geographic maps were created using ArcGIS (version 10.6). General Moran *I* index was calculated using ArcGIS to determine the spatial autocorrelation of township-level

XSL•FO
RenderX

aggregated number of recent infection cases. Kernel density estimation was performed with ArcGIS to construct a smooth surface for the geographic distribution of recent HIV infection cases. Ordinary least squares regression (OLSR) and spatial lag regression (SLR) were performed using GeoDa (version 1.12.1.139) software to determine the linear correlation between the kernel density of recent HIV infection cases and potential factors. Geodetector *q*-statistic was used to investigate the interactive effect (linear or nonlinear) of a single or every 2 of the proxies on the kernel density of recent HIV infection cases. In general Moran *I* index, OLSR, SLR, and Geodetector *q*-statistic, the statistical unit was township, which means that township-level data were used for analysis. Statistical analyses were performed using SPSS Statistics (version 23.0; IBM Corp) statistical analysis software package. Frequencies of variables were compared using the Fisher exact chi-square test. Considering heterosexual transmission has become the main route of HIV infection, the demographic characteristics between different genders were compared.

Kernel Density Estimation

Kernel density estimation (equation 1) is a process of inferring the probability density at each location, that is, constructing the probability density surface, based on the locations of residents (the points), and it can visualize the density of recent cases of infection. This method has been widely used to construct a smooth surface for the geographic distribution of HIV cases [22,23]. In this study, kernel density estimation was performed using geographic information of recent cases of HIV infection within the study area. The analysis was conducted in ArcGIS software with default parameters, and the study area boundary was used to define the extent of the analysis. The kernel density was calculated as follows [24,25]:

For $dist_i$<*radius*

where $dist_i$ specifies the distance between the point of the recent HIV infection case and location (x, y), *n* represents the total number of recent HIV infection cases, *radius* is the kernel bandwidth, and pop_i is the number of recent HIV infection cases in point . To enable township-level analysis, the average kernel density value within each township was further calculated using ArcGIS.

General Moran I Index

The general Moran *I* index (equation 2) was calculated using ArcGIS software to determine the spatial autocorrelation of township-level aggregated numbers and kernel density of recent infection cases. The general Moran *I* index was calculated as follows [26]:

where *N* represents the number of townships in the study area (*N*=151); w_{ij} denotes the spatial weight between townships *i* and *j*; x_i and x_j are the values of kernel density in the township *i* and *j*, respectively; and specifies the mean kernel density in the study area. The value of the general Moran *I* index ranged between –1 and 1 (positive autocorrelation: Moran *I*>0; negative autocorrelation: Moran *I*<0).

Linear Regression Model

We used both the OLSR model (equation 3) and the SLR model (equation 4) to identify factors associated with the clustering of recent infection cases. These 2 models assumed linear relationships between the dependent variable and explanatory variables. The SLR model further incorporated spatial dependence into the regression model with a spatially lagged dependent variable, which accounted for the fact that the dependent variable (*y*) may be spatially autocorrelated [27]. The fitness of these 2 models was compared to determine which model was most appropriate for analysis. OLSR and SLR were denoted as follows:

$$y = X\beta + \varepsilon \quad \textbf{(3)}$$

$$y = \rho Wy + X\beta + \mu \quad \textbf{(4)}$$

In both equations, *y* is a vector of kernel density of recent infection cases in each township (N=151), *X* is a vector of explanatory variables, and β is the regression coefficient of the explanatory variable. In the OLSR model (equation 3), ε represents the random error. In the SLR model (equation 4), ρ is the coefficient of the spatial lag parameter and represents the level of autocorrelation in the lag term, W_y is a vector of spatial weights, and μ specifies the nonspatial random error. Queen contiguity was used to assign spatial weights to townships (nonzero weights for townships that share a common edge or vertex and zero weights to the others).

Geodetector

Geodetector (Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences), a statistical tool, can measure the spatial stratified heterogeneity and quantify the influencing power of a single or every 2 of the proxies included. Geodetector assumes that explanatory variable and dependent variable would be coupled (linear or nonlinear) in strata if they are correlated, and the nonlinear assumption is its advantage. Thus, we used Geodetector to quantify the influencing power of a single or every 2 proxies with the *q*-statistic value. The *q*-statistic value was expressed as follows [28]:

where *h* (*h*=1,2,...*L*) is the stratification of a single factor (*X*) or every 2 interacting factors, N_h and *N* represent the number of townships in the stratum *h* (h=1,2,...,*L*) and the entire area separately (the stratification was calculated by natural break), and and denote the variances of the kernel density in the stratum *h* and the whole study area, respectively. The *q*-statistic value ranged between 0 and 1, and a larger value indicated higher influencing power.

Ethical Considerations

This study, which involved analyzing the data on recent HIV infection cases identified through expanded HIV testing in Liangshan Yi Autonomous Prefecture, was approved by the institutional review board of the National Center for AIDS/STD Control and Prevention, Chinese Center for Disease Control

XSL•FO
RenderX

and Prevention. This expanded HIV testing was incorporated into the local physical examination. All participants signed informed consent forms at the time of their examinations. The physical examination was free, and no financial compensation was provided to participants. No personally identifiable information was present in the data analyzed for this study.

Results

Demographic Characteristics of Recent HIV Infection Cases

A total of 246 (4.4%) individuals who were recently infected with HIV were identified from 5555 newly diagnosed cases in 4 key counties in Liangshan Yi Autonomous Prefecture. A total of 217 (88.2%) of them provided complete demographic information and were included in the analysis of demographic characteristics. Among the 217 individuals who were newly infected (Table 1), 92 (42.4%) were male and 125 (57.6%) were female. In both male and female, individuals aged between 30 and 44 years, those who were married, and those who had not attended school occupied the largest proportion. A significant difference was seen in the transmission modes between different genders (P<.001). A large proportion of individuals who were recently infected acquired HIV through heterosexual transmission, and this number was 87.2% (109/125) and 62% (57/92) in female individuals and male individuals, respectively.

Table 1. Demographic characteristics of individuals who were recently infected with HIV in 4 key counties of Liangshan Yi Autonomous Prefecture, China, from November 2017 to June 2018.

Demographic characteristic	Total (N=217), n (%)	Male (n=92), n (%)	Female (n=125), n (%)	*P* value[a]
Age (y)				.33
1.5-14	15 (6.9)	5 (5.4)	10 (8)

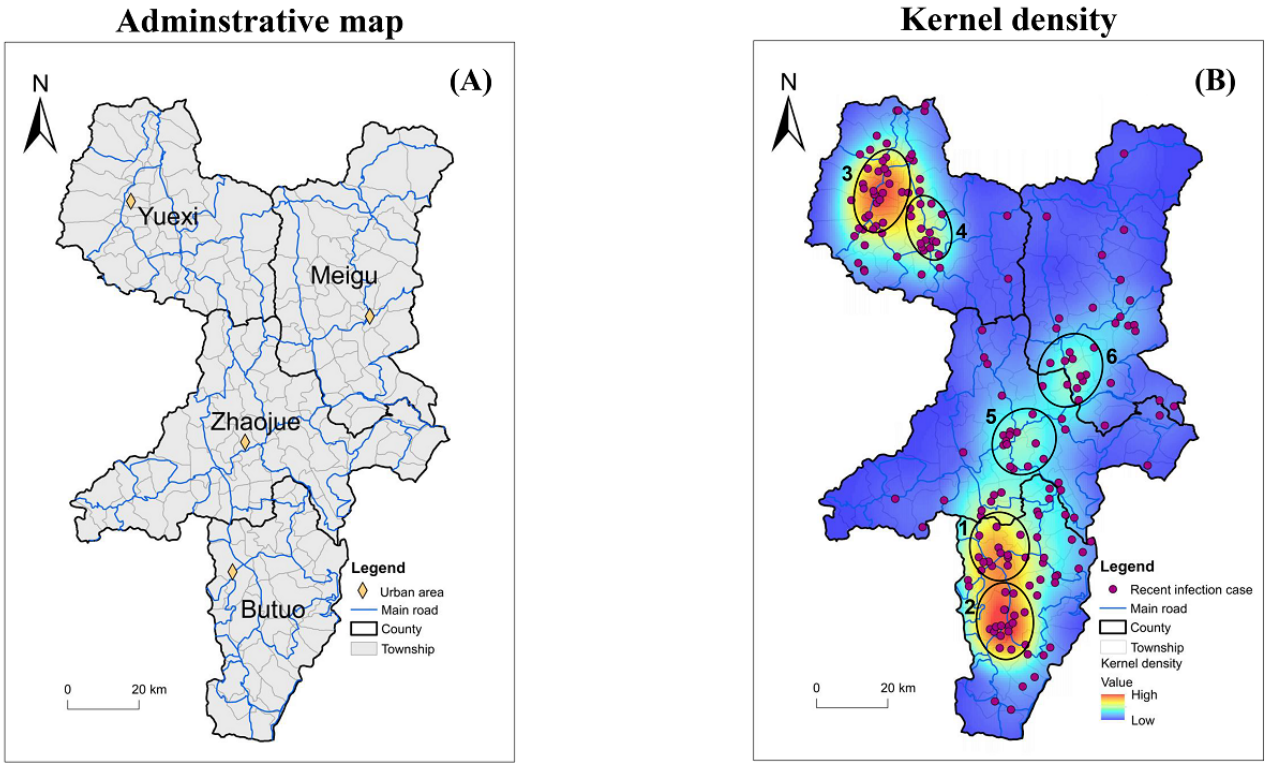
Others	15 (6.9)	5 (5.4)	10 (8)	



[a]Statistical significance was assessed between male and female individuals by the Fisher exact test.

Spatial Distribution and Clusters of Recent HIV Infection Cases

The general Moran I value of township-level kernel density of recent HIV infection cases was 0.11 (P<.01), which indicated significant positive spatial autocorrelation. To investigate spatial distribution features of recent HIV infection cases in the 4 neighboring counties (Figure 2A), the kernel density of recent HIV cases was calculated and mapped. We found 6 main clusters of recent HIV cases, and all 6 clusters were located at the intersection of main traffic roads (Figure 2B). Except for cluster 6 at the border of Zhaojue and Meigu, which is a transportation portal between Zhaojue and Meigu, other clusters were located around urban areas in the county. Our spatial distribution analyses also indicated spatial variation of recent HIV infection.

XSL•FO

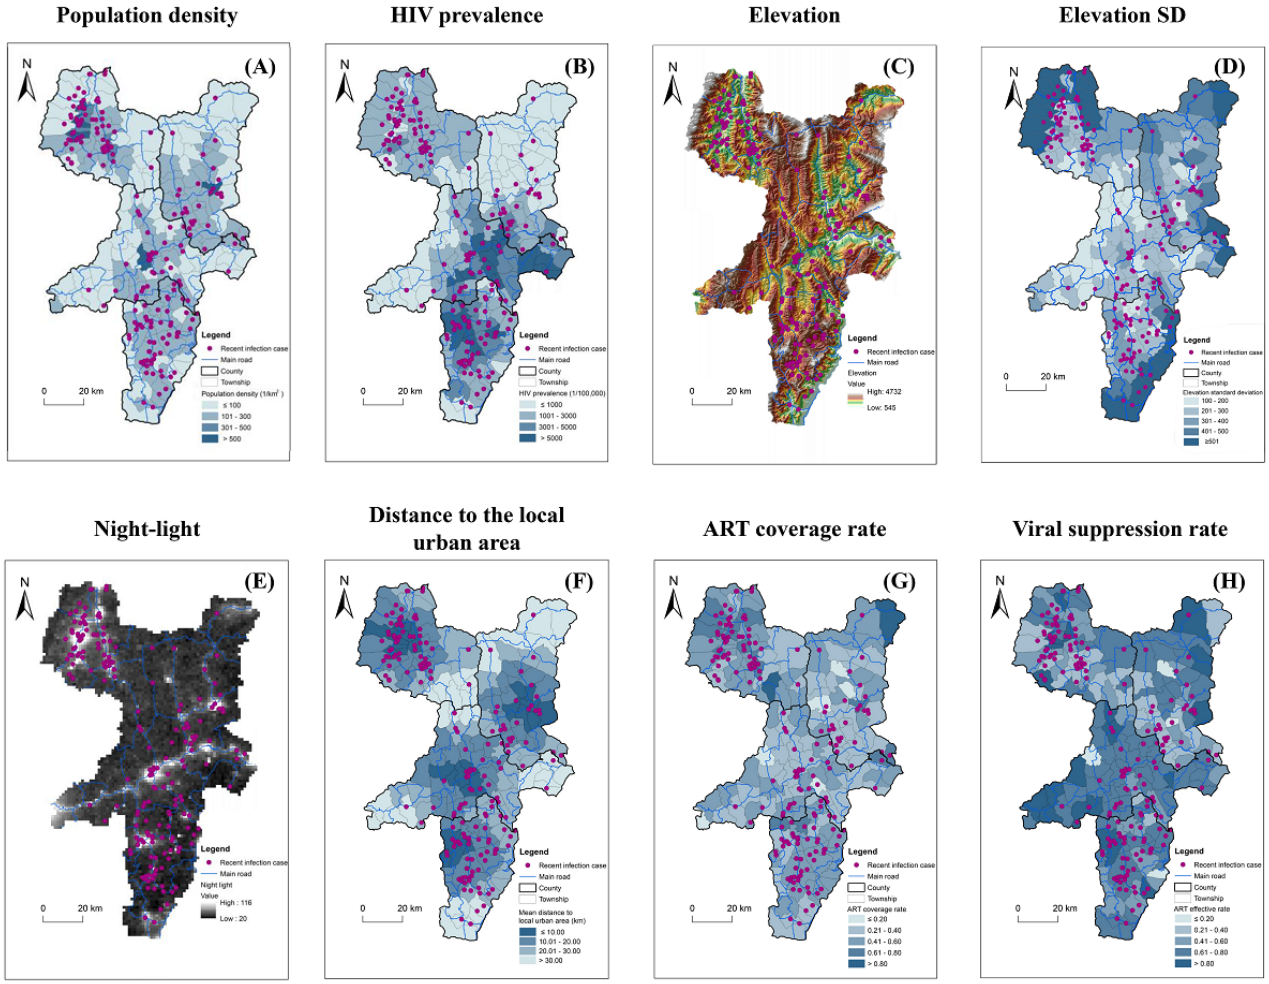
Figure 2. Spatial distribution and high-risk areas of recent HIV infection cases in 4 key counties of Liangshan Yi Autonomous Prefecture, China, from November 2017 to June 2018. (A) Administrative map of the 4 key counties. Blue lines indicate main traffic roads, and yellow diamonds indicate the local urban areas of each county. (B) The spatial distribution of recent HIV infection cases is shown using a kernel density map. The color-code shows the density of recent HIV infection cases per square map unit. The black circles show clusters of recent HIV infection cases.



Factors Associated With the Clustering of Recent HIV Infection Cases

The general Moran *I* value of township-level kernel density of recent infection cases was 0.76 ($P<.001$), which indicated significant positive spatial autocorrelation. Therefore, we further used the spatial regression analysis, SLR, which accounts for the fact that the dependent variable (y) may be spatially autocorrelated, to perform quantitative analysis and identify factors significantly associated with clustering of recent HIV infection cases and compare it with a nonspatial model, OLSR.

We investigated the factors that might impact the clustering of recent HIV infection cases while considering the unique geographic, demographic, and HIV epidemic features in the area. Population density and HIV prevalence rate of the township were incorporated into the analysis, and we found that all clusters were located in areas with high population density and high HIV prevalence (Figures 3A and 3B). Because the 4 key counties are located in a mountainous area, the altitude was taken into account. The topographical map showed that, except for cluster 2 in Butuo and cluster 4 in Yuexi, all other clusters were located in areas at a lower altitude (Figure 3C). Elevation SD indicates the steepness of local terrain, which can impact the convenience of transportation to a certain extent (Figure 3D). Nighttime light index was used to represent the general economic status at the township level. Because the 4 key counties are lower-income areas, most areas are dark. We found that, except for cluster 2 in Butuo, all other clusters were located in areas with bright night-light, indicating comparatively better economic status (Figure 3E). The distance to the local urban areas of the counties was also mapped, and it showed that all clusters were located within 20 km of the urban areas (Figure 3F). The impact of ART coverage rate and viral suppression rate of individuals infected with HIV before the survey was also examined. The results showed that all clusters were mainly located in areas with comparatively higher ART coverage rates (Figure 3G). Clear patterns related to the distribution relationship between the clusters and the viral suppression rate were not noted (Figure 3H).

Figure 3. Maps of 8 potential factors contributing to the clustering of recent HIV infection cases in 4 key counties of the Liangshan Yi Autonomous Prefecture, China, from November 2017 to June 2018. (A) Map of population density at the township level. The color intensity shows the number of individuals per square km. (B) Map of HIV prevalence at the township level. The color intensity shows the level of HIV prevalence. (C) Elevation map. The color-code shows elevation. (D) Elevation SD map. The color-code shows elevation SD. (E) Night-light map. The color-code shows the nighttime light index. (F) Map of distance to local urban center at the township level. The color intensity shows the distance range. (G) Map of antiretroviral therapy (ART) coverage rate at the township level. The color intensity shows the level of ART coverage rate. (H) Map of the viral suppression rate at the township level. The color intensity shows the level of the viral suppression rate.

In addition to visually mapping potential factors, we used a nonspatial OLSR model and an SLR model to perform quantitative analysis and identify proxies significantly associated with clustering of recent HIV infection cases. Geographic kernel density of recent HIV infection cases was used to represent clustering intensity, and the correlation between kernel density of recent infection cases and proxies, including population density, HIV prevalence, mean elevation, elevation SD, night-light, distance to local urban area, ART coverage rate, and viral suppression rate, was analyzed.

In comparison to the nonspatial OLSR analysis, the SLR model fit better, and there was a significant spatial autocorrelation in the township-level kernel density of recent infection cases (ρ=0.72; P<.001; Table 2). In the SLR model, 85% of the spatial variations in kernel density of recent infection cases can be explained by the proxies included (higher than 62% in the nonspatial OLSR model). In the SLR model, at the township level, population density, HIV prevalence, and ART coverage rate had a positive correlation with kernel density of recent infection cases, while elevation SD and distance to local urban areas had a negative correlation.

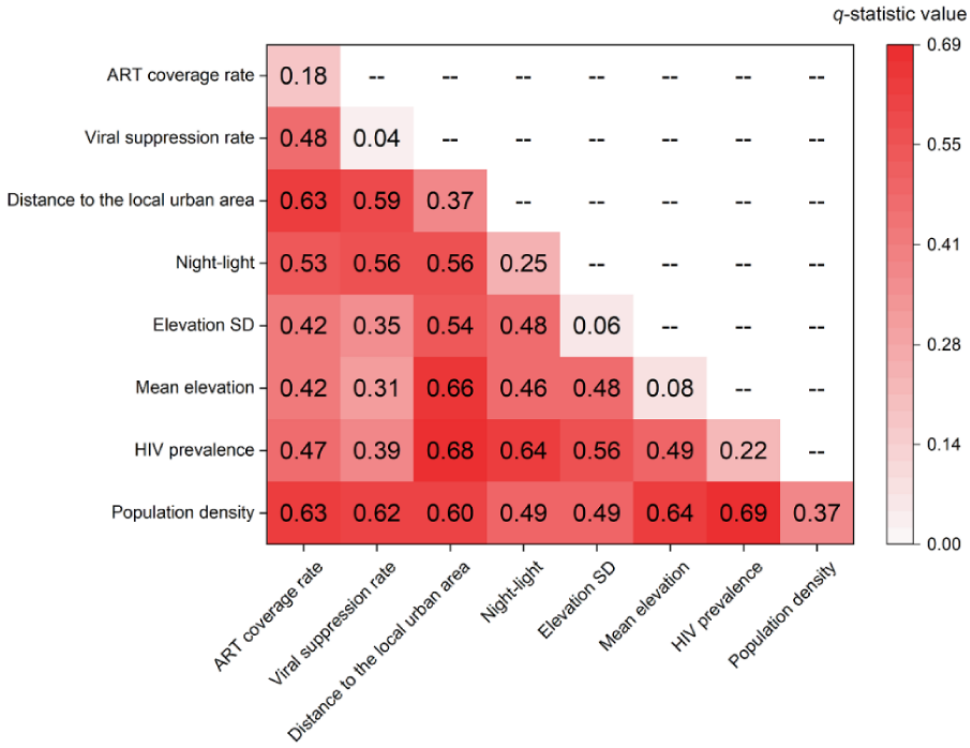
Table 2. Results from nonspatial and spatial linear models, namely ordinary least squares regression (OLSR) and spatial lag regression (SLR), and proxy factors associated with clustering of recent HIV infection cases in 4 key counties of Liangshan Yi Autonomous Prefecture, China, from November 2017 to June 2018.

Proxy factors	OLSR[a]		SLR[b]	
	β coefficient	*P* value	β coefficient	*P* value
Population density	0.91	<.001	0.59	<.001
HIV prevalence	0.05	<.001	0.02	<.001
Mean elevation	0.03	.58	–0.03	.45
Elevation SD	0.09	.40	–0.15	.02
Night-light	–7.61	.23	–2.93	.45
Distance to the local county urban area	–11.11	<.001	–3.10	.01
ART[c] coverage rate	491.52	<.001	183.80	<.01
Viral suppression rate	11.73	.88	19.73	.68



[a]R^2=0.62; *P*<.001; Akaike information criterion=2022.78.

[b]R^2=0.85; ρ=0.72 (represents the level of autocorrelation in the lag term); Akaike information criterion=1911.81; *P*<.001.

[c]ART: antiretroviral therapy.

To further elucidate the nonlinear influencing power of a single and every two proxies on the clustering of recent HIV infection cases, we performed Geodetector analysis. Our results revealed that population density and HIV prevalence showed the highest interactive influence on clustering of recent HIV infection cases, reaching a *q*-statistic value of 0.69 (Figure 4). Furthermore, for every 2 of the 5 proxies, including HIV prevalence, population density, distance to local urban area, SD of elevation, and ART coverage rate, a strong interactive effect was observed through Geodetector analysis (Figure 4). Regarding the influencing power of the single proxy factor, population density and distance to the local urban area had the highest *q*-statistic value of 0.37 (Figure 4).

Figure 4. Interactive effects of 8 potential factors on clustering of recent HIV infection cases in 4 key counties of Liangshan Yi Autonomous Prefecture, China, from November 2017 to June 2018. The color intensity at the intersection of 2 factors shows the extent to which the 2 factors interactively contribute to clustering of recent HIV infection cases. The regions are color-coded from pale red to dark red, and dark red indicates a high q-statistic value. ART: antiretroviral therapy.

Discussion

Principal Findings

Many potential factors could impact local HIV transmission, such as local HIV prevalence, socioeconomic status, transportation convenience, access to HIV-related health care, local culture, etc [19,29-32]. On the basis of the data available at the township level, we categorized the potential driving factors into 4 aspects, which were population features, transportation convenience, socioeconomic status, and access to HIV care. For every potential driving factor that we proposed to study, we tried to use the most appropriate proxy variables for the analyses. Due to a lack of data at the township level for other potential factors, for example, residents' demographic information, access to education, harm reduction, gross domestic product, urbanization situation, and preexposure prophylaxis awareness, these were not included in this study. We also did not include some potential factors that are difficult to quantify, such as attitudes toward casual sex behavior in the Yi ethnic group [19]. However, it is compelling that the factors that we analyzed could explain the clustering of recent HIV infection cases for a high proportion of 85% in the SLR analysis (Table 2). Therefore, these potential factors included in our regression analyses showed a strong explanatory effect on the clustering of recent HIV infection cases.

Our novel geospatial analyses focusing on incident HIV infection allowed us to capture the underlying drivers of the ongoing HIV epidemic. In our study, the geographic distribution of recent HIV infection cases at the township-level has a significant spatial autocorrelation, and the SLR model fitted better than the nonspatial OLSR model, which did not consider spatial features of the area. The SLR model identified 5 factors—population density, HIV prevalence, elevation SD, the distance to the local urban area, and ART coverage rate. In the nonlinear Geodetector analysis, population density and the distance to local urban areas independently contributed to the highest *q*-statistic value of 0.37, and they were the 2 main parameters used to define urbanization [33]. Compared to the nonspatial OLSR model, the SLR model further identified significant factors such as elevation SD, which indicates the steepness of the road, and was used to represent the convenience of transportation. Therefore, our results suggest that areas with higher levels of urbanization and more convenient transportation in the 4 key counties are more inclined to have spatial clustering of incident HIV infection cases. A previous study using spatial clustering analysis of newly diagnosed cases in Mississippi, United States, also showed that urban residence was an important risk factor for HIV acquisition [30] and postulated that HIV spread more rapidly in highly populated urban areas with dense sex work networks [34]. Another study in Lilongwe, Malawi, indicated that due to the proximity to transportation and commercial networks, urbanization may increase the rates of HIV transmission and put women at a higher risk than men [32]. According to a quantitative study in Africa, a 10% increase in urbanization could be associated with a 3.6% increase in adult HIV prevalence [35]. However, while all previous studies used HIV prevalence data for their analysis, our study used HIV incident infection data to reveal the link between urbanization and HIV transmission, an indicator that could serve as a more direct reflection of an ongoing epidemic. Our findings suggest that local governments in areas undergoing urban development should allocate resources toward education on healthy sex behavior to the public and provide related preventive measures to reduce the potential transmission risk of HIV infection.

In our study, the SLR also revealed HIV prevalence and ART coverage rate as significant factors. Meanwhile, the Geodetector analysis showed that both factors had a high interactive effect with population density and distance to the local urban area. Thus, it suggests that these 2 factors may contribute to HIV transmission in Liangshan in a more complex, nonlinear way. It is not surprising that HIV prevalence had a positive relation with HIV transmission. However, it is intriguing that our study found a positive relation between ART coverage and HIV transmission because it has been acknowledged by many studies that expanded ART coverage is associated with decreased HIV transmission [36]. It has been debated whether the preventive effects of ART at an individual level, as shown in the HIV Prevention Trials Network 052 trial in heterosexual couples with HIV serodiscordance, can be replicated at a population level and whether outcomes from mathematical models can be replicated in the real world [37-39]. Early infection, consistent risk behaviors, adherence to therapy, and drug resistance were factors suggested to compromise the preventive effect of expanded antiretroviral coverage [38,39]. In the 4 key counties, there could be higher ART coverage rate in urban areas with better health care services; however, including the context of an extensive sexual network in urban areas and considering the general environment of insufficient detection of HIV infection and poor drug adherence in this area [40], relying solely on expansion of ART may not result in effective reduction in the transmission and incidence of new infections. In addition, the level of pretreatment drug resistance has been moderate in these 4 counties [41]. Therefore, combination prevention strategies, including universal testing, expansion of treatment, increased drug adherence, and other combined targeted measures, are needed to effectively avert the epidemic in the Liangshan area.

Limitations

There are several limitations in our study. The analysis of incident infection cases is generally impacted by the individuals who are newly diagnosed, identified through the local testing program. In this study, the expanded HIV testing covered more than 95% of the residents; therefore, this impact was minimized. However, approximately 5% of the residents were not included in this study due to out-migration for work and population movement, which might still lead to a certain level of bias. It is also noteworthy that the HIV recency assay has a false recent rate (FRR) such that some cases of long-term infection could be misclassified as recent infection. In this study, we excluded HIV cases that received ART and determined the FRR as 1.48% in the 4 key counties. Considering the low FRR, our main findings should not be affected. Furthermore, in modeling the spatial distribution of recent HIV infection cases, kernel density was calculated to reflect the clustering of recent HIV infection cases to address the limited number of recent infections. While kernel density is not a standard epidemiological indicator and its use may affect model interpretation, it serves as a useful

XSL•FO
RenderX

preliminary tool for identifying potential clustering patterns. Future studies with larger datasets and more stable incidence rates are suggested to refine this approach.

Conclusions

Geospatial studies explicitly focused on new HIV infection cases are rare [11]. To the best of our knowledge, our study is the first to use spatial regression analysis to reveal factors associated with clustering of incident HIV infection cases. After revealing 6 clusters of incident HIV infection, we further identified population density, HIV prevalence, elevation SD, distance to local urban area, and ART coverage rate as 5 factors impacting current HIV transmission in the 4 key counties that were severely impacted by the HIV epidemic. Our novel geospatial study at the township level provides a new tool for zooming into a local area and examining unique factors in detail. We hope our analytical tools will be useful in identifying high-risk regions and populations in other areas of high HIV prevalence and thus inform more targeted public health responses, which can be used to avert epidemics.

Abstract

Background: Long-term follow-up studies investigating the relationship between ambient air pollution and cardiovascular and cerebrovascular diseases (CVD) in rural Chinese populations remain limited.

Objective: This study aimed to investigate the impact of prolonged exposure to particulate matter with aerodynamic diameter ≤2.5 μm ($PM_{2.5}$) on CVD in rural areas of China.

Methods: On the basis of a multicenter population-based prospective study, adult rural residents (aged ≥15 y) from 3 study sites (ie, Xiangtan, Hunan Province; Longxi, Gansu Province; and Zhongmu, Henan Province) with different $PM_{2.5}$ exposure levels were tracked for the incidence of CVD events between 2013 and 2023. The relationship was assessed by applying the Cox proportional hazards model and a trend test.

Results: A total of 15,502 participants were included in the study. During the 10-year follow-up period, for every 1 μg/m^3 increase in $PM_{2.5}$, the risks of CVD, ischemic stroke, coronary heart disease, acute coronary syndrome, and intracerebral hemorrhage increased by 5% (hazard ratio [HR] 1.05, 95% CI 1.04 - 1.06), 7% (HR 1.07, 95% CI 1.06 - 1.08), 8% (HR 1.08, 95% CI 1.07 - 1.09), 9% (HR 1.09, 95% CI 1.06 - 1.11), and 10% (HR 1.10, 95% CI 1.07 - 1.14), respectively. Furthermore, the risk in the high exposure group (Q4) was found to be significantly higher than that in the low exposure group (Q1; *P* for trend <.001). The subgroup analysis indicated that the risk of CVD was higher among older people compared to individuals aged <60 years, and the interaction effect was statistically significant (interaction *P* value=.03).

Conclusions: Our results indicate that long-term exposure to $PM_{2.5}$ significantly increases the risk of CVD in rural areas of China and shows regional differences. This finding may deepen our understanding of the potential public health risks associated with $PM_{2.5}$ exposure and emphasize the crucial role of environmental governance in promoting public health outcomes.

KEYWORDS

cardiovascular and cerebrovascular diseases; particulate matter; air pollution; prospective study; Cox proportional hazards model

Introduction

Background

Ambient air pollution, considered the most significant environmental risk factor for global mortality and morbidity, particularly particulate matter with aerodynamic diameter ≤2.5 μm ($PM_{2.5}$) with an aerodynamic diameter of less than 2.5 micrometers, has emerged as a significant global public health concern [1]. The Global Burden of Disease report indicates that in 2019, air pollution was responsible for the deaths of 9 million people worldwide, with 61.9% of these fatalities due to increased mortality from cardiovascular and cerebrovascular diseases (CVD) [2]. Furthermore, there are significant variations in air pollution standards worldwide [3]. The limits in China and India are considerably higher than those in high-income nations (at 35 and 40 μg/m^3, respectively). Even in countries with lower levels of air pollution, there is evidence indicating a correlation between air pollution and cardiovascular health [4]. Early large-scale cohort studies reported the impact of long-term exposure to air pollution on CVD events in Europe and the United States. The environmental $PM_{2.5}$ exposure levels were generally <35 μg/m^3 [5,6]. A study of the European Study of Cohorts for Air Pollution Effects project [7] revealed that for every 5 μg/m^3 increase in $PM_{2.5}$ concentration, there was a 13% rise in the risk of coronary events. A cohort study conducted in the United States with 1,934,453 older participants found that for every 1 μg/m^3 increase in $PM_{2.5}$, the risk of transient cerebral ischemia and heart failure episodes increased by 3.5% and 1.9%, respectively [8]. This phenomenon may be attributed to the capacity of smaller particles to penetrate deeper lung regions and enter the bloodstream, thereby inducing systemic inflammation, oxidative stress, and endothelial dysfunction [9]. Consequently, this exposure increases the susceptibility of the CVD systems to the detrimental effects of these particles [10]. However, in many countries, particularly in low- and middle-income countries, the long-term effects of air pollution on health have not been thoroughly investigated [3]. In China, particularly in rural areas, there are numerous instances of biomass burning and coal-fired power plants [4]. The $PM_{2.5}$ exposure levels in these rural areas are significantly higher than those in urban areas, far exceeding the World Health Organization's Air Quality Guidelines [3]. However, epidemiological studies that link long-term air pollution in rural China to specific CVD are limited in scope.

Objectives

This research aims to conduct a multicenter, population-based prospective study to explore the long-term association between $PM_{2.5}$ exposure and the risks of CVD among rural residents from different regions. The findings of this study may contribute to a deeper understanding of the impact of air pollution on health and provide a more robust scientific basis for the development of public health policies in China.

Methods

Study Design and Participants

A population-based multicenter cohort study was initiated in 2013 and was a 10-year follow-up survey of registered residents at 3 study sites using a closed cohort design [11] (ie, Xiangtan, Hunan Province; Longxi, Gansu Province; and Zhongmu, Henan Province) between October 1, 2023, and January 31, 2024, to track the occurrence of CVD. This cohort study was jointly organized by the Institute of Virology at the Chinese Academy of Medical Sciences and the Chinese Center for Disease Control and Prevention. It was divided into 2 phases and spanned a duration of 10 years, from 2013 to 2023. During the initial phase, we gathered the participants' sociodemographic information and disease history. In the second phase, which took place in 2014, 2015, 2018, and 2023, we monitored their disease onset status and corroborated and refined the data through the local chronic disease management system (CDMS). The inclusion criteria for the research participants were as follows: birth date before June 1, 1998 (age ≥15 y); possession of a household registration or residence permit for the village; continuous residence at the research sites for 6 months or longer in the past year; the ability to complete the investigations during the research period; and the provision of voluntary written informed consent. The exclusion criteria were individuals without a residence address at the time of the baseline survey, those lost to follow-up, and those who became pregnant. All eligible current residents living in the 3 selected research sites were included in the 10-year follow-up survey.

Ethical Considerations

The study protocol was approved by the ethics committees of the Institute of Pathogen Biology, Chinese Academy of Medical Sciences, Beijing, China (approval number IPB-2023‐35). Written informed consent was obtained from all study participants, and all participants have the right to withdraw at any time. The study provides breakfast and transportation subsidies to the participants.

Procedure

In this study, measures were implemented to ensure the quality and comparability of data across the 3 research sites. These included standardizing the research protocol, providing uniform training for researchers, and applying consistent disease diagnostic criteria.

Sociodemographic data for each research participant were systematically collected using standardized questionnaires administered by trained interviewers. The data included age, gender, educational attainment, smoking status, alcohol consumption status, weight, height, marital status, per capita household income for 2013 (calculated by dividing the total household income by the number of family members) [12], and a history of hypertension. Household income per capita was categorized based on the national mean level in 2010 (6000 RMB [US $887]) [13]. BMI was categorized as underweight

XSL•FO
RenderX

(<18.5 kg/m^2), normal weight (≥18.5 kg/m^2 to <24.0 kg/m^2), and overweight (≥24.0 kg/m^2) [14].

Assessment of Exposure to Air Pollution

The $PM_{2.5}$ air pollution dataset originates from the near real-time tracking dataset of atmospheric components in China, known as "*Tracking China Air Pollution*" [15,1617]. The $PM_{2.5}$ prediction model establishes a 2-tier machine learning framework. In the first tier, the model uses a resampled training data set and the random forest algorithm to predict high-pollution events. In the second-level model, the second random forest model is established using the residuals between the $PM_{2.5}$ concentration simulated by the Community Multiscale Air Quality model and the observed $PM_{2.5}$ concentration. In the 2-level model, a decision tree–based method is used to establish the association between missing data and other parameters, thereby compensating for the absence of satellite data. The $PM_{2.5}$ prediction at a 1 km resolution integrates high-resolution satellite remote sensing aerosol optical depth data and environmental spatial data, such as road networks, to invert the $PM_{2.5}$ concentration at a 1 km resolution, which is fully covered daily. This model effectively captures changes in $PM_{2.5}$ concentration across various spatiotemporal scales and exhibits high accuracy. The cross-validation determination coefficient (CV-R^2) ranges from 0.86 to 0.90, indicating strong predictive ability (R^2 ranges between 0.80 and 0.84). To evaluate the model's ability to detect variations in $PM_{2.5}$ levels in rural areas with a limited number of monitoring stations and on a local scale, national monitoring station data were used for model evaluation. The results indicate that the high-prediction model performs comparably in out-of-bag evaluation, test data evaluation, and yearly cross-validation evaluation, demonstrating extremely high accuracy and robustness. The long-term $PM_{2.5}$ exposure levels are assigned based on the geographical coordinates of the research participants' permanent residences. The residential address information was collected through questionnaires during the baseline survey. We used the sf package in R software (version 4.4.3; R Foundation for Statistical Computing) to match these addresses with China's township-level administrative centers' database of latitude and longitude and assigned the geographical center's latitude and longitude coordinates of each village to each research participant. All coordinates are part of the WGS84 coordinate system. We then overlaid these coordinates with high-resolution $PM_{2.5}$ raster data, extracted the $PM_{2.5}$ concentration value corresponding to each coordinate point for a specific year and date, and used this as the individual's long-term exposure level. The total $PM_{2.5}$ concentrations for each participant during 4 different exposure windows were estimated, including moving averages for 1-year, 3-year, 5-year, and 10-year periods before the measurement date.

Research Outcome

Statistical Analysis

The composite outcome of this study is the incidence rate of major adverse cardiovascular events. Major adverse cardiovascular events was defined as a composite end point, encompassing the first occurrence of any of the following events: (1) ischemic stroke (IS), (2) coronary heart disease (CHD), (3) acute coronary syndrome (ACS), (4) intracerebral hemorrhage (ICH), and (5) any other form of CVD. In addition to obtaining the relevant disease information for the primary diseases diagnosed by qualified medical institutions (collected through baseline surveys and 10 y follow-up questionnaires), the local CDMS will export data based on ID numbers and match it with our study participants. This CDMS has been developed using the National Basic Public Health Service Management System, which was launched in 2009, and it ensures 100% coverage of all grassroots medical institutions nationwide. If a diagnosis certificate cannot be provided and it is not recorded in the system, it is not considered to have the disease. To assess the impact of $PM_{2.5}$ on specific diseases more specifically, we also included the following outcomes as end points for separate analysis:

- IS: defined as the first hospitalization or emergency event due to ischemic stroke, with the primary diagnosis code being *International Classification of Diseases, Tenth Revision* (*ICD-10*), I63.
- CHD: defined as the first hospitalization or emergency event due to CHD, with the primary diagnosis code being I20-I25. This includes angina pectoris and chronic ischemic heart disease.
- ACS: defined as a severe subtype of CHD, it is characterized by the first hospitalization or emergency event due to ACS, with the primary diagnosis code being I21 (acute myocardial infarction) or I20.0 (unstable angina pectoris).
- ICH: defined as the initial hospitalization or emergency event resulting from ICH. The primary diagnostic code is *ICD-10* I61.
- Any other form of CVD: hospitalization events for other CVD not encompassed by the aforementioned categories (*ICD-10* I00-I99) will be categorized as "other" outcomes and subjected to analysis.

To ensure the accuracy of the outcome definition, we require that each event be coded as the primary diagnosis. For all suspected events, we conduct a secondary confirmation by reviewing the medical records and require that their clinical manifestations and imaging examination results conform to internationally recognized diagnostic standards.

The data were independently entered into the EpiData software (version 3.1; EpiData Consortium) by 2 trained data entry professionals. Any discrepancies between the 2 datasets were resolved through cross-referencing with the original records to ensure data integrity and accuracy. Statistical analyses were performed using R (version 4.4.3; R Foundation for Statistical Computing). Quantitative variables are presented as medians, whereas qualitative variables are summarized as counts (percentages). BMI was calculated as weight (kilogram) divided by height squared (square meter). Fisher exact test and Pearson χ^2 test were used to compare the distribution of categorical variables across groups. The Cox proportional hazards model was used to investigate the association between long-term exposure to $PM_{2.5}$ and the risk of CVD incidence over 1, 3, 5,

XSL•FO
RenderX

and 10 years of follow-up, with continuous adjustments for selected covariates. The selection of covariates was based on prior knowledge and known or potential risk factors for CVD. Specifically, these include demographic variables (eg, age, gender, and BMI), socioeconomic factors (eg, educational attainment and household income), behavioral factors (eg, smoking status and alcohol consumption), and clinical history (eg, a history of hypertension). All variables were collected at the baseline of the study and were included as covariates in the multivariate Cox model during the univariate analysis ($P<.05$). The time variable in the model was defined as study time (follow-up time) [18]. For every 1 μg/m^3 increase in $PM_{2.5}$ concentration, the hazard ratio (HR) and the corresponding 95% CI were estimated. Subgroup analyses were conducted based on demographic and baseline disease risk factors to determine HRs for specific stratifications. Two-sided *P* values less than .05 were deemed statistically significant. On the basis of the tertiles of $PM_{2.5}$ concentration, the population was divided into a low exposure group (Q1), a medium exposure group (Q2 and Q3), and a high exposure group (Q4). The quartile groups were used as ordinal variables, assigned values of 1, 2, 3, and 4, for linear trend tests. The *P* value for trend was calculated to evaluate the overall dose-response trend, and restricted cubic spline analysis was used to examine the curve shape. The interaction *P* value was determined using the likelihood ratio test to assess the modifying effect of $PM_{2.5}$ on disease associations across various subgroups.

Results

Characteristics of the Study Participants Included in the Analysis in 2013

The information on the 3 study sites and the study participants included in the analysis is detailed in Table 1. Among the 16,636 eligible participants, 15,745 actually participated in the 10-year follow-up survey, yielding a response rate of 94.64%(15,745/16,636). After excluding 57 participants who lacked geographical location information and 186 participants with incomplete data, 15,502 participants were included in the final analysis (Table 1). The total follow-up period spanned 136,310 person-years. Approximately half of the participants were male (7293/15,502), and 22.76% (3528/15,502) of the participants were aged ≥60 years. The age distribution significantly differed among the 3 study sites ($P<.001$), with a higher proportion of individuals aged ≥60 years in Xiangtan compared to Zhongmu and Longxi (Table 1). Of the participants, 25.96% (4024/15,502) reported current smoking, and 18.35% (2845/15,502) reported alcohol consumption in the past year (Table 1).

Geographical Distribution of $PM_{2.5}$ Concentration and Regional Differences in the Risk of CVD

The participants were evenly distributed across the 3 sites. From 2013 to 2023, the annual average $PM_{2.5}$ concentrations at these 3 sites exhibited a decreasing trend over time; however, they remained at relatively high levels, ranging from 35.80 to 94.91 $\mu g/m^3$. The median 10-year average $PM_{2.5}$ exposure was 51.50 $\mu g/m^3$. The lowest concentration was found in Gansu Province, whereas the highest was in Henan Province (Figure 1). Over the 10-year period, a total of 628 cases occurred, accounting for 4.05% (628/15,502). Among them, the incidence rates were relatively high among men, individuals aged >60 years, those with an overweight BMI, and those with hypertension (Table

XSL•FO
RenderX

2). For every 1 μg/m^3 increase in $PM_{2.5}$, the risk of CVD increases by 5% (HR 1.05, 95% CI 1.04 - 1.06).

[a]HR: hazard ratio.

[b]HR analysis included 15,502 participants. HR indicates the increase in incidence risk for every 1 μg/m^3 increase in $PM_{2.5}$ concentration.

[c]Not available.

[d]$PM_{2.5}$: particulate matter with aerodynamic diameter ≤2.5 μm.

[e]Stratification according to total family income/number of people in the household.

On the basis of the estimated $PM_{2.5}$ values from satellite remote sensing within a 1 km radius of the research subjects' residences, the average $PM_{2.5}$ concentration for each year from 2013 to 2022 was calculated, and the changes in $PM_{2.5}$ levels over time for the 3 locations were plotted.

Long-term exposure to varying concentrations of $PM_{2.5}$ over different periods was associated with a slight increase in the incidence of CVD, and this association was statistically significant. Overall, the risk of disease increased significantly with 1-year and 3-year $PM_{2.5}$ exposure, while it slightly

XSL•FO
RenderX

decreased with 5-year and 10-year moving average exposure (Table 3). After adjusting for all potential covariates, during the 1-year exposure window, the overall risk of disease increased by 10% for every 1 μg/m^3 increase in $PM_{2.5}$ (HR 1.10, 95% CI 1.09 - 1.11). Specifically, the risk of IS, CHD, ACS, and ICH increased by 13% (HR 1.13, 95% CI 1.11 - 1.15), 6% (HR 1.06, 95% CI 1.03 - 1.09), 16% (HR 1.16, 95% CI 1.13 - 1.19), and 18% (HR 1.18, 95% CI 1.13 - 1.24), respectively. These associations were statistically significant (Table 3).

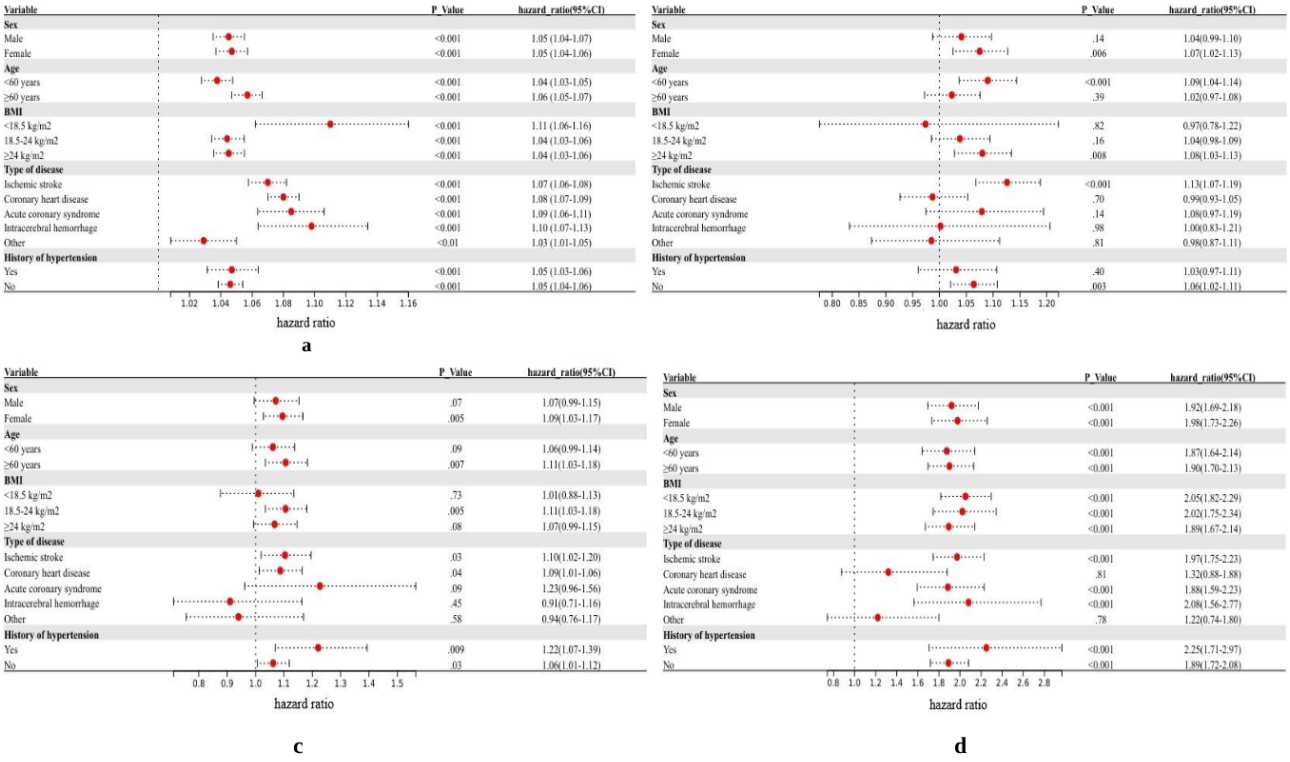
[a]$PM_{2.5}$: particulate matter with aerodynamic diameter ≤2.5 μm.

[b]CVD: cardiovascular and cerebrovascular diseases.



[c]Note: Adjusted HRs (95% CIs) of the occurrence risk are presented by per 1 μg/m^3 increment in moving average ambient $PM_{2.5}$ concentrations in different durations. The Cox model is adjusted for baseline age, gender, income, education level, BMI, smoking and drinking status, marital status, and history of hypertension.

[d]HR: hazard ratio.

Stratified analysis by different regions indicated that at the Zhongmu station, on average, the $PM_{2.5}$ concentration was the highest (73.24 μg/m^3), and its impact on the risk of CVD was higher than that at the Xiangtan and Longxi stations, with an adjusted HR of 1.89 (95% CI 1.73 - 2.06; Figure 2). Considering distinct genders, ages, BMI levels, and hypertension histories, the disease risk in the Zhongmu area is notably higher than in other regions. Additionally, at the Xiangtan, Longxi, and Zhongmu research stations, $PM_{2.5}$ exposure was positively correlated with the risk of IS, with adjusted HR of 1.13 (95% CI 1.07 - 1.19), 1.10 (95% CI 1.02 - 1.20), and 1.97 (95% CI 1.75 - 2.23), respectively (Figure 2). Additionally, the risk of ACS in Xiangtan, Longxi, and Zhongmu was 1.08 (95% CI 0.97 - 1.19), 1.23 (95% CI 0.96 - 1.56), and 1.88 (95% CI 1.59 - 2.23), respectively. For ICH, the risks were 1.00 (95% CI 0.83 - 1.21), 0.91 (95% CI 0.71 - 1.16), and 2.08 (95% CI 1.56 - 2.77), respectively.

Variation of CVD Risk Across $PM_{2.5}$ Concentration Levels

In this study, a fully adjusted model with a 10-year exposure window was used to perform stratified analyses on the association between $PM_{2.5}$ exposure and the risk of CVD across different exposure groups. The research findings indicate that, in comparison to Q1, the risk levels in Q2, Q3, and Q4 showed a gradual increase. The corresponding HRs were 1.05 (95% CI 0.88 - 1.26), 1.06 (95% CI 1.01 - 1.11), and 1.96 (95% CI 1.67 - 2.29), respectively. Furthermore, the trend test yielded statistically significant results (*P* for trend <.001), suggesting the presence of an overall dose-response relationship (Multimedia Appendix 1). The risk was notably higher in Q4 than in the younger population (aged <60 y). It is notable that the exposure concentration among the older population in different regions was higher than that of the younger population (Multimedia Appendix 1), and the interaction effect based on age was statistically significant (interaction *P* value=.03; Table 4).

Discussion

Principal Findings

The results of this multicenter, population-based, prospective study conducted in rural areas of China indicate a significant association between long-term exposure to $PM_{2.5}$ and an increased risk of CVD. In particular, the correlation between long-term exposure to $PM_{2.5}$ (over periods of 1 and 3 y) and disease risk was more pronounced, even after accounting for known risk factors. Notably, there were regional variations and dose-response trends in the risk of disease occurrence at different levels of $PM_{2.5}$ exposure.

XSL•FO
RenderX

The epidemiological evidence of the association between $PM_{2.5}$ and CVD revealed in this study significantly corroborated the findings of multicenter cohort studies conducted worldwide [19]. At the same time, it also highlighted the particularity of rural exposure. A cross-national prospective cohort study [20] has revealed that long-term exposure to outdoor $PM_{2.5}$ is associated with an increased risk of CVD in adults aged between 35 and 70 years. For every 10 $\mu g/m^3$ increase in $PM_{2.5}$ exposure, the risk of CVD death, CVD events, myocardial infarction, and stroke increased by 3%, 5%, 3%, and 8%, respectively [21]. Furthermore, the study revealed that the risk of developing CVD was higher in rural areas compared to urban areas. In our current research, similar results were also observed. In particular, the correlation between 1 to 3 years of $PM_{2.5}$ exposure and disease risk was more pronounced, with regional variations. This may be related to the following reasons: First, short-term exposure could rapidly trigger CVD events through acute inflammation and oxidative stress mechanisms, whereas long-term exposure could exacerbate the occurrence risk of atherosclerosis and CVD through cumulative effects [20]. A meta-analysis conducted by Jeroen de Bont et al [1] revealed that short-term exposure to $PM_{2.5}$ is associated with an increased risk of hypertension, stroke, and myocardial infarction. Long-term exposure to $PM_{2.5}$ was largely related to an increased risk of atherosclerosis, myocardial infarction, hypertension, stroke, and stroke mortality [22]. Second, during the study period, some participants may have relocated to new residences, which could lead to misclassification bias in the exposure assessment, potentially reducing the risk ratio. Finally, during the follow-up period, study participants may have died from causes other than CVD, particularly in long-term follow-ups, which could weaken the estimation of CVD risk. Furthermore, our study demonstrated that the effects of $PM_{2.5}$ on specific CVD differed significantly both in the overall population and in regional stratified analyses. This regional heterogeneity may arise from the complex interplay of multiple mechanisms. The variations in $PM_{2.5}$ concentrations and chemical compositions across different regions contribute to the observed disparities. The most polluted areas, such as Henan, were characterized by high population densities and an energy structure that heavily relied on coal combustion, leading to persistent high levels of air pollution from coal burning [23]. The resulting sulfate and nitrate particles made up over 40% of the $PM_{2.5}$ mass concentration. Additionally, the high-salt dietary habits prevalent in Henan, combined with prolonged exposure to $PM_{2.5}$, may have increased the risk of hypertension and vascular damage [24]. Collectively, these factors contributed to an increased incidence of CVD. In our study, the results of trend tests and restricted cubic spline analysis indicated a dose-response relationship between $PM_{2.5}$ exposure and overall CVD risk. However, this relationship was not strictly linear. These findings suggest that the impact of $PM_{2.5}$ on CVD may exhibit a "*threshold effect*" [25], whereby its toxic effects become markedly pronounced upon exceeding a certain threshold [26]. Evidence suggests that at lower concentrations, cellular autophagy can remove damaged organelles and maintain cellular homeostasis. This compensatory mechanism may partially mitigate the toxic effects of $PM_{2.5}$ on cells, thereby reducing the associated risk [22]. However, when $PM_{2.5}$ concentrations were excessively high, the oxidative stress induced by $PM_{2.5}$ increased in a dose-dependent manner, leading to a significant rise in ROS and cytochrome C expression in vascular endothelial cells. This cascade activates caspase-3, ultimately resulting in DNA fragmentation and cell apoptosis [27]. Furthermore, exposure to high concentrations of $PM_{2.5}$ can trigger multiple programmed cell death pathways in vascular endothelial cells, disrupt tight junction proteins, impair endothelial cell integrity, and consequently cause further damage to cardiovascular tissues, significantly elevating the risk of CVD [28].

Various biological mechanisms have been proposed to explain the association between $PM_{2.5}$ exposure and CVD events, including increased systemic inflammation and oxidative stress, accelerated atherosclerosis, and changes in cardiac autonomic nerve function [29-32]. Exposure to particulate matter is associated with an increased risk of heart disease, primarily through the initiation and promotion of atherosclerosis progression, which underlies the majority of CVD [33]. Exposure to $PM_{2.5}$ has been shown to increase the levels of ROS. The subsequent accumulation of ROS exacerbates oxidative stress, leading to cellular and molecular damage, including DNA, proteins, and lipids [34]. Additionally, exposure to $PM_{2.5}$ promoted the secretion of inflammatory cytokines, leading to endothelial cell activation and a series of pathological changes in the vascular endothelium, thereby fostering the development of CVD [35].

The older population is considered a vulnerable group, susceptible to a range of factors, including immune aging, comorbidities, and environmental influences. Consequently, research focused on this high-risk demographic is of paramount importance. The risk of CVD was elevated in the high-exposure group, whereas it was marginally reduced in the medium and low exposure groups relative to younger individuals. At moderate to low exposure levels, the older population's cumulative physiological compensatory capacity can partially counteract the damage caused by pollution, temporarily maintaining the homeostasis of their internal environment [32]. As previously mentioned, prolonged exposure to high levels results in a substantial rise in the production of reactive oxygen species [34]. This increase surpasses the antioxidant capacity of older people, which is already compromised, thereby exacerbating oxidative damage [36]. Although most studies and expert consensus have reached the conclusion that $PM_{2.5}$ can increase the risk of CVD, it is worth noting that some studies have failed to find a relationship between $PM_{2.5}$ and the risk of CVD [37,38]. These findings underscore the intricate and uncertain dynamic relationship between air pollution and the health outcomes of the older population, emphasizing the need for further research to accurately assess the impact of $PM_{2.5}$ on disease incidence risk and mortality within this demographic.

Limitations

First, the estimated exposure concentrations for each participant were derived from the baseline survey conducted in 2013. During the follow-up period, participants who moved away

XSL•FO
RenderX

were excluded from the analysis, as we lacked comprehensive migration histories for these individuals. This may result in selection bias. Migration patterns in rural areas were typically linked to younger age, higher socioeconomic status, and superior health conditions. This could diminish the gradient between exposure levels and disease risk, potentially leading to an underestimation of the true health impacts of $PM_{2.5}$. Future cohort studies should implement more comprehensive tracking systems to gather exposure data on migrants, thereby minimizing such selection bias as much as possible. Second, we did not evaluate the indoor $PM_{2.5}$ concentration. Ideally, individual exposure should encompass both indoor and outdoor components. Due to the absence of indoor exposure data, we used the outdoor concentration as a proxy variable, which may result in exposure misclassification. In rural areas of China, the use of solid fuels, such as coal and biomass, may exhibit a spatial correlation with outdoor $PM_{2.5}$ concentrations. On the other hand, factors such as rural ventilation practices and house structure can influence the relationship between indoor and outdoor concentrations, thereby increasing the complexity of exposure assessment. Considering these factors, unmeasured indoor exposure was more likely to diminish rather than amplify the risk ratio we reported. Future research can supplement the collection of indoor $PM_{2.5}$ data and develop individual exposure models that integrate indoor and outdoor monitoring to more accurately analyze the impact of indoor pollution sources on individual exposure. Third, we did not adjust for any other key air pollutants in the model. Both NO_2 and SO_2 were strong respiratory irritants that severely damage the respiratory and cardiovascular systems [39]. The interaction with $PM_{2.5}$ may result in a synergistic effect. Owing to the lack of sufficient precise data on air pollution exposure at that time, it may have affected our interpretation of the specific effects of $PM_{2.5}$. However, there was a moderate to high spatial correlation among air pollutants, and including all of them in a multivariate model may lead to collinearity issues [40]. In the analysis of multipollutant models, the effect of $PM_{2.5}$ was typically the most robust [31]. Simultaneously, $PM_{2.5}$ possesses direct cardiovascular toxicity, and its role as a key risk factor is independent. Future research could collect more comprehensive pollutant data at individual exposure levels to more accurately assess the health effects of $PM_{2.5}$. Finally, although we adjusted for several potential confounding factors in the multivariate model, it was impossible to completely eliminate confounding bias due to the presence of unknown and unmeasured residual confounding factors.

Despite these limitations, our research was enhanced by using data from a large-scale, population-based prospective cohort study that featured a 10-year follow-up period and high-quality outcome assessments. Short-term fluctuations in $PM_{2.5}$ can have detrimental health effects, yet long-term exposure may have more significant clinical health implications on CVD morbidity and mortality, as individuals are usually exposed to higher levels of air pollution over an extended period [31]. One significant advantage of this study is that it focuses on rural areas in China, covering a wide range of $PM_{2.5}$ concentrations (ranging from 35.81 to 94.91 $\mu g/m^3$), and conducts risk assessments for different exposure windows of specific CVD, thereby laying a solid scientific foundation for evaluating the exposure-response relationship. The generalizability of the results of this study to other rural populations requires careful consideration. The prospective design, large sample size, and detailed assessment of exposure and confounding factors have enhanced the reliability of the conclusions. Therefore, it is likely that they are applicable to rural populations facing similar environments. However, when extending the results to rural populations with significantly different pollution sources and lifestyles, caution is necessary. Future research to validate our model in other rural environments will help confirm the external validity of these associations.

Conclusions

Our research findings indicate that long-term exposure to $PM_{2.5}$ was significantly associated with an elevated risk of CVD among rural populations, and this association exhibited regional variations. In regions with high levels of $PM_{2.5}$ pollution, comprehensive measures and strategies aimed at reducing air pollution and enhancing public awareness of self-protection should be implemented to mitigate the associated disease risks. This discovery could enhance our understanding of the potential public health risks associated with $PM_{2.5}$ exposure and underscore the important role of environmental governance in promoting public health outcomes. Furthermore, future research efforts should concentrate on clarifying the impacts of $PM_{2.5}$ exposure on the health of various population groups and the underlying mechanisms, thereby contributing to the development of comprehensive intervention measures to mitigate the negative effects of air pollution on public health.

Acknowledgments

The corresponding author would like to express his gratitude to the staff of the disease control departments in various locations of the research site for their assistance in the data collection and quality control processes during the course of the project.

Funding

This study was supported by the CAMS Innovation Fund for Medical Sciences (2021-I2M-1-037), the National Natural Science Foundation of China (82473697 and 82373647), and the National Key Research and Development Program of China (2024YFC2311201).

Abstract

Background: Overweight and obesity are major risk factors for numerous chronic diseases, requiring effective prevention and intervention strategies. Community-based BMI screening may enhance awareness of weight status, but its effectiveness remains uncertain.

Objective: This study aimed to rigorously evaluate the long-term causal effects of community-based BMI screening with a light-touch intervention in Malaysia using a regression discontinuity design (RDD).

Methods: Using data from 2 waves (2013 and 2018) of a Malaysian population-based cohort study (N=6561), we applied a sharp RDD to estimate the causal effects of community-based BMI screening on health outcomes for individuals near the BMI threshold. Participants were aged 35 years or older and completed both follow-ups. The exposure was BMI screening with a light-touch intervention, including height and weight measurement, feedback on results, and referral card distribution. Main outcomes were BMI, blood pressure, and random blood glucose 5 years post intervention, along with health behaviors, health care use, and mental health status.

Results: BMI screening and intervention showed no significant impact on BMI after 5 years (0.4 kg/m², 95% CI –0.2 to 0.9, *P*=.16). Results remained robust after adjusting for covariates (eg, 0.4 kg/m², 95% CI –0.1 to 0.9 with age and sex; 0.5 kg/m², 95% CI –0.1 to 1.0 with demographic covariates) and modifying functional forms (0.4 kg/m², 95% CI –0.2 to 1.1 with quadratic specification). Robustness was also confirmed across different bandwidths, placebo tests, “donut” RDD, and when treating age as either a continuous or categorical variable. Interaction analysis revealed almost no substantial heterogeneity effects. Mechanism analysis and secondary outcomes indicated no significant effects on health behaviors (including smoking, physical activity, diet, and sedentary behavior), health care use (screening, diagnosis, and medication treatment of hypertension and diabetes), mental health outcomes (anxiety, depression, and stress levels), or cardiovascular risk factors (systolic blood pressure, diastolic blood pressure, random blood glucose; eg, systolic blood pressure showed a nonsignificant change of 0.2, 95% CI –3.5 to 4.0 mm Hg). These findings should be interpreted cautiously, as this study was sufficiently powered to detect larger, clinically meaningful changes but may have lacked power to identify more modest effects.

Conclusions: This study is the first to assess the causal effects of population-based BMI screening on long-term health outcomes in a Southeast Asian population. The findings suggest that merely informing individuals of their overweight or obese status and implementing light-touch interventions are insufficient to significantly reduce BMI or drive sustained behavior change. Nonetheless,

XSL•FO
RenderX

the results do not exclude the possibility of short-term effects, and more frequent or sustained light-touch interventions may still be effective. Future studies should design more intensive interventions and include larger sample sizes.

BMI; screening; regression discontinuity design

Introduction

Overweight and obesity are significant public health concerns and major risk factors for a range of chronic conditions such as hypertension, diabetes, dyslipidemia, cardiovascular disease (CVD), and certain types of cancer [1,2]. As of 2020, an estimated 2.2 billion adults worldwide were classified as overweight or obese, a number projected to reach 3.3 billion by 2035, representing more than 54% of the global adult population [3]. In Malaysia, the situation is particularly alarming, with approximately 54.4% of adults being overweight or obese as of 2023, marking a 10% increase since 2011 [4]. This trend imposes substantial health and economic burdens, increasing health care costs and reducing quality of life [5,6]. Given the urgency and enormity of the issue, effective prevention and intervention are needed to mitigate the growing burden of overweight and obesity.

One key barrier to effective weight management is the lack of awareness regarding personal weight status [7]. Many individuals are unaware of their BMI or fail to accurately perceive their weight, particularly those classified as overweight or obese [8]. Accurate weight perception is crucial, as studies suggest that individuals who recognize themselves as overweight are more likely to attempt weight loss [9-14]. However, the evidence linking weight perception to actual health behaviors and outcomes is mixed. While some research indicates that perceived overweight motivates healthier behaviors, such as increased physical activity or healthier eating [15], other studies report no association or even negative effects [16,17]. These inconsistencies highlight a critical need for effective interventions to address weight misperception and support health behavior changes.

Community-based BMI screening programs have been proposed as one such approach, aiming to raise awareness of weight status, the overall effectiveness of such programs in improving BMI outcomes remains uncertain. Some studies report significant reductions in BMI and related health risks following screening interventions [18,19], while others find no measurable impact [20,21]. Screening alone may be insufficient to drive significant weight loss if participants lack the resources, motivation, or sustained support to act on the feedback [22]. Moreover, prior studies lacked robust causal inference methodologies and were constrained by short follow-up periods, thereby restricting their ability to comprehensively evaluate the long-term effectiveness of BMI screening interventions.

This study uses a regression discontinuity design (RDD) to rigorously evaluate the causal effects of a community-based BMI screening program conducted in Segamat, Johor, Malaysia. RDD is a quasi-experimental approach that provides robust causal inference in observational settings by exploiting a standard threshold that determines intervention assignment. This method leverages the fact that individuals just above and just below the threshold are likely to be similar in all respects except for their assignment to the intervention group, effectively mimicking a randomized controlled trial. By comparing outcomes near this threshold, RDD isolates the impact of the intervention from other confounding factors. This study evaluates the impact of BMI screening on BMI for over 5 years, alongside secondary outcomes such as systolic blood pressure, diastolic blood pressure, and random blood glucose, which are other CVD risk factors. Additionally, mechanisms of change were analyzed, including health behaviors, mental well-being, and health care use. Subgroup analyses were also conducted to explore heterogeneity across different population groups.

Methods

Study Setting

This study analyzed data from the Southeast Asia Community Observatory (SEACO) Health and Demographic Surveillance System [23]. Located in Segamat, Johor, Malaysia, SEACO monitors 5 subdistricts, Bekok, Chaah, Gemereh, Jabi, and Sungai Segamat, of the district's 11 subdistricts. The surveillance system spans an area of approximately 1250 square kilometers, comprising nearly 13,000 households and a population of about 40,000. A baseline census was conducted from 2012 to 2017, followed by 2 large-scale health surveys (HR) in 2013 and 2018. These surveys included residents aged 5 years and older identified during the baseline census. Participants from the 2012 baseline census were invited to participate in the 2013 health survey (HR 2013), while those from the 2017 census were invited to participate in the 2018 health survey (HR 2018). Exclusion criteria included individuals not enumerated in the baseline census, as well as those who were bedridden, mentally incapacitated, or unable to provide informed consent.

The analysis included participants from HR 2013 and HR 2018. This study's population was restricted to individuals aged 35 years and older in 2013, as this age group was eligible for biometric assessments and is considered at high risk for chronic conditions. Although height and weight were collected from all individuals aged 5 years and above, the analytic dataset only included participants aged 35 years and older because the planned analysis initially focused on blood pressure, which was measured only in this age group. Among the 13,769 eligible participants from HR 2013, a total of 7024 were successfully followed up on in HR 2018.

Recruitment Procedures

Field data collection teams consisted of 15-20 members, including a project coordinator, field supervisors, and trained data collectors. Household visits involved explaining this study's objectives, addressing participant inquiries, and obtaining written informed consent. Data collection comprised structured questionnaires, screening tests, and physical measurements. During the data collection period, households that did not respond were revisited up to 3 times. If no contact was established after 3 attempts, the household was classified as "not at home (nonresponse)." Reasons for nonparticipation were systematically documented only for individuals who explicitly declined participation. A unique SEACO ID was assigned to each participant at their initial contact, facilitating the integration of demographic and health data across multiple surveys and supporting robust longitudinal monitoring.

Ethical Considerations

This study was approved by the Monash University Human Research Ethics Committee (2018-13142-45226). All participants were provided with information about this study's purpose and procedures and gave written informed consent before enrollment. Participant privacy and confidentiality were strictly protected: all data were collected and stored in deidentified form on secure servers, and the research team only accessed anonymized datasets during the analysis phase. Participants did not receive any financial or other forms of compensation for their participation. No personally identifiable information or images are included in this manuscript or the supplementary material.

BMI Measurement and Intervention

Trained field workers measured weight and height using a portable electronic scale with an integrated height sensor (Patient Focus, model GBS-721). Participants were barefoot and wore light clothing during the measurement. BMI was calculated as weight (kg) divided by the square of height (m).

This study used the following approach: all participants were notified of their BMI results by field workers after screening. Individuals with a BMI of ≥25, indicating overweight or obesity, were referred to clinics due to the association between overweight and obesity and an increased risk of CVDs [2]. These individuals are also more likely to have comorbid conditions such as hypertension or hyperglycemia, which warrant further medical evaluation. No additional interventions, follow-ups, or reminders were provided beyond the referral card. With out-of-pocket expenses at local government clinics being minimal (at RM 1 per visit, a currency exchange rate of RM1=US $0.11 was applicable), patients could access full medical consultations, including all necessary examinations and basic laboratory tests [24]. Referral card holders visiting primary care facilities were evaluated and referred by physicians as needed. The "light-touch" intervention involved BMI screening, result communication, and referral card provision, without incorporating incentives, health education, or prescribed time allocations for any activities.

Study Design

About RDD

The RDD offers a robust framework for estimating causal effects by leveraging thresholds within continuous assignment variables to determine intervention assignment. Interventions may be administered deterministically (where individuals on 1 side of the threshold uniformly receive the intervention, termed a "sharp RDD") or probabilistically (where intervention likelihood differs across the threshold, known as a "fuzzy RDD") [25-27]. This study used a sharp RDD, as referral cards were distributed based on predefined thresholds, to assess the causal effects of community-based BMI screening. Baseline BMI recorded in 2013 served as the continuous assignment variable. Overweight and obesity were defined using a BMI cutoff of ≥25 kg/m² [28]. Referral card issuance based on these thresholds indicated the need for follow-up health interventions. The findings highlight the intention-to-treat effects of BMI screening, reflected in changes in BMI observed in 2018.

The robustness of RDDs depends on the assumption that potential outcomes are continuous around the threshold. This requires comparability between individuals immediately above and below the threshold, except for their probability of receiving the intervention [29]. A key issue is whether the assignment variable was manipulated. For instance, field workers might record inflated BMI values for participants close to the threshold to increase the number of referral cards distributed. To investigate this, we analyzed the smoothness of the assignment variable at the threshold using a histogram analysis and a formal statistical test developed by Cattaneo et al [30]. This test applies a local polynomial density estimator without binning to detect potential manipulation [30]. Another issue is confounding factors that may be associated with both the threshold and the outcomes. For age to be a true confounder in this RDD, it would need to change abruptly at the threshold, which is unlikely given the smooth distribution of age around BMI thresholds. Even though younger individuals might be more likely to fall below the threshold and older individuals above it, age is likely to vary continuously near the threshold, thereby satisfying the continuity assumption of the RDD. To ensure this assumption holds, we evaluated covariate continuity near the threshold by comparing demographic, socioeconomic, and health behavior variables on either side. Significant differences were identified using chi-square or Fisher exact tests. Where differences existed, we applied the method by Imbens and Lemieux [29], using placebo tests to check for discontinuities in covariates, treating them as outcome variables.

Covariates

While the inclusion of covariates is not mandatory for unbiased causal inference in RDD, they play a crucial role in correcting imbalances in characteristics near the threshold in small samples and improving the accuracy of causal effect estimates [31]. For our analysis, adjustments were made for demographic characteristics (age, gender, marital status, and race), socioeconomic factors (education, income, and occupation), and lifestyle behaviors (smoking, alcohol consumption, and physical activity). The covariates were incorporated using an additive-separable and linear-in-parameters specification,

XSL•FO
RenderX

maintaining a shared intercept across treated and control groups [31]. To promote transparency and robustness, we initially presented the unadjusted regression discontinuity (RD) estimates, followed by those adjusted with various combinations of covariates. Physical activity was assessed using the Global Physical Activity Questionnaire, with 600 metabolic equivalent of task–minutes or more classified as meeting the World Health Organization's recommended activity level [32]. Smoking was defined as having ever smoked at least 1 entire cigarette. Alcohol consumption was defined as having consumed alcohol within the past 30 days.

Statistical Methods

We evaluated the effect of the 2013 overweight and obesity screening on 2018 outcomes using local linear regression, following the methodology of Imbens and Lemieux [29]. Linear models were selected instead of higher-order polynomials to mitigate overfitting and reduce bias in effect estimation [33]. The inclusion of quadratic terms was not statistically significant at the 5% level, suggesting no improvement in model accuracy with higher-order polynomials. Nonetheless, visual inspection highlighted a potential nonlinear association between the assignment variable and the outcomes. To address this, quadratic terms were incorporated as part of a robustness check, and findings were presented for both local linear and quadratic RDDs. A triangular kernel function was used in all models to give greater importance to data points closer to the threshold.

A regression model was fitted for BMI during the main analysis:

$$Y_i=\alpha_0+\alpha_1 Above_i+\alpha_2(BMI_i-25)+\alpha_3 Above_i(BMI_i-25)+X_i\kappa+v_i$$

Y_i represents the BMI of an individual i in 2018. The variable $Above_i$ is set to 1 for individuals whose BMI was at least 25 kg/m² in 2013. BMI_i denotes the BMI of an individual i in 2013, while X_i represents the covariate of the individual i in 2013. The parameter α_1 captures the average causal effects of community-based screening on BMI in 2018. α_2 indicates the marginal change in BMI in 2018 for individuals whose BMI was below 25 kg/m² in 2013. For individuals with a BMI at or above 25 kg/m² in 2013, the combined effect is given by $\alpha_{2+}\alpha_3$. For the evaluation of secondary outcomes, including systolic blood pressure, diastolic blood pressure, and random blood glucose in 2018, similar methodologies were applied as those used for the primary outcome analysis.

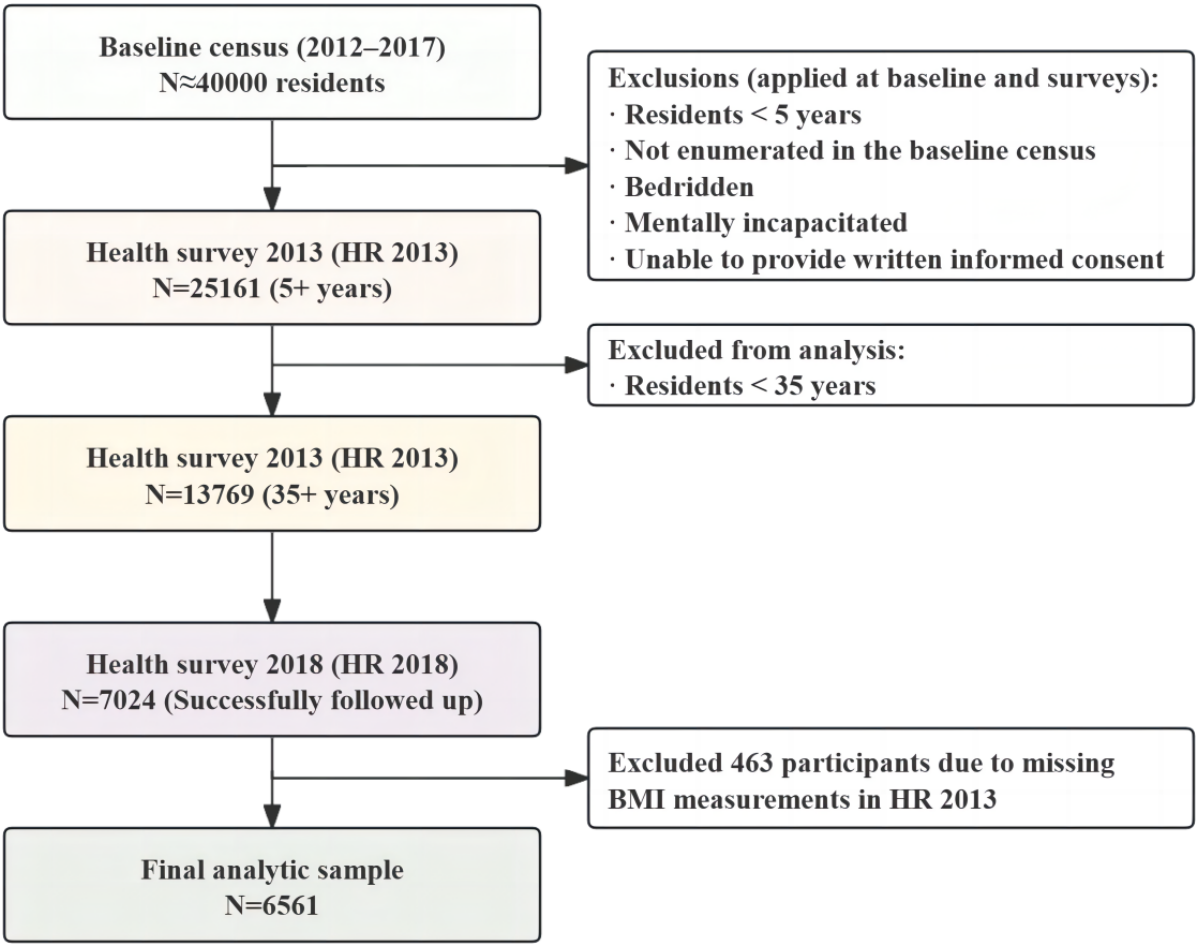
In RDDs, selecting the appropriate bandwidths—defining the range around the threshold for fitting local polynomials—is a critical methodological decision. Bandwidths influence the analytical framework, as well as the accuracy and reliability of estimated effects. Narrow bandwidths often provide better model fit by restricting the analysis to observations close to the threshold, where relationships tend to approximate linearity. However, this advantage comes at the expense of increased variance due to the smaller sample size, a challenge described as the "bias-variance tradeoff." To mitigate this issue, we used the optimal bandwidth selection method introduced by Calonico, Cattaneo, and Titiunik [34] to determine suitable bandwidths for our analysis. We conducted sensitivity analyses to evaluate the robustness of our conclusions by recalculating the primary estimates using different bandwidth settings. In the main analysis, the optimal bandwidth for BMI was 2.9 kg/m². Additionally, we examined the heterogeneity of causal effects across demographic and socioeconomic categories, such as age, sex, marital status, race, education, occupation, and perceived economic status.

Building on the primary impact evaluation, we carried out additional RD analyses to assess the broader effects of the intervention on health behaviors, mental well-being, and health care use. Specifically, we investigated changes in physical activity levels, sedentary behavior, smoking, and nutrition patterns. Psychological outcomes, such as anxiety, depression, and stress, were evaluated using the validated Malay version of the Depression, Anxiety, and Stress Scale-21 [35,36]. Health care use was defined as self-reported information on past screening, diagnosis, and medication treatment for hypertension and diabetes. To analyze binary outcome variables, we applied a modified Poisson regression model within the RD framework to estimate risk ratios, which provide an intuitive measure for interpreting binary outcomes [37]. Specifically, the RD framework used BMI in 2013 as the running variable to determine treatment assignment. Observations within a predefined bandwidth around the cutoff of 25 kg/m² were included in the analysis, with triangular kernel weights applied. The regression models accounted for the treatment effect, the linear trend of the running variable, and their interaction, as described below:

$$log(Y_i)=\alpha_0+\alpha_1 Above_i+\alpha_2(BMI_i-25)+\alpha_3 Above_i(BMI_i-25)+\varepsilon_i$$

The outcome variable Y_i represents a binary indicator derived from health-related outcomes in 2018, modeled using a log-link function. The variable $Above_i$ is defined as 1 for individuals whose BMI in 2013 was at least 25 kg/m², and 0 otherwise. The parameters α_1 , α_2 , and α_3 capture the treatment effect, the marginal trend below the cutoff, and the interaction between treatment and BMI deviations from the cutoff, respectively. By integrating the RD framework with modified Poisson regression, this approach enabled the estimation of local treatment effects and risk ratios, which are directly interpretable for binary outcomes based on BMI [38-41]. All analyses and graphical representations were carried out using R software (version 4.2.2; R Foundation).

Results



Sample Characteristics

A total of 7024 individuals were initially included in the sample. We excluded 463 (6.6%) participants due to missing BMI measurements in 2013, leaving 6561 participants (Figure 1). Given the high attrition between 2013 and 2018, we formally tested whether follow-up rates were discontinuous around the BMI cutoff. As shown in Section S1 in Multimedia Appendix 1, no statistically significant discontinuity was detected, and the results were robust to alternative bandwidth choices (50% and 150% of the optimal bandwidth). Table 1 provides an overview of the full sample and the groups within the optimal BMI bandwidths. The demographic, socioeconomic, and behavioral health traits are comparable across both groups.

XSL•FO
RenderX

Specifically, 34% (n=2239) of participants are aged 50-59 years, 40% (n=2641) are male, 85% (n=5529) are married, 47% (n=2947) possess a primary education level, and 14% (n=891) are smokers.

Manipulation of Assignment Variable

The RDD necessitates that the assignment variable (BMI in 2013) remains free from manipulation near the threshold. Figure 2 presents a histogram of the assignment variable to assess any indications of manipulation. No visual evidence of bunching was detected near the threshold, providing evidence against potential interference in screening measurements by field workers. Additionally, the formal test introduced by Cattaneo et al [30] confirmed the null hypothesis of smooth density around the threshold, further supporting the absence of manipulation in the assignment variable (Section S2 in Multimedia Appendix 1).

Figure 2. Density of baseline BMI distribution among adults ≥35 years, Segamat, Malaysia, 2013. The dashed line represents the threshold of 25 kg/m². Participants with a BMI exceeding this limit were given a referral card by field workers, indicating that they had reached a critical level of being overweight or obese. No additional interventions were provided. The sample size is 6561.

Continuity of Participants' Observed Characteristics Around Threshold

The RDD assumes no other interventions impact outcomes near the BMI thresholds. Table 2 presents the demographic, socioeconomic, and health behavior characteristics of individuals just above and below the threshold within the optimal bandwidth. Most characteristics are balanced; however, slight imbalances were detected for sex and age. These discrepancies were identified through preliminary chi-square and Fisher exact tests, which were used as screening tools to detect potential imbalances near the threshold. For covariates showing significant differences in these preliminary tests (eg, sex and age), we conducted placebo tests using the framework by Imbens and Lemieux [29]. These placebo tests treated the covariates as outcomes to directly assess potential discontinuities at the threshold. The results confirmed no significant discontinuities, thereby supporting the continuity assumption and the validity of the RDD (Section S3 in Multimedia Appendix 1).

Impact Estimates

Figure 3 depicts the effect of the assignment variable (2013 BMI) on the outcome variables (2018 BMI) within the optimal bandwidth, with the threshold represented by a dashed line. No notable shifts in BMI were identified across the discontinuity, implying that the community's overweight or obesity screening conducted in 2013 may not have significantly influenced BMI in 2018.

Figure 3. Five-year change in BMI (2013-2018) within optimal bandwidths, adults ≥35 years, Segamat, Malaysia. The dashed line marks the threshold at which field workers provided a referral card, without implementing further interventions. Thick lines depict the linear fit, while thin lines illustrate the 95% CIs. The total sample consists of 6561 individuals, including 3024 within the optimal bandwidth for BMI.

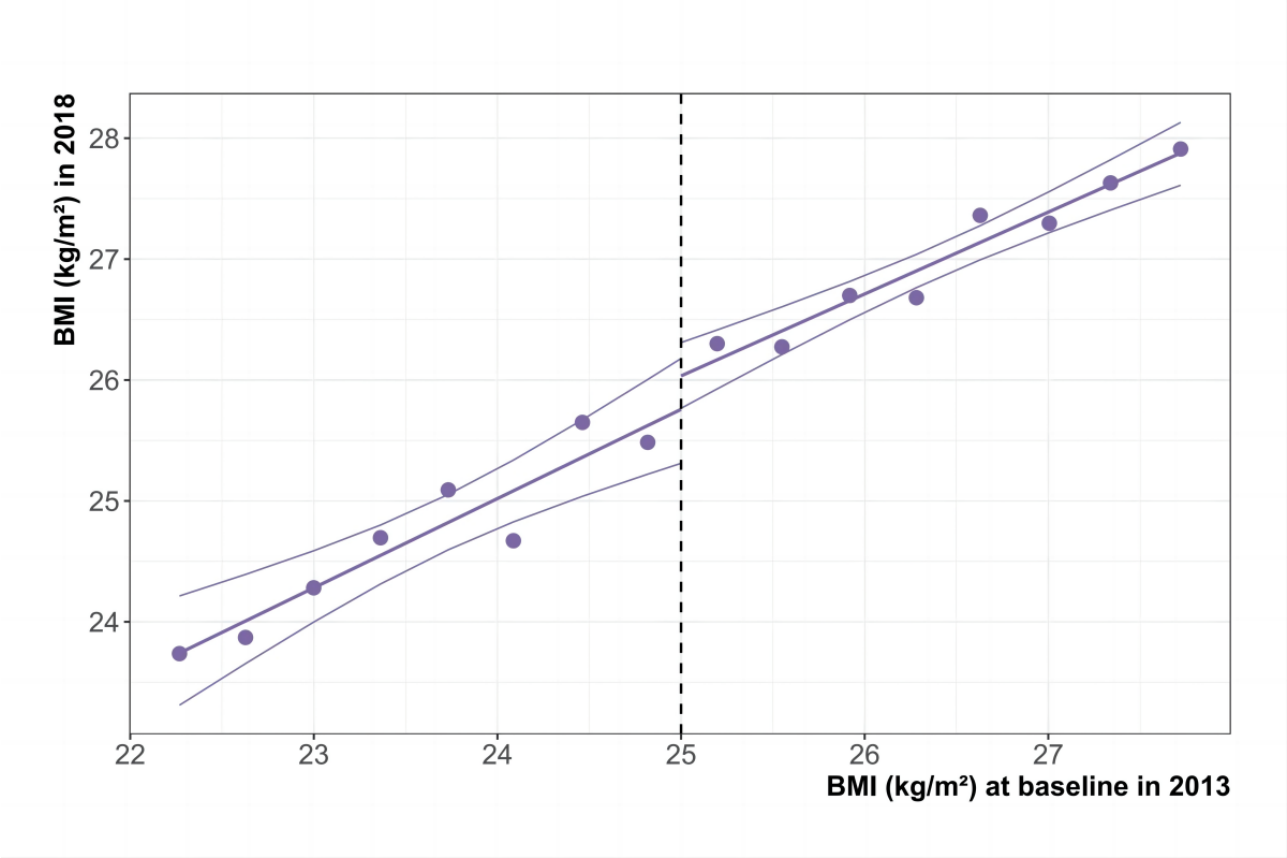

Table 3 outlines the regression estimates of the local causal effect of community screening. The analysis showed that community screening did not significantly reduce BMI (0.4 kg/m², 95% CI –0.2 to 0.9, *P*=.16) by 2018. After controlling for demographic, socioeconomic, and health behavior variables, the impact of screening remained insignificant. Consistent results were obtained using local quadratic regression approaches.

Table 3. Regression discontinuity estimates with 95% CIs for the effect of 2013 community-based BMI screening on 2018 BMI outcomes, adults ≥35 years, Segamat, Malaysia.

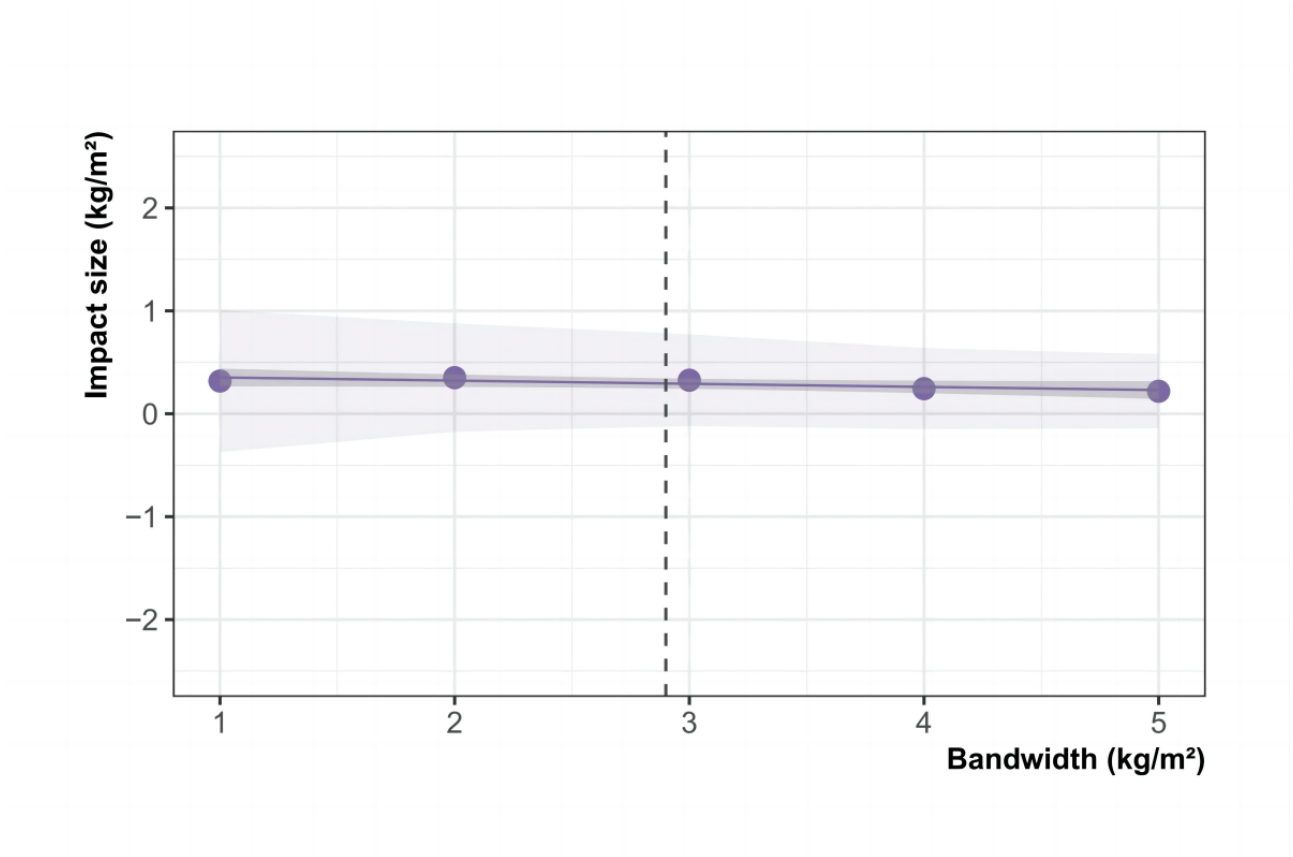
Impact of screening on BMI (kg/m²)	Without covariates	With age and sex	With demographic covariates	With demographic and social covariates	With demographic, social, and behavioral covariates
Local linear					
BMI	0.4 (–0.2 to 0.9)	0.4 (–0.1 to 0.9)	0.5 (–0.1 to 1.0)	0.3 (–0.3 to 1.0)	0.3 (–0.3 to 1.0)
P value	.16	.15	.08	.31	.30
Local quadratic					
BMI	0.4 (–0.2 to 1.1)	0.4 (–0.2 to 1.1)	0.6 (–0.1 to 1.2)	0.4 (–0.4 to 1.1)	0.4 (–0.3 to 1.1)
P value	.19	.17	.09	.31	.30

To assess heterogeneity in the effects of community screening, we conducted interaction regression analyses. Although the overall interaction by age group was not statistically significant, subgroup analyses suggested an effect among individuals aged 50-59 years (–1.3, 95% CI –2.2 to –0.4 kg/m²; P for heterogeneity=0.01). In contrast, no substantial heterogeneity and interaction were detected based on sex, race, marital status, education level, income, or occupation (Section S4 in Multimedia Appendix 1).

The sample consists of individuals falling within the optimal bandwidth around the 25 kg/m² threshold, using baseline BMI

XSL•FO
RenderX

as the assignment variable. Each cell reports the coefficient from a separate regression, using a triangular kernel function that assigns greater weight to observations nearer to the threshold. The models in the second column do not include covariates; the third column controls only for age and sex, the main covariates with baseline imbalances, to help isolate their influence and enhance the transparency of robustness checks; the fourth column controls for demographic covariates (age, sex, marital status, and race); the fifth column incorporates social covariates (education, occupation, and self-reported monthly income); and the sixth column includes behavioral covariates (smoking, drinking, and physical activity).



Secondary Outcomes and Mechanism Exploration

Additional RD analyses indicate that the intervention had no significant impact on health behaviors, such as smoking habits, physical activity, sedentary behavior, and daily vegetable and fruit intake. Mental health outcomes, including anxiety, depression, and stress levels, were also unaffected. Similarly, no significant changes were observed in cardiovascular risk factors, such as systolic blood pressure, diastolic blood pressure, and random blood glucose, as well as the use of health services for hypertension and diabetes screening, diagnosis, and medication treatment (Section S5 in Multimedia Appendix 1).

Robustness Check

We examined the robustness of our findings by evaluating the impact estimates for BMI across different bandwidths, placebo tests, and "donut" RDD. First, alongside the optimal bandwidth, we included bandwidths of 50%, 80%, 120%, and 150% to track potential changes in the estimates (Figure 4). The analysis indicated that as the bandwidth changed, the impact estimates for BMI consistently approached 0. Second, Section S6 in Multimedia Appendix 1 presents RDD estimates based on placebo tests using alternative BMI cutoff values. Specifically, when applying alternative cutoffs at 24, 24.5, 25.5, and 26, the estimates were all statistically insignificant (eg, −0.18, 95% CI −0.77 to 0.41 at BMI 24). At the true cutoff of 25, the estimate was also statistically insignificant, consistent with the overall null findings of the main analysis. Third, we further conducted a "donut" RDD by systematically excluding observations within 0.5, 1.0, and 1.5 BMI units around the cutoff. This strategy addresses potential concerns that observations located very close to the threshold may be subject to nonrandom sorting or measurement error. The results, presented in Section S7 in Multimedia Appendix 1, are qualitatively similar to the main estimates, thereby ruling out local manipulation at the threshold as a source of bias. Additionally, we tested the robustness of our results by treating age as a continuous variable rather than categorizing it into groups. This alternative specification captures finer variations in age and avoids potential biases introduced by arbitrary categorization. The results remained consistent with those obtained using the categorical approach, further supporting the robustness of our conclusions (Section S8 in Multimedia Appendix 1). These further corroborate our conclusion that community screening did not have a significant effect on BMI after 5 years.

Figure 4. Impact estimates for BMI across different bandwidths in adults ≥35 years, Segamat, Malaysia, 2013-2018.

Discussion

Principal Findings

This study examined the long-term impact of a population-based BMI screening intervention on health outcomes among adults aged 35 years and older in Malaysia. Using an RDD, the analysis provided causal evidence that the intervention did not result in a significant reduction in BMI over 5 years. This finding remained consistent across various model specifications, including adjustments for covariates, alternative functional forms, bandwidth modifications, placebo tests, and "donut" RDD. While the screening informed participants of their overweight and obesity status, the absence of measurable BMI changes underscores the limitations of screening as a standalone strategy for promoting sustained weight management. At the same time, this is the first study in Southeast Asia to rigorously evaluate the causal effects of such a simple, low-cost, and low-intensity program, with the Malaysian setting, which is marked by high primary care coverage and low costs despite being a middle-income country, and a predominantly rural population with relatively low education and income levels, providing important contextual relevance and international comparability.

Insignificant Reduction in BMI

There are several plausible explanations for the insignificant reduction in BMI observed 5 years after the intervention. First, the intervention was low intensity, consisting solely of BMI measurement and the distribution of referral cards, without structured follow-up, behavioral counseling, or actionable guidance, which likely limited its effectiveness. This "light-touch" approach does not adequately address the multifaceted drivers of obesity, such as dietary habits, physical activity, socioeconomic constraints, and psychosocial influences. Prior studies have demonstrated that low-intensity interventions are often insufficient to sustain long-term behavior change, particularly when participants lack consistent engagement or access to actionable resources for weight management [38,42]. Second, the 5-year follow-up period may have diminished any short-term effects of the intervention [43]. While initial awareness of weight status may have prompted temporary behavioral changes, the absence of reinforcement likely led participants to revert to pre-existing habits [44]. Moreover, over such an extended period, external factors such as aging, life transitions, or independent health decisions could have influenced participants' behaviors and health outcomes, further complicating the attribution of any observed effects directly to the intervention. Therefore, we cannot rule out the possibility that short-term effects occurred initially but faded over time, which may not have been captured in the 5-year follow-up. This possibility also suggests that more frequent or sustained light-touch interventions might still be effective in maintaining behavior change. Third, the universal coverage and low out-of-pocket costs of Malaysia's public health care system likely moderated the intervention's impact. With the government subsidizing approximately 98% of treatment costs at public health facilities [24,45], individuals identified as overweight or obese could independently access routine care without relying on the program's referrals. In high-resource health care settings, the referral cards may have limited additional value compared to settings where health care access is restricted. Fourth, participant characteristics may have further constrained the intervention's effectiveness. This study's population, drawn predominantly from rural areas and characterized by relatively low educational attainment, may have faced barriers such as limited health literacy and reduced understanding of the long-term risks associated with elevated BMI [46]. Additionally, the risk of adverse metabolic outcomes increases from approximately 35 years of age, and the estimated treatment effect may have been confounded by cumulative age-related changes over the 5-year follow-up. Prior evidence indicates that longer cumulative exposure to obesity elevates the risk of type 2 diabetes and other cardiometabolic conditions [47]. Finally, behavioral responses among participants with a healthy BMI (<25 kg/m^2) may also have contributed. Being informed of a normal weight could have been interpreted as reassurance, leading some individuals to relax weight control or adopt riskier behaviors. Such compensatory responses, if present, may have biased the estimated impact downward. Although our data do not allow us to directly test this mechanism, acknowledging this possibility is important for interpreting the null findings.

Heterogeneity Analysis and Mechanism Exploration

The heterogeneity analysis revealed no significant differences in BMI outcomes across demographic and socioeconomic subgroups, including age, gender, and educational attainment. Similarly, no significant differences were observed when comparing individuals just above and below the BMI threshold, suggesting that the intervention's effect was uniformly limited across subpopulations. Further exploration into the mechanisms underlying this limited impact revealed no significant changes in associated behaviors, such as fruit and vegetable consumption, physical activity, or smoking. These findings underscore the intervention's inability to address the behavioral determinants of weight management. Cardiovascular risk factors, including waist circumference, blood pressure, and blood glucose levels, also showed no significant improvement, consistent with findings from other studies [19]. Notably, receiving a referral card did not negatively affect the mental health of individuals with overweight or obesity, an important consideration for the intervention's safety profile. While some studies have reported that weight notification may increase the risk of mental health conditions [48,49], this study found no significant effects on anxiety, depression, or stress. Despite the lack of significant changes, health care use increased modestly among individuals near the BMI threshold, particularly in screening and diagnosis rates for conditions such as hypertension and diabetes. As shown in Section S4 in Multimedia Appendix 1, participants around the BMI threshold exhibited similar patterns of health behaviors but notable increases in screening, diagnosis, and, in some cases, treatment rates for hypertension and diabetes between 2013 and 2018. These findings suggest that individuals near the threshold became more attentive to their health status, which, combined with Malaysia's universal coverage and low out-of-pocket costs, facilitated greater health care use. However, these increases did not translate into measurable changes in BMI outcomes, as the comprehensive health system likely moderated the incremental impact of this light-touch intervention. A critical factor to

XSL•FO
RenderX

consider is the specificity and utility of BMI screening as a public health tool. Compared to more targeted screenings, such as blood pressure or glucose testing, BMI measurement is simpler but less directly linked to actionable health risks. While BMI screening effectively categorizes individuals based on weight status, it does not provide immediate clinical priorities or tailored recommendations, potentially diminishing its perceived urgency among participants.

Limitations

This study has several limitations. Although data were generated from the whole community in 5 subdistricts of Segamat, it does not represent a nationwide representative sample [23]. Consequently, the findings may not be generalizable to more urbanized populations or to individuals with higher socioeconomic status, higher income, better education, and greater health literacy, who may respond differently to such light-touch interventions. The 2-wave design, lacking short-term postintervention data, restricts the ability to observe dynamic changes in health behaviors or outcomes. Furthermore, the RD approach estimates causal effects only for individuals near the BMI threshold, reducing applicability to broader population groups, which may respond differently to the screening intervention. Additionally, we cannot exclude modest effect sizes due to the width of our CIs, suggesting relatively low statistical power. For BMI screening, our power calculations indicate that this study was sufficiently powered (85%) to detect larger effect sizes (eg, τ=0.8 kg/m^2) within the optimal bandwidth but underpowered to detect clinically meaningful smaller changes. Clinical guidelines typically define a ≥5% reduction in body weight as clinically meaningful because of consistent improvements in glycemia, blood pressure, and lipid profiles [50]. As BMI is proportional to weight for fixed height, this corresponds to an approximate BMI reduction of 0.05*baseline BMI. Within our analytic bandwidth (22.1-27.9 kg/m^2), a 5% weight loss translates into a BMI decrease of about 1.1-1.4 kg/m^2. Thus, while our study was likely sufficiently powered to detect such clinically meaningful individual-level effects, it was underpowered to detect smaller but potentially important shifts in population health, as seen in prior policy evaluations [51,52]. Lastly, reliance on self-reported data for secondary outcomes may introduce recall and social desirability biases, and the overall follow-up rate of about 51% raises concerns about attrition bias. Attrition differed by baseline BMI category, with lower follow-up among participants with BMI <25 compared to those with BMI ≥25 (46.1% vs 54.6%; difference=–8.5%, 95% CI –10.2% to –6.8%, P<.001), suggesting potential bias. However, the RDD focuses on local comparisons around the cutoff rather than overall representativeness, reducing dependence on complete follow-up. Moreover, continuity tests of follow-up rates at the BMI cutoff (using optimal, 50%, and 150% bandwidths) showed no discontinuities. Additional robustness checks, including bandwidth modifications, “donut” RDD and placebo tests, yielded consistent null results, indicating that selective attrition near the threshold is unlikely to bias our estimates. Thus, while attrition bias cannot be completely ruled out, current evidence suggests it is unlikely to drive the main findings. Despite these limitations, this study provides critical evidence on the challenges and potential of BMI screening, underscoring the need for more intensive, multifaceted strategies to enhance its impact on population health.

Health Policy Implications

The findings of this study underscore the need for integrating BMI screening into comprehensive public health strategies to effectively address overweight and obesity in middle-income settings such as Malaysia. While BMI screening is a low-cost and scalable tool, its impact as a standalone intervention is limited. This highlights the necessity of combining it with complementary measures to achieve meaningful and sustained health outcomes. To enhance the effectiveness of BMI screening, policy makers should incorporate tailored behavioral interventions such as personalized counseling, health education, and goal-setting. These components can equip individuals with actionable strategies and sustained motivation to adopt healthier lifestyles. Additionally, integrating follow-up mechanisms, such as regular check-ins or digital health tools, can reinforce behavioral changes and mitigate regression over time.

Structural barriers to weight management must also be addressed. Improving access to affordable healthy foods, creating safe spaces for physical activity, and promoting health literacy are critical policy measures to create supportive environments for weight management. Leveraging Malaysia’s extensive public health care infrastructure can ensure that affordable, accessible interventions reach individuals identified as at-risk through BMI screening.

Conclusions

Merely informing individuals with overweight or obesity about their weight status is insufficient to achieve significant reductions in BMI or foster sustained behavior change. More intensive interventions are required to support individuals in adopting and maintaining healthy behaviors. They should also address structural barriers to effective obesity prevention and treatment following community-based BMI screening. Nonetheless, our findings do not exclude the possibility of short-term effects. This suggests that more frequent or sustained light-touch interventions might still be effective in promoting lasting benefits. Future studies should incorporate larger sample sizes to enhance the ability to detect modest but clinically meaningful effect sizes.

Abstract

Background: Stroke is a leading cause of death and long-term disability worldwide, with an estimated 6.2 million deaths each year. In Bangladesh, data on stroke prevalence and risk factors in rural areas are limited, making it difficult to develop effective early prevention and intervention programs.

Objective: This study aimed (1) to present the prevalence of stroke in a rural community in Bangladesh and (2) to identify and associate various stroke risk factors.

Methods: Data collection was done by community health workers, as a part of the “Enriched Sastho” program of the Palli Karma Sahayak Foundation, Bangladesh. Community health workers received 2 weeks of training to ensure data quality. The presence of stroke was determined by a binary survey question, with a history of stroke=1 and absence=0. The prevalence of stroke per 1000 people was examined along with the 95% CI. In addition, the association of stroke risk predictors was calculated using multivariate logistic regression and presented in crude odds ratio (OR) and adjusted OR along with 95% CI.

Results: The study analyzed data from 1,341,589 individuals, with an average (SD) age of 29.23 (19.05) years. The overall stroke prevalence was found to be 1.07 per 1000 people, with a higher prevalence in male participants and increasing with age. The highest stroke prevalence was observed in the Khulna division (OR 1.881, 95% CI 1.671 - 2.117), and the least in the Rangpur division (OR 0.677, 95% CI 0.576 - 0.795). Individuals aged 65 - 79 years were at a higher risk of having a stroke than other age groups (crude OR 9.883 and adjusted OR 9.728 [adjusted for sex]). In addition, male participants were at greater risk of having a stroke than female participants were (crude OR 1.565 and adjusted OR 1.469 [adjusted for age]).

Conclusions: The study emphasizes the need for early prevention and intervention programs for stroke in rural Bangladesh and the importance of managing hypertension and diabetes to reduce stroke risk.

Introduction

Stroke, heart attack, irregular heart rhythms, and other cardiovascular diseases (CVDs) are the leading causes of death and long-term disability globally [1]. An estimated 6.2 million people die each year from CVDs alone, which is 11% of all global fatalities [2]. In 2019, approximately 17.9 million individuals lost their lives to CVDs, accounting for about 32% of total global deaths [3]. Stroke is the leading cause of death from CVDs [4]. There were 15.2 million fatalities from ischemic

XSL•FO
RenderX

heart disease and stroke in 2015 [5]. Khan et al [6] analyzed data from 1990 to 2017 and reported 9 million deaths were caused by ischemic heart disease globally. According to the World Health Organization, stroke was the second greatest cause of mortality and the sixth biggest cause of disability-adjusted life years (DALYs) loss worldwide in 2002 [7]. There has been a steady rise in the number of survivors with stroke and the number of stroke-related DALYs. Worldwide, there are over 62.1 million survivors with stroke [8], with 36.2 percent of those survivors left with a significant disability up to 5 years following a stroke [9]. In 2019, stroke continued to be the second most common cause of death worldwide, accounting for 11.6% of all deaths [10]. It also ranked as the third leading cause of both death and disability combined, representing 5.7% of total DALYs [10].

While 75% of stroke-related fatalities occur in low- and middle-income countries [11], there has been less research conducted in these areas. Bangladesh is a low- and middle-income country with a population of 162.2 million people, the vast majority of whom live in rural communities (74%) [12]. The government spends only US $123 per person a year on health care [13]. It is estimated that one-third of Bangladeshis are aged <35 years. There are currently 14.6 million people aged >60 years in Bangladesh, and that number is expected to rise to 55.7 million by the year 2061 [14]. It is expected that as life expectancy rises, the cost of caring for older adults will increase, notably for the health care system [14]. In Bangladesh, stroke is more common in people aged >60 years. Stroke is Bangladesh's third leading cause of death, behind coronary heart disease and infectious disease [12].

Several studies have been conducted to show the stroke prevalence in Bangladesh. In 2011, Mohammad et al [15] conducted a study on 15,627 individuals and reported the prevalence of stroke to be 3 per 1000 people. In 2015, Zaman et al [16] reported the prevalence of stroke to be 9.4 per 1000 people by taking a sample size of 1709 individuals. In 2018, Saha et al [17] conducted a study on 94,965 people and presented that the prevalence of stroke is 1.96 per 1000 people. In 2021, Mondal et al [18] reported the prevalence of stroke is 11.39 per 1000 people by taking a sample size of 25,287 individuals.

Stroke is influenced by various risk factors, with hypertension emerging as the predominant factor [19-21], closely followed by diabetes [19,21]. Hypertension is the main factor for stroke because it affects arteries throughout the body, resulting in more susceptibility to rupture or clogging. When the brain's blood vessel is constricted or blocked by a clot, a portion of the brain no longer receives the necessary blood and oxygen, which causes stroke [22]. Furthermore, diabetes stops the body from properly digesting meals, causing the body to not produce or properly use insulin. It results in a buildup of glucose in the blood and damages blood arteries, which raise the risk of stroke [23]. In addition, some other risk factors are reported in several studies such as betel consumption [19], history of heart disease [24], dyslipidemia [25], metabolic syndrome [26], early atherosclerosis [21], smoking [21], and hypercholesterolemia [21].

Even though all these studies reported the prevalence and risk factors of stroke in Bangladesh, the sample size is not very large in terms of the population of Bangladesh, and data on stroke in rural areas are lacking. To create effective early prevention and intervention programs for stroke in Bangladesh, it is vital to comprehend the problem's prevalence and its risk factors. So, the objectives of this study are to present the prevalence of stroke in a rural community in Bangladesh and to identify and associate various stroke risk factors.

Methods

Study Context

Bangladesh is a country in South Asia and is situated in the Bay of Bengal. It is divided into 8 administrative divisions [27]: Barisal, Chittagong, Dhaka, Khulna, Mymensingh, Rajshahi, Rangpur, and Sylhet. These divisions are further divided into districts, with a total of 64 districts in Bangladesh. Each district is then subdivided into subdistricts, and the subdistricts are further divided into unions, which consist of multiple villages. An overview of the administrative geography of Bangladesh is presented in Figure S1 in Multimedia Appendix 1.

Study Design, Participants, and Data Collection Procedure

The research was carried out as part of the "Enriched Sastho" program, and the operation is currently operational in 7 divisions of Bangladesh. "Enriched Sastho" is a primary and preventive health care program created by Palli Karma Sahayak Foundation, Bangladesh. The program has 1 smartphone app for community health workers (CHWs) to collect data from rural people by visiting different households (Multimedia Appendix 1). During household visits, CHWs collect information such as sociodemographic, economic, environmental, and health-related information from individuals encompassing every age group and sex. Before collecting data, CHWs received 2 weeks of training to ensure the quality of the data collection and to familiarize themselves with the process.

For this investigation, we used data that were collected from July 2018 to June 2021. A total of 104 variables were obtained during data collection, encompassing sociodemographic, economic, environmental, and health-related information. This smartphone app is connected to Amazon Web Service (AWS) and all these data are usually stored in the AWS.

In this study, the presence of stroke was determined by survey questions asked by the CHWs to the individuals. The answer was categorized in binary format. Thus, if a person had a history of stroke, then the "stroke" variable was filled with 1, otherwise 0. In addition, CHWs checked their medical history and medical records to verify the stroke confirmation.

Ethical Considerations

The United International University ethical review board authorized this study (IREB/2023/008), and all participants gave written consent before participating in this study. Data were deidentified. As this protocol was part of a community-based health care model, no compensation was given to participants for taking part in the survey.

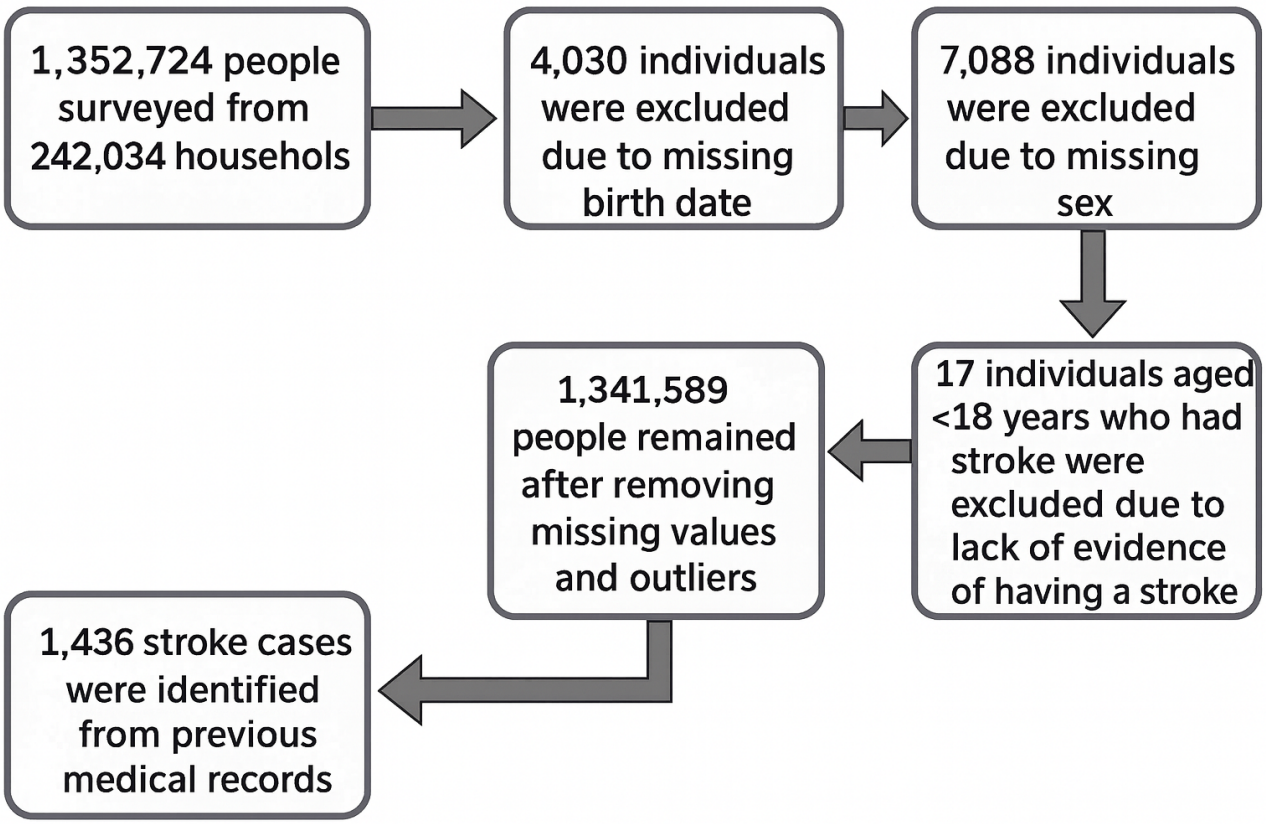
XSL•FO
RenderX

Data Sampling Procedure

Initially, data were collected from a total of 1,352,724 individuals. A total of 4030 individuals were excluded due to missing birth dates, and 7088 individuals were excluded due to missing gender. Moreover, 17 individuals aged <18 years who had a stroke were excluded due to a lack of evidence of having a stroke. Following these exclusions, the remaining dataset consisted of a total of 1,341,589 individuals.

Statistical Analysis

First, we collected data from AWS as a dump file. Then, we stored them in a MySQL server and extracted the required data from the original database by running MySQL queries. We examined the data for missing values and outliers. All the missing values and outlier-related instances were removed. We used descriptive statistics to assess the population's age, gender, education, and occupation distribution. Numeric variables were represented by their mean and SD, while nominal variables were represented by their proportion. The prevalence of stroke per 1000 people was examined along with a 95% CI. We analyzed the prevalence of stroke by divisions to understand the stroke prevalence rate in different parts of Bangladesh.



In addition, the association of stroke risk predictors was calculated using multivariate logistic regression and presented in crude odds ratio (OR) and adjusted OR along with 95% CI. The risk predictors were: five socio-demographic variables (age, gender, education level, occupation, and union name) and 5 health-related comorbidities (stroke, diabetes, hypertension, cancer, CVD, and chronic obstructive pulmonary disease). Before using multivariate logistic regression, we checked for normality, multicollinearity, and outliers. The bar chart and radar chart were used to illustrate the major findings. All these analyses were done with the help of Python (Python Software Foundation) libraries like *pandas*, *Matplotlib*, *NumPy*, *SciPy*, *Plotly*, *stats model*, and *Seaborn*.

Results

Demographic Analysis

An overview of the data sampling procedure is represented in Figure 1. From July 2018 to June 2021, the CHW questioned a total of 1,352,724 people from 242,034 households, encompassing 7 divisions. After removing missing values and outliers, a total of 1,341,589 people remained from the initial total population.

Figure 1. Sampling procedure overview.

Detailed sociodemographic information is provided in Table 1. In our study, 51.33% (688,649/1,341,589) were male participants. The average (SD) age was 29.23 (19.05) years, with the average (SD) age of male participants being 29.57 (19.28) years and that of female participants being 28.87 (18.80) years. The majority of people (600,160/1,341,589, 44.74%) had an age of <25 years while the smallest proportion (10,865/1,341,589, 0.81%) of people had an age of ≥80 years. Besides, male participants were found in greater numbers than female participants among different age groups.

Table . Sociodemographic characteristics of study population (N=13,41,589).

Age (y)	Both sexes, n (%)	Male participants (n=688,649), n (%)	Female participants (n=652,940), n (%)
<25	600,160 (44.74)	304,148 (44.17)	296,012 (45.34)
25 - 44	443,368 (33.05)	225,322 (32.72)	218,046 (33.39)
45 - 54	138,896 (10.35)	73,573 (10.68)	65,323 (10)
55 - 64	89,794 (6.69)	47,728 (6.93)	42,066 (6.44)
65 - 79	58,506 (4.36)	32,314 (4.69)	26,192 (4.01)
≥80	10,865 (0.81)	5564 (0.81)	5301 (0.81)

Stroke Prevalence

There were 1436 stroke cases among 134,1589 people with an overall stroke prevalence rate of 1.07 (95% CI 1.02 - 1.13) per 1000 people.

By Sex

Among 1436 patients with stroke, 894 were male participants and 542 were female participants. So, the stroke prevalence rate in male participants was 1.29 (95% CI 1.20–1.38) per 1000 people and that in female participants was 0.83 (95% CI 0.76 - 0.90) per 1000 people. In other words, the stroke prevalence rate in male participants was 1.55 times higher than that in female participants.

By Age

Table 2 represents the distribution of the stroke population and their prevalence rates among different age groups. The overall stroke prevalence rate was high (8.84 per 1000) among the age group of "≥80" years, and the overall stroke prevalence rate was low (0.03 per 1000) among the age group of "<25" years. In addition, the overall stroke prevalence rate increased as age increased, and the stroke prevalence rate in male participants was higher than that in female participants among different age groups. This tendency is better depicted in Figure 2.

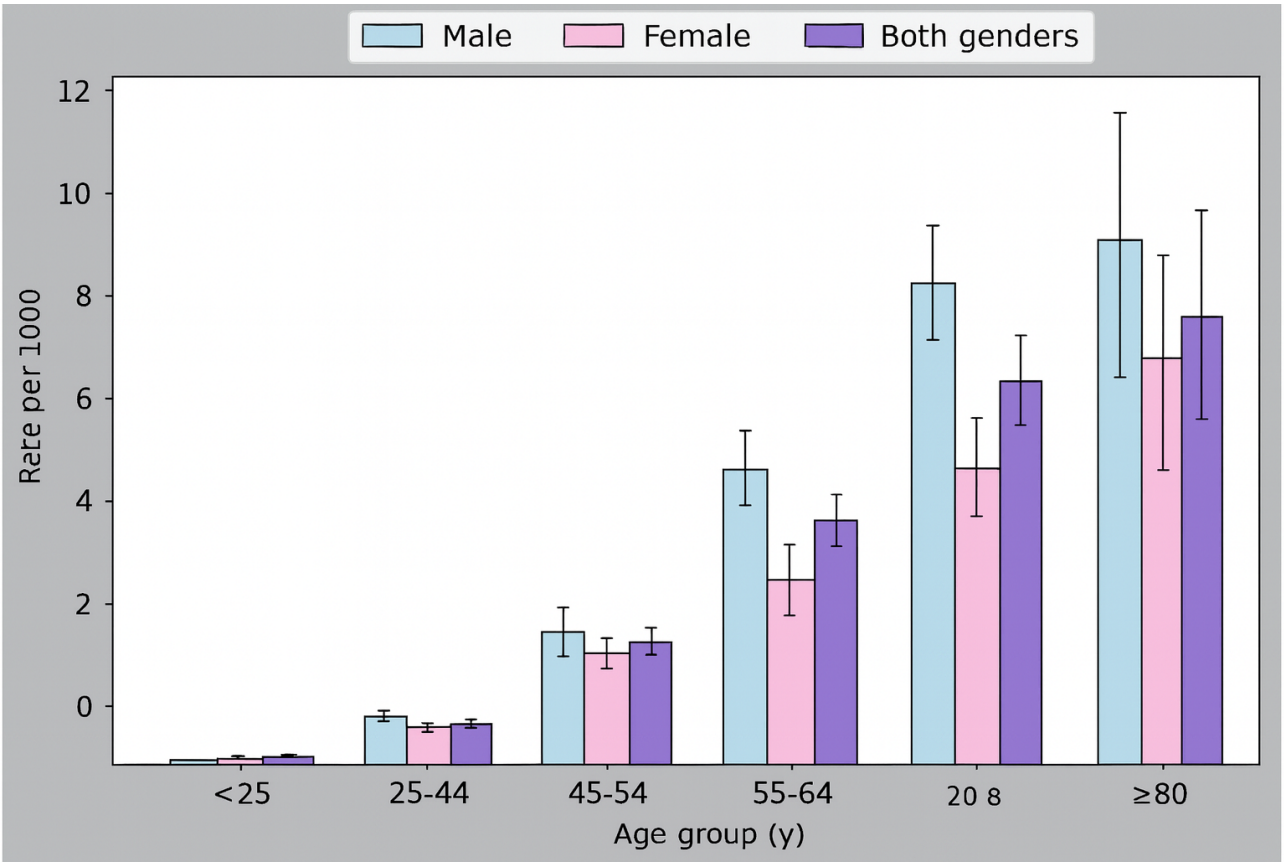

Table . Distribution of population with stroke and their prevalence rates among different age groups.

Age group (y)	Overall rate (%)[a]	95% CI	Rate in male participants (%)[a]	95% CI	Rate in female participants (%)[a]	95% CI
<25	17 (0.03)	0.01 - 0.04	8 (0.03)	0.01 - 0.04	9 (0.03)	0.01 - 0.05
25 - 44	197 (0.44)	0.38 - 0.51	113 (0.5)	0.41 - 0.59	84 (0.39)	0.3 - 0.47
45 - 54	284 (2.04)	1.81 - 2.28	164 (2.23)	1.89 - 2.57	120 (1.84)	1.51 - 2.17
55 - 64	398 (4.43)	4.0 - 4.87	258 (5.41)	4.75 - 6.06	140 (3.33)	2.78 - 3.88
65 - 79	444 (7.59)	6.89 - 8.29	295 (9.13)	8.09 - 10.17	149 (5.69)	4.78 - 6.6
≥80	96 (8.84)	7.08 - 10.6	56 (10.06)	7.44 - 12.69	40 (7.55)	5.22 - 9.88

Figure 2. Prevalence of stroke per 1000 people with 95% CI.

By Area or Divisions of Bangladesh

The prevalence of stroke by division is depicted in Table 3. In addition, Figure 3 displays a heatmap illustrating the prevalence rate of strokes at the division level in Bangladesh. The color scheme ranges from white, representing divisions with the lowest stroke prevalence, to the darkest red, indicating divisions with the highest stroke prevalence. In our study, we observed that the "Rangpur" division had the highest number of study participants, with a total of 273,718 people. On the other hand, the "Barisal" division had the lowest number of study participants, with a total of 52,330 people. In terms of stroke cases, the "Khulna" division had the highest number of cases, with a total of 370 stroke cases. Conversely, the "Barisal" division had the lowest number of stroke cases, with a total of 81 cases. It was also observed that the "Khulna" division (southwest of Bangladesh) had the highest stroke prevalence rate (1.77 per 1000 people) among all other 7 divisions (darkest red in Figure 3). The "Rangpur" division (northwest of Bangladesh) had the least stroke prevalence rate (0.62 per 1000 people; light red in Figure 3). In addition, detailed information on stroke prevalence at district and union levels is presented in Tables S1 and S2 in Multimedia Appendix 1.

Table . Prevalence of stroke by divisions.

Division	Stroke cases, n (%)	Total population	Prevalence per 1000
Barisal	81 (0.15)	52,330	1.55
Chittagong	312 (0.12)	252,239	1.24
Dhaka	165 (0.11)	146,200	1.13
Khulna	370 (0.18)	209,159	1.77
Rajshahi	200 (0.08)	240,801	0.83
Rangpur	169 (0.06)	273,718	0.62
Sylhet	139 (0.10%)	139,715	0.99

XSL•FO
RenderX

Figure 3. Division level heatmap representation of strokes prevalence in rural Bangladesh.

Table S3 in Multimedia Appendix 1 represents the prevalence of stroke by age groups for each division. From Table S3 in Multimedia Appendix 1, Barisal, Chittagong, Dhaka, Khulna, Rajshahi, Rangpur, and Sylhet had a total population of 52,330, 252,539, 146,200, 209,159, 240,801, 273,718, and 139,715, respectively. In the age group of ≥55 years, Barisal, Khulna, Chittagong, Rajshahi, Dhaka, Rangpur, and Sylhet had a total population of 6420, 26,158, 25,416, 32,946, 19,538, 35,077, and 13,610, respectively (Table S3 in Multimedia Appendix 1). These results confirmed that even though the Khulna division did not have more old people, stroke prevalence was still higher in the Khulna division.

Stroke Risk Associations

Table 4 represents the distribution of patients with stroke having other noncommunicable diseases (NCDs). From Table 4, it was observed that, among patients with stroke, hypertension was the most prevalent among all NCDs. A total of 67.55% (95% CI 65.13 - 69.97) of patients with stroke had hypertension. The second most prevalent was diabetes; 25.21% (95% CI 22.96 - 27.45) of patients with stroke had diabetes. On the other hand, cancer was the least prevalent among patients with stroke, affecting only 0.63% (95% CI 0.22 - 1.03). In addition, it is evident that female patients with stroke had a higher proportion of hypertension and diabetes compared to male patients with stroke. Conversely, male patients with stroke exhibited a higher proportion of cancer, CVD, and chronic obstructive pulmonary disease in comparison to female patients with stroke.

Table 5 represents the ORs of risk factors of stroke. From Table 5, it can be seen that individuals aged 65 - 79 years were at a higher risk of having a stroke than other age groups (crude OR 9.883, 95% CI 8.834 - 11.057, P<.05; adjusted OR 9.728 [adjusted for sex], 95% CI 8.694 - 10.884, P<.05). In addition, male participants were at greater risk of having a stroke than female participants were (crude OR 1.565, 95% CI 1.406 - 1.741, P<.05; adjusted OR 1.469 [adjusted for age], 95% CI 1.320 - 1.636, P<.05). In addition, it can be recognized that, among hypertension, diabetes, and CVD, people who had CVD were at greater risk of having a stroke (crude OR 109.888, 95% CI 92.069 - 131.156, P<.05; adjusted OR 40.232 [adjusted for age and sex], 95% CI 33.42 - 48.437, P<.05). Besides, “Khulna” divisions (southwest of Bangladesh) people were at a greater risk of having a stroke (crude OR 1.881, 95% CI 1.671 - 2.117, P<.05; adjusted OR 1.769 [adjusted for age and sex], 95% CI 1.571 - 1.992, P<.05) than other division’s people.

Discussion

Principal Results

The main findings of our study were (1) the overall prevalence of stroke was 1.07 per 1000 people on analyzing 1.3 million individuals' data, (2) the prevalence of stroke was the highest in the "Khulna" division (southwest of Bangladesh), and (3) hypertension was the major risk factor in patients with stroke. To the best of our knowledge, this study was the largest population-based investigation on the prevalence of strokes in rural Bangladesh.

Comparison With Prior Work

From Table 6, it is evident that our findings have more similarity with those obtained by Saha et al [17] who conducted the study on 94,965 individuals and reported a prevalence of 1.9 per 1000 in the general population. We reported around a 14-fold higher

XSL•FO
RenderX

sample size than that reported by Saha et al [17] and found a prevalence of 1.07 per 1000 in the general population. Other studies have calculated the prevalence on a much lower sample size as shown in Table 6. Moreover, it is noteworthy to mention that most of the studies have been performed in 1 specific region (Zaman et al [16] sampled data from only 1 rural area of "Chittagong" division; Saha et al [17] conducted a study from the data that were collected from only 1 rural area of "Rajshahi" division), whereas our study covered 7 divisions of Bangladesh.

Table . Comparison with other studies from Bangladesh.

Studies	Study setting	Age range (y)	Sample size	Prevalence rate per 1000
Mohammad et al [15]	Urban + rural	≥40	15,627	3
Zaman et al [16]	Rural	≥30	1709	9.4
Saha et al [17]	Rural	≥15	94,965	1.96
Mondal et al [18]	Urban + rural	≥18	25,287	11.39
This study	Rural		1,341,589	1.07
		<25	600,160	0.03
		25 - 44	443,368	0.44
		45 - 54	138,896	2.04
		55 - 64	89,794	4.43
		65 - 79	58,506	7.59
		≥80	10,865	8.84

Furthermore, this study was focused on rural settings. Mohammad et al [15] and Mondal et al [18] examined data from urban and rural settings and reported higher prevalence. However, these studies did not compare the prevalence between urban and rural settings. Therefore, we could not draw any conclusion from the fact that stroke prevalence may be higher in an urban setting than a rural setting. In addition, Mohammad et al [15] considered individuals aged 40 years and performed the study on 15,627 individuals. In our study of individuals aged ≥40 years, the prevalence was 3.42 per 1000 people, which is slightly higher than that observed in the study by Mohammad et al. Zaman et al [16] conducted a study on people aged ≥30 years on a sample size of 1709 and reported a prevalence of 9.4 per 1000. In our study, the prevalence was 2.23 per 1000 people for patients aged ≥30 years on a population of over 4,00,000. Here, it is noteworthy to mention that our sampled population had a higher proportion of younger people (44.74% of total individuals were aged <25 years) than other studies, which also could play a role in general prevalence calculation. Taken together, it is fair to assume that the lower prevalence reported in our study than in previous literature could be due to the following reasons: (1) the large sample size, (2) the vast region covered, (3) the rural setting, and (4) the proportion of the younger population.

We further found that male participants exhibited a considerably higher prevalence of stroke (1.55 times higher than that in female participants), similar to the findings of the previous study [17]. Moreover, we found that the stroke prevalence rate increased with age. This finding is also in line with the previous studies [12,17,18]. It is worth mentioning that we divided the age groups similarly to a previous study [17], and the age group ranges were different in previous studies [15,18].

Our division-based analysis showed that the highest stroke prevalence rate (1.77 per 1000 people) was observed in the "Khulna" division (southwest Bangladesh). This could be due to the high salt intake of the people since the "Khulna" division is one of the coastal areas of Bangladesh [28]. Islam et al [29] reported that 70% of groundwater in the "Khulna" district has a very high salinity hazard. In addition, several studies have associated a greater risk of developing hypertension with drinking high-salinity water in Bangladesh [30,31]. Furthermore, it is reported in other studies that the "Khulna" Division lacks primary and preventive health care facilities [32]. Due to this, the people of "Khulna" lack education on the disadvantages of drinking high-salinity water, smoking, and so on. Moreover, due to the lack of primary health care facilities, individuals may not seek regular medical consultations for ongoing monitoring of vital health indicators such as blood pressure and glucose levels. As a consequence, they may remain unaware of underlying conditions such as hypertension or diabetes, which are major risk factors of stroke. Taken together, we assumed that high salinity in water and lack of primary health care could be the main reasons for higher stroke prevalence in the "Khulna" division.

We found that hypertension (970/1436, 67.55%) and diabetes (362/1436, 25.21%) were the first and second most common risk factors of stroke than other NCDs. These findings are in line with the previous studies conducted in Bangladesh [17-19,22,23].

Strengths and Limitations

This research has several strengths. First, this study is the largest sample size representation of the rural population of Bangladesh. In addition, we collected data from 50 unions representing rural settings all over Bangladesh. This study demonstrated the prevalence of stroke in 7 divisions of Bangladesh, which could be an accurate prevalence estimate of stroke. Second, we found that the stroke prevalence is higher in the "Khulna" division than in other divisions. It is a major finding in the context of

XSL•FO
RenderX

Bangladesh, as the "Khulna" division has a high salt intake. We found that hypertension, diabetes, and other CVDs are leading risk factors for stroke in rural Bangladesh, which are known risk factors of stroke. Therefore, managing these diseases may help in managing stroke in rural Bangladesh.

However, this research has some limitations. Since all the data for this study were collected in a survey setting, the assessment of stroke with neurologists was not performed. However, to mitigate this challenge, the CHWs checked their medical records and medication history to make sure the information was accurate. However, we acknowledge the fact that the neurological assessment could lead to a more accurate prevalence estimation. Furthermore, we did not collect information regarding smoking, dietary habits, or family history of stroke. Future studies should include these variables to undertake better risk factor association studies.

Conclusions

This study presented a comprehensive analysis of stroke prevalence in rural Bangladesh covering 7 divisions. One of our major findings was that the total prevalence rate was 1.07 per 1000 individuals in the general population with increasing prevalence in male participants and older populations. Although we reported lower stroke prevalence than in the contemporary studies, we believe this is due to the large sample size of our study. However, one major finding is that the southeast region of Bangladesh ("Khulna" division) has a higher prevalence than other divisions do. As the water of the "Khulna" division has a high salinity hazard along with a lack of primary health care facilities, our findings could help the policymakers to take necessary steps to mitigate these issues.

Acknowledgments

The authors are grateful to Independent University, Bangladesh; AIMS Lab, Institute of Research Innovation Incubation and Commercialization, United International University, Bangladesh; CMED Health Limited; Palli Karma Sahayak Foundation for their support and cooperation to successfully conduct this study. All authors declared that they had insufficient or no funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided APF support for the publication of this article.

Funding

The research project was funded by Institute of Advanced Research (IAR), United International University under project title: *iCRP: An intelligent cardiovascular diseases risk profiling for early identification of myocardial infraction (MI) and stroke in Bangladesh* (project code: UIU-IAR-02-2022-SE-10). The research publication was funded by Independent University, Bangladesh.

Abstract

Background: Emerging pathogens and zoonotic spillover highlight the need for One Health surveillance to detect outbreaks as early as possible. Participatory surveillance empowers communities to collect data at the source on the health of animals,

XSL•FO
RenderX

people, and the environment. Technological advances increase the use and scope of these systems. This initiative sought to collate information from active participatory surveillance systems to better understand parameters collected across the One Health spectrum.

Objective: This study aims to develop a compendium of One Health data parameters by examining participatory surveillance systems active in 2023. The expected outcomes of the compendium were to pinpoint specific parameters related to human, animal, and environmental health collected globally by participatory surveillance systems and to detail how each parameter is collected. The compendium was designed to help understand which parameters are currently collected and serve as a reference for future systems and for data standardization initiatives.

Methods: Contacts associated with the 60 systems identified through the One Health Participatory Surveillance System Map were invited by email to provide specific data parameters, methodologies used for data collection, and parameter-specific considerations. Information was received from 38 (63%) active systems. Data were compiled into a searchable spreadsheet-based compendium organized into 5 sections: general, livestock, wildlife, environmental, and human parameters. An advisory group comprising experts in One Health participatory surveillance reviewed the collected parameters, refined the compendium structure, and contributed to the descriptive analysis.

Results: A comprehensive compendium of data parameters from a diverse array of single-sector and multisector participatory surveillance systems was collated and reviewed. The compendium includes parameters from 38 systems used in Africa (n=3, 8%), Asia (n=9, 24%), Europe (n=12, 32%), Australia (n=3, 8%), and the Americas (n=12, 32%). Almost one-third of the systems (n=11, 29%) collect data across multiple sectors. Many (n=17, 45%) focus solely on human health. Variations in data collection techniques were observed for commonly used parameters, such as demographics and clinical signs or symptoms. Most human health systems collected parameters from a cohort of users tracking their own health over time, whereas many wildlife and environmental systems incorporated event-based parameters.

Conclusions: Several participatory surveillance systems have already adopted a One Health approach, enhancing traditional surveillance by identifying shared health threats among animals, people, and the environment. The compendium reveals substantial variation in how parameters are collected, underscoring the need for further work in system interoperability and data standards to allow for timely data sharing across systems during outbreaks. Parameters collated from across the One Health spectrum represent a valuable resource for informing the development of future systems and identifying opportunities to expand existing systems for multisector surveillance.

Introduction

Background

In a world where anthropogenic landscape change drives zoonotic spillover, climate change exacerbates vulnerabilities in food security, and diseases further threaten biodiversity, effective and timely One Health surveillance mechanisms are imperative. The One Health United Nations Joint Action Plan (2022-2026) [1], Africa's Centers for Disease Control Event-Based Surveillance (EBS) guidance [2], and World Health Organization's "Defining Collaborative Surveillance" [3] underscore the critical need to integrate data across the animal, human, plant, and environmental health sectors. This paper examines the range of data parameters collected across the One Health spectrum through participatory surveillance methodologies.

One Health Surveillance

The One Health approach recognizes the interdependencies of human, animal, and ecosystem health, aiming "to sustainably balance and optimize the health of people, animals, and ecosystems" [4]. Numerous national and subnational systems have undertaken initiatives for data sharing to develop One Health strategies, with support from organizations such as the United Nations, World Bank, and United States Agency for International Development (USAID) [5,6]. However, challenges remain in the implementation of One Health initiatives due to years of siloed professional training, budgets, data system development, data structures, and policies [7]. Rabies and influenza viruses have served as key drivers of multisectoral, collaborative surveillance and offer valuable models for advancing One Health approaches to address multiple pathogens. The need for the inclusion of plant health has more recently come to the forefront due to its critical role in food safety, food security, and ecosystem health [8].

Historically, traditional disease surveillance systems have largely been led by government entities and are often siloed, with a primary focus on human and livestock health. There is growing awareness of the need to harness more wildlife and environmental health event information to provide early warning of broader health threats facing both humans and animals. The Africa's Centers for Disease Control EBS guidance emphasizes the integration of both formal and informal data sources, including hotlines and community-based EBS, to enhance outbreak detection [2]. To strengthen participatory surveillance systems, greater efforts are needed to capture data on putative drivers of pathogen spillover and disease emergence, including landscape change, environmental and climatic variables, and

XSL•FO
RenderX

activities at the human-animal-environmental interface that bring animals and humans into contact with each other [9]. While previous literature has examined One Health tools and individual surveillance systems, no study to date has comprehensively documented the range of parameters collected in One Health participatory surveillance systems [7,10-12].

Participatory Surveillance

Participatory surveillance involves a bidirectional process of receiving and transmitting data for actionable outcomes through the direct engagement of the target population [13]. This approach is increasingly used across multiple sectors to enhance early detection of and rapid response to emerging infections within a One Health framework. By engaging a wide variety of users including the general public, health care workers, rangers, farmers, and outdoor enthusiasts, participatory surveillance systems can provide early warning of potential outbreaks through crowdsourcing self-reported data in near real-time [14]. This active surveillance strategy empowers communities to act as the "eyes and ears" for detecting health threats at the interfaces where animals, humans, and environmental factors converge, creating opportunities for disease emergence.

Participatory surveillance systems play a crucial role in providing evidence-based feedback to users, enabling them to take timely actions to mitigate potential threats and facilitating connections with local resources for prevention and control. In the context of One Health, participatory surveillance extends beyond a human-centered lens to encompass plants, wildlife, livestock, and a multitude of environmental factors—habitats for disease vectors and water and air quality. The organizational structure of system users can vary widely, ranging from the general public to members of sector-specific associations or community alliances. For more structured community-liaison models, feedback is directed to the user group, empowering them to take action on behalf of the communities they serve.

Participatory surveillance has emerged as a powerful tool for enhancing traditional epidemiologic surveillance while fostering community engagement [15]. From reporting disease incidence to promoting mitigation behaviors, participatory surveillance has showcased its versatility across various infectious disease contexts, including influenza, cholera, COVID-19, and Zika [16-22]. One of the key benefits of participatory surveillance is its capacity to address and surmount many of the limitations inherent to traditional surveillance systems. In resource-constrained settings, conventional surveillance efforts often rely on overburdened health care and diagnostic systems and struggle to access difficult-to-reach communities, resulting in reporting delays or gaps. By empowering communities, participatory surveillance enables a proactive role in health monitoring, facilitating both prompt and comprehensive reporting of disease cases [23,24].

Ending Pandemics, a US nonprofit organization working to detect, verify, and contain outbreaks faster (and the supporter of the study presented here) developed the International Workshops on Participatory Surveillance (IWOPS), four of which have been held since 2012 in the United States, the Netherlands, Australia, and Cambodia [25]. IWOPS convened the creators, implementors, and key advocates to advance participatory surveillance approaches and strengthen partnerships among these systems. In 2016, the IWOPS community established a minimum dataset among systems collecting self-reported information to monitor the annual risk of influenza so that a common set of data standards could be developed. As a result, deidentified and disaggregated data are shared on a public platform, Global Flu View, for the purpose of improving situational awareness [26].

While Global Flu View represents one example of what is possible when participatory surveillance systems can "speak" to each other, data standards across the entire spectrum of parameters encompassing One Health are lacking. The One Health Participatory Surveillance Data Parameters Compendium (Multimedia Appendix 1) is a snapshot into the world of participatory surveillance for human, animal, and environmental health. The compendium approach was used as it not only illustrates the breadth and depth of what is being used in currently operating participatory surveillance systems across the globe, but it can serve to inform the needs of those contemplating the development of a participatory surveillance system or expansion of an existing system. As the compendium provides information on how data parameters are collected, it is poised to guide efforts to incorporate additional health sectors, adapt data parameters to align with other systems, and foster collaborations and data sharing. In the future, it could play a pivotal role in advancing data sharing, through informing the development of international data standards.

Methods

Development of Advisory Group

A multisector advisory group was assembled to guide the development of the compendium, support data collection, and provide cross-sectoral reviews encompassing animal, environmental, and public health sector perspectives. Selection criteria for advisory group members included expertise in participatory surveillance systems and integrating data from participatory systems into traditional surveillance systems. Subteams of experts in the areas of human, wildlife, livestock, and environmental health (including plants and vectors) were established. The experts represented a diverse range of public and government organizations, universities or research centers, nongovernmental organizations, and private sector entities. Geographically, they were affiliated with organizations in Asia (n=7), Africa (n=3), Europe (n=2), North America (n=10), and South America (n=2).

Ethical Considerations

The study was reviewed by the University of Arizona Institutional Review Board and deemed not to involve human participants as defined by US Department of Health and Human Services and Food and Drug Administration regulations research (IRB protocol# 00002653). Within the body of the email, individuals were provided a disclosure statement. All participants were notified that they would receive a copy of the compendium, and their system would be listed in the acknowledgments. Data included in the compendium included terms and categories of parameters collected by systems and

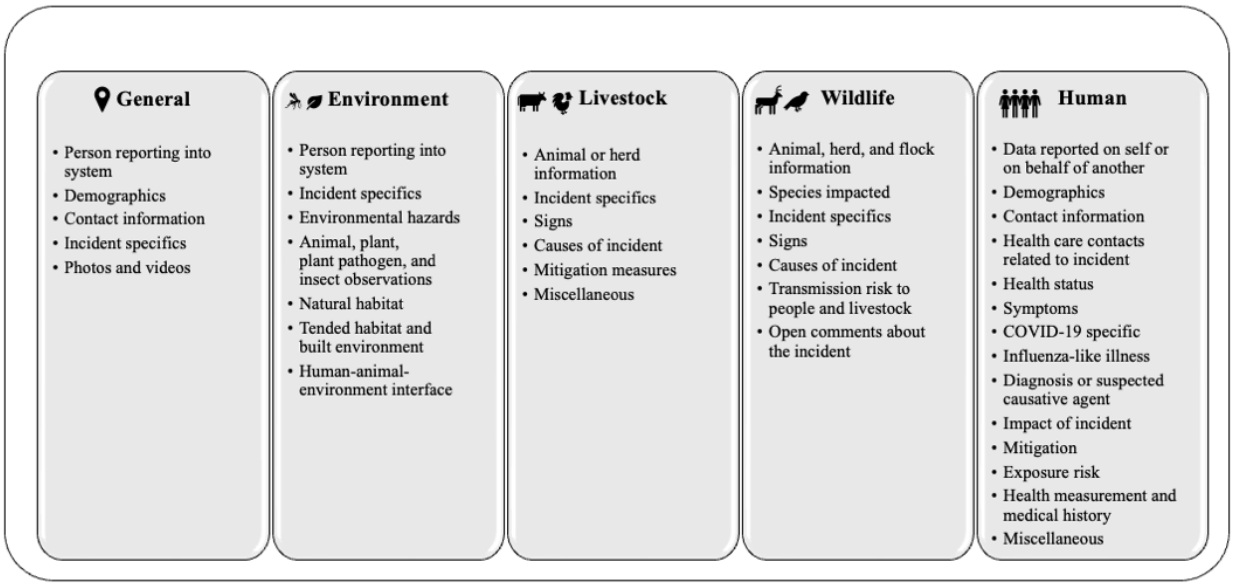
XSL•FO
RenderX

did not include any identifiable information. Participants were not compensated, and participation was voluntary.

Data Collection

An invitation letter was emailed to a closed sample of representatives of 60 systems, using contact information from the One Health Participatory Surveillance map and 2022 landscape analysis [13]. Follow-up emails were sent twice, as needed, by members of the compendium advisory group to encourage responses from system representatives who did not reply initially. Emails described the goal for developing the One Health participatory surveillance compendium and requested respondents provide data parameters from their systems, methods for collection, and any special considerations for specific parameters using an attached template. The template had been used for parameter collection for IWOPS IV [27]. System representatives were offered the option to provide the requested information in other formats, such as a link to web-based systems allowing authors to independently collect relevant questions and parameters.

Data collected were in English. Parameters had already been collected for IWOPS IV in 2022 from: AfyaData, Cambodia 115 Hotline, EDDMapS or Wild Spotter, Forest First Pest Detector, Kidenga, MoBuzz, Outbreaks Near Me, One Health App Philippines, Participatory One Health Digital Disease Detection (PODD), SickSense/Open Dream, SURPRISE, World Animal Health Information System, SMART for Health, and WildAlert (formally known as the Wildlife Morbidity and Mortality Event Alert System) [27]. For these systems, emails were sent to confirm the parameters collected and to allow for revisions.



Out of the 60 systems contacted, 41 systems (68%) responded, and 3 systems (5%) responded they were no longer active and were not included in this analysis. Completed responses were received from 36/60 (60%) active systems; data were collected directly from publicly accessible apps or websites from 2/60 (3%) systems. 38 (63%) responses include the 9 country-level programs of InfluenzaNet. Seven of the 9 InfluenzaNet programs submitted 1 set of parameters and 2 (GrippeWeb and Hälsorapport) provided parameters individually.

Data Analysis

The collected parameters were organized into 5 sections in the compendium: general, livestock, wildlife, environmental (including plants and vectors), and human health. Subcategories within each section were reviewed and refined through group discussions with the advisory group subteams specializing in livestock, wildlife, human, and environmental health. The focus of these discussions was to ensure usability, clarity, and accuracy. The human health advisory group subteam determined that parameters would be limited to those they determined directly relevant to infectious disease surveillance. The compendium focuses on parameters and does not describe structure, such as decision trees.

Advisory group representatives reviewed the parameters and overall organization of the compendium and shared perspectives on key aspects to emphasize in the discussion and conclusion of this paper. Descriptive analyses were performed to examine the categories of parameters collected, the number and types of systems represented across sectors, and advisory group feedback on the parameters. Figure 1 outlines the compendium's format, and the categories of data parameters collected.

Figure 1. Categories of data parameters included in the 2023 One Health Participatory Surveillance Compendium.

Results

Participatory Surveillance Systems Represented in the Compendium

Data parameters were collected in English from across 38 participatory surveillance systems in Africa (n=3, 8%), Asia (n=9, 24%), Europe (n=12, 32%), Australia (n=3, 8%), and the Americas (n=12, 32%); only SMART for Health data were collected in several continents (Table 1). Approximately one-third of the systems (n=11, 29%) collect data from more than 1 sector, while the majority focus on a single sector. Many programs (n=17, 45%) are dedicated solely to human health, with fewer focusing exclusively on environmental or animal

XSL•FO
RenderX

health (n=10, 26%). Most users contributing data to these systems are members of the general public (n=30, 79%), though other user groups include trained volunteers (n=6, 16%), wildlife rangers (n=2, 5%), farmers (n=2, 5%), wildlife rehabilitators and biologists (n=2, 5%), informal health care workers (n=1, 3%), and students (n=1, 3%). For example, SURPRISE is a system in which health care workers report on their own health, (n=1, 3%). Systems requesting weekly data reporting (n=16, 42%) primarily focus on human health, though some offer users the flexibility to determine the reporting frequency. Most of the remaining systems (n=20, 53%) allow users to set their reporting frequency.

[a]eWHIS: electronic wildlife health information system.

[b]PODD: participatory one health digital disease detection.

General Parameters

General parameters include those not specific to any sector—such as user demographics and contact information, incident location, and options for photo or video uploads. Systems with regular users often collect user demographics and contact information during the initial login, eliminating the need for repeated entry on subsequent logins. Substantial variation exists on how demographic data are collected—particularly as related to gender, ethnicity, education, and profession. In contrast, contact information, such as email and phone numbers, are collected uniformly across most systems. Incident location is commonly collected using automated geolocation. Additionally, some systems include mechanisms for photo or video upload to provide supplementary information.

Environmental Health Parameters

Overview

The range of parameters collected related to environmental health is as broad as the field itself—encompassing activities, such as tracking logging, monitoring water contamination, and detecting invasive species and disease vectors. Over half of the systems (8/15, 53%) collecting environmental health data also include a focus on animal and human health. Kidenga collects data on environmental factors including the risk of mosquito exposure alongside human health symptoms. SMART for Health captures key environmental and epidemiological features as well as information on wildlife and livestock. Participatory surveillance systems vary in scale, with some designed for local, relatively small geographic areas and others operating on global platforms, such as iNaturalist. Several vector-focused systems reported that weather information, such as rainfall and temperature, can be added retrospectively by linking it to date, time, and location. Natural habitat data in these systems includes landscape descriptions, while details of tended habitats include descriptions of yards, gardens, and ponds. The built environment is also considered, with systems collecting data on housing structures, water and sanitation, and energy sources, such as fuel and electricity.

Plants

Three systems collect data on plants, including the Early Detection and Distribution Mapping System, which also gathers data on animals. Collected parameters include date or season, high-resolution digital images, information on the reporter, and detailed location information. Date, time, and GPS coordinates are often extracted directly from digital image metadata and autofilled in the report. Other details include ecosystem type, whether the area is tended or untended, seasonality, and additional species, such as host or insect pests.

Species identification is commonly performed by the primary reporter, with photos allowing for additional verification. Species identification is done in 1 reporting field or across multiple fields, capturing details or images of features such as flowers, seeds, leaves, leaf arrangements, and the entire plant. All the plant-focused systems record data on invasive plants and some databases also include information on legal, noxious weed status. High-quality, high-resolution digital images and tightly calibrated geographic locations are noted to be particularly important in these systems.

XSL•FO
RenderX

Vectors

Almost half (7/15, 46.7%) of the environmental systems are explicitly designed to monitor vectors. Notably, the Early Detection and Distribution Mapping System amalgamates vector, animal, and plant surveillance. Among the 7 vector surveillance systems that primarily focus on the environmental sector, 3 exhibit a multisectoral approach. Kidenga and MoBuzz+ bridge the environmental and human domains.

Vector exposure is collected in several ways across systems including incident-specific data with details on the date and precise location of the vector bite incident, specific vector bite information, and the detection of vectors in the vicinity. Often, observations include the perceived number of vectors and their morphology.

Data encompasses information on any formal diagnoses of vector-borne diseases and community prevalence of disease. Vector identification data incorporates visual documentation using photos uploaded by the user. Photos enable experts receiving the data to visually identify and assess vector size, color, and, where possible, species. Vector habitat data includes breeding sites and the detection of larvae, which use the number of measurement containers at a given location and whether they contain larvae. A number of systems integrate the history of recent outdoor activities to better understand the potential exposure of vectors. Vector mitigation data collects information on the use of pesticides, as well as any treatments for controlling or countering vector exposure, and appropriate clothing.

Animal Health Parameters

Wildlife Health

Nine of the participatory surveillance systems collect data on wild animals. SMART for Health includes parameters to record the health of free-ranging livestock that may be present in protected natural habitats. Most of these systems were developed with the goal of syndromic wildlife disease surveillance except for 2 systems— one that was designed to collect data on geographic distribution and abundance of wild mammalian species and another that focuses on early detection of invasive wildlife species [13]. Among these 9 systems, 4 (44%) also collect information on a range of environmental variables. Many variables focus on risk factors or environmental drivers of adverse health events/disease outbreaks in animals as well as humans such as environmental disturbance, or interactions at the wildlife-livestock-human interface. In addition, WildHealthNet—Ebola integrates data on both wildlife and human health parameters specifically for Ebola Virus Disease surveillance.

Common across most of these systems are parameters specific to wildlife incidents, including species or taxa groups of wild animals involved in the event, date, and numbers and location of affected animals. For location information, a few of the systems have the capability to capture specific GPS coordinates as the user digitally enters data or to generate GPS coordinates from an address through geocoding. Typically, systems also include data on the condition of the animal(s) involved in the incident, including abnormal findings in sick, injured, or dead wild animals and a presenting syndrome or clinical classification of these animals. Depending on the system, data are reported at the level of the individual animal or species.

Wildlife health parameters are collected in a variety of formats including dropdown menus, check boxes, and fields with free text. Categorizing free text data for surveillance purposes through natural language processing models has been applied by WildAlert to categorize data for surveillance purposes. Collection of data related to risk of exposure to humans—such as handling of sick wildlife or bats roosting near a home was also included.

Two of the systems also collect data on definitive diagnosis. For systems that integrate clinical wildlife data, this data, if available, is included for both individual animals as well as events. Other parameters among these systems include circumstances surrounding the incident and the potential causes of illness, injury, or death at both individual and species levels. Furthermore, one system also allows the user to enter data on the estimated population size and number of animals at risk for wildlife incidents enabling estimations of disease occurrence among a population.

Livestock Health

Only 4 surveillance systems collect data on livestock, and all of them are multisectoral. These systems together cover a wide variety of domestic species including livestock, poultry, dogs, and cats. These systems collect data using a range of technologies including calls and mobile apps. They focus on common parameters such as species, age, sex, and location of affected animals, including the magnitude of morbidity and mortality at individual and group (herd or flock) levels. Clinical signs of illness were either reported by body systems (checkboxes) or as free text. AfyaData collects health information on the owner as well as on the animals. Only 2 systems include parameters related to companion animals.

Human Health Parameters

Data parameters on human health are collected by 23/38 (61%) systems, with the majority (17/23, 74%) collecting only human health data. Of the 6 collecting multisector data, 3 systems collect data parameters across all One Health sectors, that is, human, animal, and environmental health.

The data parameters for human health cover virtually every organ system within the human body. Across all the systems monitoring human health, fever-related terms are the most common set of data parameters for reporting symptoms of illness. Additional symptoms indicative of influenza-like illness (ILI), including headache, sore throat, and cough are also among the most common symptom parameters collected. Gastrointestinal symptoms are the next most common set of data parameters across the systems collecting human health data.

In 2020, COVID-19-specific symptoms were added to several of the systems, many of which already collected ILI symptoms to track influenza, but now added “loss of taste or smell,” for example. COVID-19 and influenza diagnostic testing and vaccination history are common among the systems monitoring human health only.

XSL•FO
RenderX

Outbreaks Near Me asks the user to report being "healthy." Only when the user reports not being "healthy" do they receive queries on symptoms, events, or other options available within a specific system. Most systems focus on symptoms of illness and the onset of the timing of the symptoms. Several systems ask about health-seeking behavior and the type of health care system visited. Kidenga asks about the health status of others in the household and others inquire about the number of people in the household.

Absenteeism from work or school or changes in daily routine due to illness is captured by many of the systems. Common parameters also include various risk factors, such as exposure to other people with similar symptoms, exposure to pets, work exposure, and recent travel history. Furthermore, a few of the systems collect data on preexisting medical conditions as well as lifestyle parameters such as exercise, smoking, and alcohol consumption.

Discussion

Overview

The One Health Participatory Surveillance Data Parameters Compendium showcases the breadth and depth of how systems are using community engagement to collect multisector data to better inform shared threats. This resource highlights opportunities to expand One Health surveillance and identifies parameters currently collected across multisector systems. It encompasses a broad array of data modes and mechanisms used for data collection, addressing challenges with optimizing user time for data entry and improving accuracy. Additionally, the compendium reveals sector-specific differences in how and when data are collected.

Principal Findings

Opportunities and Challenges for System Augmentation or Development

Only 3 systems—PODD, AfyaData, and Colab—include data from all 3 sectors. For existing single-sector surveillance systems, the compendium offers a framework to identify key parameters for expanding into this type of multisector, One Health surveillance system. For example, wildlife-focused systems could incorporate data on the surrounding environment or on the health of humans interacting with wildlife. Similarly, human health–focused systems in urban areas could expand to include data parameters on the built environment, proximal wildlife, and the health of companion animals. In rural areas, human health systems could include parameters on the health of livestock and wildlife within the shared environment. Given the increasing incidence of emerging infections, data on drivers of disease emergence—such as environmental and weather changes—are valuable contributions to participatory surveillance systems [7]. With the interconnectedness of human, animal, and environmental health, the expansion of environmental systems to include these components is a logical progression.

Most participatory systems are community-driven and developed; thus, parameters are added to a given system to address specific community needs and concerns. Therefore, piloting terms and questions within a target population is essential to ensure wording and translation are culturally appropriate and that the requested parameters are accurately captured. Ensuring integration with governmental surveillance efforts across multiple ministries and departments is also critical when expanding beyond one sector to support more sustainable and successfully coordinated One Health approaches.

Expanding a surveillance system to collect parameters across sectors requires consideration of the time users are willing to invest. Users can only reasonably be expected to spend a limited amount of time answering questions or selecting from menu options. Many systems address this by incorporating automatic data inputs, such as timestamps or geolocation, to save time and improve accuracy. Decision-tree frameworks are also used to streamline data collection and gather targeted information; for example, a "yes" response to a question about "cough" could lead to a follow-up inquiry about "bloody cough." Wildlife and vector programs frequently rely on images to minimize the number of questions and to ensure accurate species identification.

Advancements in technology allow for automated data collection, such as integrating ambient temperature measurements, which can enhance user experience, save time, and improve data quality. Variations in education and literacy levels within communities must be considered. Working closely with the community during system development can help address these challenges and foster user engagement.

Existing siloes among One Health sectors can limit the effective use of data and hinder cross-sectoral collaboration. Existing system infrastructure as well as sensitivities around data privacy can create barriers that make it difficult to collect and share parameters across sectors. Current systems also operate at varying spatial scales. For example, human health data is often protected by privacy regulations, making it unethical to include precise geocoordinates. On the other hand, some environmental parameters, such as mosquito habitats or locations of dead wildlife, require specific geocoded data to enable required actions. Data privacy is critical and can be addressed through user-specific access layers. Integrated dashboards and similar tools can enable health authorities from multiple sectors to visually identify disease hotspots, pinpoint areas with elevated disease transmission risk, and prioritize mitigation efforts. For instance, in Mo-Buzz+, public health inspectors can review reports on communal dengue cases, identify mosquito breeding sites, and detect community practices that contribute to mosquito breeding. To protect privacy, this type of information could be aggregated to a neighborhood level before being shared with public users, preserving anonymity while providing actional insights.

For livestock and plant health, additional sensitivities regarding the location of incidents may arise due to potential economic impacts. Systems address these concerns in various ways, such as obscuring publicly available information and anonymizing reporter details. Any system handling sensitive information must proactively address these concerns to ensure confidentiality and minimize potential risks.

XSL•FO
RenderX

System Structure and Timing Impact Types of Information Gathered

The types of information gathered by surveillance systems vary based on their structure. Systems designed to collect longitudinal data often include more "general" parameters during the initial registration process, reducing the need to recollect this information during subsequent logins. This approach saves the user time by focusing additional questions only on cases where the user reports "unhealthy" conditions for that week. Collecting longitudinal data from a known population allows these systems to calculate both numerators and denominators for analyzing trends and spatial-temporal patterns. Visualizing reports over time and space strengthens disease tracking and anomaly detection. This approach is most common for human health systems, as well as Garden Wildlife Health and WildAlert. In SMART for Health, users (wildlife rangers) track animal populations over time, allowing for the identification of both population and disease trends.

Some systems that collect data on wildlife and environmental factors rely on users to report opportunistically when they encounter a specific animal or setting. As these encounters may be the only opportunity to collect data on the health event, extensive data may be needed. To make the process user-friendly, these systems often incorporate photographs and automated downloads of data such as geolocation and limit the collection of extensive user and animal demographic details. While one-time reporting for plant or environmental health incidents is highly valuable for enabling prompt action, it rarely supports longitudinal surveillance or trend detection. Identification of ways to expand follow-up reporting by users may be appropriate, particularly in the context of suspected outbreaks. Systems collecting data on human-animal interactions, such as bat exposures, are especially valuable for surveillance initiatives aiming to improve understanding of the underlying factors driving pathogen spillover and disease emergence.

Dropdown menus offer the advantage of standardizing information, which facilitates data recording in the field, promotes consistent data analysis across units, and supports data integration across systems. In contrast, free text data fields capture a wide array of information from the user or when the user may not have the technical background or expertise to properly categorize a case.

Language and cultural barriers within communities can result in disparities in data capture. Addressing these challenges requires strategies such as raising community awareness and education to enhance disease literacy and improve access to health care. Using tailored engagement approaches for specific population segments and fostering collaboration with local stakeholders is essential for improving surveillance and response outcomes.

Data Standards

Improving interoperability and data sharing among participatory surveillance systems can allow for early incident detection. Improving interoperability (the ability of different systems to exchange, interpret, and use data accurately) and data sharing on a regional or global scale will require the development of data standards. Data standards facilitate international data exchange and better collaboration. A data standard is an agreed-upon approach, to allow for consistent measurement, qualification or exchange of an object, process, or unit of information. Data standards include agreements on several topic areas including representation, format, definition, structure, use, documentation, and management of data [28,29]. They enable transparency and understanding, and the use of standards promotes common, clear meanings for data [29]. Several systems in this study collect similar categories of parameters but use different questions or methods to gather the information. This variability is often necessary to account for community-specific differences, such as how questions about ethnic groups are phrased. Ideally, while user interfaces may differ to accommodate these variations, the backend systems should be designed to integrate the collected information.

Sector-Specific Findings

Human Health

It is not surprising to see fever as the most prevalent symptom among systems designed to detect early infection in humans. Many have noted that fever monitored on an ongoing basis with temporal and geospatial visualization could be an early indicator of a communicable disease threat [30,31]. Since respiratory diseases have the highest probability of causing local outbreaks, regional epidemics, and potentially a pandemic, many systems monitor for ILI and this likely accounts for the frequency of ILI-terms among the systems. Several systems collect parameters to complement symptom data reported—such as health care–seeking behavior to help track the severity of illness or travel to help understand exposure risks.

Environmental Health

The inclusion of environmental parameters in multisector systems allows systems to understand the complete context in which an incident occurs. Identification of potential vector-breeding locations, water contamination, and habitat change may allow for intervention before the spread of disease into local animal and human populations. Environmental parameters also capture how animals and people may be impacting the health of the environment.

Like wildlife health, environmental health programs often rely on event-based reporting. For example, a person enters information about vector exposure, seeing a contaminated location, or spotting a presumed invasive species. Automated features, such as automated collection of climate parameters, geolocation, and image uploads, allow the system to accurately capture a situation without solely relying on an observer's subjective reporting. To help standardize data, systems use tools such as iNaturalist, which may include predefined choices, and have internal experts reviewing photographs to correctly identify vector, animal, and plant species. The collection of incident-specific details is foundational for understanding the spatiotemporal distribution of vectors and their potential role in disease transmission.

Despite the comprehensive parameters used, the underreporting of vector-borne disease cases in humans remains a persistent

XSL•FO
RenderX

concern. This phenomenon is especially prevalent in regions with limited access to health care services or where vector-borne diseases are poorly understood [30,31].

Livestock and Wildlife Health

Relatively fewer participatory systems exist for livestock compared to systems dedicated to other sectors. Participatory epidemiology is often used to address specific outbreaks in livestock health [32]; ongoing participatory surveillance systems may not be as common due to heavy reliance on governmental surveillance programs for outbreak detection. In the compendium, livestock parameters are from systems also collecting data on wildlife, people, or the environment, reflecting the interconnectedness of livestock among each of the other sectors. Given the daily proximity of pets to owners and the potential for bidirectional transmission, the expansion of participatory surveillance to inform companion animal outbreak detection is needed.

Similar to environmental health systems, wildlife health systems are often event-based—increasing situational awareness of disease occurrence and informing on common disease threats in real time. Information stemming from these systems are commonly underused as resource for monitoring long-term trends in population health and mostly are untapped as resource by sectors outside of wildlife health.

Across wildlife participatory surveillance systems, data accuracy remains a significant challenge, as users often face difficulties accurately identifying wildlife species and describing abnormalities in sick, injured, or dead wild animals. Additionally, the integration of disparate data sources and achieving interoperability between systems is limited due to the diverse types and formats of data collected. The lack of harmonized data in wildlife health surveillance has been a long-standing issue; however, systems designed for large, multilingual, and strategically diverse user bases hold promise for reversing this trend.

The increasing use of machine learning methods, such as natural language processing, offers new opportunities for categorizing data, and enabling comparisons across multiple surveillance streams and systems [33,34]. However, these approaches require compatible language inputs or effective translation mechanisms. The compendium highlights the value of collecting and analyzing prediagnostic data during incidents, which facilitates the rapid detection of clusters of animals presenting with similar abnormalities that might signify a disease outbreak or other adverse health event in wildlife.

Comparison With Prior Work

This work builds upon the landscape analysis of participatory surveillance programs and IWOPS workshops reviewing data parameters and working toward data standards [13,25]. Prior publications have highlighted frameworks and steps for building One Health surveillance systems, including methods for better cross-sectoral stakeholder engagement and ways to overcome implementation barriers [7,10,11]. Identified barriers to the implementation of One Health surveillance systems include incompatible vocabularies, professional divisions, isolated datasets, and the lack of data standards. When developing new One Health participatory surveillance systems, this compendium provides a concrete starting point with real-world examples to facilitate dialogue on data elements and standards for sharing across siloed sectors. A critical analysis by Behravesh et al [12] of landscaping globally available One Health tools uncovered 50 tools that advance One Health. The results highlight that most of these tools addressed assessment and few addressed planning and prioritization. This compendium provides a practical One Health tool to facilitate and support planning, prioritization discussions, and One Health participatory surveillance system design. Prior studies have noted the value of participatory surveillance in war-affected camps and the use of One Health surveillance to capture the impact of the environment on refugee health [35,36]. Interactions between humans and animals are often ignored with regard to the health of refugees, but animal populations are often closely tied to refugee communities. This compendium can be applied to improve One Health disease surveillance for displaced populations in high-risk regions.

Limitations

Data parameters included in the compendium reflect a point in time and are not fully representative of the entire field of participatory surveillance. The parameters were collected in English, through an English-language survey, which may have limited participation from non-English systems. Furthermore, selection bias could be present, as systems were identified based on the participatory surveillance map. Additional validation of data parameters was not conducted because many systems are not publicly available; the parameters included in the compendium are based on the information directly provided by the systems.

Most systems use a decision-tree framework to structure their questions. The compendium does not include this format, focusing on parameters over the structural design. To partially address this limitation, the “special considerations” column in the compendium provides comments on how specific parameters relate to others. Future iterations of the compendium should explore methods to illustrate system structures, providing context for how parameters are used within their frameworks.

Given the compendium’s focus on outbreak detection, parameters related to chronic disease were not included. Future exploration on how mental health, chronic disease, toxic exposures, and other non-outbreak–related parameters are collected would be informative for participatory surveillance systems aiming to capture a broader set of health parameters.

Conclusions

Participatory surveillance enhances traditional means of health surveillance by empowering communities to identify threats at their source. The compendium highlights how existing participatory surveillance systems are already incorporating a One Health approach. Expanding opportunities for multisector data collection through these participatory systems aligns with recent guidance from the United Nations Quadripartite [3,37]. Additional research is required to inform international data standards for One Health participatory surveillance. Pilot studies could provide useful mechanisms to capture various

XSL•FO
RenderX

multisectoral data collection and sharing techniques. Furthermore, ethical issues of data privacy are always essential to consider when capturing personal information. Participatory surveillance provides critical surveillance data that can be deidentified and collated at a specific geographic level, which facilitates anonymity of the responses. The compendium offers a reference to strengthen community capabilities for developing multisector surveillance systems to inform early detection of health incidents threatening themselves, their families, and the environment. Decision makers and practitioners can use the compendium as a tool to build a new participatory surveillance system or augment their existing systems to include a One Health approach. The compendium highlights the need to work toward system interoperability and data standards to enable community-level surveillance to have national, regional, or global implications in outbreak detection and response.

Acknowledgments

The authors would like to acknowledge support from Marlo Libel for his assistance on this project, and Elizabeth Aaron for copyediting the compendium and assisting in data collection. The University of Arizona and Dr Kacey Ernst for providing human participants' review of this project. The authors appreciate the following systems sharing data parameters to ensure that they had a comprehensive compendium as possible: AfyaData, AZDGF, Cambodia 115 Hotline, California West Nile Bird Reporting, Colab, CoughWatch SA, DisApp, EDDMapS/Wild Spotter, eWHIS, FluTracking Australia, FluTracking HongKong, Forest Pest First Detector, GrippeWeb, Guardians of Health, Garden Wildlife Health Project, Health Report (Hälsorapport) Sweden, iMammalia, InfluenzaNet (including individual country-level programs in Italy, France, Germany, United Kingdom, the Netherlands, Belgium, Switzerland, Sweden, and Denmark), I-Tick, Kidenga, MoBuzz+, Outbreaks Near Me, and PODD. Generative artificial intelligence was not used.

Data Availability

All data generated or analyzed during this study are included in this published article [and its supplementary information files—Multimedia Appendix 1].

Abstract

Background: Caring for individuals with rare diseases (RDs) presents unique challenges that can significantly impact caregivers' quality of life (QoL). The World Health Organization Quality of Life-BREF (WHOQOL-BREF) is a widely used tool for assessing QoL across different populations.

Objective: This study examines the QoL of caregivers of individuals with RDs and evaluates the psychometric properties of the WHOQOL-BREF in this population.

Methods: A self-administered, anonymous, computer-assisted web-based survey was conducted among family caregivers of individuals with RDs in Poland between March and August 2024. Due to the lack of a national registry of patients with RDs, participants were recruited through convenience sampling via associations, foundations, and organizations of patients with RDs. Eligibility criteria included being 18 years and older of age, speaking Polish, being a caregiver of a person with a confirmed RD diagnosis, and providing informed consent. The survey included sociodemographic questions and the Polish version of the WHOQOL-BREF, which assesses QoL across 4 domains: physical health, psychological health, social relationships, and environment. Internal consistency was assessed using Cronbach α, and confirmatory factor analysis was conducted to examine the instrument's structural validity.

Results: A total of 942 caregivers of individuals with various RDs participated in the study. Confirmatory factor analysis supported the 4-domain structure, with further improvement in a finally modified WHOQOL-BREF model (χ^2_{243}=1043.0; *P*<.001; Comparative Fit Index=0.919; Tucker-Lewis Index=0.907; root-mean-square error of approximation=0.059). Internal consistency was satisfactory, with Cronbach α values ranging from 0.70 (social relationships) to 0.84 (psychological health). Mean domain scores on a scale of 0 - 100 were 50.2 (SE 0.59; physical health), 54.9 (SE 0.59; psychological health), 51.3 (SE 0.67; social relationships), and 52.1 (SE 0.56; environment), with minimal floor and ceiling effects (≤1.4%) across domains. Younger female caregivers reported significantly lower psychological health (eg, mean 43.6, SE 0.59 vs mean 59.9, SE 10.0 for younger male caregivers) and social relationships (mean 39.3, SE 3.34 vs mean 55.0, SE 4.75) well-being compared to other groups. Exactly 151 (16%) of caregivers rated their overall QoL as poor or very poor, and 289 (30.7%) were dissatisfied or very dissatisfied with their health, with female caregivers reporting more dissatisfaction (n=263, 32.4%) than male caregivers (n=26, 20%). Overall, our findings demonstrate the robust psychometric properties of the WHOQOL-BREF among caregivers of people with RDs and provide domain-specific normative data to guide future research and interventions.

Conclusions: The WHOQOL-BREF is a reliable and valid instrument for assessing QoL among caregivers of individuals with RDs, though the social relationship domain may require further refinement. Caregivers experience varying QoL outcomes depending on demographic factors, highlighting the need for targeted support interventions. Future research should explore cultural adaptations and potential supplementary modules to enhance the instrument's applicability in caregiver populations.

Introduction

Quality of life (QoL) is a multidimensional construct that reflects an individual's overall well-being, encompassing physical health, psychological health, social relationships, and environmental factors. In 1991, the World Health Organization (WHO) initiated a project to develop an internationally applicable measure of QoL, leading to the creation of the World Health Organization Quality of Life (WHOQOL) instrument. The WHO defined QoL as an individual's perception of their position in life within the context of their cultural and value systems as well as their personal goals, expectations, standards, and concerns. This definition highlights the subjective nature of QoL, emphasizing that it is shaped by personal experiences and influenced by broader social and environmental contexts. Importantly, QoL assessment provides valuable insights into health outcomes, treatment effectiveness, and overall well-being across diverse populations [1-3].

A subset of QoL research, health-related quality of life (HRQoL), has gained increasing attention in clinical and public health research. HRQoL focuses specifically on the impact of health conditions on an individual's well-being, playing a critical role in health care decision-making, policy development, and patient-centered care [4-6]. Over the past 3 decades, numerous HRQoL assessment tools have been developed, including both generic instruments applicable across populations and disease-specific measures tailored to particular conditions. Despite the proliferation of these tools, a significant limitation remains—the lack of internationally validated instruments capable of capturing HRQoL across diverse cultural and socioeconomic settings [7,8].

To address this challenge, the WHO developed the WHOQOL-100 consisting of 100 questions, an instrument designed to assess subjective well-being while ensuring cross-cultural validity. This instrument was developed through extensive research conducted across 15 field centers worldwide, incorporating perspectives from patients, caregivers, health care professionals, and the general population. The psychometric properties of the WHOQOL-100, including its validity and reliability, were rigorously tested in multiple cultural and linguistic contexts [1]. Recognizing the need for a shorter, more practical instrument, the WHO subsequently introduced the World Health Organization Quality of Life-BREF (WHOQOL-BREF) in 1998, a 26-item version that assesses 4 key domains of HRQoL: physical health, psychological health, social relationships, and environment. The WHOQOL-BREF has since been widely adopted in epidemiological studies, clinical trials, and public health research, demonstrating strong psychometric properties and cross-cultural applicability [2,4,7,9].

Although the WHOQOL-BREF has been validated in numerous populations, its application in certain groups remains underexplored. In Poland, the WHOQOL-BREF was validated in 2006 using a sample of healthy individuals and patients with various diseases and health conditions [6]. However, this validation process overlooked caregivers, an essential yet often neglected population in HRQoL research. Caregivers play a vital role in the health care system, providing continuous support to individuals with chronic illnesses and disabilities. Despite their crucial contributions, caregivers often experience significant physical, emotional, and financial burdens, which in turn affect their own QoL [10-13].

Caregivers of persons with RDs face particularly severe challenges. RDs are often characterized by delayed diagnoses, limited treatment options, and a lack of specialized health care resources, placing an immense strain on families [10,13-17]. Studies suggest that caregivers of persons with RDs report lower QoL compared to those caring for individuals with more common chronic conditions, mainly due to increased caregiving demands, emotional distress, social isolation, and financial hardship. The unpredictable nature of many RDs, coupled with the complexity of care required, exacerbates stress and negatively affects the physical and mental health of caregivers [5,13,18].

The burden of caregiving is multifaceted, affecting various domains of QoL. Physically, caregivers frequently experience chronic fatigue, sleep disturbances, headaches, and weakened immune function due to the demands of continuous care. Psychologically, they are at increased risk for anxiety, depression, burnout, and emotional exhaustion, with some studies indicating higher rates of suicidal ideation among caregivers [17-20]. Socially, caregivers often face reduced participation in social activities, strained relationships, and isolation, as caregiving responsibilities limit their ability to engage with friends and family. Financially, many caregivers are forced to reduce work hours or leave employment altogether, exacerbating economic difficulties and increasing reliance on social support systems. Given these profound challenges, assessing QoL in caregivers of persons with RDs is essential for understanding their specific needs and designing effective interventions to support them [14,16,19,21-23].

Despite the growing recognition of caregiver burden as a public health concern, research validating HRQoL assessment tools specifically for this population remains limited. The WHOQOL-BREF, although widely used across various patient populations, has not been systematically evaluated for its appropriateness in assessing the QoL of caregivers, particularly in the context of rare diseases (RDs). While WHOQOL-BREF is often used in studies on caregivers of individuals with RDs, the resulting QoL domain scores are typically interpreted abstractly—detached from the scale itself—or, less commonly, compared against national normative data [17,24,25]. A validated, standardized tool tailored to caregivers would offer valuable insights for clinical practice, inform health policy, and support the development of targeted interventions, ensuring that the specific needs of caregivers are effectively addressed [2,13,25,26].

To bridge this research gap, this study aims to validate the WHOQOL-BREF for caregivers of persons with RDs and establish population norms specific to this group. By generating normative data, this study seeks to enhance the clinical utility of the WHOQOL-BREF in caregiver research and contribute to the development of targeted support programs and health care policies. A comprehensive understanding of caregiver QoL

XSL•FO
RenderX

is crucial for improving the well-being of both caregivers and the care recipients they support, ultimately leading to better health outcomes for families affected by RDs.

Methods

Study Design

A cross-sectional study was conducted in 2024 in accordance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines (Checklist 1) [27].

This study used data from a self-administered, anonymous, computer-assisted web-based survey examining the association between caregiving for a person with an RD and caregivers' perceived QoL. The survey targeted family caregivers of individuals with RDs. Given the absence of a Polish registry of patients with RD and the unknown exact number of affected individuals, a convenience sampling approach was used. Several associations, foundations, and organizations of patients with RD assisted in participant recruitment by sharing the survey link on their websites and Facebook pages.

At the same time, it should be stressed that convenience sampling used in this study introduces selection bias, as participants may not represent the broader population, limiting the generalizability of findings. However, given the specific nature of the study population—namely, the small size of the groups of particular RDs, the absence of a national registry of patients with RD in Poland, and the wide geographic dispersion of caregivers—convenience sampling appeared to be the most practical and, indeed, the only feasible method. However, it is important to acknowledge several limitations associated with this approach. Most importantly, participants recruited via patient organizations may not reflect the full diversity of the broader population. This type of sampling could affect the study outcomes, potentially skewing results based on the demographics of the sample, such as age, sex, socioeconomic status, or disease severity. Consequently, this method introduces selection bias and limits the reliability and generalizability of the findings. Thus, although this strategy was appropriate under the circumstances, future research should aim to use more representative sampling techniques—such as random or stratified sampling—that may better capture the heterogeneity of caregivers of individuals with RDs and allow for a more accurate reflection of the realities of the population as a whole. Nonetheless, again, it should be stressed that due to the unique challenges of studying this population of caregivers of individuals with RDs, the use of other sampling methods is very difficult, if at all feasible.

Setting and Recruitment

The survey targeted family caregivers of individuals diagnosed with RDs. Due to the absence of a national registry of patients with RD in Poland and the unknown exact number of patients with RD, the study used convenience sampling. Recruitment was supported by various patient organizations, foundations, and advocacy groups via their websites and Facebook profiles.

At the first stage of recruitment, the study coordinator contacted several associations, foundations, and organizations of patients with RD to determine whether they were interested in participating in the study. After receiving their consent, a letter with detailed information about the purpose and method of the study, together with an invitation, was published on the organization's Facebook pages and sent out via an internal mailing to members, by which all affiliated caregivers who met the inclusion criteria were invited to participate in the study.

Eligible participants were required to be at least 18 years of age, fluent in Polish, and a parent or family caregiver of a person with a confirmed RD diagnosis. Additionally, participants needed access to the internet, the ability to use electronic devices to complete the survey, and had to provide written informed consent before participation.

The questionnaire consisted of sociodemographic questions concerning both caregivers and persons with RD along with the abbreviated Polish version of the WHOQOL-BREF [6]. This 24-item instrument assesses QoL across 4 domains: physical health, psychological health, social relationships, and environment. Two additional items do not constitute any of the 4 dimensions but are set up to measure the overall QoL and satisfaction with health.

Data Collection Procedure

The survey was conducted between March and August 2024. Initially, the research coordinator contacted multiple associations, foundations, and organizations of patients with RDs to obtain permission for distribution. Upon approval, an invitation letter containing a link to the web-based questionnaire was shared via these platforms. Participants who provided written informed consent completed the survey electronically. To enhance response rates, 3 follow-up reminders were sent in January, March, and June. The survey required approximately 20 - 25 minutes to complete.

Data Analysis

All statistical analyses were conducted using R Statistical Software (version 4.3.1; R Foundation for Statistical Computing). The study used a quantitative research design to analyze the psychometric properties of the WHOQOL-BREF questionnaire for the Polish population of caregivers of people with RDs. Descriptive statistics were calculated to summarize the demographic characteristics of the sample and the overall QoL scores in 4 domains: physical health, psychological health, social relationships, and environment. Reliability analysis was performed using Cronbach α to assess the internal consistency of the questionnaire. Confirmatory factor analysis (CFA) was used to test the hypothesized factor structure of the WHOQOL-BREF by examining the fit of the data to the model. Goodness-of-fit indices, including the Comparative Fit Index (CFI) and root mean-square-error of approximation (RMSEA), were reported to assess model adequacy.

Ethical Considerations

This study was conducted according to the Declaration of Helsinki and was approved by the Poznan University of Medical Sciences Bioethics Committee (KB 228/24, March 13, 2024). All participants were informed about the objectives and methodology of the study in an invitation letter. Informed

XSL•FO
RenderX

consent was obtained electronically through the web-based questionnaire by selecting the "I agree" option. Participants were assured that their participation was voluntary, anonymous, and confidential and that they had the right to withdraw at any time or omit any question without consequence. To ensure privacy, no personal identifying information or images were collected. Participants were also informed that, although some questions may be emotionally sensitive, they could pause or discontinue the survey at any time. Since participation did not involve any direct intervention or additional burden, no financial compensation was offered.

Results

Overview

In this section, we present a validation of the WHOQOL-BREF scale and provide insights into its empirical structure, psychometric properties, and latent score characteristics. We have implemented CFA by comparing a unidimensional baseline model with the established 4D model of the WHOQOL-BREF. Statistical fit indices such as CFI and RMSEA are provided to assess model adequacy, along with modifications to improve dimensional alignment. This section then highlights the robustness of the 4D structure, and the Structural Validity section focuses on the reliability of the WHOQOL-BREF scale, which is examined through the lens of internal consistency across the 4 domains. A descriptive analysis of the scores derived from the 4 dimensions of the WHOQOL-BREF is also presented. Finally, norms for the QoL domains in a Polish population of caregivers of persons with RDs are provided. The norms for the WHOQOL-BREF are presented as mean values, SE of the mean, 25th percentile, median, 75th percentile, minimum, maximum, and percentage of floor and ceiling effect. These norms were estimated by sex and age group.

Study Participants

Table 1 presents characteristics of the sample by sex and age category of caregivers.

Table 2 outlines the demographic and diagnostic characteristics of 942 patients with RDs. Most patients were male (n=586, 62.2%), with a wide age range (0.2 - 78 years), a mean age of 12 (SE 0.32) years, and a median of 10 (IQR 6.0-15.0) years. The most frequently reported conditions included Duchenne muscular dystrophy or Becker muscular dystrophy (n=211, 22.4%), 22q11.2 deletion syndrome (n=131, 13.9%), and Angelman syndrome (n=120, 12.7%). A total of 191 (20.3%) patients were diagnosed with one of 144 other rare or ultrarare conditions. Time to diagnosis varied considerably: while 165 (17.5%) were diagnosed within 3 months, 226 (24%) received a diagnosis within 1 - 2 years, and 130 (13.9%) waited more than 5 years. A small group (n=18, 1.9%) was still in the asymptomatic phase of the disease. These data highlight the diagnostic challenges and heterogeneity of RD populations.

Table . General characteristics of family caregivers of individuals with rare disease.

Age (years)	Male, n (%)	Female, n (%)	Total, n (%)
16 - 29	2 (1.5)	32 (3.9)	34 (3.6)
30 - 39	44 (33.8)	337 (41.5)	381 (40.4)
40 - 49	64 (49.2)	350 (43.1)	414 (43.9)
50 and more	20 (15.4)	93 (11.5)	113 (12.0)
Total	130 (13.8)	812 (86.2)	942 (100)

[a]DMD: Duchenne muscular dystrophy.

[b]BMD: Becker muscular dystrophy.

[c]PANS: pediatric acute-onset neuropsychiatric syndrome.

[d]PANDAS: pediatric autoimmune neuropsychiatric disorders associated with streptococcal infection.

Confirmatory Factor Analysis

The CFA results illustrate a comparative assessment of 3 models for the WHOQOL-BREF: the baseline unidimensional model, the original 4D WHO model, and a modified 4D model. The fit indices provide a comprehensive evaluation of the models' performance and structural validity of the WHOQOL-BREF 4D scale (Table 3).

XSL•FO
RenderX

The baseline unidimensional model yielded unsatisfactory fit indices, suggesting a poor representation of the scale's underlying structure. The chi-square statistic (χ^2_{252}=1602.8; P<.001) was significant, and the χ^2/df ratio (6.360) exceeded the acceptable threshold of 5. The CFI (0.862) and Tucker-Lewis Index (TLI=0.849) indicated a suboptimal model fit, while the RMSEA (0.075; 90% CI 0.072 - 0.079) was marginally above the acceptable upper limit. Conversely, the standardized root-mean-square residual (SRMR=0.050) remained within acceptable limits, indicating an adequate residual-based fit. In practical terms, these results suggest that treating the WHOQOL-BREF as a single-factor measure does not fully capture the complexities of caregivers' QoL, as evidenced by the modest CFI or TLI and moderately elevated RMSEA.

Table . Comparison of fit indices for different WHOQOL-BREF[a] latent models for family caregivers of individuals with rare disease.

Model	Chi-square (*df*)	χ^2/df	CFI[b]	TLI[c]	SRMR[d]	RMSEA[e]	RMSEA−95% CI	RMSEA+95% CI
Baseline model	1602.8 (252)	6.4	0.862	0.849	0.050	0.075	0.072	0.079
Original WHOQOL-BREF	1343.9 (246)	5.5	0.888	0.875	0.047	0.069	0.065	0.072
Modified WHOQOL-BREF	1043.0 (243)	4.3	0.919	0.907	0.041	0.059	0.055	0.063

[a]WHOQOL-BREF: World Health Organization Quality of Life-BREF.

[b]CFI: Comparative Fit Index.

[c]TLI: Tucker-Lewis Index.

[d]SRMR: standardized root-mean-square residual.

[e]RMSEA: root-mean-square error of approximation.

In contrast, the initial 4D model demonstrated substantial improvements across all fit indices (χ^2_{246}=1343.9; P<.001). The χ^2/df ratio decreased to 5.463, and the CFI (0.888) and TLI (0.875) approached recommended levels. The RMSEA (0.069; 90% CI 0.065 - 0.072) and SRMR (0.047) further suggested enhanced fit. Adjustments were made based on modification indices to optimize model fit; that is, correlated error terms were introduced between questions 3 and 4 (modification index equals 164.9), questions 12 and 23 (modification index equals 64.8), and questions 19 and 20 (modification index equals 56.4). While these modifications enhanced statistical compatibility, they also entailed conceptual implications. Specifically, it can be posited that each of these item pairs is likely to tap into closely related dimensions of caregiver well-being (eg, physical or psychological strain or environmental or social considerations). Consequently, the modification indices suggest that some questions, though intended to measure slightly different constructs, may elicit overlapping responses from caregivers who face similar daily challenges across multiple domains of life. Rather than perceiving these errors as mere statistical artifacts, it is more fruitful to interpret them as potential indicators of content overlap or a shared contextual factor (eg, stress or time pressure) that influences the way participants interpret these items. For researchers using the WHOQOL-BREF in caregiver populations, acknowledging and examining these correlated errors can foster a more nuanced understanding of how caregiving experiences merge otherwise distinct QoL facets. Future studies could investigate whether such overlaps are unique to certain subgroups or care contexts or if item wording could be refined to differentiate better between seemingly related aspects of QoL.

The modified 4D model demonstrated a significant enhancement (χ^2_{243}=1043.0; P<.001), exhibiting a reduced χ^2/df ratio of 4.292. The CFI (0.919) and TLI (0.907) exceeded the conventional threshold for adequate fit, while the RMSEA (0.059; 90% CI 0.055 - 0.063) and SRMR (0.041) substantiated the model's robustness. The findings suggest that the targeted modifications serve to enhance the correlation between items within their respective dimensions, thereby producing a more robust and precise measurement structure with fit indices that approach commonly accepted benchmarks.

Structural Validity

This section presents a reliability analysis of the items within the WHOQOL-BREF across its 4 dimensions. The analysis uses Cronbach α to evaluate internal consistency, with findings indicating satisfactory to high reliability across domains. Specifically, α values ranged from 0.69 for the social relationships domain to 0.84 for the psychological health domain, demonstrating varying but overall strong consistency (Table 4).

Item-level analyses provide further insight into the impact of individual items on the overall reliability of each domain. Most items contribute positively to reliability, with suggestions for potential refinement in some areas.

RenderX

Table . Internal consistency scores of the 4 WHOQOL-BREF domains obtained for Polish family caregivers of individuals with rare diseases.

Domain	Items, n	Cronbach α
Physical health	7	0.818
Psychological health	6	0.843
Social relationships	3	0.700
Environment	8	0.807

[a]WHOQOL-BREF: World Health Organization Quality of Life-BREF.

Normalized Scores for Domains of WHOQOL-BREF

This section presents a descriptive analysis of the normalized scores derived from the 4D-modified WHOQOL-BREF scale. Following the recommendations of the WHO, responses to each item were coded from 1 to 5 and transformed to a scale from 0 (lowest QoL) to 100 (highest QoL). Each item was weighted by standardized factor loadings derived from a CFA model before calculating the overall domain score (Table 5).

The factor loadings range from 0.363 to 0.801, indicating varying degrees of item contribution to their respective latent constructs. The physical health domain exhibits robust item representation, with loadings such as question 18 (0.801) and question 16 (0.794) suggesting substantial explanatory power for the physical health construct. The psychological health domain also exhibits high loadings, particularly for question 26 (0.747) and question 19 (0.688), suggesting that these items are key indicators of psychological health. Items in the environmental domain display more variability, with question 12 having the lowest loading (0.456) and question 8 the highest (0.763). The social relationships domain demonstrates moderate item loadings, with question 22 (0.619) being the most influential item and question 20 (0.477) contributing the least.

[a]WHOQOL-BREF: World Health Organization Quality of Life-BREF.

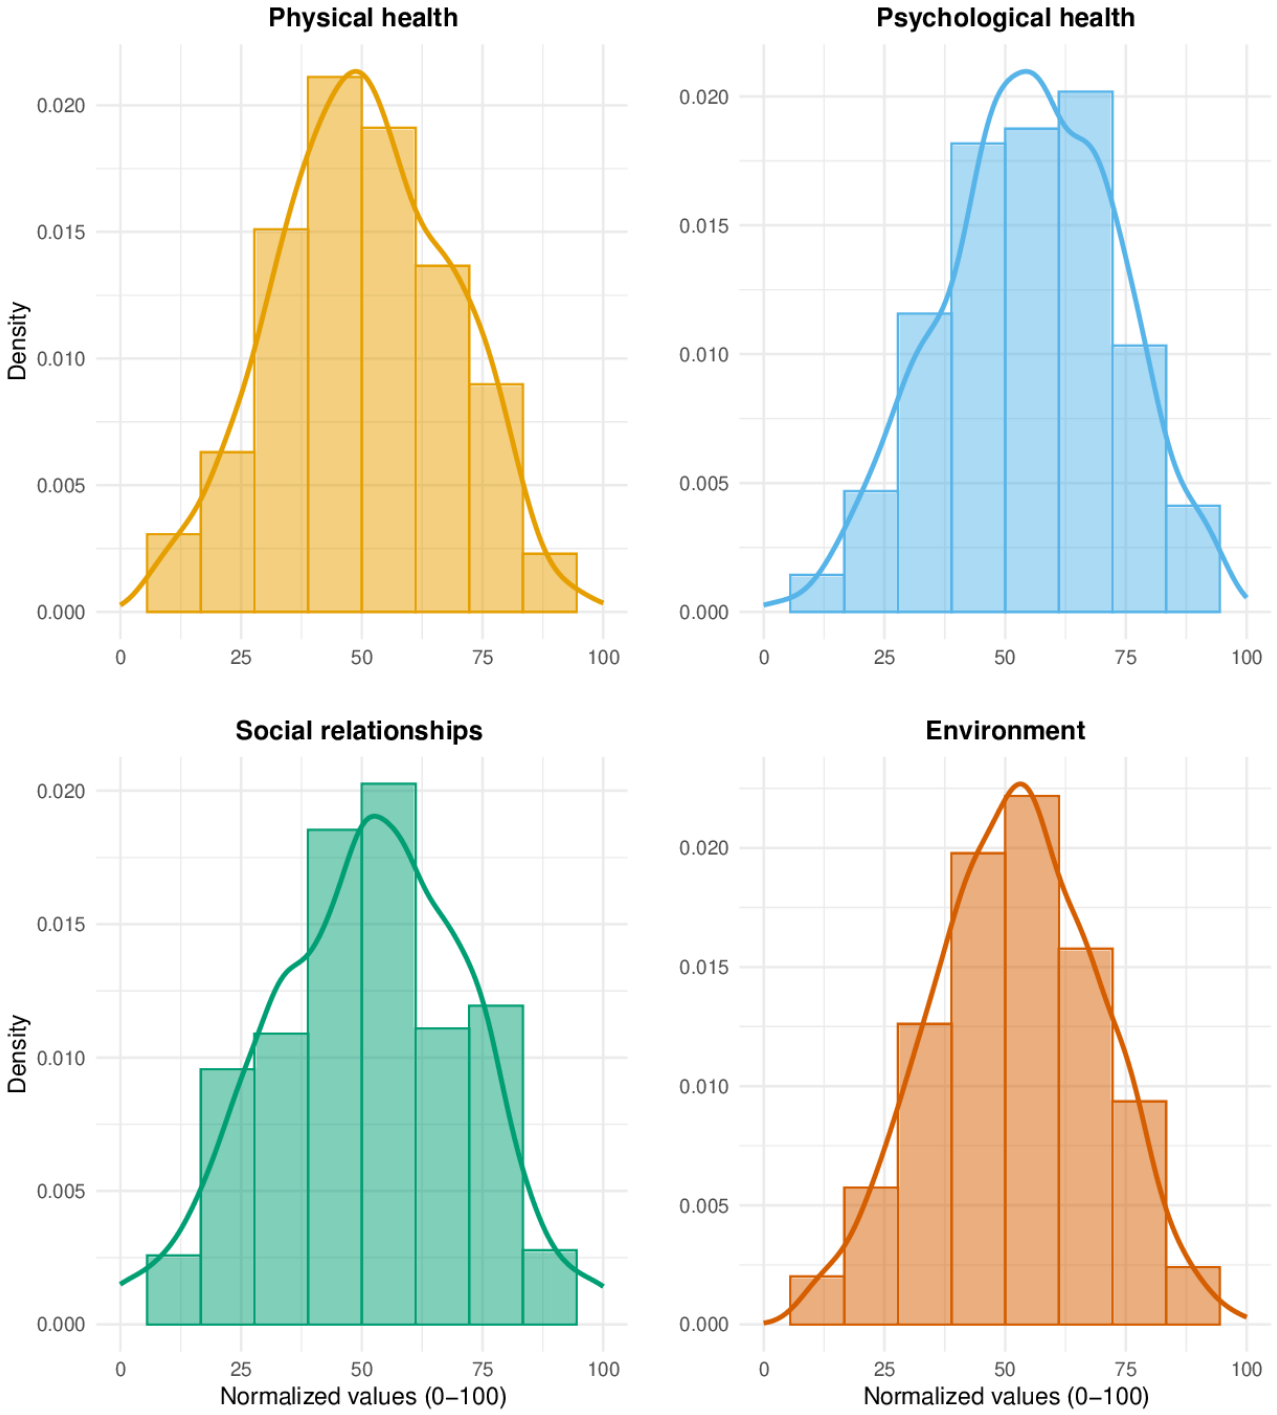

Figure 1 presents histograms and density plots for the 4 dimensions of the WHOQOL-BREF scale: physical health, psychological health, social relationships, and environment domains. Each plot illustrates the distribution of normalized scores (ranging from 0 to 100) for the respective dimension. The overlaid density curves provide a smoothed visualization of the score distribution, highlighting its approximate normality across all domains, with slight deviations observed, particularly in the psychological health and social relationships domains. The detailed descriptive statistics for the distribution of scores within each domain of the WHOQOL-BREF are delineated in Table 6.

The psychological health domain demonstrated the highest mean score (mean 54.9, SE 0.59), indicating relatively better perceived psychological well-being among respondents. Conversely, the physical health domain exhibited the lowest mean score (mean 50.2, SE 0.59). The environment and social relationships domains showed mean scores of 52.1 (SE 0.56) and 51.3 (SE 0.67), respectively. The SEs of the mean were relatively consistent, ranging from 0.56 to 0.67, indicating precision in the central tendency estimates.

Concerning the normality of the data, the skewness and kurtosis values are within acceptable ranges, thereby supporting the visual interpretation from the density plots. However, the Shapiro-Wilk test reveals statistically significant deviations from normality for the physical health, psychological health, and social relationships dimensions ($P<.01$), while the environment domain demonstrates borderline nonsignificance ($P=.05$), suggesting a near-normal distribution.

RenderX

Table . Descriptive characteristics of the latent scores for WHOQOL-BREF domains for Polish family caregivers of individuals with rare disease.

Statistic	Environment	Physical health	Psychological health	Social relationships
Mean (SE)	52.1 (0.56)	50.2 (0.59)	54.9 (0.59)	51.3 (0.67)
Range	6.8-97.8	4.8-100.0	0.0-100.0	0.0-100.0
Skewness	−0.060	−0.023	−0.155	−0.137
Kurtosis	2.624	2.551	2.629	2.681
Shapiro-Wilk statistic	0.997	0.995	0.994	0.989
Shapiro-Wilk *P* value	.05	.006	<.001	<.001
Median (IQR)	52.2 (40.4-64.5)	50.0 (37.8-63.9)	54.6 (42.6-67.2)	51.9 (34.9-67.3)
Floor effect (%)	0	0	0.1	1.4
Ceiling effect (%)	0	0.1	0	1.3

[a]WHOQOL-BREF: World Health Organization Quality of Life-BREF.

The analysis of floor and ceiling effects reveals minimal clustering at the extremes, with the social relationships domain exhibiting a 1.4% floor effect and a 1.3% ceiling effect, the highest among all domains. These negligible effects ensure the scale's capacity to capture a wide range of responses without response saturation.

Normative Data for Domains of WHOQOL-BREF

Prior to the presentation of normative data for the domains of the WHOQOL-BREF, an examination of the overall assessment of the QoL and satisfaction with health among Polish caregivers of individuals with RDs is warranted. The data presented in Table 7 reveal notable differences by sex.

Concerning the overall evaluation of QoL, the predominant response among male and female caregivers was "good," with 42.3% (n=55) of male and 39.5% (n=321) of female caregivers indicating this as their response. The second most prevalent response was "neither poor nor good," with 31.5% (n=41) of male and 39.5% (n=321) of female caregivers choosing this option. However, a higher proportion of female caregivers reported a "poor" QoL (n=108, 13.3%) compared to male caregivers (n=19, 14.6%). The percentage of caregivers who rated their QoL as "very poor" was relatively low overall, at 2.5% (n=24), with male caregivers (n=7, 5.4%) more likely to report this than female caregivers (n=17, 2.1%). Conversely, only a small percentage of caregivers reported a "very good" QoL (male: n=8, 6.2% and female: n=45, 5.5%). These findings suggest that perception of the overall QoL is more likely to be situated toward the middle or lower end of the scale for both sexes. Satisfaction with health, however, revealed more pronounced differences between male and female caregivers. While 45.4% (n=59) of male caregivers reported being "satisfied" with their health, this proportion was significantly lower for female caregivers, at 29.2% (n=237). Instead, more female caregivers expressed dissatisfaction (n=237, 29.2% compared to n=22, 16.9% of male caregivers) or were "neither satisfied nor dissatisfied" (female: n=293, 36.1% vs male: n=41, 31.5%). A small proportion of caregivers described themselves as "very satisfied" with their health (male: n=4, 3.1% and female: n=19, 2.3%), while 3.2% (n=30) of caregivers overall reported being "very dissatisfied." These results suggest that male caregivers generally report a higher QoL and greater health satisfaction than female caregivers. The elevated incidence of dissatisfaction and neutral responses among female caregivers may indicate the supplementary burdens they encounter in their caregiving roles or inherent disparities in perceived health status and well-being.

XSL•FO
RenderX

Table . Overall evaluation of the quality of life and satisfaction with the health of family caregivers of individuals with rare diseases by sex.

	Male, n (%)	Female, n (%)	Total, n (%)
How would you rate your quality of life?			
Very poor	7 (5.4)	17 (2.1)	24 (2.5)
Poor	19 (14.6)	108 (13.3)	127 (13.5)
Neither poor nor good	41 (31.5)	321 (39.5)	362 (38.4)
Good	55 (42.3)	321 (39.5)	376 (39.9)
Very good	8 (6.2)	45 (5.5)	53 (5.6)
How satisfied are you with your health?			
Very dissatisfied	4 (3.1)	26 (3.2)	30 (3.2)
Dissatisfied	22 (16.9)	237 (29.2)	259 (27.5)
Neither satisfied nor dissatisfied	41 (31.5)	293 (36.1)	334 (35.5)
Satisfied	59 (45.4)	237 (29.2)	296 (31.4)
Very satisfied	4 (3.1)	19 (2.3)	23 (2.4)

Normative data for the 4 dimensions of the WHOQOL-BREF—physical health, psychological health, social relationships, and environment—segmented by sex and age group are presented in Table 8.

Male caregivers demonstrated higher mean scores in physical health than female caregivers across all age groups. The highest mean score was observed in the youngest male group (16 - 29 years: mean 59.9, SE 10.04), gradually decreasing with age, reaching its lowest value in the 50+ year group (mean 50.4, SE 4.72). Among female caregivers, the 16 - to 29-year age group exhibited the lowest mean score (mean 43.6, SE 2.72), while the 40 - to 49-year age group demonstrated the highest (mean 51.0, SE 1.00). The absence of floor or ceiling effects in this domain indicates that the scale effectively captured a comprehensive range of physical health outcomes without concentrating on the extremes. The observed decline in physical health scores with age is consistent with patterns reported in other populations, suggesting a cumulative impact of caregiving and aging.

Psychological health scores demonstrated relative stability across age groups for both male and female caregivers. Male caregivers exhibited scores ranging from 57.4 to 58.4, while female caregivers displayed scores from 49.5 (16 - 29 years) to 56.2 (40 - 49 years). Notwithstanding the overall consistency, female caregivers in the 16 - to 29-year age group reported significantly lower psychological well-being. No ceiling effects were observed, and only minimal floor effects were present (1.1%) among female caregivers aged 50+ years, indicating that extreme values were rare.

[a]WHOQOL-BREF: World Health Organization Quality of Life-BREF.

The social relationships domain displayed greater variability, particularly among female caregivers. The lowest mean score was found in the youngest female group (16 - 29 years: mean 39.3, SE 3.34), suggesting social challenges in this group. In contrast, male caregivers demonstrated more stability, with scores ranging from 50.8 to 55.0 across all age groups. Significant floor effects were observed among female caregivers aged 16 - 29 years (6.2%) and male caregivers aged 40 - 49 years (4.7%), suggesting that many respondents experienced severe difficulties in social relationships. Ceiling effects were generally minimal, with the highest occurrence (5%) observed among male caregivers aged 50 years and older.

The scores in the environment domain demonstrated greater consistency across age groups. The mean score was highest among male caregivers aged 30 - 39 years (mean 57.5, SE 2.39) and lowest among female caregivers aged 50+ years (mean 48.5, SE 1.91). The absence of floor or ceiling effects indicated that responses were distributed uniformly across the scale. This dimension reflects a stable perception of environmental support and resources among caregivers, irrespective of age or sex.

XSL•FO
RenderX

The study's results indicate significant disparities in HRQoL within the sex and age categories of caregivers. Specifically, younger female caregivers exhibited lower scores in various domains of WHOQOL-BREF. These disparities can be attributed to the unique challenges associated with caregiving roles, personal health, and social support systems, particularly for specific demographic groups.

Discussion

Principal Findings

The WHOQOL-BREF is a widely used instrument for assessing QoL across diverse populations [4,28]. Its psychometric properties have been extensively studied, confirming its reliability and validity. However, certain aspects warrant further discussion, including its applicability across cultural contexts, domain-specific reliability concerns, and its use in both general and disease-specific populations [8,9,26,29-32].

Our study demonstrated that the WHOQOL-BREF is an appropriate tool for assessing QoL among caregivers of individuals with RDs. The instrument exhibited good internal consistency, with Cronbach α values generally exceeding 0.70. Internal consistency analysis showed values ranging from 0.69 for the social relationships domain to 0.84 for psychological health, indicating satisfactory to high reliability across domains. The item-level analysis identified specific areas where refinements could enhance reliability. Nevertheless, previous studies have reported lower reliability in the social relationships domain, highlighting a potential need for further refinement [6,8,33].

The construct validity of the WHOQOL-BREF is well established, with CFAs generally supporting its 4-domain structure. The instrument also demonstrates strong convergent and discriminant validity, correlating well with other health measures and effectively distinguishing between groups with differing health conditions [34-37]. Consistent with prior research, our findings confirm that the WHOQOL-BREF generally maintains good internal consistency, with Cronbach α values frequently exceeding 0.70. For instance, one study reported an α of 0.898 for the total score [33].

However, lower α values have often been observed in the social relationship domain, occasionally falling below 0.70. A Thai study reported a Cronbach α of 0.62 for this domain, while the other domains ranged from 0.81 to 0.85 [38]. Similarly, a Greek study found an α of 0.65 for social relationships, with other domains ranging from 0.66 to 0.87 [36]. Several factors may account for this pattern. The social relationships domain comprises only 3 items, which naturally limits internal consistency compared to domains with more items. Additionally, the items assess complex and sensitive aspects of life—such as personal relationships and sexual activity—which may be interpreted differently across individuals, particularly among caregivers of persons with RDs. Cultural, sex-based, and situational factors (eg, emotional exhaustion, social withdrawal, and limited time for interpersonal interaction) may further influence caregivers' responses, contributing to variability in this domain.

Factor analysis has been widely used to evaluate the underlying structure of the WHOQOL-BREF [6,39]. CFA results indicate that a unidimensional model yields poor fit indices, whereas the 4-domain model significantly improves model fit. Further refinements, including correlated error terms, have led to an optimized model with improved goodness-of-fit measures (χ^2/df, CFI, TLI, RMSEA, and SRMR). These findings confirm the structural validity of the WHOQOL-BREF and reinforce its intended dimensional structure [8,32]. Although CFA generally supports the 4-domain model (physical health, psychological health, social relationships, and environment domains), some studies have questioned this structure, reporting that certain items do not clearly discriminate between domains or correlate more strongly with an unintended domain [32,34,36,38]. Exploratory factor analysis in a Norwegian study also resulted in a 4-component solution, partially supporting the established domain structure [8]. Some studies suggest that the physical health domain contributes most significantly to overall QoL [33].

The WHOQOL-BREF has demonstrated strong psychometric properties across various countries and cultures. Research supports its discriminant validity, content validity, internal consistency, and test-retest reliability across different cultural settings, suggesting its suitability for cross-cultural comparisons [4,8,36,38,40]. The instrument has been translated and adapted for multiple languages, including Polish [6], Korean [33], Spanish [35,40], Portuguese [41], Thai [38], Bahasa Indonesia [42], Mongolian [43], Persian [39], Danish [32], Norwegian [8], and French [9]. The translation process generally adheres to rigorous methodologies, such as forward and backward translation and cultural adaptation procedures. Some adaptations have been proposed to enhance cultural relevance, including the incorporation of additional items related to work satisfaction, social activities, and nutrition [36]. While these modifications may improve local applicability, they could also impact comparability across studies [40].

In studies conducted within the general population, the WHOQOL-BREF has been used to establish normative QoL scores, facilitating demographic comparisons [7,9,44]. Factors such as age, sex, education level, and health status have been identified as influential [4,7,9,32,42,44,45]. For instance, some studies suggest that female caregivers report higher social QoL [26,46], while male caregivers tend to report better psychological QoL [7,9,46]. Physical health scores typically decline with age, reflecting the natural progression of age-related health issues [3,4,46,47].

In clinical settings, the WHOQOL-BREF has been validated or used for various disease groups, including cancer, chronic conditions, mental disorders, HIV/AIDS, Huntington disease, Prader-Willi syndrome, hemophilia, neurofibromatosis, rheumatoid arthritis, and spinal cord injury [4,30,31,34,36,48-54]. It serves as a valuable tool for evaluating the impact of illness on QoL and monitoring treatment effectiveness [4,28]. However, some validation studies have raised concerns regarding the internal consistency of the social relationships domain [8,29]. The instrument's generic nature allows for comparisons across different medical conditions,

XSL•FO
RenderX

ensuring broad applicability in health research. Factorial invariance testing has confirmed that the WHOQOL-BREF consistently measures QoL across different patient groups [4,8,34].

Despite its strengths, certain limitations of the WHOQOL-BREF should be acknowledged. The social relationships domain has exhibited weaker reliability in some studies, suggesting a need for refinement or supplementation with additional items. While the environment domain is a notable strength of the instrument, some researchers have recommended incorporating more sensitive response options to improve measurement precision [6,28,29,46].

The WHOQOL-BREF's reliance on self-report data enhances respondent acceptability but also introduces potential biases, such as social desirability and response tendencies. Adherence to standardized scoring guidelines is essential for ensuring accurate interpretation, and researchers should consider variations in response patterns across different populations [6,29,32].

In our study, QoL domain scores were normalized to a 0 - 100 scale. Factor loadings ranged from 0.363 to 0.801, indicating varying contributions of items to their respective constructs. The psychological health domain demonstrated the highest mean score (mean 54.9, SE 0.59), while the physical health domain had the lowest (mean 50.2, SE 0.59). Normality tests showed slight deviations, particularly in the psychological health and social relationships domains, though skewness and kurtosis values remained within acceptable limits. Minimal floor and ceiling effects ensured adequate response distribution. QoL norms were established for a Polish population of caregivers for individuals with RDs, stratified by sex and age group. Male caregivers generally reported higher physical and psychological health scores than female caregivers. Younger female caregivers (16 - 29 years) exhibited the lowest scores in several domains, suggesting potential vulnerabilities in social and psychological well-being. These findings highlight disparities related to caregiving burden, sex, and age-related factors.

Limitations

It is important to consider the limitations of this study before interpreting its results. First, although 942 caregivers replied and completed the survey, the number of caregivers of persons with RDs in Poland is significantly higher. It should be noted, however, that although it can be difficult to extend the results to the total population of caregivers of persons with RDS in Poland, to date, there is no register of individuals with rare conditions in the country. Second, since convenience sampling was used in this survey and the study sample was self-selected, it could further compromise the sample's representativeness and the results' generalizability. Third, since caregivers of persons with different RDs took part in the study, there is a possible bias related to challenges related to different conditions, symptoms, and prognoses. However, since most RDs are small in numbers, it would be difficult, if possible at all, to validate the questionnaire for a single RD. Moreover, despite some differences in caregivers' experiences, numerous previous studies demonstrated that most parents of persons with RDs face similar challenges and express similar needs. Consequently, we believe that the results may still apply to the entire population of family caregivers of persons with RDs in Poland. Especially because the sample is quite diverse, encompassing both mothers and fathers as well as various age groups. Fourth, the self-administering nature of the WHOQOL-BREF is part of its design. However, although the administration may elicit varying degrees of true responses, this bias is consistent across all questionnaires and has no bearing on the accuracy of the psychometric analyses, which are primarily comparative in nature. Fifth, we gathered our data before the Rare Disease Plan for 2024 - 2025 was formally approved by the Council of Ministers in August 2024. Sixth, a comparable sample of caregivers of healthy individuals or those experiencing more common chronic diseases could have been beneficial to the study. Seventh, because the study was conducted as a web-based survey, there is a risk that it did not reach caregivers who lived in distant areas without internet access, who were hesitant to use technological devices and social media, or who did not belong to digital associations, foundations, and organizations of patients with RDs or support groups that aided in collecting the data. Consequently, while there is no direct generalizability of the results shown here to other cross-national samples, it is challenging to evaluate bias and the causes of nonresponses when using web-based survey data. Eighth, a potential bias is also present because only 130 fathers responded to the survey. However, it should be explained that while the sample was obtained through convenience sampling, it is well-documented that in the population of family caregivers, there is a significant underrepresentation of male caregivers. Thus, while these sex differences in caregiving could affect how respondents report their QoL, particularly in areas like psychological health and social relationships due to the small number of male respondents, sex-based factor analysis was not possible. Future research should ensure more balanced sex representation and explore sex differences in WHOQOL-BREF performance. Moreover, the 2006 Polish validation of WHOQOL-BREF did not account for sex, age differences, or caregivers of individuals with RDs, highlighting the need for validation in specific populations and subgroup adaptations. Another limitation of this study is the inclusion of caregivers of individuals with 158 different RDs, which prevented detailed clinical characterization of care recipients. However, only some syndromes, that is, Dravet, Angelman, Williams, 22q11DS, and Duchenne or Becker muscular dystrophy, were represented by multiple caregivers; most conditions had only a few or even single respondents. This reflects the nature of rare, ultrarare, and hyperrare disorders, which affect very small patient populations and make it difficult to validate any tool. Future studies should consider focusing on more homogeneous caregiver groups. Next, since no other QoL instrument has ever been validated in the population of family caregivers of persons with RDs in Poland, this lack of external validation constitutes a limitation of our study and highlights the need for future research dedicated specifically to this group. Finally, this study is also limited by the WHOQOL-BREF's potential insufficiency in capturing social aspects of caregiving; future research should consider using complementary tools like the Zarit Burden Interview.

RenderX

Conclusions

The WHOQOL-BREF remains a reliable and valid instrument for assessing QoL across diverse populations. Its 4D structure is robust, and normative data provide valuable benchmarks for assessing QoL in specific groups, such as caregivers. Future research should focus on refining the social relationships domain and addressing minor fit inconsistencies to enhance the scale's applicability further. An important question arises regarding whether the social relationships domain, due to inherent differences between societies, patient groups, and caregivers of various conditions, can be conceptualized as a universal construct. While the WHOQOL-BREF remains a valuable tool for assessing QoL in diverse populations, careful consideration of item profiles and potential supplementary modules for specific age groups may further optimize its utility.

Acknowledgments

The authors thank all the caregivers who participated in the study. No generative artificial intelligence tool was used in the writing of this manuscript, calculation, or visualizing the study results. All text, calculation, table, and figures were prepared by the authors themselves.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to reasons of sensitivity but are available from the corresponding author on reasonable request.

Authors' Contributions

JD and DW conceptualized the study. JD, PJ, and DW developed the methodology. JD collected the data. DW curated the data and contributed to validation. PJ performed the formal analysis, software development, validation, and visualization. JD, PJ, and DW had full access to the data, wrote the original draft, and approved the final manuscript. JD administrated and supervised the study. All authors contributed equally to this work.

Conflicts of Interest

None declared.

Abstract

Background: Accurate population size estimates (PSE) of key populations—those disproportionately affected by HIV—are critical to forecast need and inform HIV prevention and treatment programs, though they can be difficult to ascertain due to low visibility of these groups. In Zambia, reliable estimates on the number of people who inject drugs are limited, inhibiting public health response.

Objective: We sought to estimate the population size of people who inject drugs in 3 large cities in Zambia, assess how PSEs vary across different estimation methods, and explore the strengths and limitations of each approach.

Methods: We applied 2-source capture-recapture (2S-CRC), 3-source capture-recapture (3S-CRC), and successive sampling population size estimation (SS-PSE) methods in Lusaka, Livingstone, and Ndola, Zambia. 3S-CRC methods included location-based 2S-CRC in combination with a respondent-driven sampling (RDS) survey. Data were collected from November 2021 to February 2022 and analyzed using a Bayesian nonparametric latent class model. SS-PSEs were produced using the RDS recruitment and network sizes. Kruskal tests and general linear models were used to examine sociodemographic and behavioral factors associated with being captured in 2S-CRC among RDS participants. Final city population estimates, incorporating 3S-CRC and SS-PSE with imputed visibility estimates, were generated using a Bayesian consensus estimator.

Results: Bayesian consensus PSEs ranged between 0.5% and 1.8% of the adult male population and were below 1% of the total adult population in each city. Consensus estimates were highest in Lusaka (3700, 95% credible interval [CRI] 1500 - 7500), followed by Ndola (2200, 95% CRI 1600 - 2900) and Livingstone (1200, 95% CRI 900 - 1,900). There was variability in estimates by method, with SS-PSE with imputed visibility generally providing the lowest estimates across cities, excluding Lusaka. Across methods, PSEs and uncertainty bounds (95% confidence interval [CI] or CRI depending on method) ranged from 1510 (95% CRI 1030 - 2070) to 4350 (95% CI 1410 - 18,890) in Lusaka, 360 (95% CI 290 - 530) to 2620 (95% CRI 1510 - 4680) in Livingstone, and 760 (95% CI 390 - 3060) to 4030 (95% CRI 960 - 5480) in Ndola. In all cities, fewer recaptures occurred in capture 3 (RDS) than with location sampling via 2S-CRC. Though results varied across cities, RDS participants captured through 2S-CRC differed from those captured solely through RDS in sociodemographic and behavioral risk factors, including housing, education, injection or needle sharing frequency, time since last injection, receipt of drug treatment, and experience with a peer educator in at least one city.

XSL•FO
RenderX

Conclusions: This study used rigorous methods to produce PSEs in Zambia, and is the first to produce these for major geographies in the country. Through RDS, 3S-CRC reached people who inject drugs with distinct characteristics that were less accessible via location-based sampling (2S-CRC), yielding a PSE that may better reflect the population and informing the Bayesian consensus estimate. Findings from this study can guide program planning and future surveillance activities.

KEYWORDS

people who inject drugs; population size estimation; Zambia; PWID; HIV

Introduction

In Eastern and Southern Africa, 23% of new HIV infections are estimated to occur among key populations and their partners, roughly 1% of which are estimated to be among people who inject drugs based on available data [1,2]. Though population-level HIV estimates for people who inject drugs are limited, existing data indicate that people who inject drugs experience an HIV incidence rate 6.5 times higher than that of the general population in the region, with the proportion of new HIV infections and the incidence rate ratio slightly increasing from 2010 for this group [2]. Moreover, people who inject drugs endure other harms due to injection drug use, including infections from other blood-borne viruses such as hepatitis C virus (HCV) and hepatitis B virus (HBV), injury, and overdose [3].

Accurate population size estimates (PSEs) of key populations are critical to forecast need and inform HIV and HBV/HCV prevention, care, and treatment program planning, yet they can be difficult to ascertain due to the limited visibility of these groups. Difficulties in sampling key populations, including people who inject drugs, due to discrimination and criminalization, as well as nondisclosure of key populations in health care settings, can hinder PSEs using empiric methods. As a result, the availability and quality of PSEs for people who inject drugs vary. Only half of the countries in sub-Saharan Africa have injection drug use estimates—estimates of varied quality [3]. Although 1.4 million people have been estimated to inject drugs in the region, numbers may be as high as 3.1 million [3].

In Zambia, where punitive laws against drugs and injection equipment impede harm reduction services for people who inject drugs [4,5], estimates on the number of people who inject drugs are largely absent, limiting country-level planning and service delivery coverage estimates. While a formative qualitative assessment of people who use drugs was conducted in 4 cities in Zambia between 2013 and 2015 [6] and a size estimation study with people who inject drugs was conducted in 3 districts in Zambia in 2021 [7], prior methods used were of poor quality, included broad eligibility definitions related to HIV risk, or omitted major geographies in the country.

We sought to estimate the population size of people who inject drugs in 3 large cities in Zambia and document how PSEs vary across estimation methods for these groups. Multiple methods were used in the absence of a gold standard method for PSEs. We present findings, strengths, and limitations of each estimation method, including analyses that highlight method attributes, as well as our approach and results in generating a Bayesian consensus estimate for each city.

Methods

Study Setting

Data were collected from November 2021 to February 2022. Survey cities were selected to include 3 of the most populous cities in Zambia, which have a high number of people who use drugs according to PSEs from a prior study [6]. Each city has a different typology, with Livingstone serving as a major tourist destination and border town, the capital Lusaka serving as the economic and industrial hub of the country, and Ndola serving as a gateway to the Copperbelt province and mining region. Small area estimation techniques suggest the HIV prevalence among the general population in Livingstone, Lusaka, and Ndola is 14.9%, 16.5%, and 14.1%, respectively [8], higher than the national adult HIV prevalence of 9.8% [9].

2-Source Capture-Recapture and 3-Source Capture-Recapture: Captures 1 and 2

In each city, we implemented multiple source capture-recapture where people who inject drugs were “sampled” through 3 captures. This included the distribution of unique objects at places or “hotspots” where people who inject drugs congregate at 2 points in time (captures 1 and 2), followed by a biobehavioral survey (BBS; capture 3). Details and assumptions on capture-recapture methods have been described previously, including that capture-recapture relies on assumptions specific to population closure, capture independence, homogeneous capture probabilities, and clearly defined captures [10-12]. For captures 1 and 2, implemented a week apart, volunteers had a target sample size to distribute up to twice the number of unique objects as the target BBS sample size per capture in each city (target sample size and sample size calculations for the BBS are described further below). Distribution locations and appropriate distribution objects (black and white bracelets for captures 1 and 2, respectively) were identified through a formative assessment and through support from organizations who work with people who inject drugs. Volunteers were assigned to distribute objects at these locations as well as additional locations in the volunteer’s neighborhood or preferred hangout place. Distribution occurred over 3 days to limit the possibility of someone receiving objects from different volunteers. Each day of distribution, volunteers (13-27 per city and capture) received paper-based distribution logs to be completed during distribution, along with their allotted number of objects to distribute in their allocated daily catchment areas. Different volunteers were used for each capture to reduce

XSL•FO
RenderX

dependence between captures, and any participating volunteer was excluded from the seed selection for capture 3. During each of the first 2 captures, volunteers approached both known and potential members of the people who inject drugs community and verified whether individuals had injected drugs within the past 3 months and were 16 years of age or older. After confirming eligibility (same as BBS eligibility below), volunteers inquired whether individuals had previously received the unique object and briefed them about the unique object distribution process and the upcoming survey. If individuals had not previously received the object in that capture, they were offered an object. People who inject drugs who accepted objects in capture 1 were encouraged to keep their object for 2 weeks and told that they may be asked about it in the future. In capture 2, volunteers verified if individuals had received the unique object distributed in capture 1, though they were not required to have it on them as long as they confirmed receiving it. Eligibility, object acceptance or refusal, prior receipt of object, date, time, and location of distribution were recorded on the log and later entered via tablet questionnaire. Any objects that were not distributed were returned to the survey team.

3-Source Capture-Recapture: Capture 3 (BBS)

Capture 3 comprised a BBS with survey methods aligned to the Biobehavioural Survey Guidelines for Populations at Risk for HIV [13]. Participants were recruited using respondent-driven sampling (RDS), a chain referral approach used to recruit populations for whom no sampling frame exists [14]. Individuals were eligible to participate in the BBS if they met the following criteria: self-reported drug injection for nonmedical purposes in the past 3 months; aged 16 years or older; lived in the surveyed city for the past 3 months; spoke English, Bemba, Kaonde, Lozi, Nyanja, or Tonga; willing to provide verbal informed consent; and in possession of a valid survey coupon (for coupon recipients). Seeds, well-connected people who inject drugs who met the eligibility criteria, were identified through a formative assessment and through support from organizations serving people who inject drugs. Seeds were purposively selected to ensure diversity across age, sex, education, area of residence, language, nationality, socioeconomic status, and key populations organization affiliation, and were instructed to recruit 3 of their peers via coupon. Peers who were eligible and participated in the BBS were provided 3 coupons and encouraged to recruit 3 of their peers, and so on.

After providing consent, tablet-based questionnaires were administered via interviewer and covered topics such as demographics, sexual and injection risk behaviors, knowledge, attitudes, and practices related to HIV, stigma and discrimination, and social and structural networks. Data validation and completion checks were preprogrammed to minimize data entry errors. To inform 3-source capture-recapture (3S-CRC), participants were asked about object acceptance or refusal and prior receipt of objects for both captures 1 and 2. Where participants did not physically possess the objects during the interview, they were asked to identify the objects from several images. Interviews lasted approximately 1 hour, after which participants who provided consent were tested for HIV, syphilis, HCV, and HBV.

Using the sample size calculator for survey-based viral load suppression in the Biobehavioural Survey Guidelines for Populations at Risk for HIV as is best practice for BBS [13] and assuming a design effect of 2 and a nonresponse rate of 5%, we calculated a sample size of 195 HIV-positive participants would produce a 2-sided 95% confidence interval (CI) ranging from 50% to 70% when viral load suppression among HIV-positive participants was 60%. To achieve a sample size of 195 HIV-positive participants per survey city, assuming an HIV prevalence of 25%, we estimated a sample size of 780 participants per survey city. After consultation with key population stakeholders in Zambia, it was determined that the target sample size of 780 people who inject drugs would not be achievable in each city, given the expected size of the population and the willingness of people who inject drugs to participate in a study. This sample was subsequently allocated across the 3 cities based on population size and recruitment feasibility. Each city's target sample size was then increased slightly to improve the precision of city estimates and better assure statistical equilibrium and convergence (Lusaka: n=350, Livingstone: n=235, and Ndola: n=260).

Successive Sampling Population Size Estimation

Successive sampling population size estimation (SS-PSE) methods [15] with and without imputed visibility were also used to estimate the population size of people who inject drugs in the survey cities. SS-PSE models the total number of persons in the target population using RDS data from the BBS and, as a result, relies on the inherent assumption that the social network of the population of interest is fully connected. It also assumes that the probability of recruitment for an individual is proportional to their network size, and that the network size is known accurately. SS-PSE methods use the self-reported individual network size question asked in the survey, combined with a prior estimate for the population size, and a Bayesian model to estimate the size of the target population [16]. SS-PSE with imputed visibility is an extension that introduces a measurement error model for network size, which helps account for misreporting and bias in self-reported network size [17].

Bayesian Consensus Estimation

For published reports, technical and stakeholder consultation guided the statistical estimation of a single consensus estimate, which combined estimates from the separate PSE methods.

Consultation took place in 3 parts. First, the project technical staff reviewed and compiled prior information, then computed the PSE using each method. The results were discussed, and an initial decision was made to include only the SS-PSE with imputed visibility and 3S-CRC estimates, based on data quality and plausibility. To elicit feedback from the wider project and key population interest groups, a meeting was convened with the Zambia Key Populations Consortium, a network of key population members. Priors and confidence in each method were finalized for input into the Bayesian consensus estimates calculation (using the "Triangulator" app, further described below).

XSL•FO
RenderX

Statistical Analysis

Data analysis for counts, proportions, and PSEs was conducted using R (version 4.0.5; R Foundation for Statistical Computing). PSEs and credible intervals (CRIs) for 2-source capture-recapture (2S-CRC) and 3S-CRC were derived using a Bayesian nonparametric latent-class model in the *shinyrecap* package [18]. Size estimation was based on the number of participants overlapping (or recaptured) across capture events. The Bayesian model assumes that there are several unobserved subgroups of the population which each have different capture probabilities for each capture event. Using RDS data, bivariate analysis was used to compare sociodemographic factors and drug injection practices by capture history to understand potential differences between those captured through 2S-CRC or the BBS alone.

SS-PSE was computed with the Gile estimator in the *sspse* package (version 0.6) using RDS recruitment histories and self-reported network sizes [19]; measurement errors were estimated with and without imputed visibility. There was very limited information on people who inject drugs in the study cities before our study, so prior populations for SS-PSE were based primarily on the percentage of the population who were estimated to be injection drug users based on a review of previous studies in sub-Saharan Africa [20]. Other evaluations of the people who inject drugs population in Zambia suggested that almost all people who inject drugs were male, so census estimates of the male aged 15 - 64 years population for each city were used to compute priors based on an estimate of 0.6% of this population being people who inject drugs [7]. This resulted in initial estimates of 5000 for Lusaka, 1200 for Ndola, and 400 for Livingstone. The Livingstone prior estimate was increased to 800, because the study contacted more than 800 distinct people who inject drugs during the unique object distribution and the RDS recruitment. To account for the large prior uncertainty while constraining estimates to be plausible proportions of the general population in each city, we set the lower quartile for the prior at half of these estimates, and the upper quartile as twice these estimates. The prior estimates were reviewed and agreed with key population stakeholders and experts from the collaborating Zambia organizations before being input into the SS-PSE calculation.

Results from the RDS survey were produced using R (version 4.0.5, *RDS* package, version 0.9 - 3) with bootstrap variance estimation of 95% CIs [21]. Using Taylor series variance estimation, SAS (version 9.4; SAS Institute Inc) was used for indicator validation and sensitivity analyses. Complete case analysis was used when data were missing, as missing data were minimal.

Final statistical computation of the consensus estimate was carried out using a Bayesian approach, which weights the available estimates and their variance by a "design confidence" weight based on judgment of the methodological reliability of each estimate [22]. Design confidence scores of 75 and 65 were assigned to the 3S-CRC estimates and SS-PSE with imputed visibility estimates, respectively. These confidence factors were set conservatively in collaboration with this study's technical group to account for potentially unmet assumptions and to recognize the substantial divergence of the estimates from different methods from each other and our original priors. Priors for the consensus estimate were set for the lower and upper limits of the people who inject drugs population in each city. Lower bounds used the number of unique individuals captured in each city, and upper bounds were set at approximately 10% of the total city population to avoid unwanted downward influence on the estimates.

Ethical Considerations

This activity was reviewed and approved by the United States Centers for Disease Control and Prevention, Columbia University Medical Center Institutional Review Board, Tropical Diseases Research Centre Ethics Review Committee, and the Zambia Ministry of Health National Health Research Authority. Permission and administrative approval from the Zambia Ministry of Health and the National Health Research Authority were obtained before data collection. Letters of support from the Ministry of Home Affairs (Police) and the Drug Enforcement Commission were obtained to ensure that researchers and people who inject drugs were not prosecuted during the survey's period. Consent was neither required nor sought from people who inject drugs in captures 1 or 2, as aggregate data collected were not classified as human subjects research. To reduce the potential risk of breach of confidentiality, BBS participants provided verbal informed consent. BBS data collection sites were selected to ensure privacy protection, and all survey staff were trained in Good Clinical Practices and signed a confidentiality agreement. Participants received a maximum of K430 (approximately US $27) in cash for compensation of transportation costs, time, and peer referrals in the BBS. Nonidentifying codes were used to link participant questionnaire and biomarker data. Data included in this analysis were deidentified.

Results

2S-CRC: Captures 1 and 2

In Livingstone, 426 and 432 individuals were approached in captures 1 and 2, respectively. In capture 1, a total of 415 (97%) individuals were eligible, and of those, 20 had previously received an object and been sampled in the capture (Table 1). Of those who had not previously been captured and were offered an object, 97% accepted, resulting in a total of 383 people who inject drugs sampled in capture 1. In capture 2, a total of 421 (97%) met study eligibility criteria, and of those, 7 had previously received an object and been sampled in capture 2. Overall, 411 people who inject drugs accepted an object and were sampled in capture 2. Of those sampled in capture 2, a total of 99 (24%) self-reported to having received an object in the first capture and been sampled in capture 1.

[a]For capture 3, there were additional eligibility criteria, as noted above in the Methods section.

[b]Among those who self-reported to be people who inject drugs.

[c]Among those not captured in the current capture.

[d]N/A: not applicable.

In Lusaka, 700 and 763 individuals were approached in captures 1 and 2, respectively. In capture 1, a total of 617 (88%) individuals were eligible, and of those, 29 had previously received an object and been sampled in the capture. Of those who had not previously been captured and were offered an object, 93% accepted, resulting in a total of 548 people who inject drugs sampled in capture 1. In capture 2, a total of 697 (91%) met study eligibility criteria, and of those, 73 had previously received an object and been sampled in capture 2. Overall, 597 people who inject drugs accepted an object and were sampled in capture 2. Of those sampled in capture 2, a total of 209 (35%) self-reported to having received an object in the first capture and been sampled in capture 1.

In Ndola, 449 and 473 individuals were approached in captures 1 and 2, respectively. In capture 1, a total of 442 (98%) individuals were eligible, and of those, 1 had previously received an object and had been sampled in the same capture. Of those who had not previously been captured and were offered an object, 97% accepted, resulting in a total of 428 people who inject drugs sampled in capture 1. In capture 2, a total of 450 (95%) met study eligibility criteria, and of those, 3 had previously received an object and been sampled in capture 2. Overall, 432 people who inject drugs accepted an object and were sampled in capture 2. Of those sampled in capture 2, a total of 44 (10%) self-reported having received an object in the first capture and been sampled in capture 1.

PSEs generated using 2S-CRC were highest in Ndola (4030, 95% CRI 960 - 5480), followed by Lusaka (1510, 95% CRI 1030 - 2070) and Livingstone (1550, 95% CRI 870 - 1930; Table 2).

[a]PSE: population size estimation.

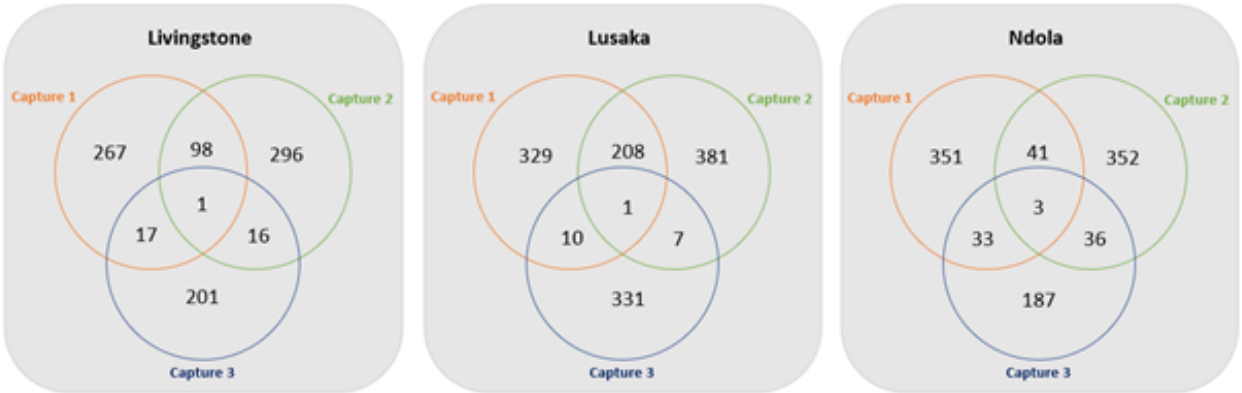
[b]CI: confidence interval; CRI: credible interval. Capture-recapture methods report CRIs while SS-PSE report CIs.

[c]SS-PSE: successive sampling population size estimation.

[d]SS-PSE represents medians.

[e] Estimates and CIs/CRIs are rounded to the nearest tens.

Across cities, the most common recruitment locations for captures 1 and 2 were bars, taverns, clubs, or shebeens (informal drinking establishments), as well as streets or parks in Lusaka and Livingstone. More than half of the people who inject drugs in Ndola were recruited from bars, taverns, clubs, or shebeens in both captures and recruitment from this location type increased nearly 2-fold between captures 1 and 2 in Lusaka and Livingstone. Across all cities, many people who inject drugs were recruited from "other" locations, which included free-text responses of homes (capture 1: 25%; capture 2: 5%) and markets or shops (capture 1: 11%; capture 2: 8%).



3S-CRC: Capture 3 (BBS)

Lusaka recruited the largest number of purposive seeds (n=12) to participate in the BBS, followed by Ndola (n=8), and Livingstone (n=7). In Livingstone, 249 individuals were screened, 235 were eligible, and 235 were enrolled in the BBS (Table 1). In Lusaka, 479 individuals were screened, 349 were eligible, and 349 were enrolled. In Ndola, 303 individuals were screened, 259 were eligible, and 259 were enrolled. Coupon return rates were highest in Ndola (54%), followed by Lusaka (52%) and Livingstone (48%).

The target population was predominantly male, with an estimated 83% (95% CI 73.9 - 92.9) of people who inject drugs in Livingstone, 96% (95% CI 94.9 - 98.0) of people who inject drugs in Lusaka, and 67% (95% CI 58.2 - 75.6) of people who inject drugs in Ndola assigned male sex at birth. Median age (IQR) was 22 (20-28), 25 (22-29), and 27 (23-32) years for men in Livingstone, Lusaka, and Ndola, respectively, and 29 (23-34), 22 (21-24), and 29 (24-35) years for women in Livingstone, Lusaka, and Ndola, respectively. Most people who inject drugs completed secondary school education or higher (Livingstone: 56%, 95% CI 50.1 - 63.0; Lusaka: 62%, 95% CI 56.7 - 67.4; Ndola: 87%, 95% CI 82.6 - 91.4) and were currently unemployed (Livingstone: 58%, 95% CI 51.4 - 66.0; Lusaka: 78%, 95% CI 72.8 - 83.4; Ndola: 45%, 95% CI 26.6 - 36.0). All but 7 of those recruited across all 3 cities were born in Zambia.

Figure 1 provides overlaps or recaptures across all captures by city, which were used as inputs to generate PSEs using 3S-CRC. In all cities, fewer overlaps occurred with 3S-CRC than with 2S-CRC. PSEs generated using 3S-CRC were highest in Ndola (3350, 95% CRI 2820 - 3930), followed by Livingstone (2620, 95% CRI 1510 - 4680) and Lusaka (2320, 95% CRI 1690 - 10,740; Table 2).

Figure 1. Venn diagram of total captures and recaptures of people who inject drugs from 3-source capture-recapture methods by city, Zambia, 2021.

RenderX

Bivariate analysis demonstrated differences in sociodemographic factors and drug injection practices among people who inject drugs by capture history (Table 3). In Livingstone, people who inject drugs participating in the BBS who were not captured via location sampling (2S-CRC) had a higher prevalence of homelessness, levels of education completed, and receipt of drug treatment, and differences in the frequency of injection in the last 6 months and of ever "blue toothing"—injecting oneself with a friend's blood to get high—compared to BBS participants who were previously captured. In Lusaka, people who inject drugs participating in the BBS and who were not captured via location sampling had a higher prevalence of living in a home compared to other housing types, more frequent injection in the last 6 months, never using a shared needle, and had differences in levels of education completed, and time of last injection compared to BBS participants who were previously captured. In Ndola, people who inject drugs participating in the BBS who were not captured via location sampling had a higher prevalence of recent injection and never using a shared needle and a lower prevalence of ever speaking to a peer educator or outreach worker about HIV, levels of education completed, and ever blue toothing, and had differences in housing type compared to BBS participants who were previously captured.

	Previously captured[a] (n=34), % (95% CI[b])	Not previously captured (n=201), % (95% CI)	*P* value[c]	Previously captured[a] (n=18), % (95% CI)	Not previously captured (n=331), % (95% CI)	*P* value[c]	Previously captured[a] (n=72), % (95% CI)	Not previously captured (n=187), % (95% CI)	*P* value[c]
No	100.0 (89.7 - 100.0)	94.9 (91.5 - 98.3)		93.0 (68.9 - 100.0)	90.3 (86.7 - 93.8)		94.2 (91.3 - 97.0)	93.7 (89.6 - 97.8)	

[a]Previously captured represents people who inject drugs who participated in the biobehavioral survey (capture 3) and reported receiving an object in captures 1 or 2.

[b]CI: confidence interval.

[c]*P* values computed using Kruskal test for difference in medians, and a survey-weighted quasi-binomial general linear model for categorical variables.

[d]Median network size was 5, 4.5, and 3 in Livingstone, Lusaka, and Ndola, respectively.

[e]Responses not mutually exclusive.

[f]Indicates that *P* values were not calculated due to insufficient data or no variation between groups.

SS-PSE

The SS-PSE was highest in Lusaka (4350, 95% CI 1410 - 18,890), followed by Ndola (2010, 95% CI 690 - 7400) and Livingstone (450, 95% CI 340 - 810; Table 2). For all cities, SS-PSE was higher without imputed visibility than with it. SS-PSE with imputed visibility was 360 (95% CI 290 - 530) in Livingstone, 2040 (95% CI 660 - 30,410) in Lusaka, and 760 (95% CI 390 - 3060) in Ndola.

Bayesian Consensus PSE

Integrating 3S-CRC and SS-PSE with imputed visibility estimates, the final Bayesian consensus PSE ranged between 0.5% to 1.8% of the adult male population and all below 1% of the total adult population in each city (Table 4). The consensus PSE was highest in Lusaka (3700, 95% CRI 1500 - 7500), followed by Ndola (2200, 95% CRI 1600 - 2900), and Livingstone (1200, 95% CRI 900 - 1900).

Table . Bayesian consensus population size estimates for people who inject drugs by city, Zambia, 2021.

City	Estimate (median)	95% CRI[a]	% of males aged 15 - 64 years district population[b,c]	% of total people aged 15 - 64 years district population[b,c]
Livingstone	1200	900 - 1900	1.8 (1.4 - 2.9)	0.9 (0.7 - 1.5)
Lusaka	3700	1500 - 7500	0.5 (0.2 - 0.9)	0.2 (0.1 - 0.5)
Ndola	2200	1600 - 2900	1.1 (0.8 - 1.5)	0.6 (0.4 - 0.7)

[a]CRI: credible interval.

[b]District population estimates were used because estimates for smaller catchment areas were not available. In addition to the estimated percentage of the total district population, the estimated percentage of males in the district population is provided because site samples have a high proportion of men. Estimates and CRIs are rounded to the nearest 50. Further, 95% CRI indicate the interval where the true population parameter falls with 95% probability, given the observed data.

[c]District population [23].

Discussion

Principal Findings

Our study found higher estimates of people who inject drugs than prior estimates of people who inject drugs in other parts of Zambia [7], yet ours were relatively consistent with estimates for sub-Saharan Africa where prevalence of injection drug use is estimated to be 0.3% (0.1% - 0.6%) of the adult population and 0.5% (0.1% - 1.0%) among adult males [3]. The prior PSE study in Zambia estimated a much lower number than our Bayesian consensus estimates and provided no uncertainty ranges; a total of 907 people who inject drugs across all 3 districts were estimated after applying correction factors for census enumeration, and 846 people who inject drugs were estimated using wisdom of the crowd methods [7]. The methods used in the prior PSE study in Zambia had several limitations. It applied census methods to enumerate the number of people who inject drugs at hotspots and used wisdom of the crowd methods with purposively recruited "gatekeepers" in Solwezi, Kitwe, and Kabwe [7]. Both methods likely underestimated the number of people who inject drugs, given biases in location sampling.

3S-CRC, used in our study, has increasingly been used to estimate the population size of key populations [24-30] and has several strengths. Estimation using 3 or more captures can account for heterogeneity among captures, including subpopulations with different behaviors or social visibility. In our study, there were more recaptures between location-based captures (2S-CRC) than with the RDS survey (3S-CRC), suggesting that the RDS survey was able to reach people who

XSL•FO
RenderX

were less likely to be found in unique object distribution locations. Future research should explore heterogeneity within networks for people who inject drugs and how differences in recruitment methods influence both recruitment probabilities and the resulting PSE.

BBS participants who had been captured in capture 1 or 2 had differences in housing type and level of education compared to BBS participants not previously captured in all cities, though variations of results by city were seen. These 2 groups had differences in the frequency of sharing needles and frequency of injection, time of last injection, experiences with peer educators or outreach workers, and receipt of drug treatment in one or more cities. Notably, heterogeneity in results by city suggest biases in recruitment methods may be more localized. For example, in Ndola, BBS participants not previously captured via location sampling had lower engagement with a peer educator or outreach worker than those who were previously captured, while other cities had no differences in engagement between these groups.

It is important to acknowledge the assumptions of the PSE approaches used in this study. SS-PSE relies on prior knowledge or assumptions about the target population and assumes a fully connected social network among the target population; given this was the first BBS among people who inject drugs in Zambia, inputs used to generate PSEs through SS-PSE relied on information from prior studies in other settings and may not accurately reflect the context for these geographies in Zambia. Similar assumptions about a connected social network apply to the RDS recruitment process, including the validity of the sample as the third capture-recapture group. Capture-recapture methods ideally assume a closed population, independent capture samples, and equal probability of capturing individuals in the target population, though the use of 3 or more captures and appropriate estimators can allow for some relaxation of these assumptions.

Efforts to minimize the violation of these assumptions were taken in this study. To minimize in- or out-migration of people who inject drugs, the first 2 captures occurred over a short duration, and all captures occurred no more than a week apart. People who inject drugs were sampled from a different set of locations in captures 1 and 2 to help ensure independence and seeds for RDS were selected independently from unique object distributors.

Limitations

We were not able to produce separate PSEs for people who inject drugs by sex, as data on sex were not collected in captures 1 or 2. While we had planned to produce PSEs using service multiplier methods, it was not possible due to limited service providers and a lack of people who inject drugs–specific program data in Zambia. We used wisdom of the crowd methods via the RDS survey, where BBS participants were asked to provide their best estimate (or “most accurate” estimate), as well as their estimate of the highest and lowest possible number of people who inject drugs, aged 16 years or older, living in the survey city. Ultimately, given concerns about the quality and weakness of the method, PSEs generated using wisdom of the crowd were omitted from the Bayesian consensus estimate and excluded from this paper. Some activities in this study were implemented during restrictions associated with the COVID-19 epidemic, which may have limited access to subpopulations of people who inject drugs, particularly those who may have been reached via location sampling methods.

Conclusions

Using rigorous methods, this study provides PSEs for people who inject drugs in Zambia and is the first to produce PSEs for major geographies in the country, including Lusaka, Livingstone, and Ndola. We use multiple methods to derive PSEs; present findings, strengths, and limitations of each method; and document our approach to generating Bayesian consensus estimates. Findings from this study highlight heterogeneity among people who inject drugs in Zambia, including that some people who inject drugs may not be accessible via location sampling, which can guide programming and surveillance strategies to reach these groups. Transparency around underlying data and methodological approaches used to generate consensus estimates, as provided here, can support the field and enhance modeling activities, including extrapolation of size estimation. Critically, the consensus PSE generated in this study can inform HIV and HBV/HCV prevention and treatment program planning, including target setting and coverage estimation, and guide future surveillance activities for key populations in the country.

Acknowledgments

We are grateful to the participants and study team and appreciate the important contributions to the study from the Zambia Survey Advisory Group, including representatives from US Centers for Disease Control and Prevention (CDC), the National HIV/AIDS/sexually transmitted infections (STI)/tuberculosis (TB) Council (NAC), Tropical Diseases Research Centre (TDRC), ICAP, and the Zambia Key Populations Consortium. We thank all civil society organizations participating in the Zambia Key Populations Consortium for their critical support in this study's implementation. From TDRC, we specifically acknowledge Kelvin Kapungu, Shepherd Khondowe, and Innocent Bwalya for their support with data collection and site supervision. This research has been supported by the President's Emergency Plan for AIDS Relief (PEPFAR) through the CDC under the terms of cooperative agreement “Supporting sustainable surveillance systems among key populations (KP) and support the Government of Zambia to improve HIV-related services for KP” (CDC cooperative agreement 1NU2GGH002056).

Abstract

Background: Despite rapid development, cancer registries in low- and middle-income countries, such as China, have the persistent problems with up to 6-year delay and a lack of reported details about small areas.

Objective: This study aimed to develop an approach to provide more up-to-date localized cancer surveillance using linked administrative data. We used lung cancer as an example.

Methods: Based on data of hospitalization record front pages (HRFPs) between 2013 and 2022 from all the secondary and tertiary hospitals in Shandong Province, China, we identified incident cases of lung cancer in 2022 with 2013‐2021 being the washout period. Deaths from lung cancer were ascertained for 2022 using linked HRFPs and death registration data. We estimated age-standardized incidence and mortality rates (ASIR and ASMR) of lung cancer in 2022 using Segi world standard population, age-specific incidence and mortality rates by sex, and county-level ASIR and ASMR to illustrate regional disparity. We grouped the counties by municipalities and calculated the Theil indices for within-municipality inequality and between-municipality inequality.

Results: The HRFPs captured 79,672 incident cases of lung cancer in Shandong in 2022 (45,527 males, 34,145 females). The ASIR of lung cancer in Shandong was 42.46 per 100,000 in both sexes (49.19/100,000 in males vs 36.67/100,000 in females). A total of 40,626 lung cancer-specific deaths were ascertained (28,185 men and 12,441 women). The ASMR was 19.76/100,000 in both sexes, 26.29/100,000 and 11.38/100,000 in males and females, respectively. The IQR of county-level ASIR and ASMR were 17.13/100,000 and 10.41/100,000, respectively. The inequality was primarily due to within-municipality disparities, with within-municipality Theil T indices higher than between-municipality Theil T indices (0.0572 vs 0.0033 for ASIR, 0.0824 vs 0.0011 for ASMR).

Conclusions: The cancer surveillance approach based on linked administrative data could provide up-to-date small-area estimates of cancer burden, when cancer registry data are not yet reported and for areas not covered by cancer registries. It could reveal disparity of cancer epidemiology, which provides leads for further investigation into the underlying causes and potential solutions for equity improvement.

(JMIR Public Health Surveill 2025;11:e74062) doi:10.2196/74062

KEYWORDS

cancer incidence; cancer mortality; small-area analysis; administrative health data; epidemiology

Introduction

With an estimated 20 million new cancer cases and 9.7 million cancer deaths in 2022 worldwide, cancer ranks as the third contributor to the global burden of disease [1]. The role of cancer registries as a key source of information for surveillance of cancer burden to reveal the need for global cancer care has been well recognized [2]. At the national and subnational level, timely and locally accurate information about the incidence and mortality of cancer enables the identification of high-risk areas, monitoring of the effectiveness of health interventions, and development of the targeted solutions to address a broad range

XSL•FO
RenderX

of determinants of health, potentially diverse across areas [3,4]. Despite the rapid development of cancer registries in low- and middle-income countries like China, challenges remain regarding delayed reporting [5,6], issues with data accessibility [7-9], and population coverage [10].

With the growing availability of high-quality data based on hospitalization records and other forms of administrative data [11], it is both important and feasible to attempt alternative or complementary approaches to cancer surveillance beyond cancer registries. Indeed, medical insurance claims data have been demonstrated as a reliable source for cancer surveillance [12,13]. Similarly, researchers have also proposed electronic health records, hospital record data in particular, for cancer surveillance as a supplement to or in the absence of a cancer registry [14,15]. Studies from Canada, Spain, and Australia examined the performance of incident hospitalization record in estimating cancer incidence against cancer registries and found high concordance between the two, especially for particular cancer types such as lung cancer and colorectal cancer [16-18]. With the increasing availability of administrative health care data, their use may offer a more detailed and timely surveillance of cancer epidemiology that can inform more effective resource allocation and policy making.

We selected lung cancer as the example in this study due to the heavy burden of this disease. Among all the types of cancer, it has long been the leading cause of both new cancer cases (age-standardized incidence rate [ASIR] in 2022: 40.78/10,000) and cancer deaths (age-standardized mortality rate [ASMR] in 2022: 26.66/10,000) in China [6]. In Shandong Province in particular, lung cancer has been the top cause of cancer death since 2004 [19].

In this study, we sought to develop a timely approach to estimating small-area lung cancer incidence and mortality rates for one of the most populous provinces in China and its counties by linking population-based hospital discharge records and death registration. A small area, depending on the purpose and data availability of the study, may be a neighborhood, a census tract, or a county [20]. In this study, the geographic scale of a small area refers to a county. We also mapped the county-level lung cancer incidence and mortality rates to evaluate the degree of intercounty disparity of lung cancer incidence and mortality.

Methods

Study Setting

Shandong Province is located on the eastern coast of northern China, covering an area of 157,100 km^2. It had a population of 101.6 million people, or about 7.2% of China's total population in 2022 [21]. The province's gross domestic product per capita in the same year was 86,143 Chinese yuan (or US$12,800), equivalent to the level of an upper-middle–income economy by the World Bank categorization [22-24]. Qualified cancer registry data in Shandong covered approximately 33.26 million registered residents, accounting for about 33.24% of the province's total population [25]. Within the province, there are 17 municipalities which in turn consist of 137 counties (including districts and county-level cities). The eastern coastal areas in Shandong are economically more developed, especially Qingdao Municipality and its neighboring municipalities (Weihai, Yantai, Weifang, and Rizhao), compared with other areas in Shandong [26].

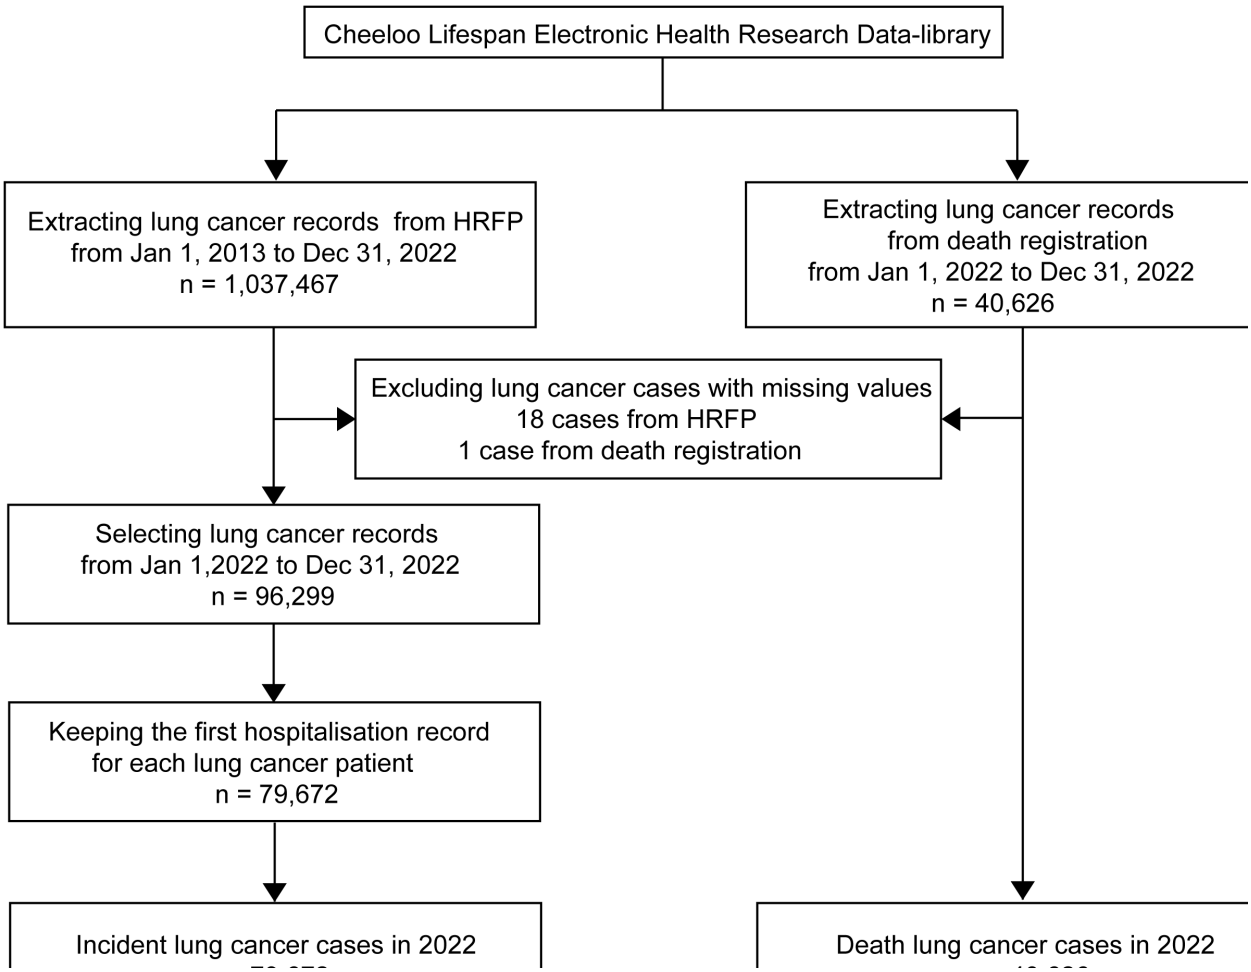
Data Sources

This study used the hospitalization record front pages (HRFPs) data from all secondary and tertiary hospitals in Shandong and the death registry covering the whole population in the province. The HRFP covered a wide range of information, including patient demographics, residence, health-related, and hospitalization-related information, among others. Both datasets were stored in the Cheeloo Lifespan Electronic Health Research Data-library (Cheeloo LEAD), which is an electronic health data platform linked via encrypted individual identity numbers [27] . We extracted the following data from HRFP from the Cheeloo LEAD between January 1, 2013, and December 31, 2022: sex, year of birth, date of admission, county of residence, and diagnosis upon admission recorded in *International Classification of Diseases, Tenth Revision (ICD-10)* code [28]. We further extracted records for people who died between January 1, 2022, and December 31, 2022, from the death registers, covering sex, year of birth, county of residence, and cause of death (also based on *ICD-10* code). These data were complemented by county-level and provincial population data from the latest census reported by Shandong Provincial Bureau of Statistics [29].

This article followed the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) reporting guideline [30] (see Checklist 1).

Identification of Incident Lung Cancer Cases and Deaths

We identified lung cancer–related hospitalization using *ICD-10* codes from C34.0 to C34.9. To avoid classifying prevalent cases as incident cases, we excluded cancer patients with hospitalization records due to lung cancer in previous years (ie, 2013 - 2021). In other words, we adopted a washout time window from 1 year up to 9 years [2]. While a longer washout period appeared to generate more precise results, the benefit of an extra washout year beyond 1 year appeared nonsubstantial (see Figure S1 in Multimedia Appendix 1). For patients with records of multiple hospitalizations for lung cancer, an incident lung cancer case was defined based on the first definite lung cancer–related hospitalization.



We used the corresponding date of admission as the date of diagnosis [31]. As the number of cases with missing information for each of the variables listed in the previous section was below 10, we removed the cases with missing values (a total of 18 cases were excluded).

We ascertained lung cancer–specific death cases based on lung cancer–related records in the death registers from January 1, 2022, to December 31, 2022, with the corresponding registration date as the date of death. *ICD-10* codes were used to determine the primary cause of death. We excluded 1 death case with missing values.

XSL•FO
RenderX

The procedure of identifying incident lung cancer cases and deaths from lung cancer in Shandong in 2022 is shown in Figure 1.

Figure 1. Identification of incident and death lung cancer cases in Shandong, China, 2022. Hospitalization record front pages were identified as lung cancer with diagnoses in *International Classification of Diseases, Tenth Revision* codes from *C34.0* to *C34.9*. Records from death registration were identified as lung cancer-related death with cause of death in *ICD-10* codes from *C34*.0 to *C34.9*.

Statistical Analysis

We evaluated crude, age-specific, and ASIR of lung cancer in Shandong in 2022 by gender with the corresponding resident population as the denominator (structure of the resident population in Shandong in 2022 by gender is shown in Figure S2 in Multimedia Appendix 1), using the formulas below.

Crude incidence rate=New lung cancer cases in the year of interestTotal population in the same year×100,000

Age-specific incidence rate=New cases of a disease in a given age groupTotal population in the same age group×100,000

Age-standardised incidence rate=∑(Age-specific incidence rate×Standard population in corresponding age group)∑Standard population×100,000

Age-standardization was based on Segi world standard population. Crude, age-specific, and ASMR were calculated following a similar method.

Lung cancer incidence and mortality were also calculated at the municipal and county levels. We calculated the difference between the third quartile (Q3) and the first quartile (Q1) as the IQR to quantify geographical disparity in age-standardized incidence and mortality rates of lung cancer at the county and municipality levels. In addition, we used the Theil index to estimate the overall inequality in these rates [32,33], because it could be disaggregated. We grouped the counties based on municipalities where they were located and calculated the Theil indices (Theil T and Theil L) for these groupings, estimating both within-municipality inequality (disparities between counties within each municipality) and between-municipality inequality (disparities between municipalities). A higher Theil index indicates greater inequality [34]. Details about calculating Theil T and Theil L can be found in xMethods Part S2 in Multimedia Appendix 1.

We also evaluated the internal validity of this cancer surveillance method by examining the stability of incidence rates over the years from 2019 to 2022, referring to a criterion on data quality by the International Agency for Research on Cancer [35]. The same formulas for estimating the ASIR and ASMR of lung

XSL•FO
RenderX

cancer in the year 2022 were adopted for the years 2019 to 2022. Based on the previously reported lung cancer incidence time trends [36], we assumed a threshold of an annual growth rate of 10% as indicating the stability of the data over time. The external validity was assessed by comparing the estimates derived by the method in this study with the cancer statistics reported by the national cancer registry in China for the same time period.

All statistical analyses in this study were performed using R software (version 3.4.1; R Foundation for Statistical Computing), with maps also generated using R software.

Ethical Considerations

This study received ethical approval from the Ethics Committee for Public Health of Shandong University (registration number LL20241105). As the study used preexisting, deidentified secondary data, the Ethics Committee waived the requirement for informed consent. Before analysis, all personally identifiable information was removed and replaced with anonymous identifiers. The privacy and confidentiality of all research subjects were strictly maintained. No compensation was provided to the participants.

Results

Number of Incident Cases and Incidence Rate of Lung Cancer at the Provincial Level

In 2022, there were an estimated 79,672 incident cases of lung cancer in Shandong, including 45,527 males and 34,145 females. The estimated crude incidence of lung cancer in 2022 was 78.40 per 100,000 people. Crude lung cancer incidence rate in males (88.35 per 100,000) was higher than in females (68.15 per 100,000). The ASIR of lung cancer using Segi population was 42.46 per 100,000. The ASIR was 49.19 per 100,000 in males and 36.67 per 100,000 in females, resulting in a male-to-female ratio of 1.34 (Figure 2A).

The incidence of lung cancer rose rapidly after age 50 years, peaked around 75, and gradually dropped in people older than 75 in both men and women. Only in age groups between 35 and 50 was the incidence of lung cancer higher in females than in males.

From 2019 to 2022, the annual growth rate in the lung cancer ASIR in Shandong was within 10%, indicating the reliability of the lung cancer incidence estimates over time (Table S1 in Multimedia Appendix 1).

Number of Deaths and Mortality Rate From Lung Cancer at the Provincial Level

A total of 40,626 lung cancer-specific deaths were ascertained in Shandong in 2022, among which 28,185 were men and 12,441 were women. The estimated crude mortality of lung cancer in 2022 was 39.98 per 100,000 people (54.69 per 100,000 in males, and 24.83 per 100,000 in females). The ASMR of lung cancer using the Segi population was 19.76 per 100,000, which was higher in males than in females (26.29 per 100,000 vs 11.38 per 100,000; male-to-female ratio: 2.56).

Age-specific mortality from lung cancer started increasing after age 50 years and peaked in the age group 75 - 80 years in both sexes (Figure 2B). Except for age groups younger than 45 years, in which both men and women experienced a mortality close to zero, the mortality was consistently higher in males compared with females.

Geographical Disparity of Incidence and Mortality at the County Level

The IQR was substantial for county-level ASIR at 17.13 per 100,000 people (Table 1). The Theil index for the ASIR and ASMR of lung cancer was 0.0605 and 0.0835 for Theil T, and 0.0586 and 0.0787 for Theil L, respectively (Table 2). The overall inequality was primarily due to within-municipality disparities, with the within-municipality Theil index accounting for 0.0572 for ASIR and 0.0824 for ASMR in Theil T, and 0.0261 for ASIR and 0.0295 for ASMR in Theil L. The minimal county-level ASIR was observed in Luozhuang of Linyi Municipality (southern Shandong) at 9.50 per 100,000 people, while the maximum was observed in Shinan of Qingdao Municipality (eastern Shandong) at 158.16 per 100,000 people (Figure 3A; see Figure S3A, S4A, and S5A in Multimedia Appendix 1 for maps for crude county-level incidence rate, crude municipal-level incidence rate, and municipal-level ASIR, respectively. Meanwhile, the IQR of municipal-level ASMR was smaller (10.41 per 100,000 people). The minimal county-level ASMR was observed in Penglai of Yantai Municipality (northeastern Shandong) at 1.41 per 100,000 people, while the maximum was observed in Zhanhua of Binzhou Municipality (northern Shandong) at 38.62 per 100,000 (Figure 3B; see Figure S3B, S4B, and S5B in Multimedia Appendix 1 for maps for crude county-level mortality rate, municipal-level mortality rate, and municipal-level ASMR, respectively).

Discussion

Principal Findings

This study established a novel approach to cancer surveillance by linking data from hospital discharge records and death registries. Using this approach, we estimated that the age-standardized lung cancer incidence and mortality rates were 42.46 per 100,000 and 19.76 per 100,000, respectively, in Shandong, China, in 2022. The IQR of county-level ASIR was 17.13 per 100,000, while the IQR of county-level ASMR was 10.41 per 100,000. The analyses based on Theil indices suggested that the regional disparity of ASIR and ASMR of lung cancer was primarily due to inequality between counties within each municipality. Hotspots of high ASIR and ASMR counties were also identified. This study demonstrates the potential of using routinely collected administrative hospital records in estimating local cancer incidence and death, offering a reliable approach for up-to-date and small-area cancer surveillance in the future.

For internal validation, we assessed the ASIR and ASMR from 2019 to 2022 and found the rates stable during the period (ASIR: average growth rate 2.242% in males, 6.114% in females; ASMR: average growth rate 2.944% in males, 3.289% in females; see Table S1 in Multimedia Appendix 1). Regarding external validation, we found the lung cancer ASIR and ASMR in Shandong in 2022, we estimated (42.46 per 100,000 and 19.76 per 100,000), comparable to those from the national prediction for the same year by the National Cancer Center based on cancer registry data 2010 - 2018 (40.78 per 100,000 and 26.66 per 100,000, respectively) [6]. Similar to the national level estimates, the lung cancer ASIR and ASMR we found were higher in males than in females, with a male-to-female ASIR ratio of 1.34 (1.71 in the national cancer report) and ASMR ratio of 2.56 (2.69 in the national cancer report) [6]. As mentioned earlier, the estimated annual growth rates from 2019 to 2022 for ASIR using this approach were 10% and thus considered stable [37]. Therefore, our findings are in line with previous studies that demonstrated the comparability of hospital discharge data and cancer registry data [16-18].

The analysis in this study revealed within-municipality disparities in lung cancer estimates. High ASIRs and AMSRs were found in counties to the north and east of Shandong Province (see Figure 3), where the economic development level is relatively higher compared with other parts of the province. This association with regional socio-economic status is similar to that in a previous study on global lung cancer burden, which reported positive correlations between ASIR and ASMR and human development index [38]. A possible explanation might be the regional difference in tobacco smoking prevalence, as a survey in 2016 - 2017 in Shandong found a higher prevalence of smoking in the eastern part compared with the middle area [39]. Air quality and access to diagnostic services might also play a role [40]. Yet there is a lack of evidence on the correlation of those factors with lung cancer incidence and mortality on the geographic scale of small areas in China, which may be explored in the future, for example, in Shandong via linking the data in this study with data sources on the distribution of potential factors such as tobacco smoking exposure, air pollution, etc.

Our approach to rapid and local cancer surveillance by linking two administrative datasets has some advantages that warrant its consideration as a complement to cancer registries. First, it allows the rapid estimates of cancer burden. In this study, we used the records up to 2022 to calculate the incidence and mortality in 2022. It achieved much higher timeliness compared with the 6-year delay of cancer registry data [41]. Compared with medical claims data [2], for which a 6-month delay was expected owing to the lag between discharge and reimbursement, our approach using hospital discharge records could be captured in real-time without delay. Indeed, with more up-to-date data, even more timely estimation can be achieved. Second, the hospital discharge records were generated and reviewed by health care professionals during hospitalization and heavily scrutinized by the health administration, which ensured high data quality as demonstrated in previous studies [42-44]. Third, linked records from all hospitals in an area of interest achieved an almost universal coverage of local residents, while the cancer registries in Shandong only covered 33.24% of its population [31]. It is true that if a patient visited hospitals outside Shandong Province, the corresponding record would not be captured in this study. Yet, due to geographical access and higher reimbursement, patients with cancer were generally diagnosed at health care facilities not far from their residences. Therefore, the impact of multiple hospital visits on the identification of incident cancer cases was considered not leading to substantive underestimation of the results in this study. In areas where the cancer registry sites are yet to be established, the approach using routinely collected hospital discharge records may provide reasonably comprehensive cancer statistics. This also offers a potentially powerful solution for generating high-resolution cancer statistics using existing data in China and other low- and middle-income countries.

While administrative data harbor great potential in disease surveillance, among other health-related topics, there are multiple barriers to use administrative data of sufficient volume for research [45]. First of all, the health-related records may not be digitized and structured into a dataset available for data analysis and linkage, especially in low-resource settings. In addition, data linkage algorithms, data accuracy, and coding standardization make synthesizing data across different institutions/regions a challenging project [46,47].

Limitations

This study has some limitations that warrant consideration when generalizing the findings. First, people who only sought cancer care outside Shandong would be missed. This issue would be magnified in an area lacking cancer-specialty resources. However, given that Shandong is a large middle-income province in China with sufficient cancer treatment capacity, it is highly unlikely that a substantial proportion of residents with cancer would rely purely on inpatient care outside the province. Second, outpatient cancer care was not included in this study. However, for an illness as severe as cancer, diagnostic tests, investigations, and confirmed diagnosis can rarely be completely provided in ambulatory settings, and the Chinese Lung Cancer

XSL•FO
RenderX

Clinical Guidelines recommend hospitalization for surgery in almost all cases [43]. Hence, this limitation is unlikely to lead to a serious underestimation of the cancer incidence.

Implications

Our study has some potential implications. First, we have demonstrated the feasibility of producing timely and small-area cancer incidence and mortality rates for a large population in a low- and middle-income setting. Considering the economic disparity within the province, our approach to cancer surveillance would be potentially suitable for a wide range of countries and areas [48]. Second, the increasing availability and standardization of administrative data means that administrative data should be increasingly made use of in generating more timely and spatially precise estimation of cancer incidence and mortality [49-51]. Third, the obvious disparity within the province (particularly within municipalities) suggests the importance of local level surveillance, policy making, and resource allocation that can reveal and address such geographical inequality. Fourth, linking claims data with hospital records and death registry where possible in the future could further improve the accuracy of estimation. It is also recommended that a comparison between the estimation of cancer incidence and mortality using our approach and cancer registries be conducted to further validate this approach based on linked administrative health data.

Conclusions

This study developed and validated a timely and spatially precise cancer surveillance method for a province of 100 million population in China using administrative data. The ASIR of lung cancer was 42.46 per 100,000, with a between-county IQR of 17.13 per 100,000. Meanwhile, the ASMR of lung cancer was 19.76 per 100,000, with a between-county IQR of 10.41 per 100,000. Besides providing new insights for cancer prevention and control in China, our study demonstrates the power of a novel approach linking hospital discharge records with death registries in enabling timely and geographically sensitive cancer surveillance. The fact that such data were routinely generated in this low- and middle-income setting with large population implies wide applicability as a complement to cancer registries.

Abstract

Background: Electronic health care databases are widely used for epidemiological studies. However, they may contain inactive records of individuals no longer participating in the health care system. These inactive records create a methodological challenge as they systematically appear as unexposed with no recorded outcomes. Given the widespread health care system engagement during the COVID-19 pandemic, the English National Health Service (NHS), which hosts a national pandemic planning and research dataset with linkage to COVID-19 vaccination and emergency care data, makes it an ideal setting to identify the extent of overrepresentation due to inactive health care records and assess ways to mitigate them.

Objective: The objective of this study is to report any differences between the general practitioner–registered adult population size based on health care records compared to census estimates for England and to apply methodology that could be used to correct for such differences.

Methods: We compared the number of adult patients within the General Practice Extraction Service Data for Pandemic Planning and Research (GDPPR) with a valid general practitioner registration as of 1st October 2021, with estimates published by the Office for National Statistics (ONS) for the English population. We used an approach adapted from a weighting method to correct for non-response bias in surveys and down-weighted individuals with no evidence of recent activity in their records.

Results: There were 61,194,033 registered NHS patients (in the GDPPR) compared with 56,550,138 in the ONS census-based population. De-duplication on NHS number reduced the population to 57,876,641, including 46,835,968 adults, with the biggest overrepresented group aged 30 - 45 years. Of the 46,835,986, 1,121,954 (2.4%) individuals had their initial weights down-weighted due to non-engagement with the health care system since January 2019. The down-weighting removed most of the differences between NHS and ONS populations.

Conclusions: There are notable differences in the adult population size as per GDPPR when compared to census estimates. While the overall population size in the GDPPR data was seen to be inflated when compared to ONS census estimates, this was differential with respect to sociodemographic variables. A weighting-based approach can be applied to correct for the inflated denominator. Not correcting for it in large health care datasets, including the English NHS data, could introduce selection bias in epidemiological studies.

Introduction

Electronic health care databases are widely used resources for conducting epidemiological studies, offering advantages of potentially large sample sizes, reduced costs, and rapid analysis compared to prospective designs. These databases contain longitudinal patient records from routine clinical practice, enabling researchers to evaluate epidemiological associations in real-world settings across diverse populations. However, the secondary use of data collected primarily for administrative or clinical purposes introduces unique methodological challenges that must be addressed to ensure valid inference [1].

An important challenge in database studies is the presence of inactive records—electronic records of individuals who are no longer active participants in the health care system but remain in the database without formal disenrollment. Unlike traditional loss to follow-up in prospective studies where researchers are aware of missing data, inactive records in electronic databases create a particular form of selection bias because they continue to contribute person-time to analyses despite no longer being under observation. While studies have recognized the issue of inactive records potentially inflating the denominator for database [2-4], the precise extent of the issue has not been fully assessed. The COVID-19 pandemic in England offers a valuable opportunity to study denominator inflation, particularly given the high levels of health care engagement observed during this period [5]. England's National Health Service (NHS) provides comprehensive state-funded health care—including primary, community, and specialist services—to approximately 56 million people, creating an ideal setting for examining this methodological issue.

NHS care includes the provision of medications and the administration of nearly all vaccinations. All NHS patients have a unique personal identifier, an NHS number, which allows records to be linked across NHS services. Additionally, primary care is a registration-based system, with each patient registered with a single general practitioner (GP) [6,7]. Furthermore, NHS computerized medical records (CMRs) have been in use in primary care since the 1980s [8]. Additionally, since 2011, there has been automatic transfer of CMR between practices, even when they use different brands of computer systems [9].

During the COVID-19 pandemic, England was one of the first health systems to use COVID-19 vaccines widely, with high levels of COVID-19 primary series vaccine uptake in adults [10]. The NHS has made a large nationwide cohort available for research through NHS England's trusted research environment (TRE) [11]. This cohort included the NHS primary care data collections, known as the General Practice Extraction Service Data for Pandemic Planning and Research (GDPPR), which was linked at the individual level to COVID-19 vaccination, COVID-19 virology test results, hospital, and death certificate data.

The discrepancy in population size between GDPPR and Office for National Statistics (ONS) census estimates has been pointed out before [4]. The phenomenon, in NHS data, where an individual may have multiple unique health care records because of not notifying the health care system when they moved to a different GP practice [4,12,13] is known by different terms in the literature, including over-registration, "ghost" patient records, and inactive records. We subsequently refer to such records as 'inactive records' in this paper. We aimed to assess the extent of any potential discrepancy in population sizes between the NHS England GDPPR dataset and the ONS census estimates (eg, due to over-registration) and then develop and implement a method to minimize the impact of this discrepancy for epidemiological studies.

Methods

Data Source

We used de-identified routinely collected electronic health care record data from primary and secondary care in England accessed via the NHS Digital TRE. Access to the NHS Digital TRE was obtained through a Data Access Request Service (DARS) application. The linked data used for this analysis included GP registration data from GDPPR [10], COVID-19 Second Generation Surveillance System from Pillar 1 and Pillar 2 for COVID-19 PCR testing data, COVID-19 vaccination status data, and Hospital Episode Statistics. Linked and pseudonymized patient-level data were provided to us by NHS Digital within the secure TRE. Details on the data flow, end-to-end linkage process, and data privacy can be found on the NHS Digital website [14]. We used data as of October 1, 2021, for our analyses. In this linked dataset, patient age and sex were obtained from the GDPPR and Personal Demographics Service. The other variables used in this analysis (COVID-19 status, vaccination status, and health care engagement) were defined as yes or no binary flags based on the information from the relevant data source (Second Generation Surveillance System for COVID-19 status, Hospital Episode Statistics for hospital admission).

We assessed the total number of unique, pseudonymized patient identifiers with a valid GP registration as of October 1, 2021, and compared it to estimates published by the ONS for the English population over a comparable time period [15,16]. We refer to this overall GP registration estimate as the "population denominator," as this will constitute the source population that study-specific cohorts will be constructed from in epidemiological studies that will use these CMR data. We then implemented a method for the denominator correction based on the approach used in a Scottish vaccine pharmacovigilance study [17,18] which is, in turn, based on a weighting method to correct for non-response bias in surveys [19]. We adapted this method to apply to the NHS England data.

Step 1

We obtained data from NHS England from GP practices in England as of 1 October 2021. Duplicate records and records missing age and sex were excluded. We used age, sex, and NHS region as the sociodemographic variables for the population weighting. These variables were chosen on the basis that these are some of the key determinants of the differential representation of population groups in the NHS England data [12].

XSL•FO
RenderX

Step 2

We restricted these analyses to those aged 18 years and over for consistency with the UK COVID-19 vaccine rollout policy and also due to difficulties with validating children's GP registration data.

Step 3

We obtained population proportions from the ONS on the projected mid-2020 English population stratified for each year of age (≥18 y) for males and females by the following NHS regions: East of England, London, Midlands, North East and Yorkshire, North West, South East, and South West.

Step 4

Each individual record in the NHS England analytic dataset was then assigned a weight to match the target distributions obtained from Step 4 such that the weights add up to the target population size (ie, England's mid-2020 population). These weights were derived using age, sex, and NHS region. For each individual, k, within the NHS England population, the initial study weight, w, was calculated as:

$$w_{ijrk} = N_{ijrk} / n_{ijrk}$$

where N is the number of individuals in the ONS census population in age group i with sex j and region r, and n is the corresponding figure for the NHS Digital population.

Step 5

Patient records with recent health care system engagement, defined as *any* of the following since 1st January 2019: GP consultation, hospitalization, laboratory test results, COVID-19 testing, and COVID-19 vaccination were reweighted to 1, as such an encounter would confirm that the individual health care record is active.

Step 6

Weights for those patient records without a recent health care system engagement were updated such that the total revised weights (in the overall NHS England data) sum to the ONS estimate of the population of England age ≥18 years. For each individual, k, in age group i with sex j and region r, the revised weight, w*, was calculated as follows:

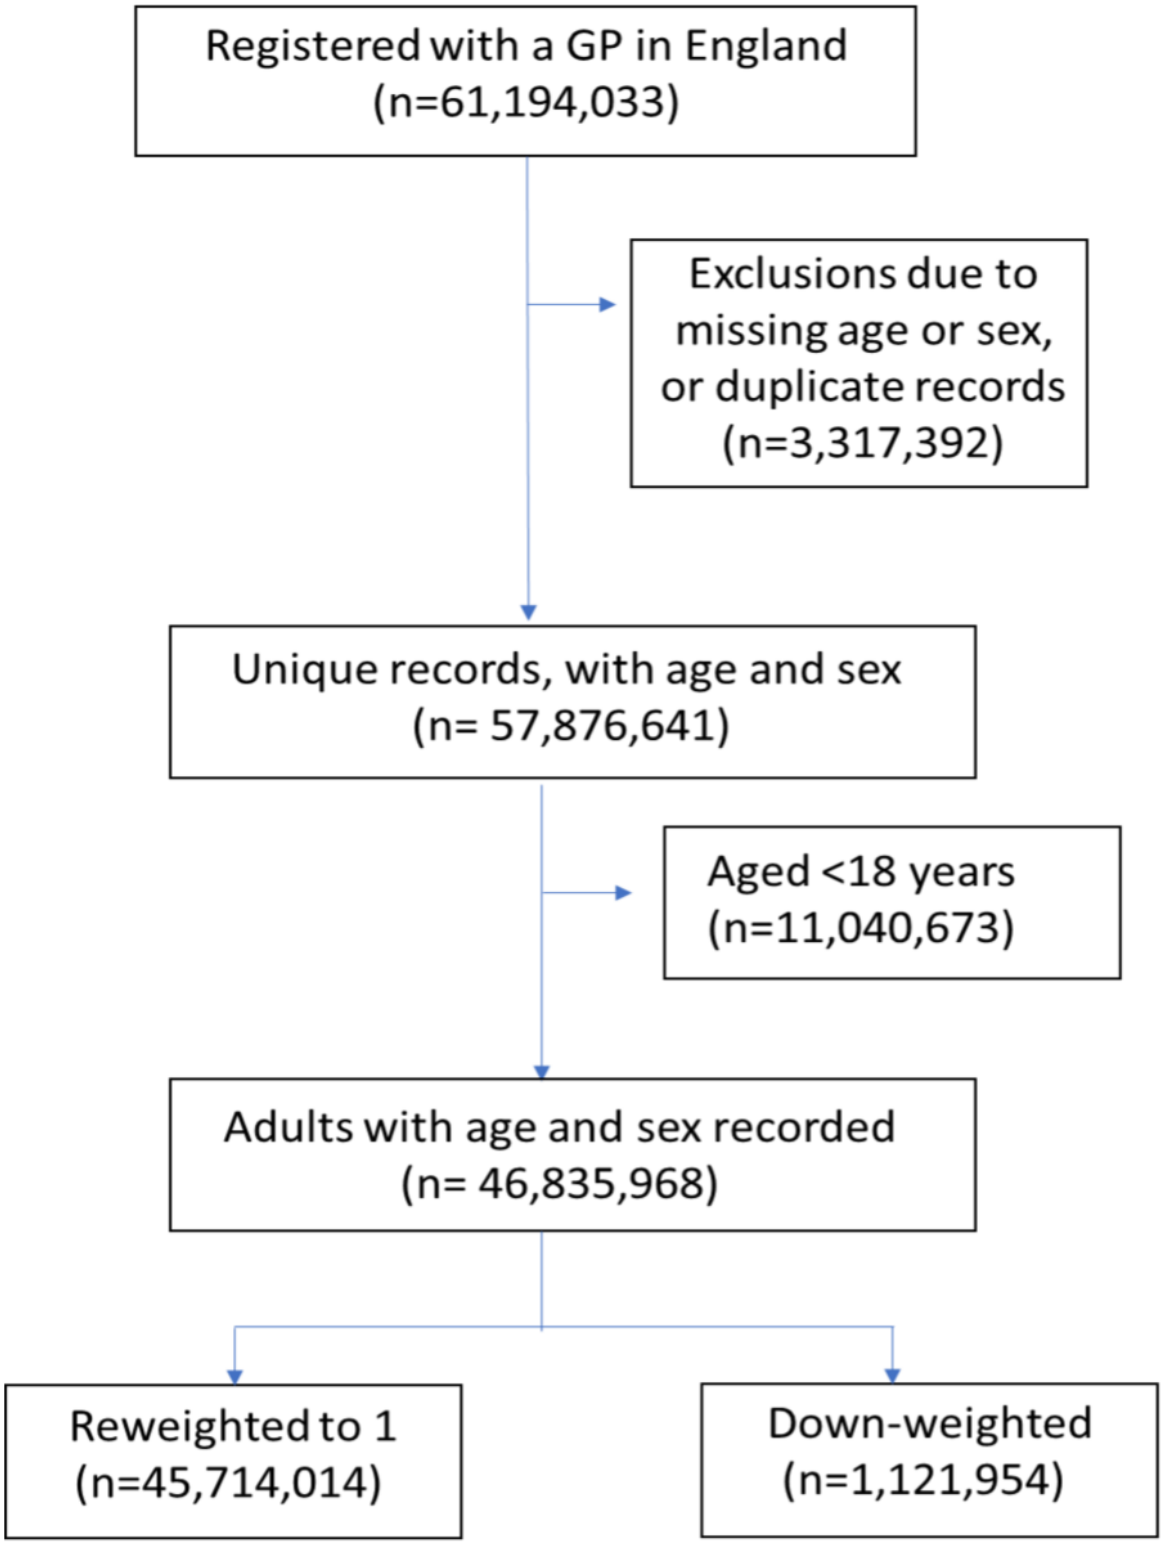
$$w^*_{ijrk} = S_w - S_h / S_{w_nh} - S_{wnh}$$

where S_w is the sum of the original weights (and therefore equals the total ONS population size), S_h is the sum of the updated weights for individuals with a recent health care engagement (as defined in Step 5), and S_{w_nh} is the sum of the original weights (assigned in Step 4) of individuals without a recent health care engagement.

A validation of the revised weights was performed by comparing the patient profile (in terms of age, sex, and region) of the unvaccinated population in the NHS England data to the unvaccinated patient profile information provided by the ONS [20].

Finally, we also conducted an illustrative bias analysis to demonstrate the impact of the bias introduced by not accounting for inactive records in a hypothetical vaccine effectiveness (VE) study.

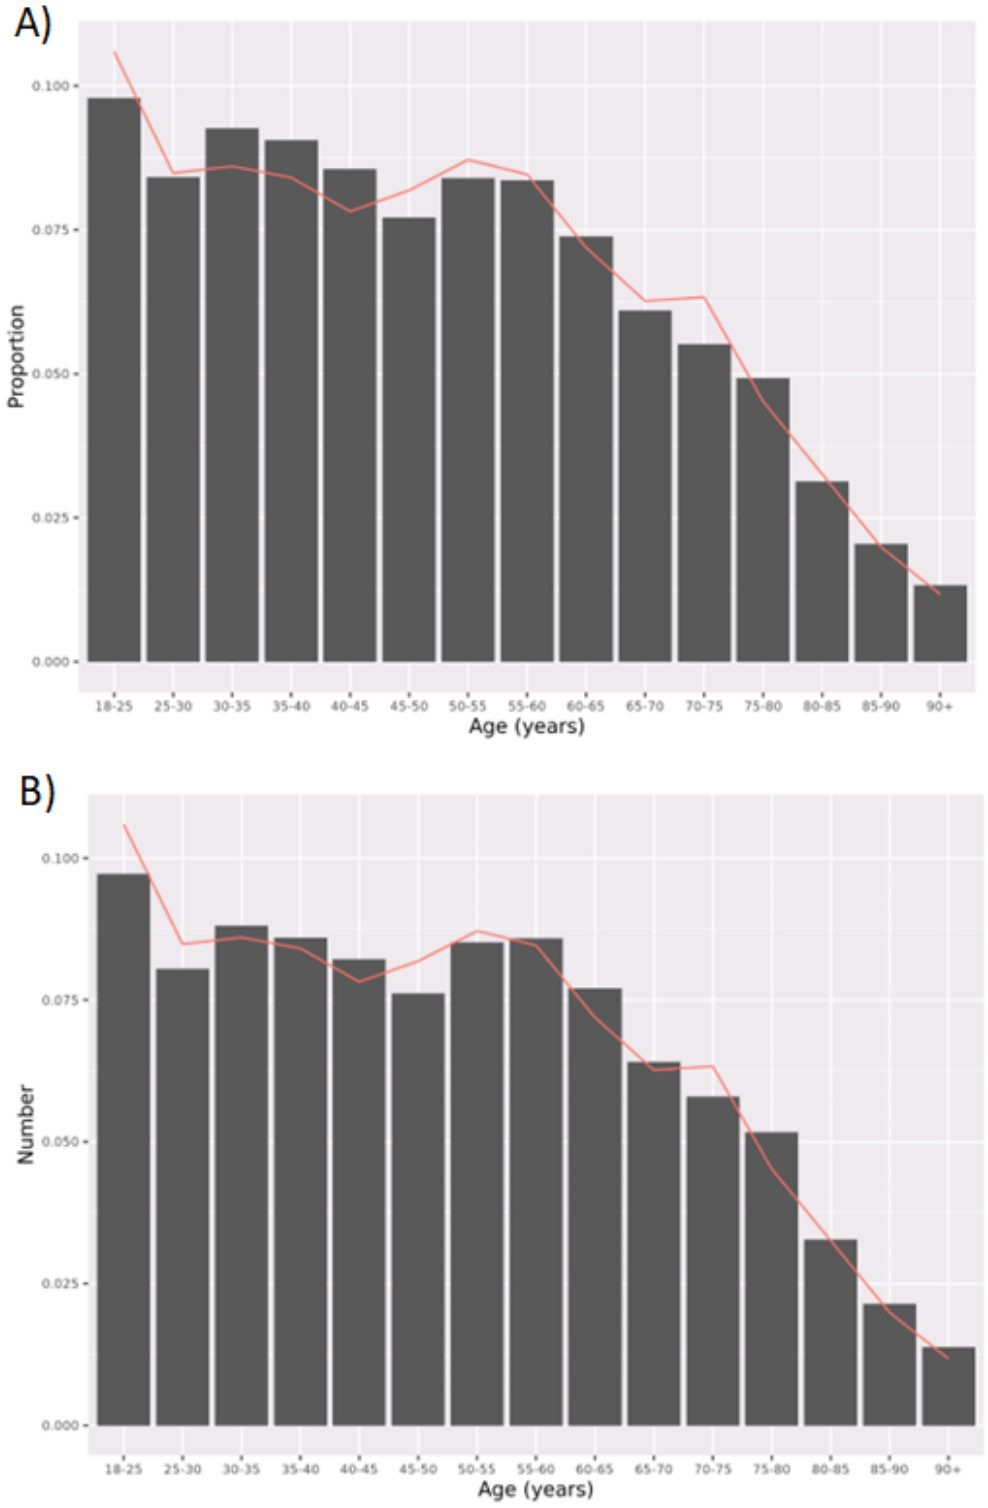
Ethical Considerations



We undertook this work as a part of the RAVEN study, which investigated the effectiveness of the AZD1222 vaccine using CMR from England (Real-world Oxford/AstraZeneca Vaccine Effectiveness Study in England; NCT05047822) [21].

Results

There are 61,194,033 individuals registered at GP practices in England as of 1 October 2021, according to NHS England [22]. However, the ONS estimated the population of England to be 56,550,138 in mid-2020 (including 44,456,850 records for individuals aged ≥18 y) [23]. After de-duplication (ie, removing duplicate records with the same pseudonymized patient identifier) and removing records with missing age or sex, the NHS England data had a total of 57,876,641 unique NHS numbers (including 46,835,968 records for individuals aged ≥18 y) (Figure 1). Age-stratified (categories of age) counts of the NHS England population when compared to ONS estimates revealed that individuals aged 30 - 45 years were the most overrepresented groups, and those between 65 and 75 years were among the most underrepresented (Figure 2).



XSL•FO
RenderX

Figure 1. Study flow diagram showing exclusions at each stage.

XSL•FO
RenderX

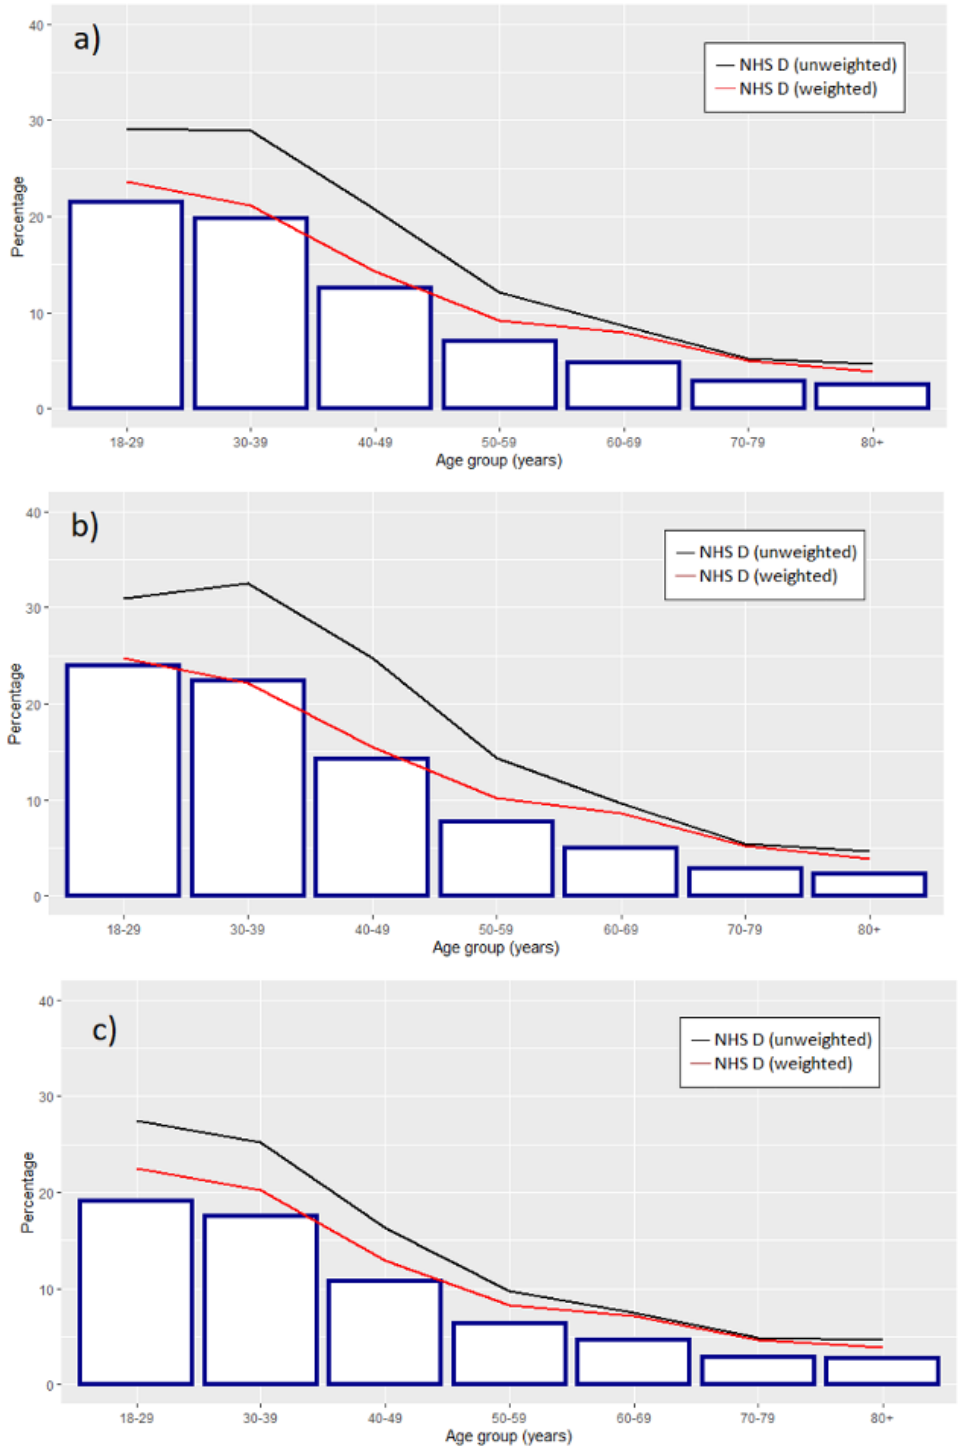
Figure 2. Age distribution (by age group) of the NHS England data (columns) compared to ONS Census data (line) (A) before and (B) after applying weights for inflated denominator correction.

A total of 97.6% of the NHS England adult population had their initial weights revised to 1 on the basis that they had had some form of engagement with the health care system. Of 46,835,968 individuals, 1,121,954 (2.4%) had their initial weights down-weighted due to non-engagement with the health care system since January 2019. The median (IQR) age of the overall NHS population (≥18 years) was 48 years (18-63), whereas the median (IQR) of the down-weighted population was 36 years (18-44). Of the 46,835,968 NHS England records (population aged ≥18 years), 82% had a record of at least 1 COVID-19 vaccination, 62% had a record of a COVID-19 test, 97% had a recorded GP visit, 28% had been admitted to hospital at some point, and 24% had a record of a lab result (any lab test for any condition) since the 1st of January 2019.

Once the final weights were derived, the magnitude of the overrepresentation of the 30 - 45 years age category was

XSL•FO
RenderX

decreased, although some degree of overrepresentation in these age groups still persisted (Figure 2).



To assess the impact of the denominator correction, we compared the age and sex distribution of the weighted (denominator corrected) population to the unvaccinated patient profile published by the ONS (in individuals aged ≥18 years between 8/12/2021 and 31/12/2021) based on a subset of the national population [20]. Overall, large differences were seen between the unweighted NHS England data and the ONS estimates. These differences were largely minimized when using the denominator-corrected weighted NHS England data. The most overrepresented group in the NHS England data appeared to be those aged 30 - 45 years (Table 1). While most of the overrepresentation in the age groups between 18 and 49 years was seen to have been corrected for when using the weighted data, some degree of overrepresentation was still seen in the age groups between 50 and 80+ years (Table 1, Figure 3, and Multimedia Appendix 1).

Table . Comparison of age distribution of the NHS England data compared to ONS census data before and after weighting.

Age, years	ONS (%)	NHS Digital	
		Unweighted (%)	Weighted (%)
18-25	10.6	9.8	9.7
25-30	8.5	8.4	8.1
30-35	8.6	9.3	8.8
35-40	8.4	9.1	8.6
40-45	7.8	8.6	8.2
45-50	8.2	7.7	7.6
50-55	8.7	8.4	8.5
55-60	8.5	8.4	8.6
60-65	7.2	7.4	7.7
65-70	6.3	6.1	6.4
70-75	6.3	5.5	5.8
75-80	4.5	4.9	5.2
80-85	3.2	3.1	3.3
85-90	2.0	2.0	2.2
90+	1.2	1.3	1.4

Figure 3. Comparison between the age distributions in the NHS England weighted and unweighted data and the ONS published data among unvaccinated individuals in (A) the overall population, (B) males, and (C) females. NHS D: GDPPR data from the NHS Digital Trusted Research Environment.

In our bias analysis, for a hypothetical VE study, we assumed an analytic dataset of 10,000 individual records. In Scenario A (reference case), we correctly excluded all inactive records, analyzing only the 9700 active patients. With 60% vaccination coverage, a 1% event rate among vaccinated and a 5% event rate among unvaccinated individuals, we calculated a true VE of 70%. In Scenario B, we incorrectly included 300 inactive records (3% of total) in the analysis, all classified as unvaccinated with no events. This inflated the unvaccinated denominator to 4180 while keeping the event count unchanged, resulting in an underestimated VE of 67.7%, representing an absolute bias of 2.3% (−3.3% relative bias). In Scenario C, we implemented the weighting approach described in this paper, where inactive records received a mean weight of 0.2 and active records a mean weight of 0.9. This approach effectively reduced the contribution of likely inactive records while maintaining

XSL•FO
RenderX

most of the influence from active records. The weighted analysis yielded a VE estimate of 69.5%, much closer to the true VE seen in Scenario A with only a 0.5% absolute bias (−0.7% relative bias). A higher level of denominator inflation will be associated with a greater degree of absolute bias in VE estimates if inactive records are not accounted for (Multimedia Appendix 2).

Discussion

Main Findings

Our assessment of the NHS England GDPPR data showed that the population size of individuals registered with a GP in England was inflated overall, but specific age groups were underrepresented when compared to the ONS census estimates. The differential nature of the discrepancy could cause certain demographic groups to be over- or under-represented in the NHS England data, which in turn has the potential to influence the results of epidemiological studies that use these data. Possible reasons for "over-registration" and the presence of these inactive records include young, mobile individuals who may have moved out of the country. The NHS number was introduced in 1995; its precise structure and systematic use within NHS information systems were made mandatory in 2009 [24]. Prior to this, multiple registrations were possible. Over-registration has also become much less of a problem since GP2GP transfer of records was introduced in 2011 [9].

Comparison With Other Studies

Inactive electronic medical records are known to be correlated strongly with sociodemographic factors [12,25], which is a finding that our study corroborates. While methods proposed to adjust for this inflated denominator include data-cleaning exercises [12] and identifying an "active patient" denominator through a validation sample [2], the success of these methods relies on selecting a representative validation sample, and given the large sociodemographic and spatial variation in denominator inflation, this may not be feasible. The COVID-19 pandemic period, which saw nationwide engagement with the NHS, could provide a unique opportunity to infer the "active" status of a patient's records. We have described a method to first identify the extent of the denominator inflation by inferring "active" registrations through engagement with the health care system (ie, GP consultation, hospitalization, laboratory test result, COVID-19 testing, or COVID-19 vaccination) during the pandemic period and then to correct for it by reducing the weights of those records that did not have any engagement with the health care system during this period. A similar weighting approach that was derived based on population age and sex distribution has been successfully implemented in a series of COVID-19 VE studies based on Scottish data [17,26,27]. We adapted to the English context by also taking regional variability into account. We note that in cohort profiles for OpenSafely and Clinical Practice Research Datalink, similar differences are seen between the adult age-sex profile and ONS data [28,29]. In this paper, we specifically looked at the NHS data in England; however, this issue is a wider problem that could occur in other secondary health care databases as well.

Implications

Not properly accounting for the inflated denominator in NHS England data could introduce selection bias if it results in follow-up time being differentially accrued in one of the study arms. We illustrated the impact of inactive medical records on a hypothetical VE study in a bias analysis. Inactive records systematically appear as unvaccinated, since they cannot receive documented vaccinations, and without recorded outcomes, since events cannot be documented. This biases the association between vaccination and the outcome of interest by artificially inflating the denominator of unvaccinated individuals without a corresponding increase in events, leading to underestimation of event rates in the unvaccinated group and consequently underestimation of VE. The weighting method that we have proposed seeks to address this bias by decreasing the amount of information contributed to by records with lower weights, which are more likely to be inactive records. Our approach made the observed vaccination and outcome status more closely approximate to the true vaccination and outcome status. The extent of this selection bias will depend on the degree of denominator inflation and also on the sociodemographic factors that the inflation is differential with respect to. The success of the weights in minimizing the impact of selection bias from inactive records will depend on the extent to which they can approximate the true vaccination and outcome status.

We identified an average of 2.4% inflation in the population aged ≥18 years, with this being much higher within specific sociodemographic groups. Indeed, population underrepresentation (as seen in the 65 - 75 y age group) would also result in a similar type of selection bias. Our weighting approach accounts for both underrepresentation and overrepresentation using the same method, ie, reducing the weights of those records without a recent health care system engagement during the COVID-19 pandemic.

Strengths and Limitations

A strength of the weighting approach that we propose is that these individual records are not discarded entirely. The estimated weights can be thought of as confidence scores for each record, and when taken into account in a weighted regression model, they still allow the down-weighted records to contribute information to the model but minimize the impact of any selection bias. The weighting method that we have applied sits within the paradigm of inverse probability weighting methods that are widely used to minimize confounding in epidemiological studies [30]. Current approaches to addressing the impact of inactive records have notable limitations. Complete case analysis that attempts to exclude inactive records often relies on arbitrary rules, such as requiring a minimum number of health care encounters within a specified period. However, such approaches may inadvertently exclude truly healthy individuals with legitimately low health care utilization, introducing another form of selection bias. Alternatively, ignoring the issue by including all records risks substantial underestimation of VE, as our bias analysis demonstrates. Validation samples, where a subset of records undergoes intensive verification through direct patient contact or linkage to external data sources, provide gold-standard identification of inactive records but are

XSL•FO
RenderX

resource-intensive and often infeasible at scale. Probabilistic linkage to external data sources (eg, death registries, migration records) can identify specific causes of inactivity but may miss others and introduce complex data governance challenges. Statistical multiple imputation approaches handle uncertainty in inactive status but rely on correctly specified imputation models and may be computationally intensive for large databases. Our proposed weighting method offers several advantages: it retains all available data, acknowledges uncertainty in inactive status classification, can incorporate diverse predictors of inactivity, and is computationally efficient even with millions of records. However, it requires careful validation of the weighting algorithm and may be sensitive to misspecification of the weighting model. The optimal approach likely depends on specific study contexts, with hybrid methods potentially offering the most robust solution for large-scale VE studies. This is an avenue for future research.

Our method for denominator correction has other limitations as well: It assumes that reference population estimates used to derive the weights are based on perfect information. The limitations of ONS census estimates are well-known [12], and it is indeed possible that sociodemographic determinants of census completion are correlated with GP registration. Further, we do not include ethnicity and social deprivation in our analysis, which is a limitation of our weighting scheme. There is evidence to suggest that ethnicity and social deprivation are other key determinants of over-registration [12], but explicitly including these variables in the weighting would require that marginal frequencies be available for the variables in both the GP records database and the census data, which were not available for this analysis. The IMD score, which is the national mapping of deprivation, uses postcodes as of 2019, which means newer postcodes since then do not have a mapping [31]. Further, ethnicity recording is not usually complete either and may need supplemental mapping [32], which would bring with it additional complexities when analyzed. The robustness of a weighting scheme that does not explicitly account for ethnicity or socioeconomic deprivation will hinge on the extent to which the NHS region can be used as a proxy for the 2 variables. Finally, the weighting system does not distinguish between genuine inactive records versus active records of individuals who may have chosen not to engage with the health care system during the pandemic, therefore, potentially also assigning a low weight to these individuals.

Our method does not correct for inherent limitations of the reference population data used. We have also limited the analyses presented in this paper to the adult population (≥18 y), as there are challenges with using census data to validate primary care records of children. Also, we have only explored variables in primary care and have not allowed for diagnoses made in secondary care (eg, cases of chronic liver disease), which may compensate for the gap in primary care diagnosis.

It is also worth noting that while the widespread health care engagement that was observed in England during the COVID-19 pandemic provided a unique opportunity to assess the active status of health care records, a similar population-wide engagement is unlikely in the near future. The ascertainment of the size of the inactive population and application of our weighting method could potentially also be extended to non-pandemic periods. For instance, the weighting algorithm could incorporate routine health care utilization patterns as predictors of active status, including prescription refill consistency for chronic medications, attendance at preventive screenings, completion of age-appropriate vaccinations, and regular check-ups for specific demographic groups (eg, prenatal visits, well-child visits, and geriatric assessments). Validation could follow a three-pronged approach: (1) temporal validation comparing algorithm performance across different calendar periods, (2) external validation through linkage with a subset of verified active or inactive statuses from administrative sources, and (3) sensitivity analyses examining how varying thresholds of predicted inactivity affect VE estimates. Researchers should calibrate weights to their specific health care system's characteristics, accounting for factors like insurance coverage patterns, referral requirements, and electronic record integration across care settings, which all influence the observable signals of patient activity. This methodological challenge presents a rich opportunity for future research to further develop and validate standardized approaches for addressing bias in epidemiological studies due to the presence of inactive records.

Conclusions

Denominator inflation in large CMR datasets is a known issue. In this paper, we provide tools for identifying an active population in the NHS England data using a system of sampling weights to minimize the selection bias introduced by denominator inflation. We recommend, where appropriate, that epidemiological analyses of large CMR datasets, including the NHS England data, be implemented as weighted regressions taking into account the likelihood of population over- or under-representation. This is especially necessary for closed data access mechanisms on such data where analyses are often performed in specific defined datasets and an assessment of the impact of mis-specifying the denominator may be difficult, or impossible, to undertake.

Acknowledgments

This work was funded by AstraZeneca. We would also like to thank Julian Sherlock for his contributions in preparing the dataset that was used for the analyses described in this paper.

Abstract

Background: Population size estimation (PSE) for key populations is needed to inform HIV programming and policy.

Objective: This study aimed to examine the utility of applying a recently proposed method using Google Trend (GT) internet search data to generate PSE (Google Trends Population Size Estimate [GTPSE]) for men who have sex with men (MSM) in 54 countries in Africa, Asia, the Americas, and Europe.

Methods: We examined GT relative search volumes (representing the relative internet search frequency of specific search terms) for "porn" and, as a comparator term, "gay porn" for the year 2020. We assumed "porn" represents "men" (denominator) while "gay porn" represents a subset of "MSM" (numerator) in each county, resulting in a proportional size estimate for MSM. We multiplied the proportional GTPSE values with the countries' male adult population (15 - 49 years) to obtain absolute size estimates. Separately, we produced subnational MSM PSE limited to countries' (commercial) capitals. Using linear regression analysis, we examined the effect of countries' levels of urbanization, internet penetration, criminalization of homosexuality, and stigma on national GTPSE results. We conducted a sensitivity analysis in a subset of countries (n=14) examining the effect of alternative English search terms, different language search terms (Spanish, French, and Swahili), and alternative search years (2019 and 2021).

Results: One country was excluded from our analysis as no GT data could be obtained. Of the remaining 53 countries, all national GTPSE values exceeded the World Health Organization's recommended minimum PSE threshold of 1% (range 1.2% - 7.5%). For 44 out of 49 (89.8%) of the countries, GTPSE results were higher than Joint United Nations Programme on HIV/AIDS (UNAIDS) Key Population Atlas values but largely consistent with the regional UNAIDS Global AIDS Monitoring results. Substantial heterogeneity across same-region countries was evident in GTPSE although smaller than those based on Key Population Atlas data. Subnational GTPSE values were obtained in 51 out of 53 (96%) countries; all subnational GTPSE values exceeded 1% but often did not match or exceed the corresponding countries' national estimates. None of the covariates examined had a substantial effect on the GTPSE values (R^2 values 0.01 - 0.28). Alternative (English) search terms in 12 out of 14 (85%) countries produced GTPSE>1%. Using non-English language terms often produced markedly lower same-country GTPSE values compared with English with 10 out of 14 (71%) countries showing national GTPSE exceeding 1%. GTPSE used search data from 2019 and 2021, yielding results similar to those of the reference year 2020. Due to a lack of absolute search volume data, credibility intervals could not be computed. The validity of key assumptions, especially who (males and females) searches for porn and gay porn, could not be assessed.

Conclusions: GTPSE for MSM provides a simple, fast, essentially cost-free method. Limitations that impact the certainty of our estimates include a lack of validation of key assumptions and an inability to assign credibility intervals. GTPSE for MSM may provide an additional data source, especially for estimating national-level PSE.

Introduction

The Joint United Nations Programme on HIV/AIDS (UNAIDS) estimated that in 2022, about 39 million people were living with HIV worldwide [1]. HIV burden is higher among men who have sex with men (MSM), people who inject drugs, sex workers, and transgender persons, which together are often described as key populations (KP) [1]. KPs and their paying or nonpaying sexual partners may account for 70% of new HIV infections worldwide, with an estimated 80% of new HIV infections outside sub-Saharan Africa (SSA) and 55% of all new infections within SSA [1,2].

Key population size estimation (PSE) is needed to estimate the number of individuals belonging to a KP in a given geographical area [3,4]. PSEs provide the denominator values to inform KP programming and policy [5]. However, PSE is a difficult field and its methods often lack rigor in design or implementation, and the many methods available reflect the lack of an acceptable gold standard [3,6]. Challenges to PSE include lack of sampling frames, mobility, and nondisclosure of KP-defining behaviors [3,4]. Further, most PSE methods produce local estimates whereas national PSE estimates are often obtained through "expert opinion," simple projection, or modeling and less often through national-level empirical data such as direct survey questions or the network scale-up method, both used in general population-based surveys [6,7]. Direct survey questions about KP-defining traits experience reporting bias and require a major effort unless they can be added to an already planned general population survey. The frequent lack of reliable national-level PSE constitutes an even larger challenge compared with the availability of local PSE and complicates national, regional, and global HIV estimation work [3,8-10].

The rise of the internet facilitates web-based activities to improve public health, including in the field of digital epidemiology and infoveillance [11]. Recently, a new PSE method using Google Trends (GT) internet search data was proposed in a proof of concept paper by Card et al [12] GT is a free cloud-based app that displays the relative frequency of user-specified Google search terms as trends across time and user-selected geographical areas [12-14]. Card et al [12] used GT and Canadian census data to estimate the local PSE of MSM in urban and rural locations throughout Canada. Card et al [12] related search terms presumed to be representative of MSM ("gay porn") to that presumed to be representative of the general (male) population ("porn"). By relating these 2 sets of values, Card et al [12] estimated the relative size of MSM in these Canadian towns. To date, no other published PSE exists using this method.

The literature on pornography consumption by sex and sexual orientation is limited and often the MSM population is not represented. However, a major porn website reported that about a third of its visitors globally in 2021 were reportedly women [15,16]. Further, women, regardless of sexual orientation, may also watch gay porn, possibly in substantial numbers [17]. Beyond this, we found no meaningful gray literature or peer-reviewed articles about internet pornography consumption in low- and middle-income countries (LMICs) or pornography consumption by MSM in LMICs. We are also not aware of (gray) literature about the proportion of heterosexual and homosexual men searching Google for (gay) porn in LMICs.

We expanded the literature search to include high-income settings. A study conducted in the United States reported that more men than women consume pornography (92%:68%, respectively) over the span of a year [18]. The study did not report the type of pornography consumed or disaggregate male respondents by sexual orientation or practice [18]. A separate study from Norway with a sample of some 2300 male and female participants suggested that more men than women consume some pornography (94% of men and 68% of women) [19]. However, only 5% (n=106) of participants identified as gay/lesbian/bisexual, no breakdown of sexual orientation by sex was given, and no information on the type of pornography consumed by participants was available [19].

The aim of this study was to examine the potential utility of using GT data to obtain MSM PSE in selected LMICs.

Methods

Preliminary Literature Search

A nonsystematic literature search was conducted to better understand the behavior of pornography consumption of the general population and sexual minorities, by sex, as well as the relative frequencies with which these populations search for (gay) porn in general (via Google) or by directly accessing specific porn sites.

Selection of Countries

We analyzed GT data for a selected set of 54 countries that receive support from the US President's Emergency Plan for AIDS Relief, the US Government's initiative to support global HIV responses, for which information on MSM PSE has been sought [2,20]. These countries are located in SSA (n=29), Asia (n=13), the Americas (n=11), and Ukraine (Tables 1 and 2).

[a]These estimates are for descriptive purposes only, to examine issues related to the potential utility of the method proposed by Card et al [12]. They represent the MSM population national population size estimates (percentage of MSM) for the year 2020. The percentage of MSM was calculated by taking the average relative search volume score produced by Google Trends for "gay porn" and dividing it by the average relative search volume score produced by Google Trends for "porn." MSM population size estimate (number of MSM) was calculated by taking the percentage of MSM population size estimate and dividing it by the total male population (ages 15 - 49 years). Key populations (KPs) Atlas percentage of MSM population size estimate was calculated by dividing the absolute MSM population size estimate taken from the United Nations Programme on HIV/AIDS (UNAIDS) KPs Atlas dashboard by the total adult male population (ages 15 - 49 years), and then multiplying by 100. The absolute value difference was calculated by subtracting the GT absolute MSM population size estimate value from the KPs Atlas MSM population size estimate absolute value. All absolute values under 10,000 are rounded to the nearest 100. All other absolute values are rounded to the nearest 1000. UNAIDS Global AIDS Monitoring system (GAM) values are regional values transcribed from the UNAIDS open-source Spectrum 6 guide. The countries used to create these regions and respective values may not be in full alignment with the countries included in the population size estimate analysis, therefore direct 1:1 comparisons should not be made. Max:Min ratio: The ratio based on the largest and smallest PSE % value in each region.

[b] Absolute values are not provided as Google Trends does not provide absolute search frequency values.

[c]UNAIDS: United Nations Programme on HIV/AIDS.

[d]GAM: Global AIDS Monitoring system.

[e]IQR values were included for available regions. Regions without an IQR listed did not have one available.

[f]KP: key population.

[g]Max:Min ratio: 1.6 (GT) and 2.3 (UNAIDS KP).

[h]Not available (data missing for the country).

[i]Max:Min ratio: 2.2 (GT) and 12.9 (UNAIDS KP).

[j]Max:Min ratio: 2.3 (GT) and 86.3 (UNAIDS KP).

[k]Max:Min ratio: 6.3 (GT) and 51.3 (UNAIDS KP).

[l]Max:Min ratio: 1.5 (GT) and 5 (UNAIDS KP).

[m]Max:Min ratio: 1.2 (GT) and 2.4 (UNAIDS KP).

Table . Regional median Google Trends Population Size Estimate, United Nations Programme on HIV/AIDS (UNAIDS) Global AIDS Monitoring system (GAM), and key populations (KP) Atlas for men who have sex with men (MSM) populations for the year 2020.[a]

Region	Median regional percentage MSM population size estimation[b]		
	GT[c], %	UNAIDS GAM, %	UNAIDS KP Atlas, %
Eastern Africa	1.64	1.67	0.24
Southern Africa	1.68	1.67	0.83
West Central Africa	1.73	1.28	0.40
Asia	2.86	1.63	—[d]
Europe	2.86	2.11	1.47
Caribbean	3.60	2.71	3.17
Central & South America	5.26	3.37	2.54

[a]Absolute values are not provided as Google Trends does not provide absolute search frequency values.

[b]Google Trends (GT) and KP Atlas regional estimates only include estimates from included countries with available data (Table 1). UNAIDS GAM data separate regions differently and include countries that vary from our GT or the KP Atlas regional data: UNAIDS GAM includes eastern and southern Africa in 1 estimate and separates Asia and Europe into 2 estimates (1.63% for Asia and the Pacific, 2.11% for Eastern Europe and Central Asia). Region names were not adjusted in the above table to align with GAM data.

[c]GT: Google Trends.

[d]Not available.

Ethical Considerations

No ethics or review board approval or informed consent was obtained or applicable for this work. All data used in this paper are anonymous, aggregate, and publicly available and sourced.

GT-Based Population Size Estimation

GT provides results based on exact search terms, unlike the "topical" search results that Google's main search engine provides. GT does not provide absolute search frequency values; instead, GT offers relative search volume (RSV) values across time (eg, 52 wk) in a specified space (eg, Kenya), ie, it normalizes search frequencies for specific search terms (eg, porn) to a range from 0 to 100, where a search term's maximum frequency (for the specified geographic area and during the specified time frame) is set at 100 and 0 reflects no search for that term [11,13,14]. Importantly, GT allows users to add "comparator" terms (eg, gay porn) next to the main term (eg, porn); the RSV values for such comparator terms are normalized against the main term's RSV values [13,21]. For the purpose of PSE calculation, the main term "porn" may represent all men whereas the comparator term "gay porn" may be viewed as a subset of men who represent the subpopulation of gay men or MSM. To generate an MSM PSE from the RSV values we divide the comparator RSV value (gay porn) by the larger same-time, same-place RSV value (porn).

National Size Estimates

PSE data collection was carried out through GT's application [13]. We applied this analytic approach for the year 2020 using "porn" and "gay porn" as the main and comparator search terms for each of the 54 countries. The time period for data collection was set as the year 2020, the most recent year for which we could obtain all necessary data for this analysis. Weekly RSV values for "porn" and "gay porn" for the year 2020 were exported, summed, and proportional size estimates obtained. For example, for Botswana, the average of the weekly RSV values for "porn" was 78.3, the corresponding average for "gay porn" was 1.66 and the proportional PSE was therefore calculated as 1.66/78.3=2.1%. This was repeated for all countries. We then calculated the absolute Google Trends Population Size Estimate (GTPSE) by multiplying the proportional GTPSE by the total male population aged 15 - 49 years in each country, the most used age range for KPs. The sizes for countries' 15 - 49 year-old male general population in 2020 were obtained through Spectrum (version 6.1, Avenir Health).

Local Size Estimates

GT data can be restricted to subnational areas. Separately from national estimates, for each country, we also attempted to obtain local GTPSE for the political (or, if different, commercial) capital city. Where data were unavailable for the political or commercial capital city, we used data from the district that contained the capital city. The calculation to obtain relative GTPSE was then the same as for the national level. We did not produce absolute subnational GTPSE.

Consistency of GTPSE Results With WHO-Recommended Minimum Estimate

We assessed whether the GTPSE results met the World Health Organization (WHO) and UNAIDS recommendation that national MSM PSE should represent at least 1% of the general adult male population [22,23].

Comparability

We compared the country-level GTPSE against 2 reference data sources used by UNAIDS: the KP Atlas database and the Global AIDS Monitoring system (GAM) [22,24,25]. The KP Atlas database stores countries' self-reported absolute MSM size estimates using a wide range of PSE methods, often projected up to national scale from local estimates, with primary data collected over different periods of time. Proportional KP Atlas

XSL•FO
RenderX

PSE values were computed by dividing the absolute MSM PSE values from the KP Atlas over the male general population (15 - 49 years). UNAIDS' GAM is a global data warehousing system that informs policy and facilitates monitoring, including KP size estimates. Using GAM data, UNAIDS curated a table with regional relative MSM PSE (median and IQR) deemed reasonable.

Covariates Potentially Affecting GTPSE

Overview

We examined the potential effect of select covariates on the relative GTPSE values by performing regression analysis for each covariate. The country-specific covariates we examined included internet penetration, urbanization, stigma, and criminalization of homosexuality. The covariate data are provided in Table S1 in Multimedia Appendix 1; these data were not used to adjust GTPSE values.

Internet Penetration and Urbanization

Internet penetration data were extracted from the World Development Indicators database through the World Bank and the Internet World Statistics database, indicating the percentage of each country's total population with access to the internet. Urbanization data were obtained from the World Development Indicators database through the World Bank, indicating the percent of the total population in each country considered urban [26,27].

Stigma

Country-level stigma values were extracted from the Global Acceptance Index [28]. This index was developed using computer modeling informed by responses to questions that measure attitudes toward lesbian, gay, bisexual, transgender, or intersex people from 11 different global surveys to create a stigma score in 175 countries toward lesbian, gay, bisexual, transgender, or intersex persons. The system scores countries on a scale of 1 to 10; higher scores indicate less stigma [28].

Criminalization

The State-Sponsored Homophobia International Lesbian, Gay, Bisexual, Trans, and Intersex Association report was used to evaluate the effects of criminalization of homosexual orientation or behavior on GTPSE [28]. The report classifies countries based on their level of legal protection or criminalization of sexual orientation and same-sex sexual acts. These classifications, ranging from most severe to most protected, include the death penalty, up to lifelong imprisonment, up to 8 years imprisonment, de facto criminalization, no criminalization or legal protections, limited protections, employment protections, broad protections, and constitutional protections. We converted these classifications into a quantitative ranking ranging from +4 to −4. The most severe classification (death penalty) was assigned the rank value "+4" and descended to the least severe/most protective classification (constitutional protection) with a rank value "−4."

Sensitivity Analysis

Using a subset (n=14) of the 53 countries we performed 3 sensitivity analyses at the national level. The 14 countries were randomly selected among countries with prominent languages being French, Spanish, or Swahili. The first sensitivity analysis probed the effect of select non-English search languages. The 14 countries comprised 4 using Swahili (Kenya, Tanzania, Uganda, Democratic Republic of Congo [DRC]), 5 using French (Cote d'Ivoire, Senegal, Cameroon, Mali, Haiti), and 5 using Spanish (Dominican Republic, Panama, El Salvador, Nicaragua, Honduras) as their national/dominant language. We generated GTPSE using search terms in Swahili ("ngono" and "ngono za mashoga"), French ("porno" and "porno gay"), and Spanish ("porno" and "porno gay") and compared them to the original relative GTPSE values. Using the same 14 countries, the second sensitivity analysis probed the effect of different search terms in English on GTPSE, that is, "sex," "gay sex" as well as "sex," "anal sex" and compared them to the original GTPSE (porn and gay porn). The third sensitivity analysis probed the effect of using different calendar years, ie, (2019 [pre-COVID] and 2021) and compared them to the original 2020 GTPSE values, using the original English language search terms.

Results

GTPSE and Comparability

Of the 54 countries examined, 1 (South Sudan), was omitted for lack of RSV values. All remaining 53 countries had GTPSE exceeding 1% (Table 1), similar to GAM values (all exceeding 1% as well) and compared with KP Atlas values where 24 out of 53 (45%) countries showed values above 1%. GTPSE ranged from 1.16% to 7.46% (median 1.99%, IQR 1.54% - 3.48%), compared with 0.06% to 6.04% (median 0.99%, IQR 0.34 - 1.93%) in the KP Atlas, and 1.38% to 2.82% in GAM regions. In 48 out of 53 (91%) countries, relative GTPSE exceeded estimates in the KP Atlas values; KP Atlas values were larger in 5 countries (DRC, Liberia, Lao People's Democratic Republic [PDR], Thailand, and Jamaica). Absolute differences between GTPSE and KP Atlas ranged from −312,900 (Thailand) to 6,221,800 (India). Table 2 displays regional median GTPSE, ranging from 1.64% (East Africa) to 5.26% (Central/South America), larger in all regions than the corresponding KP Atlas values and largely similar to GAM values in most regions. Table 1 also displays the ratios between the largest and smallest country-level %PSE for each region, separately for GT and KP Atlas values. While substantial variability is seen in all regions and for both data sources (GT and KP Atlas), in all regions the observed heterogeneity was consistently higher for KP Atlas values compared with GT values.

Local GTPSE pertaining to political or commercial capitals or the larger sub-national areas encompassing these are displayed in Table 3. We could obtain local estimates for 51 out of 53 (96%) countries' capital cities; GT did not provide data for Nairobi (Kenya) and Kathmandu (Nepal). Among the 51 cities with estimates, the GTPSE ranged from 0% to 13% (median 2.2%); most cities' estimates (44/51, 86%) exceeded 1%. Five cities yielded noncredible GTPSE values of 0%, including Bujumbura (Burundi), Dodoma (encompassing Dar es Salaam, Tanzania), Ouagadougou (Burkina Faso), Monrovia (Liberia), and Vientiane (Laos PDR). Of the 44 subnational GTPSE with

XSL•FO
RenderX

values >1%, 18 (41%) were below the same-country national GTPSE.

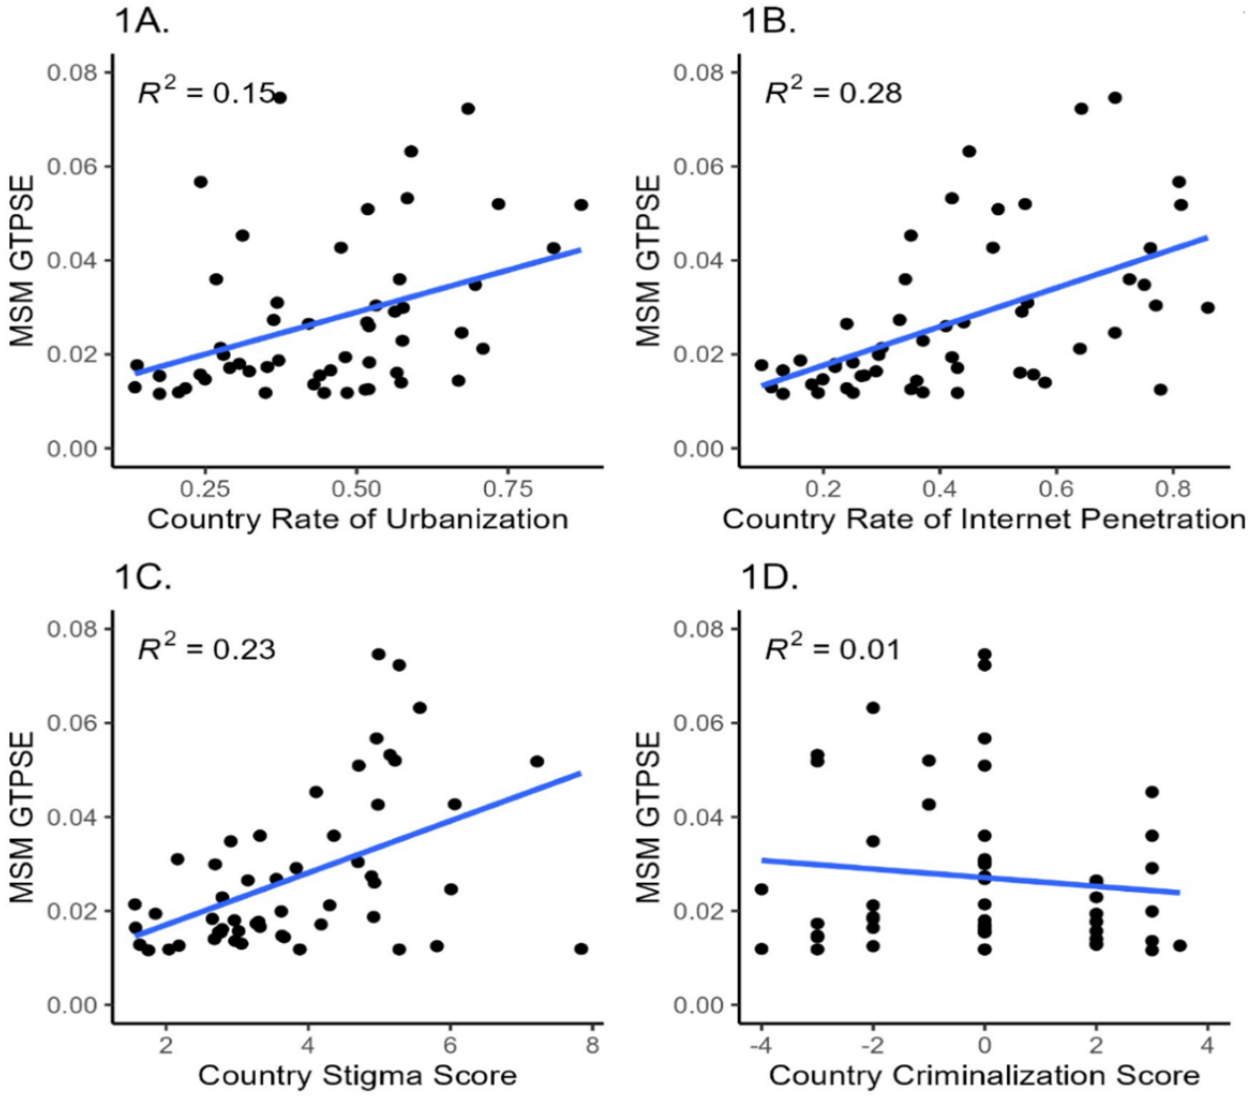
[a]Absolute values are not provided as Google Trends does not provide absolute search frequency values.

[b]Local MSM GTPSE for 53 countries for the year 2020 was calculated by restricting the geographic entity to the desired capital city or commercial hub. Where Google Trends (GT) did not provide data for a given city, we substituted the place name with the largest city by population or by district that had data available in GT. This is noted by listing what was available in GT in parenthesis next to the capital city. Kenya and Nepal were excluded from this analysis due to insufficient regional data available in GT.



[c]Not available (data missing for that country).

Effect of Covariates

Figure 1A-D displays the correlations between national-level GTPSE and urbanization, internet penetration, stigma, and criminalization. Coefficients ranged from 0.01 (criminalization) to 0.28 (internet penetration).

XSL•FO
RenderX

Figure 1. The linear relationship between the Google Trends national population size estimates and the rate of urbanization in each country (n=53). (A) The linear relationship between the Google Trends national population size estimates and the rate of urbanization in each country (n=53). (B) The linear relationship between the Google Trends national population size estimates and the rate of internet penetration in each country (n=53). (C) The linear relationship between the Google Trends national population size estimates and the level of stigma against LGBTQ+ persons in each country (n=53). (D) The linear relationship between the Google Trends national population size estimates and the degree of criminalization against men who have sex with men population in each country (n=53). LGBTQ+: lesbian, gay, bisexual, transgender, queer, and other identities; MSM: men who have sex with men; GTPSE: Google Trends Population Size Estimate.

Sensitivity Analysis

Table 4 displays how the GTPSE generated from the alternative search terms compares to the original search term GTPSE. In most countries "Porn/Gay Porn" produced higher PSE values compared with "sex/anal sex" (13/14, 93%) as well as compared with "sex/gay sex" (12/14, 86%). For "sex/gay sex," all 14 countries produced estimates exceeding 1%. For "sex/anal sex", 3 out of 14 (21%) countries did not produce estimates reaching the 1% threshold, including Mali for which zero search results were reported for "anal sex."

[a]2019 and 2021 values were computed in the same way as the reference 2020 estimates.

[b]Absolute values are not provided as Google Trends does not provide absolute search frequency values.

[c]PSE: population size estimation.

Discussion

Principal Findings

Our analysis suggests that national-level MSM GTPSE is feasible in almost all countries. Importantly, all estimates appeared plausible, that is, they exceeded the WHO/UNAIDS suggested minimum threshold of 1%. Heterogeneity of GTPSE across same-region countries was pronounced within all regions yet smaller than the ratios based on the UNAIDS KP Atlas values which contained numerous PSE values well below the 1% threshold.

Our analysis draws on several strengths. We successfully applied the GTPSE method to many low and middle-income countries, suggesting that GTPSE appears to have wide geographic applicability. We compared the values against 2 PSE data sources at UNAIDS, assessed the potential effect of various covariates on GTPSE values, and conducted a sensitivity analysis with varying English search terms, non-English search languages, and different calendar years. Google is the dominant search engine in all countries covered in this analysis, with a market share ranging between 84% and 99% (data shown in Table S1 in Multimedia Appendix 1) [27]. Although no absolute search volume data were available to us, searches for "porn" globally were among the top 20 search terms in 2023 with about 65 million searches globally each month according to one source [29] although this is still well behind the largest porn site-specific searches. GTPSE may emerge as another example of digital public health and epidemiology that includes real-time surveillance of disease outbreaks [30], assessing the impact of global public health days [31], informing health and health policy research [32], or understanding spatiotemporal patterns of dry eye disease [33].

While most local estimates were plausible (>1%), 14% (n=7) did not reach the WHO/UNAIDS minimum threshold, and 2 more locations did not produce a GTPSE value at all due to lack of GT data and how GT organized the subnational data despite some of the affected cities' large population sizes. This is not an uncommon finding, as other PSE methods in active use typically do not meet the WHO/UNAIDs minimum threshold. For a few other country or commercial capital cities with no direct GT data available, such as Johannesburg (South Africa), we could obtain a subnational estimate using the larger district or province within which the city (eg, Johannesburg and Pretoria) are located. This may limit the utility and comparability of such local estimates. About one-third of the local (relative) estimates did not reach or exceed the same country national level estimates, somewhat contrary to our expectation that rural-to-urban migration among MSM may be more pronounced than that of other men and so yielding higher GTPSE values [9]. In Card et al's [12] study on Canadian towns and cities the estimates ranged from 2% to 4% compared with 0% to 13% among the local estimates, whereas the Canadian national estimate was 2.8% compared with 1.2% - 7.5% across all countries we examined. While not a limitation, it is worth noting that weekly RSV data varied widely (data not shown), confirming the recommendation to use GT data for size estimation only over longer time periods, such as a full calendar year.

Limitations

Like most PSE methods, GTPSE has limitations. In particular, the assumptions underlying the GTPSE method deserve close

XSL•FO
RenderX

scrutiny: straight men only search for porn, MSM only search for gay porn, MSM and straight men search for (gay) porn in equal proportions, and women do not search for (gay) porn at all or do not affect the generated GTPSE for MSM. Violations of these assumptions will result in bias if they affect RSV for porn and gay porn to differing extents, hence altering the proportion of porn searches that are directed at gay porn. While the literature from LMIC settings on this topic is very sparse, reports and literature from high-income settings suggest that gay porn is also consumed by heterosexual men and women, suggesting that some bias may be present. Complicating speculations about the magnitude and direction of bias is the fact that specific porn websites' user statistics may not accurately reflect searches for (gay) porn on Google. Women's search behavior on Google regarding gay porn may increase or decrease the GTPSE estimates depending on the frequency relative to searches for just porn.

Regrettably, Google does not provide access to its algorithm generating the RSV data nor can users filter GT searches by age or gender. An inherent limitation in using GT data includes the lack of deduplication in the search data (although repeated searches by the same user within a short time period are not counted multiple times by Google) and the lack of absolute search volume data. Not having access to the absolute search volume data impedes the computation of uncertainty intervals (which in most national settings may be expected to be small due to the large search volumes involved). However, absolute search volume information may eventually be made available by Google and is already offered to some extent by select third-party companies. Absolute search volume data may also inform the choice of search language and even search terms and may facilitate composite GTPSE metrics by incorporating multiple GTPSE metrics stemming from different language search terms. Restricting GTPSE-relevant data to male users may further refine GTPSE values by excluding female users, a limitation our analysis could not overcome. VPN (virtual private network) also has the potential to introduce errors if users select a country other than their place of residence. The adoption of VPN may vary considerably across time and by country, and, among US President's Emergency Plan for AIDS Relief countries. According to one industry website in 2020, VPN was highest in Ukraine (7.9%) and lowest in Kenya (0.5%) [34]. Taken together, these limitations constitute a major source of uncertainty about the bias and precision of GTPSE. For that reason, GPTSE should be regarded as an approximate reference value. Clearly, they do not attain the rigor or transparency of statistically principled estimation from accurately measured data, which the currently best available PSE methods do offer. Additionally, GTPSE may not be feasible for a few countries, perhaps due to poor or little data availability on search terms and frequencies.

GTPSE seems infeasible for size estimation among transgender persons, sex workers, or people who inject drugs. Unlike (gay) porn, where the search is about a web-based product (visual depictions of porn), searches for sex work or clients, transgenderism, or injecting drug use are not directly tied to the internet, and may exhibit a more variable search terminology, and may lack fitting "denominator" search terms (analogous to "porn").

Overall, the GTPSEs often were substantially higher than the KP Atlas estimates but were more closely aligned with the reported GAM regional estimates. The KP Atlas estimates are based on a broad range of PSE methods typically generating local PSE that may or may not be projected to national scale, or summed or averaged across multiple localities, and may refer to various time points (calendar years) and various age ranges. Many KP Atlas based MSM PSE were implausibly low (<1%), suggesting that substantial differences to GTPSE may often be due to KP Atlas underestimates. The regional GAM estimates are based on a more curated database of PSE after excluding estimates with subpar quality and hence of perhaps more trustworthy quality [22]. However, GAM regions do not exactly overlap with the regions we used for GTPSE and the KP Atlas estimates.

The national MSM GTPSE values were robust against varying levels of urbanization, internet penetration, stigma, and criminalization or protection of homosexuality, negating the need for adjustment and increasing comparability across different settings. The largest influence was seen with internet penetration which can be expected to increase over time. In the sensitivity analysis, the largest differences to the original GTPSE values were seen using alternate English language search terms. Among the 14 examined countries, almost half (43%) of the alternate estimates were below 1% and hence considered implausibly low. This indicates that search term selection is important, especially for comparison across time and space. Further exploration may be warranted to evaluate if country or region-specific English or non-English slang terms may produce plausible estimates; however, the limited sensitivity analysis suggests that "Porn/Gay Porn" may be dependable and consistently produces plausible values. The use of similar search terms in French, Spanish, and Swahili yielded universally lower results; Swahili, not a nationally dominant language in most countries, appears particularly unsuitable as it frequently produced 0% PSE values. As most countries display prominent non-English language use, countries may want to consider using the predominant language (used for web searches) when applying this method while considering any language's geographic scope in-country. The results also appeared robust across time (two years affected by the COVID pandemic plus 1-year pre-COVID) as the 2 adjacent years produced plausible and (same country) consistent results. The lack of uncertainty intervals however impeded a more meaningful interpretation of the results from the sensitivity analyses.

Conclusions

Generating national-level PSEs for KPs is challenging for many countries. GTPSE is a simple method with the potential to address this problem efficiently without the need of additional resources. However, the lack of validation of key assumptions and the inability to generate credibility intervals suggest important uncertainty regarding the accuracy and precision of the estimates. Additional research, such as expanding or building on our sensitivity and covariate analysis, to address or better

XSL•FO
RenderX

understand these limitations may further improve the quality and utility of GTPSE for MSM in LMICs.

Abstract

Background: Chronic obstructive pulmonary disease (COPD), congestive heart failure (CHF), and acute pulmonary edema (APE) are serious illnesses that often require acute care from prehospital emergency medical services (EMSs). These respiratory diseases that cause acute respiratory failure (ARF) are one of the main reasons for hospitalization and death, generating high health care costs. The prevalence of the main respiratory diseases treated in a prehospital environment in the prepandemic period and during the COVID-19 pandemic in Spain is unknown. The Madrid Community EMS is a public service that serves all types of populations and represents an epidemiological reference for supporting a population of 6.4 million inhabitants. The high volume of patients treated by Madrid's medical advanced life supports (ALSs) allows us to analyze this little-studied problem.

Objectives: Our goal was to lay the groundwork for comprehensive data collection and surveillance of respiratory failure, with an emphasis on the most prevalent diseases that cause it, an aspect that has been largely overlooked in previous initiatives. By achieving these objectives, we hope to inform efforts to address respiratory failure and establish a standardized methodology and framework that can facilitate expansion to a continuous community-wide registry in Madrid, driving advances in emergency care and care practices in these pathologies. The aim of this retrospective observational study was to determine the pathologies that have mainly caused respiratory failure in patients and required medicalized ALS and to evaluate the cost of care for these pathologies collected through this pilot registry.

Methods: A multicenter descriptive study was carried out in the Madrid Community EMS. The anonymized medical records of patients treated with medical ALS, who received any of the following medical diagnoses, were extracted: ARF not related to chronic respiratory disease, ARF in chronic respiratory failure, exacerbations of COPD, APE, CHF, and bronchospasm (not from asthma or COPD). The prevalence of each pathology, its evolution from 2014 to 2020, and the economic impact of the Medical ALSs were calculated.

Results: The study included 96,221 patients. The most common pathology was exacerbation of COPD, with a prevalence of 0.07% in 2014; it decreased to 0.03% in 2020. CHF followed at 0.06% in 2014 and 0.03% in 2020. APE had a prevalence of 0.01% in 2014, decreasing to 0.005% in 2020 with the pandemic. The greatest economic impact was on exacerbation of COPD in 2015, with an annual cost of €2,726,893 (which equals to US $2,864,628).

Conclusions: COPD exacerbations had the higher prevalence in the Madrid region among the respiratory diseases studied. With the COVID-19 pandemic, the prevalence and costs of almost all these diseases decreased, except for ARF not related to chronic disease. The cost of these pathologies over 5 years was €58,791,031 (US $61,832,879).

Introduction

Chronic obstructive pulmonary disease (COPD) is a public health epidemic. The current state of the art displays a high prevalence and high burden [1]. COPD is the fourth leading cause of death worldwide, accounting for 3.5 million deaths in 2021, approximately 5% of all global deaths [2]. Although systematic reviews on the prevalence of COPD at the hospital level have been published previously [3,4], the literature on current prevalence estimates of COPD exacerbations, treated in prehospital emergency medical services (EMSs), is sparse. In particular, there are few published data on differences in COPD prevalence between rural and urban areas and between countries [5-7]. In this context, relevant and timely information on COPD prevalence in this context is essential to inform, develop, and implement context-appropriate policies and programs for the prevention and optimal control of COPD exacerbations.

Congestive heart failure (CHF) is another highly prevalent disease with significant morbidity and mortality worldwide [8]. There are geographical variations in the epidemiology of CHF [9]. There is a substantial lack of data from the out-of-hospital setting as well, where CHF has different evolution depending on the acute treatment administered [10,11]. Acute pulmonary edema is associated with high mortality. It requires emergency management and usually admission to hospital [7,12,13]. Prospective studies have shown that early treatment applied by prehospital EMS improves short time outcomes and lower hospital readmissions, but the population susceptible to early treatment is unknown [14,15].

COPD, CHF, and acute pulmonary edema (APE) are serious illnesses that often require acute care from EMS [5,6,16]. Respiratory diseases that cause acute respiratory failure (ARF) are one of the main reasons for hospitalization [7,17], generating high health care costs [18,19]. These diseases include bronchospasm as well [20]. Studies on the prevalence and expenditures of prehospital EMSs are scarce [5,21-23]. Consequently, more precise epidemiological data are needed to address these issues and obtain a more accurate picture of the amount of care and the costs generated by these pathologies [24,25] in the prehospital EMS setting.

The main objective of the Acute Respiratory Failure Treated by the Prehospital Medical Emergency Service of Autonomous Community of Madrid (SUMMIRA) project is to determine the prevalence of the most frequent respiratory diseases assisted by the Autonomous Community of Madrid's (CAM) advanced life supports (ALSs). The secondary objective is to measure the EMS economic cost of health care for patients. We present the following article in accordance with the STROBE (Strengthening the Reporting of Observational studies in Epidemiology) reporting checklist (Multimedia Appendix 1).

Methods

Study Design

The SUMMIRA study is an observational, quantitative, multicenter, and cross-sectional study of patients attended by the EMS of the CAM for 6 years.

Sample Size

Between 2014 and 2020, 583,984 persons of the population of the Madrid Community were clinically treated by the CAM ALSs, after a triage in the 112 health emergency telephone number. Based on these medical examinations, the subjects were included in the study. A cohort of 22,085 subjects was identified as having decompensated COPD; 22,085 with a main diagnosis of CHF; 4676 with APE; 17,843 presented ARF not related to chronic respiratory failure (CRF); 6921 were diagnosticated with bronchospasm; and 17,851 were related with ARF in CRF. This study involved a total of 96,221 patients included from the electronic medical records (EMRs).

Study Setting

The CAM has a population of 6.4 million inhabitants from 2014, both urban and rural areas. The CAM has 47 ALSs [26]. The ALSs are responsible for (1) emergency care, namely, patient care at home or on public roads in the Madrid Community and (2) interhospital transfers. The CAM is also in charge of the Helicopter Emergency Medical Service.

Each emergency care is provided by a health professional team formed by an emergency physician, an emergency nurse, and 1 or 2 emergency technicians; these teams assist at home and other places and take care of the patient in the mobile intensive critical unit (ALS).

The EMRs analyzed are those performed by the ALS physicians who attended the pathologies under study. These are the patients attended by the ALS of the Community of Madrid after the patients or their families called 112 (both in the city and in the outskirts).

The EMRs are located in a program named Integrated Management System of the Coordinating Center [27]. Integrated Management System of the Coordinating Center is a highly secure system of clinical data that has received urgent health care from the ALSs of the CAM.

Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki. This study was reviewed and approved by the Madrid Regional Ethics Committee on Medication Research (dated: June 6, 2022/N° V8.2022). All data used in this study have been deidentified or anonymized to protect the privacy of participants. No information is available that would allow for the direct or indirect identification of individuals. The Madrid Regional Ethics Committee approval covers secondary analysis without additional consent.

XSL•FO
RenderX

Since the study involved the secondary analysis of previously collected data, the ethics committee determined that the project was exempt from further review under the category of anonymized, preexisting data analysis. The study complied fully with international ethical standards and the protection of participants' rights.

All EMRs in this study have been anonymized to protect the privacy of participants. Rigorous measures were taken to ensure the confidentiality of the data and the integrity of the information collected complying, therefore, with the principles regarding data processing referred to in Article 5 of European Union Regulation 2016/679 of the European Parliament and Council of April 27, 2016 (General Data Protection Regulation).

Sampling and Recruitment Procedure

Inclusion Criteria

Patients with EMRs were treated by the CAM ALSs who, according to usual clinical practice, had been diagnosed with ARF not related to CRF, exacerbation of chronic obstructive pulmonary disease (ECOPD), CHF, bronchospasm, or APE according to the codes of the *International Classification of Diseases, Ninth Revision* [9] between 2014 and 2020. Medical diagnostic criteria based on clinical and historical data were followed. The population residing in the CAM per year was taken as the reference population, according to the Spanish National Institute of Statistics [28].

The diagnoses of APE and ECOPD were defined as a "clinical picture" in the prehospital and hospital emergency manuals [29-31], with consensus documents [32,33] and systematic review such as by Bello et al [34] . The diagnostic criteria for COPD and APE are described in Multimedia Appendix 2 and Table 1. The other pathologies were diagnosed following the diagnostic criteria of the 12 Octubre Physician Manual [35] in accordance with another prehospital emergency manual [36] and the Servicio de Urgencias Medicas de Madrid (SUMMA112; Prehospital Emergency Medical Service of Autonomous Community of Madrid) Physician Clinical Guide for Acute Heart Insufficiency (Multimedia Appendix 3).

Table . Prevalence of congestive heart failure, exacerbation of chronic obstructive pulmonary disease (ECOPD), acute pulmonary edema, and bronchospasm acute respiratory insufficiency not related to chronic respiratory failure, of Madrid region population, based to the Madrid Community census [37], and the prehospital emergency medical service´s electronic medical record of Madrid from 2014 to 2020 (n=583,984).

[a]Results from the retrospective observational research Acute Respiratory Failure Treated by the Prehospital Medical Emergency Service of Autonomous Community of Madrid (SUMMIRA).

Exclusion Criteria

Patients without a health identification number or without an adequate record in the basic minimum dataset were excluded. All patients diagnosed with asthma were excluded since they could be included among the patients with ARF related to chronic respiratory disease (Figure 1).

XSL•FO
RenderX

Figure 1. Cohort selection of patients assisted by the Madrid Community emergency medical service from January 1, 2014, to December 31, 2020. Acute Respiratory Failure Treated by the Prehospital Medical Emergency Service of Autonomous Community of Madrid (SUMMIRA) Study. COPD: chronic obstructive pulmonary disease.

Economic Analysis

The prevalence for each pathology was calculated by dividing the total number of individuals who presented the corresponding medical diagnosis in a given year by the population of Madrid at that time, according to the Spanish National Institute of Statistics.

The direct economic cost of CAM EMS care for the pathologies treated was calculated from the expenditure according to public references [38]. The health care cost data were extracted from the public prices for the provision of public health services and activities of the ALSs published in the Official Gazette of the CAM on August 21, 2017 (price list with an application date until December 2023). The reference cost for this study was the average cost of €611 (US $64,261), which is the arithmetic mean of mobilizing and assisting a patient by a terrestrial ALS unit in the public EMS of the Madrid Community [39]. The ALS provides advanced care, as it contains all the electromedical material and personnel that are required to form a mobile intensive care unit. The cost of ALS care (emergency medical services costs) includes physician care, emergency nursing assistance, and all required ventilatory support techniques, depending on the severity of the patient's condition, with pharmacological treatment, oxygen therapy, invasive and noninvasive mechanical ventilation, and transfer to the hospital.

The direct economic impact was obtained by multiplying the cost of care for each pathology treated in the CAM's ALSs by the number of times care was required. All persons within the CAM were able to receive care, as it is included in the universal emergency health care coverage of the Madrid Health Regional Government (public administration). The economic analysis was done in Microsoft Excel 365 and SPSS software (version 26; IBM Corp), with a copyright license from the Madrid Health Regional Government.

Results

Table 1 shows a total of 96,221 patients who were included between 2014 and 2020. The most prevalent pathology among all those studied was COPD, with an initial prevalence of 0.068% (4415/6,454,440) in 2014, which decreased to 0.030% (2020/6,779,888) in 2020. CHF had a prevalence of 0.056% (3593/6,454,440) in 2014, decreasing to 0.029% (1938/6,779,888) in 2020. The prevalence of ARF in CRF was 0.044% (2872/ 6,454,440) in 2014 but decreased to 0.023% (1553/6,779,888) in 2020. The prevalence of bronchospasm (not from asthma or COPD) decreased from 0.015% (1000/6,454,440) in 2014 to 0.007% (462/6,779,888) in 2020. APE's prevalence decreased from 0.013% (819/6,454,440) in 2014 to 0.005% (353/6,779,888) in 2020. The prevalence of ARF in patients not related to CRF decreased from 0.041% (2648/6,454,440) in 2014 to 0.034% (2289/6,663,394) in 2019 and increased to 0.038% (2531/6,779,888) in 2020, reversing this trend of ARF observed, especially in CHF and ECOPD.

The prevalence of APE shows a decreasing pattern from the onset. The other pathologies start with an upward trend, although in the second year, they reverse the trend and gradually decrease. The prevalence of bronchospasm maintains an upward trend until 2017 and from then on it starts to decrease progressively. In 2020, a sharper peak of decrease is assessed in all pathologies, except ARF not related to CRF, the latter being the only one to increase.

A decrease in most respiratory diseases (Table 2) was observed in 2020, both for patients with ECOPD, APE, or bronchospasm

XSL•FO
RenderX

(nonasthmatic, non-COPD) and for patients with CHF (Figures 2A-F and 3), except for ARF not associated with CRF, which corresponded in time and form with the COVID-19 pandemic period [40]. From 2017 on, a decrease in all types of ARF was observed, especially CHF and COPD.

Table 2 shows the economic cost of each pathology and its economic impact in each year. The greatest economic impact was observed in 2015 for ECOPD, with an annual cost of €2,726,893 (US $2,867,982). The estimated cost of all pathologies over 5 years was €58,791,031 (US $61,832,879).

Table . Direct economic impact of the congestive heart failure, exacerbation of chronic obstructive pulmonary disease (ECOPD), acute pulmonary edema (APE), bronchospasm, and acute respiratory failure not related to chronic respiratory failure of the Madrid region population; based on the prehospital Madrid emergency medical service's electronic medical records[a].

Results from the retrospective observational research Acute Respiratory Failure Treated by the Prehospital Medical Emergency Service of Autonomous Community of Madrid (SUMMIRA). COPD: chronic obstructive pulmonary disease.

Discussion

Principal Findings

Among the findings, we can mention that to our knowledge this is the only study in the prehospital EMS that has analyzed the prevalence of these pathologies in Spain and in Europe, so it can serve as a reference for future European studies on this topic. It was measured by the costs categorized by diagnosis. Finally, it is worth mentioning the large sample size, which provides greater reliability to the study. Few studies have quantified the direct costs incurred by ALSs in these pathologies [25,41-45]. A study carried out in Sweden and Belgium quantified a type of direct cost, such as transport for ECOPD, at 3% of the total direct costs [42]. In France, the cost of medical transport per patient was estimated to be €192 - 273 (US $202-287) in 1996 [46]. In this study, the cost of air ambulance transportation, but not that of emergency medical care, was estimated.

In the ALS of the CAM, the demand by patients with dyspnea as the main diagnosis among patients with ECOPD was known, although there were no data to differentiate among ECOPD, bronchospasm, and other processes. Therefore, we needed to accurately calculate the prevalence of ARF in ALS to more precisely estimate the economic impact of these pathologies and their complete clinical picture, which includes emergent prehospital care [47].

The results of the SUMMIRA project have made it possible to estimate the global quantification for prehospital emergency care due to SARS-CoV-2 in the CAM, served by the ALSs of the CAM. The pathologies studied showed a continuously decreasing trend throughout the period analyzed, coinciding with the mortality data related to ECOPD published in the CAM [22]. The only different trend was the peak produced by ARF not associated with chronic failure, which, despite showing a decreasing trend from 2014 to 2019, increased the number of cases in 2020 at the same time as the COVID-19 pandemic in Spain [48].

These other declines previous to 2020 may be the result of many factors, such as regional success of tobacco control measures, improved information and prevention of allergens, better treatment of respiratory and cardiac comorbidities, and a reduction of universally high rates of underdiagnosis of chronic respiratory diseases [25]. The decreasing trend in the number of cases of most of the chronic respiratory diseases studied, such as COPD, CHF, and APE, before 2020, led us to estimate an improvement in disease control in chronic patients to date and a subsequent influence of the cases due to the COVID-19 pandemic [49].

The economic impact of chronic diseases on patients has not been quantified in the most recent COPD studies [7,21,50], as only primary care and hospital expenditure have been taken into account [22,45,51]. A descriptive North American study lasting 5 years with a large sample (166,908 patients) in which patients

XSL•FO
RenderX

with respiratory distress transferred to the hospital was analyzed [6], but the population prevalences were not calculated.

Furthermore, there is a comparative dilemma between the different activities of the EMS's ALSs in different countries. Some of them in Europe, such as the paramedical system, cannot discharge patients since transfer to hospital is part of the work protocol because some of them do not have doctors within health care teams who can discharge patients [52-54]. In this sense, the Spanish system of EMS [55] helps prevent care overload in hospitals since the physicians of ALSs allow patients to remain at home and can be treated there, improving adequately after receiving treatment and thus achieving benefits for both patients and the health system. Considering the number of cases of the diseases found, it would be advisable to evaluate the prevalence of these diseases in other similar European and national emergency health systems to have an updated global vision.

The set of decreasing trends in the prevalence of ECOPD is in line with the trend in industrialized countries [56]. Plausible causes include the greater control of adverse risk factors, as well as the increase in public health measures that protect against respiratory diseases (tobacco, asbestos, protective measures in occupational risks, etc) [18,25,57,58].

Limitations

This work had a shortcoming in the population sample. This cohort did not include the care provided to the patients who go directly to the hospital emergency department; it is a prehospital cohort. The cohort would be bigger if it would include the patients of the Madrid Municipal Emergency Assistance and Rescue Service (SAMUR), though the number of patients treated by them is minimal because their assistance is limited to the public thoroughfare of Madrid capital, and by regular form this type of patient is treated at home and primary care that is covered by SUMMA112.

We have separated the average cost of the assistance provided by the advanced terrestrial life support services of the CAM to estimate the economic cost. Advanced air life support has also treated some patients, which is valued in Table 3.

Table . Case study of congestive heart failure, exacerbation of chronic obstructive pulmonary disease (ECOPD), acute pulmonary edema, bronchospasm, and acute respiratory insufficiency not related to chronic respiratory failure of the Madrid region population per year treated by Servicio de Urgencias Medicas de Madrid Helicopter Emergency Medical Service (SUMMA112 HEMS), from 2014 to 2020[a].

Condition	2015	2016	2017	2018	2019	2020
ECOPD	1 ECOPD	1 ECOPD	2 ECOPD	2 ECOPD	3 ECOPD	1 ECOPD
Acute respiratory failure related to chronic respiratory failure	1 Acute respiratory failure in chronic respiratory failure	2 Acute respiratory failure in chronic respiratory failure	2 Acute respiratory failure related to chronic respiratory failure	1 Acute respiratory failure related to chronic respiratory failure	2 Acute respiratory failure related to chronic respiratory failure	1 Acute respiratory failure related to chronic respiratory failure
Acute pulmonary edema	1 Acute pulmonary edema	1 Acute pulmonary edema	2 Acute pulmonary edema	1 Acute pulmonary edema	3 Acute pulmonary edema	N/A[b]

Acute respiratory failure not related to chronic respiratory failure	N/A	2 Acute respiratory failure not related.to chronic respiratory failure	2 Acute respiratory failure not related to chronic respiratory failure	1 Acute respiratory failure not related to chronic respiratory failure	3 Acute respiratory failure not related to chronic respiratory failure	N/A

[a]As can be valued in the Official Gazette of the Madrid Council [38], the cost per medical helicopter intervention in this period time is €5746 (US $6043).

[b]N/A: not applicable.

Our study shows a reduction in the costs of CHF over the years in EMS. The decrease may be explained by factors such as reduced severity and better treatment of acute coronary syndrome [21]. We have not found any similar bibliography in the prehospital setting. The 2019 Heart Failure Association Atlas reported a heart failure prevalence ranging from ≤12 in Spain [51]. At the European level, there is considerable heterogeneity of data between European countries, ranging from an overall prevalence of 14 per 1000 in the Netherlands [24] to 39 in Slovenia, Lithuania, and Germany but with a common point: EMS use in heart failure is an independent predictor of 30-day mortality [50]. In exacerbations of COPD, the patients have a significant comorbidity burden and experience high rates of hospitalization and mortality [59]. It can lead to several conclusions in the area of public health: (1) the measures taken by primary and specialized care have been effective in control of exacerbations of this type of pathology, and furthermore (2) despite reducing costs, in seasonal outbreaks a greater investment [51] of costs would be needed to reinforce the resources that deal with the ECOPD in the prehospital emergency services.

This study opens the possibility of including these values in the database of the economic impact of chronic respiratory diseases such as COPD, CHF, and APE, which are currently not considered [6-8]. In addition to the registration of their prevalence in the different months of the year, an analysis of the needs required in public health can be made to make investment plans in the times of the year when there is a higher prevalence. Moreover, it could be taken into account when

XSL•FO
RenderX

assessing the costs associated with SARS-CoV-2–related bronchospasm and ARF in prehospital critical care for future respiratory transmission pandemics.

Conclusions

The results found in this study are in line with the general hospitalization downward trend in high-income countries of a decrease in the number of cases from 2014 to 2020 for the most common respiratory diseases treated in hospital emergencies [21,51,56]. The prevalence of ECOPD in the Madrid EMS was higher than the other respiratory diseases studied. In 2020, with the COVID-19 pandemic, a decrease in the prevalence and costs of the pathologies studied was observed, except for the prevalence of ARFs not related to chronic failure. The greatest economic impact was for ECOPD in 2015, with an annual cost of €2,726,893 (US $2,867,982). The estimated cost of these pathologies in 5 years was €58,791,031 (US $61,832,879).

Acknowledgments

The authors thank the support of the medical director and the medical deputy director of the Servicio of Urgencias Médicas of Madrid (SUMMA112); data exploration team of the IT Department of SUMMA112; Mr Juan Pajuelo Ayuso; Mr José Gómez Martínez, and Mrs Nuria Rodríguez Rodil; Candelas Gil, Head of the Medical Library Service of the Autonomous University of Madrid, Spain; and the Primary Care Biomedical Research and Innovation Foundation (FIIBAP). This work has been presented as oral communication at the XXXIX Annual Meeting of the Spanish Epidemiology Society (SEE) and at the XIX Congress of the Spanish Society of Public Health and Health Administration (SESPAS). This article sheds light on the changing prevalence of the most frequent respiratory diseases treated by emergency medical services, the influence of the COVID-19 pandemic on them, and the costs involved in their care in the out-of-hospital emergency setting.

Data Availability

The datasets generated analyzed during this study are not publicly available due to privacy requirements and ethical restrictions. Reasonable requests for data access are available by contacting the corresponding author and submitting application documents. Anonymized data from this study are available from the corresponding author upon reasonable request. The descriptive multicenter study that is presented is based on a health care casuistry by filtering the codes of the respiratory pathologies registered in the Electronic Medical Record on the Integrated Management System of the Coordinating Center platform.

Integrated Management System of the Coordinating Center is a computer application that operates under the supervision of the Information Systems Security Office of the Department of Health of the Community of Madrid. It is included in the Integrated Management System of the Prehospital Emergency Medical Service of Autonomous Community of Madrid (SUMMA112) Coordination Center. These data are protected by security systems and guarded by the technical managers of the Information Systems Security Office of the Department of Health of the Community of Madrid (OSSI). There is a high level of security in the treatment and storage of medical records from the Medical Emergency Service of the Madrid Region, which depends on the General Directorate of Information Systems and Health Equipment of the Madrid Health Service.

Authors' Contributions

AMCS, CHG, VQC, AMPA, and AGM were involved in the conception and design of the work. AMCS, CHG, and VQC contributed to the screening process, data extraction, and quality assessment of papers. AMCS, CHG, and VQC interpreted the data and drafted the manuscript. The manuscript was critically reviewed and enriched by CHG, AMPA, and AGM. All authors read and approved the final manuscript and agreed to be accountable for all aspects of this work.

Conflicts of Interest

None declared. All authors have confirmed the maintenance of confidentiality and respect for the rights of the patient in the document of responsibilities of the author, the publication agreement, and the transfer of rights to the journal.

Abstract

Background: Colorectal cancer (CRC) incidence and mortality in those aged 50 years and above have decreased over the past 2 decades. However, there is a rising incidence of CRC among individuals under 50 years of age, termed early-onset colorectal cancer (EOCRC). Patients with EOCRC are diagnosed at an advanced stage and may be in more psychosocial, emotional, and financial distress.

Objective: Our study examined the epidemiological shifts in CRC in Singapore, a multiethnic country.

Methods: CRCs diagnosed at age 20 years and above were identified from the Singapore Cancer Registry (SCR) from 1968 to 2019. Patient characteristics included gender, ethnicity, and age of CRC diagnosis. Population information was obtained from the Department of Statistics Singapore (SingStat). Age-specific incidence rates (ASRs) and age-standardized incidence rates (ASIRs) were calculated. The cohort was divided into 3 age groups: 20-49, 50-64, and ≥65 years. Temporal trends in incidence rates were modeled with joinpoint regression. Birth cohort models were fitted using the National Cancer Institute (NCI) age-period-cohort analysis tool. Cancer-specific survival analysis was performed with the Cox proportional hazards model.

Results: In total, 53,044 CRCs were included, and 6183 (11.7%) adults aged 20-49 years were diagnosed with EOCRC. The ASR of EOCRC rose from 5 per 100,000 population in 1968 to 9 per 100,000 population in 1996 at 2.1% annually and rose to 10 per 100,000 population in 2019 at 0.64% annually. The ASR for CRC among adults aged 50-64 years rose at 3% annually from 1968 to 1987 and plateaued from 1987, while the ASR for adults aged 65 years and above rose at 4.1% annually from 1968 to 1989 and 1.3% annually from 1989 to 2003 but decreased from 2003 onwards at 1% annually. The ASR of early-onset rectal cancer increased significantly at 1.5% annually. There was a continued rise in the ASR of EOCRC among males (annual percentage change [APC] 1.5%) compared to females (APC 0.41%). Compared to the 1950-1954 reference birth cohort, the 1970-1984 birth cohort had a significantly higher incidence rate ratio (IRR) of 1.17-1.36 for rectal cancer, while there was no significant change for colon cancer in later cohorts. There were differences in CRC trends across the 3 ethnic groups: Malays had a rapid and persistent rise in the ASR of CRC across all age groups (APC 1.4%-3%), while among young Chinese, only the ASR of rectal cancer was increasing (APC 1.5%). Patients with EOCRC had better survival compared to patients diagnosed at 65 years and above (hazard ratio [HR] 0.73, 95% CI 0.67-0.79, $P<.001$) after adjusting for covariates.

XSL•FO
RenderX

Conclusions: The rise in the incidence of rectal cancer among young adults, especially among Chinese and Malays, in Singapore highlights the need for further research to diagnose CRC earlier and reduce cancer-related morbidity and mortality.

early-onset colorectal cancer; epidemiology; Singapore; joinpoint regression; age-period-cohort; public health; health disparity

Introduction

Colorectal cancer (CRC) presents a significant health care problem as it is the third-most common cancer diagnosed and the second-leading cause of death worldwide. In 2020, CRC accounted for 10% of the worldwide cancer incidence and 9% of cancer deaths. Currently, 2 million new cases are diagnosed annually worldwide, which is projected to rise to 3.2 million per annum by 2040 [1,2].

With the implementation of population-wide, average risk CRC screening for all adults aged 50 years or above, CRC incidence and mortality in this age group have progressively decreased over the past 2 decades. However, there is emerging evidence that the incidence of CRC in people under 50 years of age is rising, especially in high-income countries. Based on the World Health Organization–International Agency of Research on Cancer Incidence in Five Continents Plus database, the incidence of early-onset colorectal cancer (EOCRC) rose in 27 (54%) of 50 countries, with the highest incidence rates of 14-16 per 100,000 person-years seen in the United States, Australia, New Zealand, and South Korea [3]. In United States, since the 1990s, colon and rectal cancer incidence has been increasing at 1.3% and 2.3% per year, respectively, for adults aged 40-49 years [4]. This is in contrast to the declining incidence of CRC among adults aged 55 years or older. Similar trends in colon and rectal cancer incidence were observed in Australia, with an increase of 1.7% and 0.9% per year, respectively, for adults aged 40-49 years [5].

EOCRC may be associated with hereditary syndromes, such as Lynch syndrome and familial adenomatous polyposis, but these only account for 1%-3% of the total number of new CRC cases. The large majority of EOCRC cases are still sporadic and contribute 10%-12% of new CRC cases. EOCRC is more likely to occur in the left colon, with higher rates of mucinous and poorly differentiated cancers, which may be associated with poor prognosis [6]. Patients with EOCRC tend to possess an underappreciation of symptoms; more reluctance to seek medical assistance, leading to delayed diagnosis; and more advanced stage at diagnosis [7]. They present with unique challenges—as younger patients with young children, heavy financial commitments, and fertility preservation [8]. The rise in the incidence of EOCRC may be a consequence of increased endoscopic capacity, which may lower the threshold for performing colonoscopy in younger patients. However, another important factor is the strong birth cohort effect observed worldwide, which may be the result of changes in exposure to risk factors. Although most studies have found EOCRC prevalence to be independent of gender, racial disparities in EOCRC incidence have been described in the United States, with a higher incidence seen in African Americans [9,10].

Singapore has a multiethnic resident population of 4 million, of which 74% are Chinese, 13% Malays, and 9% Indians [11]. In Singapore, CRC has the highest incidence among all cancers for the past several years, which, therefore, imposes a substantial burden in terms of complications, mortality, health care resources, and medical costs [12]. According to the *Singapore Cancer Registry Annual Report 2021*, there were a total of 12,239 new cases of CRC diagnosed from 2017 to 2021. There was a notable rise in the age-standardized incidence rate (ASIR) of CRC from 19.4 per 100,000 population in 1968-1972 to 37.5 per 100,000 population in 2017-2021 among men. A similar trend among females was observed, at 15.4 per 100,000 population in 1968-1972 to 26.9 per 100,000 population in 2017-2021. Among those aged 40-49 years, CRC was the most common cause of cancer among men and the fourth-most common cause of cancer among women. There were differing trends in the ASIRs of cancer among the 3 main ethnic groups. Although the Chinese had the highest ASIR of cancer throughout the years, there is evidence of a closing ethnic gap in cancer incidence between the Chinese and Malays [13]. Although there has been an overall increase in survival rates for CRC over the past decades, the age-specific patterns and effects of gender and ethnicity on the incidence trends in CRC in Singapore are not well studied. Therefore, the aim of this study was to perform a comprehensive analysis of temporal trends in colon and rectal cancer incidence in Singapore.

Methods

Study Design and Data Source

The Singapore Cancer Registry (SCR) is a population-based registry that was established in 1968 and is part of the National Registry of Disease Office. The SCR collects notifications from medical practitioners about all patients with cancer diagnosed in Singapore, as mandated by the National Registry of Diseases Act 2007. The data are internationally comparable and valid, with completeness of about 97.5%. Annual audits of the data are performed to ensure data accuracy of at least 95% as the data are critical to guide cancer prevention policies and cancer research [14].

Patients aged 20 years and older diagnosed with colon cancer (*International Classification of Diseases* [ICD]-9 code 153, ICD-10 code C18) and rectal cancer (ICD-9 codes 154.0, 154.1; ICD-10 codes C19.9, C20.9) from 1968 to 2019 from the SCR were included in this study. Recurrent and metachronous CRCs, premalignant tumors, carcinoma in situ, extranodal colorectal lymphoma, and sarcomas were excluded. Information about the Singapore population was obtained from the Department of Statistics Singapore (SingStat), which provides publicly available data that were used to define the denominator for incidence rates [11]. Patient characteristics included gender,

XSL•FO
RenderX

ethnicity, and age at diagnosis. The tumor, node, and metastasis (TNM) stage at diagnosis was available for patients diagnosed from 2003 onward.

Colon cancers were separated from cancers of the rectosigmoid and rectum, which were grouped together as rectal cancer for analysis. Age-specific incidence rates (ASRs) were calculated as the number of new CRC cases diagnosed each year divided by the population at risk for that age group. The population at risk was defined as the group of individuals susceptible to CRC during the period of interest. ASIRs were calculated as the sum of weighted ASRs using the direct method and the Segi-Doll World Standard as the reference population.

Joinpoint Analysis

The cohort was initially divided into 3 age groups: 20-49, 50-64, and ≥65 years. EOCRC was defined as CRC diagnosed at age 20-49 years. Annual incidence rates from 1968 to 2019 were estimated for the 3 age groups. Joinpoint regression analysis was used to describe the temporal trends in cancer incidence, identify points of change in direction, and estimate the magnitude of the change in rates. Joinpoint analysis estimates the annual percentage change (APC) by assessing observed data and fitting a series of joined straight lines to determine the APC over each period. The changes are tested for statistical significance [15,16]. It assumes that the regression function is piecewise linear, and the segments are continuously connected at unknown change points [17]. Compared to the traditional Monte Carlo permutation method, the data-driven weighted Bayes information criterion (BIC) was used for model selection as it was computationally more efficient yet produced similar results [18].

Age-Period-Cohort Modeling

Birth cohort models were fitted using the National Cancer Institute (NCI) Age Period Cohort web tool [19]. Age-period-cohort modeling provides estimates of parameters that describe relationships between observed incidence rates and age, calendar period, and birth cohort based on age groups and time periods of equal length. There was no information available for those aged ≥70 years for several time points from SingStat population estimates. Therefore, age-period-cohort analysis was limited to those aged 20-69 years. Input data were CRC cases and population counts for 10 five-year time periods (1970-1974, 1975-1979, …, 2015-2019), 10 five-year age groups (20-24, 25-29, …, 65-69 years), and 19 birth cohorts generated starting from the 1905-1909 to the 1995-1999 birth cohort. Cohort effects were presented as incidence rate ratios (IRRs) for a given birth cohort, with the 1950-1954 as the reference birth cohort. Additionally, local drifts estimated the age-specific net APC in incidence rates across the different age groups.

Survival Analysis

Cancer-specific survival was defined as the period from the date of CRC diagnosis to the date of death due to CRC. Patients who died of other causes were censored at their date of death; similarly, patients who were still alive were censored at the date of last follow-up. Clinical characteristics, such as surgical, radiation, and chemotherapy treatments received, were available. Multivariable survival analysis was performed with the Cox proportional hazards model.

Ethical Considerations

The study was approved by the SingHealth Institutional Review Board (IRB 2022/2415) to access and analyze data from the SCR. Informed consent was waived (waiver of consent was approved by the SingHealth IRB) as study data were deidentified.

Results

Characteristics of the Study Population

In total, 53,044 CRCs were included, with 32,880 (62%) colon and 20,164 (38%) rectal cancers. Figure 1 describes the flowchart of identifying and extracting patients from the SCR. Furthermore, 6183 (11.7%) EOCRCs were diagnosed, with 3585 (58%) colon and 2598 (42%) rectal cancers. Clinical characteristics of the study population are described in Table 1. There was a higher proportion of stage 3 (37.4% vs 32.4%) and stage 4 (26.1% vs 24%) CRCs and a lower proportion of stage 2 (21.2% vs 28.1%) CRCs among EOCRCs compared to patients diagnosed at an age of 65 years and above (P<.001).

Joinpoint Regression Analysis of Incidence Rates of Colorectal, Colon, and Rectal Cancers

The ASIR of CRC rose from 15 in 1968 to 36 per 100,000 population in 1992 at an APC of 3.5% and plateaued (Figure 2). The ASIR of colon cancer rose from 8 in 1968 to 20 per 100,000 population in 1990 at an APC of 4.3% and plateaued. The ASIR of rectal cancer rose from 7 in 1968 to 14 per 100,000 population in 1990 at an APC of 2.5% and decreased to 12 per 100,000 population in 2019 at an APC of –0.5%.

XSL•FO
RenderX

Figure 2. Joinpoint regression of the ASIR of CRC, colon cancer, and rectal cancer. APC: annual percentage change; ASIR: age-standardized incidence rate; CRC: colorectal cancer. See Multimedia Appendix 1 for a high-resolution version.

The results of joinpoint regression are shown in Table 2 and Figure 3 for CRC, colon cancer, and rectal cancer stratified by age group. For EOCRC, the ASR rose from 5 in 1968 to 9 in 1997 at an APC of 2% and increased to 10 per 100,000 population in 2019 at an APC of 0.6%. For those aged 50-64 years, trends were similar to the ASIR of CRC for the overall Singapore population. For those aged 65 years and above, the ASR of CRC rose from 113 in 1968 to 299 in 2002 at an APC of 4.11% and decreased to 242 per 100,000 population in 2019 at an APC of –1.03%.

The ASR of early-onset colon cancer rose from 3 in 1968 to 5 per 100,000 population in 1995 at an APC of 2.2% and thereafter had a nonsignificant increase at an APC of 0.4%. For those aged 50-64 years, colon cancer trends were similar to the ASIR of CRC for the overall Singapore population. For those aged 65 years and above, the ASR of colon cancer rose from 57 in 1968 to 193 in 2005 at an APC of 4.95% and decreased to 170 per 100,000 population in 2019 at an APC of –0.92%.

The ASR of early-onset rectal cancer rose from 2 in 1968 to 5 per 100,000 population in 2019 at an APC of 1.5% per year. For those aged 50-64 years and 65 years and above diagnosed with rectal cancer, trends were similar to the ASIR of rectal cancer for the overall Singapore population (Table 2 and Figure 3).

Table 2. APC[a] of CRC[b], colon cancer, and rectal cancer ASRs[c] by age group and tumor location. See Multimedia Appendix 1 for a high-resolution version.

Figure 3. Joinpoint regression of the ASRs of CRC, colon cancer, and rectal cancer by age group and tumor location. APC: annual percentage change; ASR: age-specific incidence rate; CRC: colorectal cancer. See Multimedia Appendix 1 for a high-resolution version.

Effect of Gender

The male population had higher incidence rates for colon and rectal cancers. Similar to the ASIR, for both genders aged 50-64 years and 65 years and above, the incidence of CRC, colon cancer, and rectal cancer rose before it plateaued or decreased in the recent 2 decades (Table 3 and Figures 4 and 5). Among those aged 50-64 years, there was a rapid initial rise in colon cancer among women compared to men (APC 5% vs 3.8%).

For males aged 20-49 years, there was a rising incidence in CRC (APC 1.5%), mainly rectal cancer (APC 1.9%), with a smaller rise in colon cancer (APC 1.1%). For females aged 20-49 years, similar to older females aged 50-64 years, there was a rapid initial rise, particularly in colon cancer (APC 3.8%); however, in recent years, for colon cancer, rectal cancer, and CRC, the APC has been <1% (Table 3 and Figure 5).

Effect of Ethnicity

Similar to the ASIR, for Chinese patients aged 50-64 years and 65 years and above, the ASR of CRC, colon cancer, and rectal cancer showed an initial rise but plateaued or decreased in the recent 2 decades. In Malays across all 3 age groups, there was a persistent rise in the ASR of CRC, colon cancer, and rectal cancer (APC 1.4%-3.2%) without evidence of it plateauing. In Indians aged 50-64 years and 65 years and above, there was a smaller persistent rise in the ASR of CRC, colon cancer, and rectal cancer (APC 1%-1.4%) without evidence of it plateauing (Tables 4-6 and Figures 6 and 7).

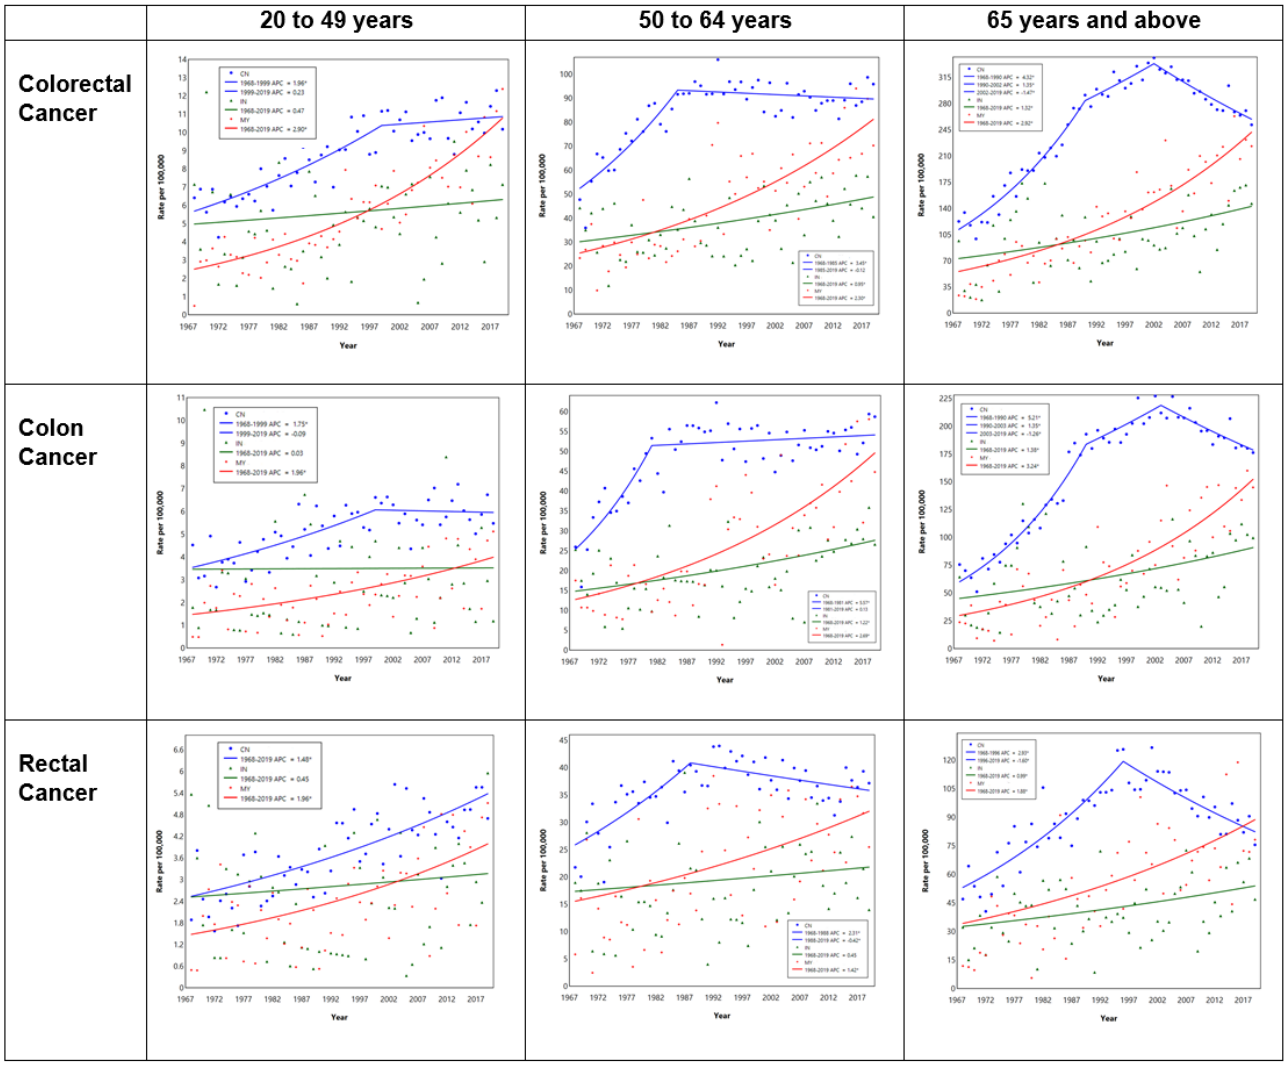

Figure 6. Joinpoint regression of ASIRs of CRC, colon cancer, and rectal cancer by ethnic group (Chinese/CN: blue; Indian/IN: green; Malay/MY: red). APC: annual percentage change; ASIR: age-standardized incidence rate; CRC: colorectal cancer. See Multimedia Appendix 1 for a high-resolution version.

Malay patients aged 20-49 years had the highest rise in the ASR of CRC (APC 2.9%), colon cancer (APC 2%), and rectal cancer (APC 2%). Among Chinese patients aged 20-49 years, the ASR of rectal cancer persistently rose (APC 1.5%), while the ASR of CRC and colon cancer plateaued from 1999. In Indians aged 20-49 years, there was a small and nonsignificant rise in the ASR of CRC (APC 0.5%) and rectal cancer (APC 0.5%), as shown in Tables 4-6 and Figure 7.

APC: annual percentage change; ASR: age-specific incidence rate; CRC: colorectal cancer. See Multimedia Appendix 1 for a high-resolution version.

Age-Period-Cohort Model of IRRs and APCs for CRC, Colon Cancer, and Rectal Cancer

Table 7 and Figure 8 show the IRRs by birth cohort for CRC, colon cancer, and rectal cancer. Compared to the reference birth cohort of 1950-1954, there was a trend toward higher IRRs for colon cancer among the 1970-1990 birth cohorts; however, these changes were not statistically significant. In addition, compared to the reference birth cohort of 1950-1954, the IRRs for rectal cancer among the birth cohorts from 1905 onward were marginally lower. However, there was significant increase in the IRR for rectal cancer among the birth cohorts from 1970 onward, and this peaked in the 1980-1984 birth cohort (IRR 1.35, 95% CI 1.043-1.748). Subsequent birth cohorts from 1985 onward had similar IRRs as the reference birth cohort (Figure 7 and Table 7).

Figure 9 shows the net age-specific APC or local drift for CRC, colon cancer, and rectal cancer incidence rates. There was an increase in the incidence rates for CRC among those aged 25-69 years, with an average APC of 0.61% (95% CI 0.44-0.79) for all age groups over the entire period. There was an increase in incidence rates for colon cancer among those aged 40-69 years, while there was an increase in incidence rates for rectal cancer among those aged 35-69 years.

Survival Outcomes

Patients with EOCRC had better cancer-specific survival compared to patients diagnosed at 65 years and above (hazard ratio [HR] 0.73, 95% CI 0.67-0.79, *P*<.001) after adjusting for the TNM stage, gender, tumor site, surgery, radiotherapy, and chemotherapy (Table 8).

Table 8. Multivariable cancer-specific survival analysis of patients with CRC[a] using the Cox proportional hazards model.

Variables and groups	HR[b] (95% CI)	*P* value
Age (years)		
20-49 vs ≥65	0.73 (0.67-0.79)	<.001
50-64 vs ≥65	0.74 (0.70-0.78)	<.001
TMN[c] stage		
2 vs 1	3.84 (3.23-4.56)	<.001
3 vs 1	11.14 (9.43-13.16)	<.001
4 vs 1	58.70 (49.66-69.38)	<.001
Gender: male vs female	1.06 (1.02-1.11)	.006
Tumor site: rectum vs colon	0.55 (0.52-0.58)	<.001

[a]CRC: colorectal cancer.

[b]HR: hazard ratio.

[c]TNM: tumor, node, and metastasis.

Discussion

Principal Findings

Historically, CRC has been more commonly associated with older age groups, but in recent years, many countries have reported a concerning rise in cases among younger individuals. Although the overall incidence of CRC has been declining in older people, there has been a notable increase in the incidence of EOCRC, particularly in individuals younger than 50 years. In the United States, the overall annual, CRC ASIR has decreased by 46% from 66.2 per 100,000 population in 1985 to 35.7 per 100,000 population in 2019. Notably, CRC is now the most common cause of cancer deaths among individuals less than 50 years old [20]. However, from 2011 through 2019, the CRC incidence rate increased by 1.9% per year for individuals younger than 50 years. Rectal cancer has driven the EOCRC epidemiological trend with an increase of 2% per year. There was a steep decline in incidence among adults aged 50 years and older in the United States at 3%-5% annually in the late 2000s, and this is likely attributed to changing patterns in the risk factors and uptake of CRC screening. Incidence rates have been increasing in adults aged 20-39 years since the mid-1980s and in those aged 40-54 years since the mid-1990s [21]. Similar trends are seen in Canada, the United Kingdom, Australia, New Zealand, Europe, and Asia [5,22-25]. The rising incidence of EOCRC in East Asia may be due to an increase in the prevalence of risk factors, such as smoking, alcoholism, and obesity among young individuals [26]. A population-based study in Taiwan, Korea, Japan, and Hong Kong suggests that

XSL•FO
RenderX

from 1995 to 2014, the pooled incidence of early-onset colon and rectal cancers increased by 2.1% and 3.8%, respectively, among men. Similarly, the pooled incidence of early-onset colon and rectal cancers increased by 2.2% and 4%, respectively, among women [27]. In China, the incidence rate of EOCRC rose from 3.6 to 12.1 per 100,000 population from 1990 to 2019 at a rate of 4.6% per year [25].

Our analysis of incidence trends over time suggests that the rising incidence of EOCRC in Singapore is nuanced. The rising trend for people under 50 years of age is particularly for rectal cancer, especially in males. This trend also affects, in particular, the Malays but also the Chinese, with the Indians less affected. Our study supports the increasing literature that the increase in EOCRC is not confined to the West and may be a worldwide phenomenon. The cause of these observations is still unclear, but it can be explained by the cohort effects. The IRR for rectal cancer has been increasing among the 1970-1984 birth cohorts and suggests that it is the changes in exposure to these birth cohorts that influence the risk of carcinogenesis. High consumption of processed meat, alcohol, a sedentary lifestyle, a lack of dietary fiber consumption, smoking, and obesity are known lifestyle factors associated with CRC. However, these modifiable risk factors are present in all age groups and not specific to young individuals and cannot explain fully the rising incidence among young people [28,29]. It has also been reported that there are similar rates of obesity between EOCRC and older patients with CRC [30]. The increasing prevalence of the use of antibiotics and alterations in the gut microbiome may play a role in the development of CRC through effects of bacterial-derived metabolites and virulence factors. Results of a recent study show an increase in *Fusobacterium* spp. in the microbiome of EOCRC [31]. Understanding the generational shifts in early life exposures may provide further insights into the etiologies of EOCRC [7].

Most tumors in EOCRC are in the sigmoid colon and rectum [32]. The reasons regarding the steep rise in the incidence of rectal compared to colon cancer among young adults are unclear. Understanding the differences in the molecular profile between rectal and colon cancers may be key toward developing preventative strategies. EOCRC in young adults has been associated with synchronous and metachronous tumors, a more poorly differentiated histology, and mucinous and signet ring histology compared to older patients [7,33]. The rates of high microsatellite instability (MSI-H) are higher in EOCRC due to the higher incidence of Lynch syndrome. However, among the microsatellite-stable (MSS) cohort of metastatic CRC, patients with EOCRC have lower rates of *KRAS* and *BRAF* V600 mutations [31]. These observations suggest that the underlying biological process and basis of these clinicopathological conditions in EOCRC are different from those found in people above 50 years old.

The male gender is associated with a higher incidence of CRC compared to females. The incidence of rectal cancer is higher among young males compared to females. In 2019, the incidence rate of early-onset rectal cancer was 6.2 per 100,000 population among men, while it was 3.6 per 100,000 population among women. The higher proportion of men diagnosed with rectal cancer suggests a differential distribution of the tumor location between genders. Although the etiology between the gender differences is uncertain, it may be attributed to the varied exposure in dietary and lifestyle risk factors between both gender groups [34]. Some studies have explored the protective effect of estrogens and progestins against CRC in hormone replacement therapy in postmenopausal women [35,36].

The Chinese population in Singapore had the highest ASIR of CRC when compared to Indians and Malays. Previously, the Asia Pacific Consensus identified Chinese as an ethnic group that is more susceptible to CRC, and this was supported by cohort studies in Singapore and Malaysia [37-40]. In this study, although the incidence initially increased among the Chinese, the incidence rates have plateaued and declined over the past decade, except for early-onset rectal cancer, which continues to rise at 1.5% per year among young Chinese adults. However, the steep increase in the incidence of both colon and rectal cancers among the Malays across all age groups is concerning. This observation is supported by another study of age-period-cohort analyses in the SCR, stratified by ethnicity, that suggests a rising risk of CRC across all periods among the Malay population [41]. The rising incidence of EOCRC predominantly among Malays was also observed in Malaysia [42]. The varied epidemiologic trends across the 3 ethnic groups may be attributed to the differences in health-seeking behavior and lifestyle exposures between the groups in Singapore [41]. Modifiable risk factors, such as the rising rates and high prevalence of obesity among the Malays and the increased consumption of sweetened food, may play a role [43]. Malays were also less likely to participate in cancer screening compared to the Chinese. There is a need for tailored cancer-screening promotion campaigns to narrow the knowledge-behavior gap among the Malays [44]. Socioeconomic indicators, such as educational attainment, homeownership rates, and income levels, have shown improvement across all racial groups in Singapore [45]. Although there is a relatively similar socioeconomic environment in Singapore, the varying rates of the rise of EOCRC among the 3 races suggest that cultural, dietary, or genetic factors may potentially contribute to these differences. Further studies should be conducted that compare the lifestyle factors and social practices among the 3 ethnic groups and evaluate the impact on CRC incidence.

Our study suggests that patients with EOCRC have better cancer-specific survival compared to patients with CRC aged 65 years and older. However, there are conflicting data with regard to the survival outcomes of EOCRC compared to patients with late-onset CRC after adjustment for stage. A survival analysis of 35,713 patients with stage 3 colon cancer from the ACCENT database revealed that patients with EOCRC have improved overall survival, disease-free survival, and survival after recurrence. After adjusting for molecular markers (MMR, KRAS, BRAF), the prognostic impact of age of onset was lost [46]. However, there was a poorer 3-year relapse-free survival among patients with stage 3 EOCRC based on the pooled analyses of 16,349 patients from the International Duration Evaluation of Adjuvant Chemotherapy (IDEA) database. This was despite better treatment adherence and higher administered treatment intensity among the younger patients, hence suggestive of a more aggressive disease biology [47].

XSL•FO
RenderX

The current screening guidelines for CRC in Singapore start at 50 years of age for asymptomatic, average-risk individuals and have no impact on the incidence of early-onset CRC. Recently, the American Cancer Society recommended initiating CRC screening at age 45 years instead of 50 years for average-risk individuals to address the rising CRC incidence among young adults [48]. This recommendation was based on modeling data that suggest that this will prevent 29,400 CRC cases and 11,000 CRC deaths in the United States over the next 5 years [49]. Compared to the rising incidence of colon and rectal cancers in the United States, Europe, and Australia, our study suggests that rectal cancer among young adults is rising. Therefore, it is important for physicians to investigate young adults who present with anorectal symptoms, such as rectal bleeding, tenesmus, anal pain, and changes in bowel habits. Although these findings may suggest a need to re-evaluate the recommended age range for screening and consider extending screening to those 45-49 years of age, the incidence of EOCRC in Singapore remains low, and this strategy may not be cost effective. Despite the launch of the National Colorectal Screening Programme in 2011, the uptake of CRC screening remains low nationally at 41.7% [50,51]. However, flexible sigmoidoscopy among young adults is a less costly alternative as compared to colonoscopy and may capture the majority of EOCRCs since the tumor location of EOCRC is usually in the sigmoid colon or the rectum.

Strengths and Limitations

Although this study provides a comprehensive overview of CRC trends in Singapore, further research into the biological basis of carcinogenesis among young adults and differences in modifiable risk factors among ethnic groups is warranted. Age-period-cohort analysis was limited due to missing population data of those aged 70 years and above. Additionally, the study was limited due to the lack of information about the proportion of hereditary cancer syndromes in the cohort. The prevalence of hereditary cancer syndromes among EOCRCs ranges from 5% to 35% compared to 2%-5% for CRCs overall [52-55]. Although genetic predisposition may be associated with EOCRC, the majority of EOCRCs are still sporadic. Additionally, screening of families with hereditary cancer syndromes may only capture a small proportion of EOCRCs [52]. Future research should focus on identification of risk factors and predictors of EOCRC to determine high-risk groups that should be targeted for screening before 50 years of age. It may be a more viable strategy to develop risk stratification tools that combine family history and blood-based tests to identify high-risk neoplasia among young adults.

Conclusion

The incidence of rectal cancer among people under 50 years of age in Singapore appears to be increasing, especially among the Chinese and Malays. The differences in the epidemiologic trends among the 3 main ethnic groups may be due to varied lifestyle factors and social practices. Although it is possible that the observed increase may be attributable to lifestyle changes in the population over time, further studies are required to determine the underlying etiology. In contrast, CRC rates are decreasing among those above 65 years of age, and this may be due to the impact of the national screening program. These findings suggest the need for further research to diagnose CRC earlier among young adults and reduce the associated cancer-related morbidity and mortality.

Acknowledgments

The authors would like to acknowledge the National Registry of Diseases Office, Health Promotion Board, Singapore, for providing access to colorectal cancer data from the Singapore Cancer Registry. CHLR is supported by the Research Training Fellowship (MOH-001300-00) from the National Medical Research Council Singapore. The work was also supported by the Goh Hak Su Professorship in Colorectal Surgery.

Data Availability

Data collected from the Singapore Cancer Registry are not available publicly.

Abstract

Using social media recruitment for public health research presents both opportunities and challenges. Despite its increased use, few studies have detailed the practical issues, challenges encountered, and alternative strategies available for social media recruitment. This paper explores strategies for recruiting Indigenous and Native American populations in California for a study on COVID-19 vaccination and social networks. We describe different recruitment approaches, challenges faced, and pros and cons of strategies used to enhance data quality and efficiency, including survey design considerations, Facebook targeting versus use of research panels, quality assurance checks, and decisions around participant incentives. Our local setting involved recruiting Native American and Mesoamerican Indigenous individuals living in California through social media platforms. We highlight key adaptations to survey design, recruitment strategies, and data cleaning processes, noting what approaches that were effective and those that were not. Despite targeted efforts and community collaboration, recruitment was limited, and fraudulent data from bots significantly compromised data quality. Standard Facebook targeting approaches were largely unsuccessful. Our findings suggest that the increasing sophistication of artificial intelligence is becoming a substantial obstacle to authentic participant recruitment through social media. We offer recommendations to improve recruitment of hard-to-reach populations and mitigate AI-related fraud risks in future research.

KEYWORDS

social media recruitment; indigenous populations; Native American populations; public health research; survey design; data quality

Introduction

Native American and Indigenous populations have historically been underrepresented in health research due to longstanding structural, geographic, and cultural barriers, including limited trust in research institutions, language barriers, digital access challenges, and lack of culturally tailored outreach [1,2]. The rise of social media has sparked interest in its use for recruiting participants in both observational studies and online intervention evaluations. While most research focuses on social media to recruit for interventions, fewer have used it for observational research [3,4]. Social media has been promoted as an effective method for recruiting "hard-to-reach" populations in high-income countries, particularly sexual and gender minorities, with some studies examining effectiveness, cost-efficiency, and representativeness, and some providing guidance on specific approaches or challenges [5-9].

Despite the expansion of digital tools during the COVID-19 pandemic, few studies have described the use of online methods to engage Native American or Mesoamerican Indigenous communities. Some efforts have explored web-based health promotion or survey research with tribal communities, often emphasizing the importance of tribal sovereignty, trust-building, and culturally grounded methods [10,11]. However, few papers have systematically reported the methodological challenges, outcomes and lessons learned of social media recruitment in these population. Moreover, the rise of advanced artificial intelligence (AI) technology has exacerbated these challenges due to the proliferation of bots and fraudulent entries. Thus, there is a gap in practical guidance for researchers aiming to

XSL•FO
RenderX

use social media as a recruitment tool, particularly for hard-to-reach populations in the age of AI.

In this "Notes from the Field," we report our experience recruiting Native American and Mesoamerican Indigenous populations through social media in California for a study examining COVID-19 vaccination and social networks. The parent study aimed to recruit 800 Native American and Mesoamerican Indigenous individuals living in California, as well as 800 participants who were racially and ethnically representative of California's general population. Between January 2024 and February 2025, we recruited a total of 1173 participants, including 209 Native American and Mesoamerican Indigenous individuals. Recruitment approaches included Facebook and Instagram advertisements, outreach through community partner (CBOs), and use of a preformed research panel from Qualtrics (Table 1). Our survey included 50 questions, took approximately 30 minutes to complete, and used validated measures assessing social networks, vaccine attitudes, social media use, and sociodemographic variables. We pilot-tested the tool with students and members of our Indigenous Community Advisory Board to ensure cultural relevance and clarity, and was subsequently revised based on the feedback. In total, we received 5099 survey responses from the general population, of which 3926 were excluded due to suspected poor quality or fraudulent data. Our final sample included 137 (12%) Native American and 72 (6%) Mesoamerican Indigenous participants, far from our initial goal.

Table . Recruitment strategy and output.

Recruitment strategy	Incentive	Responses collected (N=3382)	Responses kept (n=1173)	NA/AI[a] (n=137)	Indigenous (n=72)
Meta ads - general incentive	$30	1212	334 (27%)	39	3
Meta ads - Raffle	Raffle	246	35 (14%)	2	1
Meta ads with Facebook Messenger screener	Raffle	315	95 (30%)	5	5
Qualtrics preformed panel	Set by them	1518	662 (44%)	76	49
CBO[b] distribution	$30	91	47 (52%)	15	14

[a]NA/AI: Native American/ American Indian.

[b]CBO: community-based organization.

Study results were used to examine how social networks influence vaccine decision-making and to inform the design of an intervention to address vaccine hesitancy among these subgroups. This study received institutional review board approval from participating universities and the California Rural Indian Health Board (UCSF IRB #23-38709, CRIHB IRB #2024-003) . It was also guided by a Community Advisory Board composed of Native American and Mesoamerican community members. The lead research team includes individuals from these communities.

This "Notes from the Field" highlights what was effective and what fell short in our methods and approach, and offers recommendations on recruitment strategies, survey design, and post-data collection quality assurance for researchers interested in utilizing social media for recruiting racial and ethnic minority groups in the United States.

Lessons Learned

Survey Design

We designed a survey suitable for a small screen, recognizing that some participants would complete it on mobile devices with limited time [12]. Pilot testing indicated that longer surveys increased dropout rates, prompting us to limit survey completion time to under 20 minutes. Additionally, answer options requiring extensive scrolling caused participant disengagement. To improve retention, we adapted the survey by using concise questions that fit entirely on a single screen.

Based on prior experience, we anticipated the risk of bots submitting fraudulent data to claim incentives and took proactive measures to mitigate this issue. We implemented several "bot-catching" quality checks, which also helped identify disingenuous participants rushing through the survey. Many online survey platforms offer built-in tools to verify human participants, such as CAPTCHAs, a screening mechanism where participants complete easy tasks but are challenging to bots and "invisible" reCAPTCHA's, which humans bypass unnoticed but are designed to trap bots. Recent studies have shown that they are increasingly vulnerable to sophisticated bots and human-assisted workarounds, making them a necessary but insufficient defense when used alone [13]. In our survey, many responses were dropped due to failed CAPTCHA verification; however, approximately 70% (n= 2367/3382) of the responses ultimately deemed ineligible had successfully passed the CAPTCHA screen.

We also experimented with "Honeypot" questions, which are questions that try to trick chatbots or insincere participants rushing who may not be reading the question but simply providing responses. These questions prompted respondents to select a specific answer (eg, the third option). However, we found that bots were able to bypass these as well. Ultimately, open-response fields, such as "other" with a fill-in-the-blank option or short-answer questions, proved more effective. These

XSL•FO
RenderX

fields allowed us to assess whether responses were rational and relevant, to help confirm participant authenticity.

After designing the survey, the next step was programming it using Qualtrics, an electronic survey platform, to integrate screeners, consent forms, and the survey itself. These platforms generate sharable links, making it easy to distribute surveys via social media. However, one drawback is that participants are redirected to an external webpage, often causing drop-offs. A potential workaround is embedding the survey directly within platforms like Facebook Messenger. However, this imposes limitations on the types of questions and branching logic that can be used, requiring simpler formats as these platforms are not specifically designed for complex surveys.

The screening process varied across recruitment strategies. When participants were recruited through Facebook and Instagram and directed to Qualtrics, the screener appeared as the first set of survey questions and included items on residence, age, and race and ethnicity (the race/ethnicity item was omitted when recruitment was open to the general population). Using this approach, only 33 of the 1,212 responses received were deemed ineligible based on the screener. In the Messenger-based approach, participants first completed a brief screener embedded within Facebook Messenger. Those who met eligibility criteria were then provided a link to the Qualtrics survey, which began with the consent form. Approximately 100 individuals were screened using this method, with half (n=50) determined ineligible. For the panel recruitment, we provided eligibility criteria to the panel provider (Qualtrics), who prescreened participants and invited only eligible individuals to participate. These participants were directed straight to the survey's consent form. Across all recruitment strategies, approximately 18 individuals did not consent to participate after reaching the survey.

Recruiting

Social media platforms offer advanced advertising tools that have transformed recruitment strategies. For instance, Meta's Ads Manager allows for efficient creation, monitoring, and optimization of campaigns. One major benefit of using Meta ads is the ability to implement highly targeted recruitment. Campaigns can focus on broad geographic regions or pinpoint specific areas, such as a single zip code. Additionally, targeting criteria can be refined based on factors like language, age, gender, and specific interests, allowing researchers to precisely reach their intended audience.

Using Meta's advertising tools, we targeted recruitment to zip codes with high concentrations of our target population. In collaboration with our community advisory board (CAB), we refined targeting criteria to include interests we hypothesized would resonate with the population, such as the Mexican national soccer team and Ranchera music for individuals with Mexican heritage. Images for ads were selected in partnership with the CAB and with insights from Upswell, they varied depending on the target audience. Campaigns were divided by demographics so we could turn off when we had reached the recruitment target. The objective of the campaign was survey clicks and the ads were active for two-week periods over four months. However, this approach yielded low recruitment rates. A more strategic selection of target interests, informed by deeper community insights or additional testing, could have improved this approach.

To enhance recruitment, we next employed a preformed panel—a curated group of individuals who had previously agreed to participate in research studies. We chose Qualtrics for this purpose, as our survey was already designed within their platform, and our university maintained an existing partnership. While this approach required significant upfront costs (and initial payment to Qualtrics), it proved more cost-effective compared to social media in the end in terms of cost per participant recruited. After filtering out suspected fraudulent responses, we found that recruitment through Meta ads cost approximately 10 times more than using the Qualtrics panel per high quality (real) participant recruited. In addition to cost benefits, the panel led to much faster recruitment compared to social media. However, given that our focal population included hard-to-reach groups (especially the Mesoamerican Indigenous population living in California), the pool of eligible individuals within the panel was quickly exhausted.

Incentives and Suspected Fraudulent Data

Participant compensation was a critical aspect of our recruitment strategy. Initially, based on community partner recommendations, we offered a $30 USD gift card to all participants. However, this led to a high volume of suspected fraudulent data, with 73% (n=884) of responses discarded during the initial data collection phase due to bots and fake submissions. To address this issue, we transitioned to a raffle system, offering a US $100 prize to 1 in 50 respondents. However, recruitment remained limited and fraudulent entries persisted—even after further improving the raffle odds to 1 in 10, recruitment levels did not increase and we continued to encounter suspected fraudulent data.

To balance recruitment needs with data quality, we implemented a system of individual, one-time survey links for each participant. These links could only be used once by one person, and thus, could not be shared or used multiple times over by a chatbot. Participants still received the link through a social media ad, but it could not be circulated further. This allowed us to offer a higher incentive while controlling access to prevent bots and fake entries. However, this method was labor-intensive for both our team and the participants. Interested individuals were required to email or text us to request access, after which we manually provided them with a survey link. While effective in improving data authenticity, this process limited our potential reach. We focused recruitment efforts on controlled channels, including Facebook and WhatsApp groups managed by our community partners, as well as direct contacts. While these methods helped ensure the authenticity of participants, they presented several challenges. Many individuals in our target population did not use email, and the delay between participants expressing interest and receiving their unique survey link further reduced follow-through.

During data collection, we encountered a high volume of suspected fraudulent entries, identified through re-CAPTCHA scores and other quality checks. Many fraudulent entries bypassed these measures in place by Qualtrics, requiring us to

XSL•FO
RenderX

conduct extensive manual data review and cleaning to ensure sample quality. To address these challenges, we reprogrammed the survey screener to run through Facebook Messenger. When users clicked on the ad, it opened an automated chat that included the survey screener, and eligible participants were then provided with the survey link. While this approach reduced bot activity, it came with trade-offs: overall participation decreased, the process was less cost-effective, and the platform's interface presented additional challenges.

Following data collection, we began a systematic data-cleaning process to ensure sample quality. We excluded all responses with a bot likelihood score below 0.5 provided by Qualtrics. Furthermore, we examined the geolocation of respondents' IP addresses to ensure they met our eligibility criteria, discarding those outside our target area. We also removed duplicate IP addresses; however, this process also carried the possibility of excluding legitimate responses from multiple participants within the same household.

To further improve data quality, we applied time filters to discard responses completed too quickly (ie, beyond two standard deviations from the mean). Additionally, collecting email addresses to distribute gift cards provided another opportunity for verification. We manually reviewed these emails for authenticity, flagging suspicious entries characterized by random strings of numbers or letters (eg, la675829@gmail.com).

Conclusions

Our experience with recruitment through social media revealed two key lessons. First, while social media has been effective for recruiting general populations and some specific subgroups, such as sexual and gender minorities, this approach was challenging in engaging our study's hard-to-reach populations—Mesoamerican Indigenous and Native American individuals in California. This was true despite the study team's prior experience working with these populations, expertise in social media recruitment, and input from a community advisory board on survey design and recruitment strategies. Language barriers, as our survey was only available in Spanish and English, may have contributed to these difficulties, highlighting the need for more culturally and linguistically tailored approaches to recruitment.

Second, the prevalence of suspected fraudulent data was more difficult to address than our team's prior experiences collecting data via social media in both the United States and globally. Sophisticated bots are capable of bypassing traditional quality checks, highlighting a need for strategies to differentiate authentic participants from automated responses. Identifying and filtering out fraudulent data required significant time and resources, increasing costs. Thus, it is possible that the age of easy, fast, inexpensive research through social media may be waning with increasingly sophisticated AI developments. To sustain the social media as a beneficial research tool, novel approaches to detect and prevent fraudulent entries are critically needed.

Abstract

Incorporating youth perspectives into health research can enhance quality, relevance, and ethics while also providing youth with mentorship, exposure to academic research, and professional development opportunities. This has led to a growing number of youth advisory boards (YABs). However, despite increased attention to YABs, the mentions of YABs remain low in the published research on youth and health. Furthermore, little published work has reflected on the importance of engaging with youth of color in YABs. This is critical both because of the perspectives and insight they bring to the research process and to help close the participation gap in extracurriculars among youth from racial and ethnic minoritized groups. To contribute to the literature on YABs and health equity, we offer an overview and reflection on the development and implementation of the Midwest Youth Wellness Initiative on Technology (MYWIT), a 1-week virtual, financially compensated summer YAB for youth of color aged 13 to 17 years centered on amplifying youth voices on questions related to digital technology and mental health. MYWIT youth advisors successfully codeveloped a novel research question and semistructured interview guide on the topic of navigating social media algorithms. The MYWIT process also highlighted the importance of youth compensation levels, scheduling, recruitment strategies, and overall resource constraints. We hope to encourage researchers to reflect on the value that even short duration YABs can add to the research process and how YABs can be structured to better recruit and support advisors who experience economic, institutional, and structural barriers to participation.

advisory boards; adolescents; social media; qualitative research; community engagement

Introduction

There has been an increasing recognition of the importance of incorporating youth perspectives into the research process to enhance quality, relevance, and ethics while also providing youth with mentorship, exposure to academic research, and professional development opportunities [1]. This has led to a growing number of youth advisory boards (YABs), also known as young people's advisory groups or youth advisory committees, where youth are recruited to help shape one or more stages in the research process. Health-focused researchers in particular have sought to create YABs [1-4], in part due to increased mandates by funders for patient and provider involvement [5].

This also aligns with the promotion of human rights, as Article 12 of the United Nations Convention on the Rights of the Child (UNRC) states that children shall hold the right to freely express their views in all matters affecting them [6]. In 2021, the UNRC clarified that the right to expression also applies to decisions relating to the digital environment [7]. Although the United States has not ratified the Convention, it remains a critical reference point for ethical research and practice. Amplifying youth voices in research on digital technologies and well-being has become particularly pressing as a growing number of policymakers and public figures have called for regulating youth access to social media and internet-enabled smartphones. More research is critically needed in this area, both to unravel the complexity of current evidence on the mental health impacts of digital technologies and to identify strategies for protecting youth without it coming "at the expense of children's other rights" such as freedom of expression, information, and assembly [7]. To ensure evidence-based government and platform policies that promote well-being and health equity, youth perspectives, particularly those of youth from vulnerable and minoritized groups, are essential to crafting research

XSL•FO
RenderX

questions and methods that reflect the lived experiences of youth.

Despite increased attention to YABs, mentions of YABs remain strikingly low in the published research on youth and health [8]. Further, little published work has reflected on the importance of engaging with youth of color in YABs. This is critical both for the perspectives and insight they bring to the research process and to help close the gap between youth from racial and ethnic minoritized and racial and ethnic majority groups in participating in nonsports-related extracurriculars [9]. Specifically, Hispanic youth have relatively low levels of participation in nonsports-related extracurricular activities, and non-Hispanic Black youth have not increased their participation rate in nonsports-related extracurriculars at the same pace as other groups [10].

These disparities in participation matter not just to college and future earnings trajectories [10-12], but more directly to well-being and health outcomes. Youth who participate in nonsports-related extracurriculars are less likely to smoke tobacco, drink alcohol, or use marijuana [10]. Access to these benefits is uneven and difficult to access for those without financial resources. Cuts to public services and a shift to a "pay-to-play" model of extracurriculars skew access toward higher-income families [9,11]. Youth with college-educated parents are also more likely to participate in extracurricular activities [10]. Further, youth participation in the paid workforce has been shown to displace their own participation in extracurricular activities, which may further disadvantage lower youth with fewer economic resources [13]. YABs seeking to incorporate perspectives from youth of color must therefore consider these financial needs.

In short, (1) YABs can offer benefits to youth of color and the advancement of equity-focused research on technology and well-being, and (2) it is critical that YABs financially compensate youth of color for their time to facilitate their participation over competing demands and formally recognize their contributions. Collaborative research with members of the public, particularly with those from racial and ethnic minoritized groups, has a responsibility to center "questions of equity and justice" [14]. To contribute to the literature on YABs and health equity, we offer a brief overview and reflection on the development and implementation of a 1-week virtual, financially compensated summer YAB for youth of color aged 13 to 17 years residing in the US Midwest. We call the YAB the Midwest Youth Wellness Initiative on Technology (MYWIT). The MYWIT is a collaborative effort between faculty at Michigan State University and the University of Wisconsin-Milwaukee. We launched the MYWIT in 2022 via seed funding from the Technology and Adolescent Mental Wellness YAB Initiative at the University of Wisconsin-Madison to help meet the goal of amplifying the voices of youth from racial and ethnic minoritized communities in research on digital technologies and youth mental health. Together, we created a research protocol and a draft semi-structured interview guide, illustrating the value of youth perspectives even in the formative stages of health equity research.

Youth Advisory Boards

YABs are closely related to youth participatory action research (YPAR), but generally stop short of allowing youth to cocreate and participate in all aspects of the research process and may lack the intention of "shifting power structures" inherent to the YPAR orientation [15]. While acknowledging this limitation, YABs offer an advantage in terms of logistical flexibility, allowing for more widespread adoption across a range of methodologies, time frames, and disciplines. They can be used to help develop a single research study or to provide insight and guidance on a broader research area or endeavor [1]. YABs thus have the potential to become a widely adopted tool in public health and medical research. The involvement of target populations in research can improve study feasibility and the usefulness of findings for practice [16,17]. Participating in the research process can also have benefits for youth above and beyond any financial compensation received, including positive outcomes related to leadership (eg, confidence and self-efficacy), academic/career (eg, time management, and oral and written communication), and social support (eg, sense of belonging and community) [2,18]. A YAB can collaborate on tasks such as generating or refining ideas, offering feedback on data collection tools, troubleshooting study challenges, and aiding in interpreting and disseminating findings [1,2,19]. Given the range of scope for YABs, guidelines have been proposed to ensure consistent reporting on how youth contribute to research [8].

However, YABs are not without challenges. Studies of YABs note several barriers to engaging with youth, including navigating ethics approvals, uncertainty about the value that youth could add, concerns about risk and the potential for harm to youth advisors, insufficient time and resources, lack of support from institutions, and recruitment challenges [20,21]. Prior work has also noted difficulties with scheduling, access to technology, attendance, and social dynamics such as a reluctance to share or the formation of cliques [2,19]. Youth may also experience anxiety about engaging with a process that is new to them [22]. Furthermore, YAB conveners must work to ensure that they provide advisors with meaningful experiences and that contributions are felt to be respected and valued rather than tokenistic, even if suggestions are not feasible within the current research environment due to discordance with institutional policies or a lack of funding [17,21,23]. These challenges also highlight the broader issue of "adultism," which privileges the perspectives and norms of adults through bias against youth [24,25]. While YABs are designed to elevate the voices of youth, norms, and expectations may still lead to an environment where youth needs are not centered or their perspectives are not fully respected [17]. Finally, the lack of alignment between the institutional expectations placed on faculty and the extensive work needed to develop and implement a YAB also mean that the work of supporting a standing YAB may need to be taken on by academic staff [23], which necessities substantive funding or other forms of institutional support. These barriers are key to overcoming for YABs to fulfill their potential of working toward addressing health equity.

The Midwest Youth Wellness Initiative on Technology (MYWIT)

Aims

The MYWIT holds the goal of working toward health equity by amplifying the voices of adolescents aged 13 to 17 years who self-identify with communities of color around the Midwest region of the United States. Specifically, the MYWIT program aims to (1) diversify the voices heard within conversations about how technologies impact teen well-being, (2) encourage advisors to share their experiences with technologies and discover new research questions that have never been asked before, (3) train advisors in the scientific method so that they can contribute to shaping research studies and consider a research-related career, and (4) prepare advisors to be leaders by providing them with a platform and skill set to communicate their ideas with others.

Format and Recruitment

In the first year of the MYWIT (ie, 2022), we operated using an academic year model, with online meetings every other month over the course of 12 months. Owing to challenges with scheduling and attendance, as also noted in a prior study [2], we opted to pilot a 1-week virtual summer camp model in 2023, meeting for 3 hours each morning on Zoom between July 17 and 21, 2023. Summer is also a time when extracurricular activities hold particular value due to summer learning loss [26]. A virtual format was selected due to the broad Midwestern catchment of the MYWIT, making a singular in-person meeting impossible. While virtual YABs can lead youth to feel less comfortable sharing their personal reflections and perspectives, prior YABs suggest that this barrier decreases over time as the advisors begin to feel more comfortable with each other [2]. Furthermore, online YABs eliminate the need to worry about how advisors will travel to meetings [1]. The objective was to offer youth an introduction to social science research methods and then support the advisors in collaboratively developing a research question and data collection tool to support future research. The Institutional Review Board at the University of Wisconsin-Milwaukee determined that the work did not qualify as human subject research. As compensation for their time, advisors received a US $100 honorarium if they attended all 5 sessions (with exceptions made for emergency situations). While contact information for a trusted adult was gathered in case of an emergency, the honorarium was distributed directly to each advisor via email in the form of two US $50 Amazon gift cards. All advisors were also offered the opportunity to coauthor this manuscript, which has been noted as a rare but important means of recognizing youth participation [17,27].

In addition to two mid-career faculty leads (one from sociology and one from public health) who served as codirectors, the MYWIT was supported by two undergraduate students (one from political science and one from public health) compensated through a university mechanism to support undergraduate research. All team members were female with a broad range of backgrounds (Latina, Asian, Middle Eastern, and European). In spring 2023, the undergraduate student mentors recruited eligible teens through the dissemination of a recruitment flyer (Figure 1) via personal contacts, outreach to local youth organizations throughout the Midwest, and through university staff that worked with high school recruitment and TRIO Upward Bound programs. Of 12 applications received, 4 youths (3 from Milwaukee, WI and 1 from Ann Arbor, MI) responded to emails and text messages to schedule informal interviews and complete emergency contact information. All advisors were between the ages of 16 and 17 years; 2 identified as male and 2 as female; 3 identified as Black or African-American and 1 as Asian and White. The number of advisors enrolled was lower than our initial target of 7-8. Additionally, no Hispanic youth enrolled as advisors. Notably, the cohort size was larger and more diverse in the first year of the program. It is not clear if the change for this cohort was due to the shift away from the academic year model as the recruitment strategy was similar for both cohorts. One participant indicated a need for technology resources and was provided with a university-owned tablet for the duration of the program. Having devices available and screening for need is critical since limited access to devices is a potential barrier to equitable participation for online YABs [2].

Lesson Topics and Research Output

Faculty and student mentors collaborated on organizing the program through brainstorming sessions informed by prior experiences with teaching research methods and a suggested outline for how to structure each day created by ChatGPT 3.5. The team had prior experience tailoring research design to high-school students; both faculty leads had mentored incoming first-year college students and one of the student mentors had engaged in research with the codirectors in her first summer after high school. Each morning, we started with an icebreaker or game related to technology or wellness for advisors to build rapport and prepare them for the day's activities and topics. We created Canva slides for lessons and used Google Jamboard and Padlet to engage youth advisors in brainstorming, feedback, and collaboration activities. Each day's activities primed the advisors for the next day's topic and equipped them with new

XSL•FO
RenderX

concepts, terminology, and skills related to research. Camera use was encouraged but not required.

The topic for each day can be seen in Table 1. Lessons on research were paired with research output-oriented activities each day. To begin, we asked advisors to brainstorm research topics related to technology in their lives. On day 2, they developed the research question: "How do minority youth navigate social media algorithms to meet their needs (social and consumer needs)?" Specifically, advisors felt that social media algorithms often showed them products not aligned with their needs (eg, haircare products for White hair types) or that targeted them in ways that felt manipulative (eg, ads for colleges that feature diverse students, when most of the student body is White). While it is difficult to study algorithms directly due to their proprietary nature, prior research suggests that social media algorithms may either target or exclude users from racial and ethnic minoritized groups in discriminatory ways and may also privilege social media content from White creators, denying users and creators "equal access to services and opportunities" [28,29]. Thus, the question centered on how youth from racial and ethnic minoritized communities work to navigate social media algorithms to better find the products and communities that meet their needs. Although the undergraduate student mentors and faculty codirectors reflect a broad range of racial and ethnic backgrounds, we note that we lacked concordance with the Black or African-American majority of the advisors. While advisors spoke about racialized experiences on social media, this lack of concordance may have shaped interactions in ways that either encouraged or inhibited discussion about these topics [30].

Table . The Midwest Youth Wellness Initiative on Technology (MYWIT) summer programming, 2023.

MYWIT summer program	Lessons and activities	Research output from advisors
Day 1: Introduction to Mental Health and its Relationship to Technology	1. Introductions and icebreaker 2. Interactive tutorial on current evidence and advisor perspectives on the pros and cons of social media for youth mental health 3. Jamboard brainstorming session: "Now it's your turn to be the researcher. What questions need to be asked? What needs to be explored?"	List of ideas for research studies about technology and youth well-being
Day 2: Research 101	1. Icebreaker 2. Educational session on the scientific method, social science research, and research ethics 3. Activity comparing social science research with natural science research 4. Refinement of brainstorming from Day 1 to reach one shared research question 5. Education session on common social science research and data collection methods 6. Activity for picking a data collection method aligned with the research question	A single open-ended research question to guide the rest of the week: "How do minority youth navigate social media algorithms to meet their needs (social and consumer needs)?" A data collection approach and target population: Semistructured interviews Youth age 13 to 17 years All minoritized groups Social media users (any platform)
Day 3: Developing a Research Plan and Expert Panel	1. Icebreaker 2. Education session on how to craft effective interview questions 3. Padlet brainstorming session for interview questions to respond to research question 4. Advisors led a mock interview with one of the undergraduate student mentors followed by question refinement 5. Expert panel and question and answer sessions with technology and mental health entrepreneurs	List of ideas for semistructured interview questions
Day 4: Finalizing the Research Plan and Program Reflection	1. Icebreaker 2. Final revisions to interview questions 3. Jamboard brainstorming session on what advisors hope will change based on the study and how to recruit participants 4. Padlet reflection on the MYWIT: What did you learn? What did you enjoy? What would you change?	Final list of semistructured interview questions List of study justifications and recruitment strategies Reflections and advice on the youth advisory board process
Day 5: Post Program and College Advice (short session)	1. Guidance on how to highlight the MYWIT participation on college applications and resumes 2. Advice for how to participate in research as an undergraduate student 3. Sharing of information on how to stay in touch and assessing interest in being involved in implementing the proposed study	List of advisors interested in continued work

On days 3 and 4, advisors designed a research protocol and semistructured interview guide that could be implemented in the future (Textbox 1). To provide additional professional development content, the MYWIT also featured an invited panel of entrepreneurs of color who work in the fields of technology and mental health and concluded with a session on how to translate their new research expertise into posthigh–school experiences. With the exception of this final day, which was led fully by the student mentors, each day had one of the codirectors present to support the advisors.

RenderX

Textbox 1. Interview questions developed by youth advisors on the topic of how youth from racial and ethnic minoritized groups navigate social media algorithms.

1. What is your favorite app?
2. How is your social media feed different now than when you first joined?
3. What kinds of things have you done to personalize your social media feed? How has that worked for you?
4. What kinds of obstacles have you encountered when navigating social media?
5. How does social media affect your mental health?
6. What social media app do you use to get recommendations or inspiration for things you want to buy?
7. What social media app do you use to search for things you want to buy?
8. What kinds of products do you look for on social media?
9. What word or phrase would you use to search for these products?
10. How does it make you feel looking for products on social media that fit your needs?
11. Do you feel like it is hard to find products for you on social media? Why?
12. Have you ever felt excluded by an ad on social media?
13. Can you give an example of a time when you felt excluded by an ad on social media?
14. How do you feel about social media advertisements targeting minorities?
15. What app do you use to search for communities online?
16. How do you use that app to interact with people?
17. How did you find those communities on that app?
18. Do you feel like it is hard to find communities for you online?
19. Have you ever felt left out from communities on social media because of your culture? Can you give an example?
20. How does it make you feel looking for communities on social media to fit your needs?
21. Do you post on social media?
22. What kinds of hashtags or buzzwords do you use to get your posts seen by the people they are meant for?
23. What would you change about the app to make it more inclusive for your community?
24. What would you change about the app to make navigating the app easier?

Experiences and Recommendations

Lessons Learned

At the end of the week, everyone reflected on the process and their recommendations via three questions on Padlet: (1) What did you learn? (2) What did you enjoy and what worked well? (3) What would you change? Additionally, advisors were asked to share further brief reflections via email following the final day. Below, we present the synthesized reflections across the groups (codirectors, student mentors, and advisors). Table 2 provides additional detail on key lessons learned.

XSL•FO
RenderX

Table . Key lessons from the Midwest Youth Wellness Initiative on Technology (MYWIT).

Topic	Key lessons
Recruitment	1. Recognize that recruitment is the most difficult task. 2. Budget extra time for recruitment. 3. Significantly overenroll in anticipation of attrition before the program begins so that the final cohort is larger.[b] 4. Cold calling youth-serving organizations was not effective. 5. Adopt rolling application review until the YAB[a] begins. 6. Reduce the amount of time between the application going live and the start of the YAB[b] 7. Holding advisor interviews can help assess the level of interest and commitment to attend. 8. Inviting advisors' friends to participate did not prove to be a very effective recruitment strategy. 9. Most advisors came from organizations that researchers and youth mentors had direct connections with or from a posting on the Michigan State University's website. Outreach within team member networks is a promising means of recruitment.
Programming and Engagement	1. Interactive icebreakers were important to encourage participation from advisors. 2. From the beginning, have a clear attendance policy (cameras on, how many days they can miss, etc). 3. Change the scope and duration of the program to allow for more in-depth work. Mentors and Codirectors suggested shorter program length with longer days, while Advisors suggested a 2-week program with shorter days.[b] 4. The most reliable communication to ensure daily attendance was texting. Emails seemed to work less frequently. 5. Family or financial commitments may prevent advisors from giving their full attention during sessions. 6. Incentives should be informed by what advisors might make in hourly employment during the duration of the program. 7. Additional resources are needed to support study development and implementation with the same set of advisors. 8. Consider in-person meetings or ways to make online meetings more engaging.[b] 9. Despite obstacles, youth advisors have novel and valuable insights into research goals and processes.

[a]YAB: youth advisory board.

[b]Indicates items based in part on advisor feedback

Advisors

Each of the advisors shared what they learned, what they enjoyed, and what they would change about the experience. Responses highlighted learning how to craft research questions and collect relevant data. Advisors also noted that they valued learning that other youth shared their concerns about digital technologies and enjoyed learning about social media and health. One advisor noted that learning how to develop interview questions was interesting because it taught them how to gather information without making assumptions about research participants. Another stated that they found it a fun, low-stakes entry into scientific research, allowing them to build up confidence for future opportunities. Advisors reported enjoying getting to craft a question that they care about and the panel discussion with Milwaukee, WI technology experts on relevant careers. Some feedback they provided for improvement included having a shorter application time span so that more youth would join and not forget about the program in the middle of the summer, enrolling more youth, and extending the program over 2 weeks and having shorter days instead. Additionally, two advisors indicated that in-person meetings would have been helpful. One explained that they felt the online format made sense for the time, but that having future programs in-person would facilitate conversations, as there were frequent silences during meetings that could be attributed to many of the advisors not turning on their cameras, leading to black screens with no face showing.

Undergraduate Student Mentors

Student mentors reported learning as peer mentors to the youth advisors, specifically enhancing their community engagement and mentorship experience for future careers. Both were nervous about explaining the program in a way that would be interesting and exciting to the advisors but enjoyed the challenge of practicing how to communicate clearly. Seeing how well the youth advisors engaged made the student mentors feel confident in their own communication growth. The students learned that if there are clear explanations and expectations of the youth advisors, they will feel empowered and motivated to participate,

XSL•FO
RenderX

which will enhance the likelihood that the products contribute toward health equity. Student mentors also learned the importance of adjusting communication from emails to phone calls or texts to send reminders to advisors and keep them engaged. Recommendations for change include a later start time for youth to be more engaged and recruiting more advisors to make it a more dynamic experience.

Faculty Codirectors

Codirectors had initially been worried about the low enrollment numbers, which persisted despite proactive efforts to recruit advisors, and the financial incentive offered. Ultimately, the 4 advisors generated valuable insights into research goals and processes, with the momentum of the 1-week schedule potentially offsetting the small group size. It is possible that the smaller-than-anticipated cohort size helped to achieve this positive outcome, as the literature on virtual focus groups indicates that smaller sizes (4 to 6) are preferred to achieve engagement and foster trust in the absence of traditional face-to-face communication [31].

However, not all advisors were able to participate equally during the week. One advisor joined from their place of summer employment and was thus not able to consistently make use of video and audio functions on Zoom. Developing clear guidelines in advance for what counts as full participation is essential. Furthermore, incentives may need to be increased to better reflect what youth could earn in hourly employment during the duration of the program. The loan of a tablet computer to an advisor also posed complexities in terms of institutional policies, with the university requiring that the student sign a document that they would cover the cost of the tablet if it was lost. Accordingly, a tablet that was valued less than the incentive for participation was chosen to avoid creating a potential hardship in the event it was lost or damaged. Considering ways to overcome economic, institutional, and structural barriers to participation is critical for any program seeking to prioritize the voices of youth from minoritized and marginalized communities as a step toward centering equity in technology and wellness research.

Furthermore, while the MYWIT is out of necessity virtual due its broad catchment area, others may wish to explore in-person YABs. Although past works suggest that in-person YABs also struggle with attrition [3,32], initial recruitment may be easier if youth are seeking a more traditional and immersive summer experience. We may also reconsider our policy on camera use being optional during online meetings to help foster a greater sense of community among the advisors. Camera use can be an equity concern, due to camera access, internet speed, and a desire to obscure the residential environment. In addition to the provision of devices when needed, one approach to consider might be to encourage the use of virtual backgrounds to allow cameras to be on, while still maintaining greater privacy [31].

Despite these challenges, the codirectors were extremely pleased with the rapid pace at which advisors picked up key research concepts, the insights advisors offered, and their passion for technology and youth wellness. Undergraduate mentor support was also pivotal for establishing rapport with the advisors. For example, undergraduate mentors helped to troubleshoot communication by suggesting the use of text messages rather than email. While this may appear to be an obvious choice, institutional norms for communication with college students via email (particularly at public institutions, where email is considered a public record) can obscure the actual communication preferences of youth and young adults. This serves as an indication of the critical importance of reflecting on and working to shift “adultism” when engaging with YAB work [24].

The research question that the advisors developed was one that the team had not previously considered, and the proposed interview questions were critical to fully understanding how the advisors operationalized the concept of navigating social media algorithms. Accordingly, the YAB provided significant value to the research process through the development of unique research questions and methods informed by the lived experiences of the advisors and their perceptions of social media, which is key for working toward health equity. Overall, the objective of training advisors in the scientific method so that they can contribute to shaping research studies was achieved and the building blocks for a viable future study were created. Going forward, the MYWIT would benefit from additional financial and time resources to support (1) rapidly developing and launching the resulting study idea, and (2) allowing advisors to participate in actual study implementation.

Next Steps

Sufficient resources are essential to support YAB work. For the MYWIT, we hope to obtain grant funding to support translating the advisor-developed project into a full-scale study, including resources to support youth, either through a YAB to offer guidance at key stages or a YPAR approach to more formally engage youth as partners throughout. A previous study on YABs indicates that advisors, with support and training, can excel at qualitative data collection and analysis [32]. The inability to move directly into the implementation of the ideas should not be seen as an indication that the YAB failed to generate valuable ideas and guidance, but rather an artifact of a small initial budget and the institutional prioritization of grant-funded work. Insufficient financial resources have been noted as one of the most common barriers to engaging youth in the research process [21]. Further reflective of the ways in which the organizational work needed to support a YAB is often misaligned with university expectations for faculty [23], we also hope to obtain the funding needed to hire not just student mentors but also academic staff to support future YAB work. This would also help create stability and continuity in the YAB over time [23]. Finally, we hope to draw on the recruitment lessons outlined in Table 2 to increase youth compensation and adopt new recruitment strategies to create a larger pool of advisors. This will also help to ensure engagement remains robust even if an advisor faces unexpected constraints that prevent their full participation.

Conclusions

Through sharing our experiences with a compensated YAB for youth of color in the US Midwest, our hope is to not just

XSL•FO
RenderX

encourage researchers to reflect on the value that even short-duration YABs can add to the research process, but also how YABs can be structured to better support advisors from racial and ethnic minoritized groups. While prior work has stressed the potential value of YABs and how they might be organized [2,3,8], this second question has received less attention. Sharing lessons, both in terms of what worked and what did not, is critical for identifying how best to leverage the value of YABs in shaping research on technology and health equity.

Acknowledgments

We thank the Midwest Youth Wellness Initiative on Technology (MYWIT) advisors (Nyahsha Stallings, Rosemary Buchtel, and others) for their time and commitment to research. We also want to acknowledge financial support from the Technology and Adolescent Mental Wellness (TAM) grant program at the University of Wisconsin–Madison and the Support for Undergraduate Research Fellows (SURF) program at the University of Wisconsin-Milwaukee.

Conflicts of Interest

None declared.

Abstract

Background: In recent years, social media has emerged as a pivotal tool in implementation science efforts to address the HIV epidemic. Engaging community partners is essential to ensure the successful and equitable implementation of social media strategies. There is a notable lack of scholarship addressing the operational considerations for studies using social media strategies in community-partnered HIV research. This article seeks to bridge this gap by consolidating field notes and practical considerations derived from 3 ongoing NIH-supported studies focused on Ending the HIV Epidemic in the United States.

Objective: This article aims to inform the design, planning, and implementation of operationally effective community-partnered social media strategies in HIV research, ultimately contributing to enhancements in HIV practice and improved outcomes across the HIV prevention and care continua.

Methods: Supported by the University of California, Los Angeles Rapid, Rigorous, Relevant (3R) Implementation Science Hub, the 3 Ending the HIV Epidemic projects convened to form the community-partnered social media campaigns working group. The working group used the Consolidated Framework for Implementation Research to help identify and organize key barriers and facilitators of relevance to implementation of the projects' social media strategies. Given the high degree of interrelatedness across reported factors, the working group thematically synthesized the content into 5 practical considerations to inform use of community-partnered social media strategies in HIV research.

Results: The practical considerations identified by the community-partnered social media campaigns working group include the following: (1) the power and pitfalls of social media platforms (ie, opportunities and challenges inherent to social media

XSL•FO
RenderX

platforms that may affect use of social media strategies in HIV research), (2) messengers and messages matter (ie, ensuring the appropriateness, acceptability, and quality of social media messengers and content), (3) the significance of the sociopolitical environment (ie, characterizing the sociopolitical environment surrounding HIV and its potential impact on implementing social media strategies to reach priority populations), (4) investing in academic-community partnerships (ie, cultivating positive and productive academic-community partnerships to support implementation of social media strategies in HIV research), and (5) the alignment of the institutional environment and research approach (ie, assessing and working to address features of institutional environments that may impact implementation of social media strategies in community-partnered HIV research).

Conclusions: As use of social media in HIV research and practice continues to grow, the practical considerations presented in this paper can help research teams anticipate factors that may impact implementation of community-partnered social media strategies and take early action to mitigate potential challenges. By understanding and addressing the unique challenges and opportunities of social media in community-partnered HIV research, we can leverage these platforms to accelerate progress toward ending the HIV epidemic.

(JMIR Public Health Surveill 2025;11:e73318) doi:10.2196/73318

KEYWORDS

HIV; social media; community partner; academic-community partnerships; Ending the HIV Epidemic

Introduction

Technological advances have transformed the landscape of health interventions, with the use of social media emerging as a pivotal implementation strategy [1]. Social media platforms play an integral role in disseminating information, fostering community engagement and communication, and promoting healthy behaviors [2-4]. In the context of HIV prevention and care, social media is increasingly used to promote awareness and uptake of evidence-based interventions, such as pre-exposure prophylaxis (PrEP) [5,6]. In addition, HIV researchers have leveraged social media in studies aiming to enhance program reach, strengthen coordination across health care sectors, guide clinical decision-making, and improve treatment retention and adherence [7]. Social media is also routinely used as a recruitment tool for HIV-related studies [8,9]. Its capacity to engage diverse populations, particularly those hard to reach due to geographic distance and stigma, underscores the growing relevance of social media in implementation science efforts to address the HIV epidemic [10].

The rapid growth of social media also presents challenges. Platforms such as Facebook (Meta Platforms), Instagram (Meta Platforms), TikTok (ByteDance Platforms), and YouTube (Alphabet Platforms) each have unique characteristics and user demographics, necessitating tailored strategies to connect with target audiences [11,12]. Not all target audiences have equitable access to the internet or familiarity with social media platforms, reflecting a digital divide that can further exacerbate health disparities [13]. Furthermore, protecting the privacy and confidentiality of individuals on social media, particularly in the context of HIV, is paramount. Doing so requires special considerations different from and beyond those typically required in in-person settings [14,15]. The constant evolution of social media technology, algorithms, and policies can also affect the visibility and reach of health intervention content [16]. Involving community partners is essential to effectively mitigate these challenges and ensure successful and equitable implementation of social media strategies in HIV implementation science efforts.

Despite the widespread adoption and implementation of social media, there is a notable lack of scholarship addressing the operational considerations for studies using social media strategies. This article aims to bridge this gap by consolidating field notes from 3 ongoing Ending the HIV Epidemic (EHE) Center for AIDS Research and AIDS Research Center supplement projects. Funded by the National Institutes of Health, these grants focus on enhancing the implementation science knowledge base needed to support the federal EHE initiative using partnered approaches among academic researchers, local health officials, and community groups to address HIV prevention and treatment needs in areas with high HIV transmission [17]. The 3 projects highlighted here each incorporate community-partnered social media strategies in their research to address this public health challenge.

Using the Consolidated Framework for Implementation Research (CFIR) [18] as a conceptual guide, we systematically identified the social media strategy characteristics, outer setting factors, inner setting factors, and processes involved in leveraging social media in each of these ongoing HIV implementation science projects. We aim to assist others engaged in HIV research by identifying common implementation determinants relevant to the use of community-partnered social media strategies across the 3 studies and synthesizing the content into practical considerations that can help researchers anticipate and mitigate potential challenges. Ultimately, these insights are intended to inform the design, planning, and implementation of operationally effective community-partnered social media strategies in HIV research, contributing to enhancements in HIV practice and improved outcomes across the HIV prevention and care continua.

Methods

Study Setting

Overview

The University of California, Los Angeles Rapid, Rigorous, Relevant (3R) Implementation Science Hub (hereafter referred to as the Hub) is funded by a National Institute of Mental Health EHE supplement award to the University of California, Los

XSL•FO
RenderX

Angeles Center for HIV Identification, Prevention, and Treatment Services (grant P30MH058107). The Hub aims to deliver expert technical assistance, coaching, and consultation to funded EHE implementation science projects and develop HIV-related implementation science capacity and collaborations locally, regionally, and nationally. The Hub's unique goal is to provide leadership and support for rapid, rigorous, and relevant (3R) HIV-related implementation research, emphasizing pragmatic study designs and methods that address health equity and produce sustainable solutions. As part of its routine services, the Hub team facilitates all-awardee meetings to provide opportunities for networking, collaboration, and collective problem-solving among its assigned EHE projects. Through these convenings and with the Hub's support, 3 projects that were each using community-partnered social media strategies expressed interest in collaborating on a manuscript to share practical considerations and lessons learned. The leads of these 3 projects (RGH and LJ; JJL; and AAA, JMP, and SH) and members of the Hub team (ABH, CL, EPR-C, SJL, and TBL) formed the community-partnered social media campaigns (CPSMC) working group to pursue this collaborative manuscript. Descriptions of each project and their use of social media are provided in the following subsections (summarized in Table 1).

Table 1. Summary of community-partnered social media campaign working group projects and their use of social media.

Project	Target population	Project goal	Social media strategy goal	Social media strategy description
A	SGDY[a] and AYA[b] in Tampa Bay, Florida	Identify HIV testing and PrEP[c] deserts and inform the development of equity-focused HIV interventions	Recruit participants for data collection activities	Geotargeted advertisements on Instagram as well as on social dating apps (ie, Grindr and Adam4Adam) and Google Ads
B	Latino and Latinx MSM[d] in King County, Washington	Implement and evaluate a culturally relevant social media campaign to increase uptake and use of HIV testing and PrEP	Increase uptake of and engagement in HIV services	Instagram and Facebook campaign in partnership with a local Latinx LGBTQ[e] organization
C	Black men in Shelby County and Davidson County, Tennessee	Promote men's sexual health and wellness and combat HIV stigma in the Black community	Deliver an intervention to address HIV stigma	Black barbers as men's health ambassadors sharing curated posts and videos on their social media platforms (X, Facebook, Instagram, and LinkedIn)

[a]SGDY: sexual and gender diverse youth.

[b]AYA: adolescent and young adult.

[c]PrEP: pre-exposure prophylaxis.

[d]MSM: men who have sex with men.

[e]LGBTQ: lesbian, gay, bisexual, transgender, queer.

Project A: Using Social Media to Recruit Participants for Data Collection Activities

The Mapping Adolescent and Young Adult HIV Testing and PrEP Deserts within the Tampa Bay Region: Promoting Equity Among Sexual and Gender Minority Youth project (principal investigators: RGH and LJ) assesses existing HIV surveillance data, characterizes adolescent and young adult (AYA)–centered HIV care and prevention services (with a focus on PrEP use), and collects and analyzes perspectives from AYA and sexual and gender diverse youth and other key community stakeholders toward promoting equity in HIV treatment and prevention services. Identification of HIV testing and PrEP deserts (broadly defined as areas where the demand or need for HIV testing among AYAs is greater than the supply of AYA-focused HIV and PrEP sites) [19] is a central study outcome that will inform the development of community and clinical interventions. The project uses geotargeted web-based advertisements to recruit AYA participants for ideation workshops focused on understanding the problem of HIV and PrEP deserts in the Tampa Bay, Florida, area, using three types of media channels:

(1) social media applications (ie, Instagram), (2) social dating applications (ie, Grindr and Adam4Adam), and (3) paid search campaigns (ie, Google Ads).

Specific media channels, including the existing social media channels of the project's community partner organization, were selected and advertisement content was developed using feedback from community partners to effectively reach the target population. Content included images of individual AYAs, couples, and relevant medical objects (eg, PrEP and HIV tests) as well as messages focused on empowerment and advocacy for sexual health. Social media content required a distinction between static (preapproved, unchanging materials, eg, stock images) and dynamic (interactive or adaptive materials, eg, trend-driven videos) content for institutional review board (IRB) approval. Dynamic content also included the use of contemporary audio or music and pop-culture trends, as well as strategic hashtags to engage local populations.

Project B: Using Social Media to Increase Uptake of and Engagement in HIV Services

The Implementation of a Culturally Relevant Social Media Campaign to Increase HIV Testing and PrEP uptake in Latinx MSM project (principal investigator: JJL) harnesses the innovative capacity of social media applications in engaging community members for HIV prevention. The study team is implementing and evaluating a culturally relevant and community-informed social media campaign to enhance uptake of HIV testing and PrEP among Latino and Latinx gay, bisexual,

XSL•FO
RenderX

and other men who have sex with men (MSM) in King County, Washington. Project aims include the following: (1) implement the culturally tailored social media (ie, Instagram and Facebook) campaign to facilitate HIV testing and PrEP uptake among Latino and Latinx MSM in partnership with a community organization dedicated to providing HIV and other services to the local Latino and Latinx lesbian, gay, bisexual, transgender, and queer community; (2) evaluate the effectiveness of the campaign in shaping behavioral determinants and HIV testing and PrEP uptake among clients at the organization; and (3) identify the costs and conditions that influence reach, maintenance, and scalability of the campaign to increase HIV testing and PrEP uptake in the Latino and Latinx MSM community.

A community-informed social media campaign was developed specifically for Latino and Latinx MSM and piloted in collaboration with the study's community partner organization, Entre Hermanos, in a previous study [20]. Guided by the unified theory of behavior [21,22], which identifies determinants of health behaviors (ie, normative pressures, beliefs and expectancies, self-concept and image, affect and emotions, and self-efficacy) [23], the study team developed culturally tailored social media content that addresses salient unified theory of behavior constructs and barriers to HIV prevention identified among Latino and Latinx MSM through qualitative interviews and focus groups [24]. The content reflected their specific needs and preferences, and a pilot study demonstrated the feasibility of the social media content in reaching high-risk Latino and Latinx MSM in King County [20]. For this study, the project team implemented the social media campaign on Facebook and Instagram over a 2-month period in Washington State to evaluate its impact on behavioral predictors of HIV testing and PrEP and HIV testing and PrEP use outcomes among Latino and Latinx MSM who seek services at Entre Hermanos.

Project C: Using Social Media to Deliver an Intervention to Address HIV Stigma

The Cutting Out Stigma: A Barbershop-Based Strategy to Reduce Stigma towards Black Men Living with HIV in TN project (principal investigators: AAA, JMP, and SH) involves implementing a barbershop-based health education and multimedia intervention focused on promoting men's sexual health and wellness and combating HIV stigma in the Black community in the 2 counties in Tennessee with the highest HIV prevalence and incidence—Shelby County (home to Memphis) and Davidson County (home to Nashville). This multipart intervention includes the following: (1) training Black barbers as men's health ambassadors to foster important conversations about HIV in the context of sexual health and wellness, and to share relevant community resources with barbershop patrons and (2) launching a multimedia HIV stigma reduction campaign involving print, audiovisual, and social media in and around Black barbershops in Tennessee.

The social media strategy comprises 26 messages that first introduced and branded the participating barbers as men's health ambassadors; provided information about HIV ("Fact Fridays"); provided motivational or educational information about general health in addition to sexual and mental health and wellness; and provided opportunities for barbers to create and share their own live videos ("Cuts and Convos"), pictures, and text ("Choose Your Style, Choose Your Health"). Participating barbers were asked to post curated messages at least once weekly on their social media platforms (X, Facebook, Instagram, and LinkedIn). Barbers were advised to post on prespecified days and times and to use tailored hashtags to optimize campaign reach. Where possible, barbers also were asked to collaborate with or tag the study team's social media account to further promote the reach of the messaging. The last component of the social media strategy involved the creation of short videos that feature some of the participating barbers in a local barbershop discussing men's sexual health and HIV. Barbers play these short videos on the screens in their barbershops at least 3 times weekly and share them via social media. The goal of the social media strategy and broader multimedia campaign is to spark conversations and engagement regarding HIV and HIV-related stigma, and to help reframe the stigmatizing narrative about HIV in the community.

Data Collection

Each project used constructs from the CFIR [18] in its initial project logic model to describe contextual factors germane to its planned project strategies and activities. Given the comprehensive nature of the CFIR and its preexisting application across projects, we used the CFIR innovation, outer setting, and inner setting domains as conceptual anchors and the domain constructs as a framework to help identify and organize key barriers and facilitators of relevance to implementation of the projects' social media strategies.

The academic project leads of the 3 projects (RGH, JJL, and AAA and JMP) began by identifying constructs relevant to their respective projects within the CFIR innovation, outer setting, and inner setting domains and describing how these constructs were operationalized and addressed in the context of implementing their social media strategies. During this process, academic project leads consulted with other members of their research teams as needed to ensure complete identification of key constructs. Academic project leads then engaged in informal conversations with their respective community partners to elicit and document their experiences with strategy implementation in the context of a research process involving academic-community partnerships. Community partners discussed barriers to and facilitators of strategy implementation, as well as benefits and challenges of participating as community partners in the projects. All original insights represented in this paper reflect this within-project examination of the experiences and perspectives of project team members, including academic and community partners engaged in research and implementation activities.

Data Analysis

The initial constructs identified by academic project leads were compiled in a Microsoft Excel matrix and reviewed for common constructs across the projects by the Hub project director (EPR-C). The matrix and common constructs were presented to the CPSMC working group and reviewed, discussed, and refined over 2 CPSMC working group meetings, as well as through opportunities for individual review and written

XSL•FO
RenderX

feedback. Given the high degree of interrelatedness across CFIR constructs and reported factors, after a set of common constructs was compiled, 2 Hub team members (EPR-C and TBL) worked together to thematically synthesize the content into preliminary practical considerations for use of community-partnered social media strategies in HIV research.

Notes from the individual conversations between academic project leads and community partners were reviewed and assessed by EPR-C and TBL for concordance with the preliminary practical considerations. The practical considerations were then modified to integrate community partner perspectives and experiences. The modified set of practical considerations was then reviewed over 2 CPSMC working group meetings, opportunities for individual review and written feedback, and iteration by EPR-C and TBL until consensus was reached.

Ethical Considerations

The 3 projects discussed in this paper are considered research and were, respectively, reviewed and approved by the Johns Hopkins University School of Medicine IRB (approval #IRB00377619; project A), the University of Washington IRB (approval #STUDY00015837; project B), and the Vanderbilt IRB (approval #240024; project C). Ethics approval and consent to participate is not applicable to the initiative described in this paper.

Findings

Overview

The five practical considerations identified by the CPSMC working group to inform use of community-partnered social media strategies in HIV research include the following: (1) the power and pitfalls of social media platforms, (2) messengers and messages matter, (3) the significance of the sociopolitical environment, (4) investing in academic-community partnerships, and (5) the alignment of the institutional environment and research approach. Each consideration and relevant subconsiderations are detailed in the following subsections in the form of synthesized reflections and recommendations from the project teams, drawing on relevant examples from the 3 projects' experiences in the field.

Consideration 1: The Power and Pitfalls of Social Media Platforms

Numerous opportunities and challenges inherent to social media platforms may affect the use of social media strategies in HIV research. While each social media platform has unique characteristics that may impact its appropriateness for a given project, our focus is on highlighting considerations relevant to the use of any platform.

Platforms and User Preferences Constantly Evolve

Each social media platform has unique features that evolve over time, continuously interacting with evolving user preferences and business environments. Shifting cultural trends, social dynamics, and platform features perpetually influence the preferences of diverse and heterogeneous user groups. Due to these constant shifts, with new trends continuously emerging and others dissipating, social media strategies that resonate with a particular community today may be less impactful tomorrow.

Ongoing engagement with the community is essential to stay attuned to these changes and to ensure that a campaign remains responsive and effective. For example, in project B, Latino and Latinx MSM community members suggested using particular hashtags and emojis of current relevance to best connect with their community. Notably, keeping pace with user preferences and behaviors requires a significant investment of time and resources. For these 3 projects, ensuring the continued relevance of particular social media approaches demanded ongoing monitoring and adaptation, which may be constrained by time, personnel, and funding. Moreover, evaluating the impact of social media strategies amidst this dynamic environment poses further obstacles, as the metrics and benchmarks for success may themselves undergo rapid transformation.

Projects May Be Limited by Platform Policies and Guidelines

Social media platforms face their own hurdles in managing the evolving landscape of user-generated content, sometimes resulting in the prohibition of content and social media strategies that particularly resonate with target communities. For example, project B noted that they were blocked from posting the content and images that were most popular with the Latino and Latinx MSM community they were trying to reach, posing a major barrier to implementation of their campaign. Furthermore, platform guidelines are constantly changing and may prohibit specific text and images that were previously acceptable for dissemination, as experienced by project B, potentially necessitating adaptations to planned content. Each social media platform also has unique content specifications, such as word count limits; varying levels of reliance on static images, videos, and text-based content; and restrictions on use of hyperlinks that must be considered in assessing its appropriateness for a given project.

Use of Social Media Introduces Unique Data Use and Security Complexities

Researchers must be aware of the potential risks to the privacy and confidentiality of participants inherent in using these platforms, as the evolving nature of social media introduces uncertainties regarding data use, security, and participant anonymity. Limited guidelines exist for how to best address these risks in the context of research, but individual projects should consider potential ways to mitigate and acknowledge these risks as they develop and implement their use of social media. The CPSMC working group projects highlighted the importance of early communication with IRBs regarding recommended practices for addressing data use and security concerns to avoid extended delays in IRB review and project implementation.

Reaching Your Population of Interest With Social Media

Social media is a powerful tool that can facilitate opportunities to reach populations that have not been effectively reached through traditional clinical and public health outreach, particularly given the widespread popularity and accessibility of social media platforms in the United States. All 3 CPSMC

XSL•FO
RenderX

working group projects emphasized the importance of assessing and addressing the unique needs and preferences of their populations of interest in identifying the appropriate platforms and approaches to most effectively reach them. Furthermore, while social media can facilitate reach to large and diverse communities, a disconnect may exist between the intended audience and actual message recipients. Factors such as algorithmic biases, user engagement patterns, and content sharing dynamics can influence who ultimately receives and interacts with the content. Platforms may offer some targeting options, but they may not always be as granular as desired to reach particular groups (eg, MSM and trans women). Even when these features exist, some individuals might not be open about their identities nor willing to disclose their identities on social media platforms. These limitations may add another layer of complexity to the implementation of social media campaigns for specific communities. While social media platforms may support reaching certain populations, the level of specificity available for targeting may not adequately align with project goals.

The high potential reach of social media platforms may also pose particular challenges for community partners. For example, project C's men's health ambassadors initially raised concerns about how far their messaging may go on social media given their local environment of HIV-related stigma and discrimination. Conversely, while project B's community partners highlighted their excitement about potentially removing the geographic boundaries of their impact via the use of social media, they were not able to do so in practice because their organization only had the capacity to provide local services.

Social Media Is Increasingly Part of Routine Operations in Community Organizations

All 3 projects identified increased use of and investment in social media among community partner organizations in recent years. For example, the clinical organization partnering with researchers on project A noted that they have increased staff dedicated to social media as well as enhanced attention to metrics on the impact of their social media channels. Likewise, the organization has increasingly relied upon social media for outreach to populations of interest, including the AYA populations of focus in project A. The prevalent use of social media by community organizations may help facilitate the use of social media strategies in community-partnered HIV research.

Consideration 2: Messengers and Messages Matter

Identifying Your Messengers

The messengers a research team uses to deliver their social media strategy can have a pronounced impact on strategy success. All 3 CPSMC working group projects gave significant consideration to identifying messengers who would draw the attention and trust of the communities they were seeking to reach. Messengers may include individuals represented as messengers in social media images as well as the message poster or source. For example, project A clearly indicated the source of the content and visibly displayed the logo or name of the trusted partner organization in social media images to help support engagement. The CPSMC working group projects highlighted that if social media messages appear to be coming from a source that is not accepted, relevant, and credible in the eyes of the target audience, the audience is unlikely to positively engage with the content.

Involving Social Media Experts to Ensure High-Quality Content

Social media expertise is a crucial element of successful social media strategy implementation. It may be provided by members of the project team or by external contracted entities. CPSMC working group members noted that public communications and social media education are typically not included in the traditional investigative training pathway, which may result in projects needing to rely more heavily on external expertise. When possible, it is useful to work with experts in social media who have experience communicating about HIV or other potentially sensitive health topics to the population of interest. For example, project C contracted with a Black-owned media and marketing company with expertise in health interventions to help develop their HIV stigma reduction multimedia campaign. As one of their men's health ambassadors noted, "Social media marketing can be effective if it's done really well or people will remove it, block it."

The Importance of Community Input

Community partners are necessary opinion leaders, champions, and external change agents. All 3 projects emphasized that any HIV-focused study intending to implement social media strategies should consider how best to include community partners who reflect and are meaningfully connected to the population they are working to reach throughout their strategy development and implementation process. Community input on social media strategies may also be gathered via focus groups with members of the population a study intends to reach (as was done in project B), pilot-testing, and other idea generation and feedback opportunities with community members. Community partners involved in project B emphasized that "overall, community members were responsive to our campaign because it was designed for Latinos by Latinos." The 3 projects stressed that the quality of social media messaging reflects the care that was taken to design the message to reach, connect with, and inform the population of interest, which requires community input.

While community input is crucial and may offer consistent guidance on certain elements of a social media strategy, it is also important to acknowledge the heterogeneity in communities. All 3 projects observed diverse community member opinions that did not always lead to consensus about the preferred look and feel of their social media content. For example, project A shared that photographs of local youth self-reporting as sexually or gender diverse within an Instagram campaign were considered by some community partners to be denoting too much vulnerability and not demonstrating empowerment. Likewise, project B noted that some participants desired images that "looked like them," which was a key element of their content development process, but given the diversity within the Latino and Latinx MSM community, not everyone always felt represented. Still, all 3 CPSMC working group projects agreed that a community-engaged development process

XSL•FO
RenderX

was invaluable to refining messages and identifying trusted messengers.

Your Content in Context

The context in which an HIV social media strategy is implemented has major implications for how content may be received. The high potential reach unique to the use of social media strategies can pose challenges in contexts where HIV is highly stigmatized. As a men's health ambassador involved in project C shared, some people in their local area of Tennessee "don't want to be attached to [HIV] and don't want to be bothered." While the potential to reach a large audience is generally advantageous for spreading awareness and disseminating information, it may pose additional challenges for research efforts navigating sensitive topics in environments marked by stigma and discrimination. To minimize this risk, the CPSMC working group projects emphasized that researchers using social media strategies should use inclusive and empowering content that presents communities in ways that align with how they desire to be portrayed, being careful to avoid perpetuating stigma.

Relatedly, an important piece of guidance that arose from community input in these projects was to avoid negative framing of disparate health outcomes. Community members emphasized that images and text should have a positive tone that avoids stereotypes or foreboding messages. Paying attention to communities' strengths and resilience may be particularly important for social media strategies focused on marginalized groups, especially in contexts where there is a high level of stigma related to HIV and sexual health. Research teams should also anticipate potential mistrust by community members around targeting specific populations. Studies may need to actively work to establish trust, demonstrate trustworthiness, and consider historical harms in communities of interest to come to a place where their content can be positively received and considered credible by community members.

Consideration 3: The Significance of the Sociopolitical Environment

The sociopolitical environment surrounding HIV and its effect on implementing social media strategies to reach priority populations can have a tremendous impact on project success. To illustrate the importance of considering the sociopolitical environment, these dynamics are explored in the context of each project in the following subsections.

Project A: Social Media as a Recruitment Strategy When Traditional Strategies Are Nonviable Due to Local Attitudes Toward the Target Population

Lesbian, gay, bisexual, transgender, and queer individuals in Florida, as in other states, face worsening disparities in health care access and treatment that heavily influence the implementation of HIV-focused research. Sexually and gender diverse youth within the state are particularly susceptible to severe discrimination, lack of culturally competent care, and marginalization as past HIV-focused treatment and prevention programs were largely closed or minimized in the wake of legislative measures, including the "Don't Say Gay" bill [25] as well as a ban on gender-affirming treatment for youth [26] passed within the state in 2023. As a consequence of these sweeping policy changes, traditional recruitment strategies, such as in-person discussions, use of flyers, and brick-and-mortar-based information, were no longer available for project A, which focused on the inclusion of sexually and gender diverse youth. Furthermore, within the pediatric health care organization involved in the project, clinical programs, such as the adolescent medicine and gender-affirming care clinic, were closed, and clinical and research teams were subject to personal threats for providing care to this population. With local and regional channels to reach and support this highly vulnerable population suspended, social media–based recruitment became the primary and safest method for outreach for project A. This recruitment strategy, while limited to the structure and scope of public-facing platforms, offered the only way by which to communicate information related to sexual health to populations at risk for HIV in a way that protected content from new laws and processes that limit traditional "free speech" opportunities available in other states to engage diverse populations in HIV-focused research.

Project B: Community Acceptability and Supportive Policies Engender a Welcoming Atmosphere for a Social Media Campaign

Project B's decision to develop a social media campaign for Latino and Latinx MSM via their academic-community partnership stemmed from the community's receptiveness to technology-based outreach strategies for HIV prevention. The popularity of social media, coupled with expanded efforts to increase HIV prevention in Washington State and particularly in King County, created a welcoming atmosphere for public initiatives to encourage use of HIV-related services. Specifically, Washington has supportive policies that help eligible people with HIV obtain medications as well as PrEP drug assistance programs that provide financial assistance for people interested in accessing PrEP. Project B's community partner organization was also involved with learning collaboratives as part of King County's EHE efforts, which support health care organizations across the county in better identifying and serving people at risk for HIV. These initiatives demonstrated a readiness and favorable environment for project B and helped facilitate the implementation of its social media campaign.

While perceptions of HIV vary widely across different communities and counties within Washington, progressive policies and supportive programs may contribute to a relatively accepting environment for individuals living with or at risk for HIV. Thus, social media strategies and interventions for HIV prevention may be more feasible in Washington compared to places with more restrictive environments.

Project C: A Social Media Strategy to Address HIV Stigma Plans for Stigma-Based Community Reactions

The broad sociopolitical environment in Tennessee is characterized by various legal and cultural factors that act as barriers to addressing HIV. While pervasive HIV-related stigma has been identified as a key contributor to the disproportionate effects of HIV across the Deep South [27], in Tennessee, this stigma has manifested in some of the most stringent HIV-related criminalization laws in the country. For example, until July

XSL•FO
RenderX

2024, Tennessee was the only US state that imposed a lifetime registration as a "violent sex offender" if convicted of engaging in sex work while living with HIV [28].

Over the last several years, Tennessee has made gradual progress on key HIV prevention and treatment outcomes. However, recent political decisions indicative of continued stigma around HIV and populations most impacted by HIV have the potential to reverse this progress. In 2023, Tennessee rejected millions of federal dollars for HIV prevention, while simultaneously funding prevention efforts from the state's budget and prioritizing new populations (pregnant people, survivors of sex trafficking, and first responders) over populations with the greatest risk and burden of HIV in the state [29]. In the context of project C, the stigma and fear culturally associated with HIV were carefully considered during each step of the social media strategy design and implementation process. In addition, the barbers who became men's health ambassadors as part of the project expressed that social media amplification of the campaign would make some individuals in their communities assume that the barbers have HIV. They said that preparation for how to challenge this assumption would be useful and appreciated. In this way, the broad potential reach of social media was a source of potential concern for project C's strategy implementers who were aware they may become targets of stigma and discriminatory behavior if assumed to have HIV.

Consideration 4: Investing in Academic-Community Partnerships

Identifying the Right Partners

In any academic-community research partnership, cultivating a positive relationship, establishing shared project goals, and identifying the contributions from and benefits for both partners is paramount. For researchers aiming to implement HIV-related social media strategies, this process starts with identifying a community organization that is experienced with and sensitive to HIV-related topics, and trusted by and, where possible, culturally congruent with the population to be reached. It is also helpful for the organization to have social media and communications expertise, ideally specific to reaching the priority population with health messaging. Having a strong previous working relationship with the organization and its leadership is very useful, as was the case with projects A and B, or the study team must invest in building that strong working relationship in preparation for strategy implementation, as in project C [30].

Building Research Literacy

Many community organizations conduct effective programmatic work with populations highly impacted by HIV and have limited knowledge of research. Among the community partners working on these 3 projects, there was variable familiarity and experience with research. For example, while project A's community partner organization, a clinical setting, had previously participated in research, a member of their clinical leadership team shared that "research is just not built into the organization." He also described receiving "blank stares when we talk about data." The CPSMC working group projects noted that researchers seeking to start or strengthen partnerships with community organizations should be prepared for a potential lack of familiarity, comfort, and interest in research among staff. Likewise, key elements of research projects, such as administration of grant funding, project roles, and project timelines, may not be intuitive to community partner staff, which may cause challenges during project initiation and implementation. Sharing the research purpose and components and outlining the practical, administrative elements of project implementation with community partners early on will help build research literacy and lay the foundation for a successful academic-community partnership.

Communicating Effectively

With all partnerships, and particularly when working with community organizations newer to research, it is key for the academic partner to provide clear, transparent, and tailored communication that meets the community partner organization where they are. The academic team should endeavor to communicate the relevance and intended impact of the project as it relates to the community organization's work and avoid using technical jargon. In addition, routinely inviting and responding to questions from community partners is important. All 3 CPSMC working group projects noted that trust is at the core of any positive partnership, and therefore, communication between partners should be timely and reliable.

Pursuing the Win-Win

Often, academic-community partnerships are developed primarily to serve research-related goals set forth by the academic partner. Funds are typically provided to community partners via subcontract to support their participation. However, projects A and C noted that in practice, it can remain challenging to add research activities to a staff person's plate outside of their routine role. A member of the clinical leadership team for project A's community partner organization also noted it can be tricky to assign and supervise research-related roles among existing staff, asking "How do I give feedback on a role they weren't hired for?"

Given these challenges, it is crucial for researchers to work to identify and support benefits of participation for community partners. Researchers may consider eliciting information from staff at their partner organization about what they hope to gain from participating. For example, becoming men's health ambassadors was seen as a growth opportunity for some of the barbers participating in project C. One commented they wanted to be "a part of something greater" by participating in this project to improve HIV-related outcomes. Some also expressed concern about not being integrated into future efforts after "building a team of believers" through this work, presenting an important opportunity for the academic team to consider how to keep them engaged as long-term champions. Ensuring allocation of appropriate financial incentives for community partners is also key, particularly for those who may not have consistent wages paid by the organization, as was the case in project C.

XSL•FO
RenderX

Consideration 5: The Alignment of the Institutional Environment and Research Approach

Overview

The 3 CPSMC working group projects unanimously agreed that while academic-community partnerships have increasingly been used in HIV research to facilitate the development of interventions and strategies tailored to the unique needs of communities most impacted by HIV, this approach remains unfamiliar to many academic institutions and their IRBs. All 3 projects experienced tension between the increased national priority for HIV researchers to conduct community-partnered research and institutional structures that were not created with community-partnered research frameworks in mind nor designed to support community-partnered research. The projects reported struggling with IRB-related policies and infrastructures that hinder the implementation of timely, bidirectional community-partnered research. Additional challenges included institutional restrictions and limited guidance regarding implementing social media strategies as part of these research endeavors. This section highlights the importance of assessing and working to address features of institutional environments that may impact implementation of social media strategies in community-partnered HIV research, exemplified by the experiences of the CPSMC working group projects.

Assessing Institutional Preparedness to Support Your Research

All 3 projects described experiencing significant institutional constraints and generally conservative approaches by institutional IRBs when reviewing their community-partnered HIV research protocols. They commented that despite community engagement and partnership increasingly being included as required elements of proposals for HIV research funding nationally, community-partnered research methodologies are still considered novel and are misaligned with the research infrastructures of many academic institutions. For example, they reported challenges with the inclusion of community partners as "coinvestigators" on IRB protocols, limiting true partnership and coownership of studies. They also highlighted a lack of resources and support from IRBs to help community partners become familiar with institutional processes and requirements, such as training modules on human research protections tailored for community partners.

These challenges were heightened when combining a community-partnered HIV research approach with social media strategies. Although most IRBs are well-attuned to supporting traditional recruitment strategies, projects noted that there appear to be few precedents as to how social media and other digital platforms could be used to connect with potential participants while still protecting participant privacy and confidentiality. In addition, because user interactions with content feed each social media platform's private algorithms that shape future content displays, participants may receive future information on the platform that is uncontrolled by and unpredictable for the research team and their institutional IRB. This uncertainty may create potential challenges for the IRB's efforts to ensure human participants' protection and sometimes results in significant constraints on the research team's social media strategy design and implementation. Furthermore, the CPSMC working group projects found their IRBs to be generally unfamiliar with the use of nonstatic content (eg, videos and reels). They noted that IRBs often do not have guidelines or systems for assessing these dynamic forms of information sharing, which are increasingly popular among social media users. Although social media–based approaches to recruitment, engagement, and intervention delivery are increasingly used in research and have been highly effective in reaching populations most impacted by HIV, the experiences of these 3 projects suggest that institutional IRBs may be underprepared to support implementation of social media strategies.

Navigating the Impact of Your Institutional Environment on Your Research

These challenges place community-partnered HIV research projects implementing social media strategies in situations where projected timelines are almost certain to be delayed pending their institution's readiness to provide relevant support and guidance for their research approach. Two of the 3 CPSMC working group projects experienced major IRB-related delays that halted important study progress for several months. Crucially, these institutional challenges and resulting delays can create delays in payment and confusion and frustration among community partners.

The projects noted that some of this frustration among community partners may have stemmed from a lack of understanding about the function of IRBs and how they work, further reflecting the need for academic partners to invest in building research literacy among all members of their project teams. Likewise, some partners were not familiar with the risks and responsibilities of engaging in human participants research and complying with IRB requirements. Certain requirements were also found off-putting by community partners, such as the requirement to engage in an informed consent process using a document that contained standard IRB language that felt "uncomfortable" or "unnatural." Compounded with restrictions and delays that hindered project progress, project C noted that this discomfort resulted in some community partners questioning the intentions of and need to rely on academic institutions. One partner from project C asked, "Do we always have to wait on something to make a difference?" and "Do we always need some outside source for the community, or do we have what we need?"

The CPSMC working group projects came to consensus in emphasizing that academic partners are ultimately responsible for ensuring community partners are equipped to adhere to institutional policies and procedures and are prepared for administrative processes that may cause delays in project activities and, in some cases, payment to community partners. Given the observed lack of resources and support from IRBs to help community partners become familiar with institutional processes and requirements, researchers must be prepared to provide education about what to expect with respect to the academic institution; subcontracting processes; and the purpose, policies, and procedures of the IRB that are relevant to community partner roles in the project. Researchers should also be prepared to proactively advocate for the needs of their

XSL•FO
RenderX

community partners in an attempt to support strong and sustainable academic-community partnerships.

Discussion

Implications of Findings

The federal EHE initiative has brought renewed attention and investment to addressing the HIV epidemic in the United States. A "whole-of-society" initiative, EHE emphasizes innovative, community-engaged approaches to optimizing HIV research and practice [31]. In community-partnered HIV research, social media is increasingly used as a strategy to reach potential participants and deliver interventions [5-7]. However, it remains a newer approach, and there is little practical guidance available for HIV researchers interested in using social media strategies. This article features the voices and experiences of 3 research teams and their community partners, offering real-world, pragmatic insights from their projects that are more likely to be shared informally among the research community than published in peer-reviewed journals. These insights provide essential guidance to inform the effective implementation of community-partnered social media strategies in HIV research. Five practical considerations were identified, addressing the unique nexus of HIV research, academic-community partnerships, and social media strategies.

While we intend for these notes from the field to offer pragmatic guidance for researchers, this article also serves to spotlight salient implementation barriers commonly identified across 3 distinct HIV research projects. Despite previous calls to address the discordance between institutional structures and community-partnered research approaches [32], the experiences of these 3 projects demonstrate that there remains an urgent need to develop solutions to this ongoing challenge. The barriers experienced by the CPSMC working group projects are largely consistent with those identified in other recent literature. For example, a scoping review of 15 US-based community-engaged research projects by Onakomaiya et al [33] described four key challenges related to working with IRBs: "(1) community partners not being recognized as research partners; (2) cultural competence, language of consent forms, and literacy level of partners; (3) IRBs apply formulaic approaches to community-engaged research; and (4) extensive delays in IRB preparation and approval potentially stifle the relationships with community partners." While there is increased emphasis on community-engaged methods by academic institutions and federal funders, as evidenced by their calls for community-partnered research applications, this ongoing misalignment reflects a culture and infrastructure that are not fully prepared to support community-partnered research. Furthermore, as identified by these 3 projects, these barriers limit researchers' abilities to build strong, sustainable relationships with community partners. Educating IRBs on community-partnered research methodologies, revisiting policies that create barriers to community-partnered research [34], and developing and disseminating human participants research training modules tailored for community partners [35] could help bridge the gap between current institutional infrastructures and community-partnered research approaches.

Likewise, IRBs have limited preparedness to assess and support projects using social media strategies. As noted by the CPSMC working group projects, use of social media in human participants research has raised new ethical and regulatory complexities, and there remains limited guidance for IRBs from federal regulatory bodies. In the absence of that guidance, IRBs and researchers have a responsibility to carefully consider the unique participant privacy and autonomy implications of using social media strategies, balanced with the immense positive potential of using these tools in research endeavors. While protecting research participants is important for engaging in responsible research activities, we are potentially losing creative, innovative, and effective approaches to help end the HIV epidemic by not optimizing the implementation of social media strategies in HIV research. The rubric proposed by Bhatia-Lin et al [36] to assist studies to determine ethical and regulation-consistent use of social media platforms may offer a useful framework for these considerations.

More broadly, the insights shared in this paper highlight the need to continue working toward addressing the historical separation between academia and the community and creating a culture that values and respects building and maintaining strong community partnerships. In the context of implementing social media strategies in community-partnered HIV research, partnership with the community is particularly essential for engaging trusted messengers and developing culturally relevant messages. Likewise, it is critical for research teams to proactively address potential communication and research literacy barriers that may hinder the full realization of their community-partnered HIV research and its potential impacts.

While this article provides practical considerations and guidance regarding implementation of social media strategies in community-partnered HIV research, future research is needed to add to the evidence base on best practices for using social media in HIV research and to continue expanding the growing body of literature on community engagement and partnership in HIV research [37]. Further study is also needed to characterize the unique features of various social media platforms and types of content for use in HIV research, and to assess the effectiveness of community-partnered social media strategies in improving HIV-related outcomes. In addition, developing approaches projects can use to design their social media strategy to match their particular context and research aims would be a useful contribution to the HIV research field and beyond. Though this article focuses on HIV-related research, we also anticipate many of the insights shared here would be transferable to investigators implementing social media strategies and conducting community-partnered research in other fields.

This article offers practical considerations in the form of notes from the field derived from 3 ongoing studies. While instructive, these considerations do not comprehensively represent the many types of social media platforms, content, and strategies used in community-partnered HIV research and are limited to the experiences of the 3 CPSMC working group projects. In addition, we do not capture the effectiveness of these strategies as part of this paper, as all investigations are ongoing. Exemplars of effectiveness studies are available in the literature [38,39]

XSL•FO
RenderX

and can provide useful guidance for determining appropriate outcomes for social media strategies.

Conclusions

As use of social media in HIV research and practice continues to grow, the practical considerations presented in this paper can help studies anticipate factors that may impact implementation of community-partnered social media strategies and take early action to mitigate potential challenges. The potential of social media to reach and engage populations most impacted by HIV is significant, and ongoing research is needed to harness its potential. By understanding and addressing the unique challenges and opportunities of social media in community-partnered HIV research, we can leverage these platforms to accelerate progress toward ending the HIV epidemic.

Acknowledgments

The authors would like to thank all the team members of and contributors to the 3 projects described in this manuscript for making these projects possible, contributing to the insights discussed in this manuscript, and helping advance the national effort to end the HIV epidemic in the United States. We would like to specifically acknowledge key collaborators Martha Zuñiga and Joel Aguirre, who were the lead personnel supporting project B from the project's community partner organization, Entre Hermanos. The development of this manuscript was supported by the University of California, Los Angeles Rapid, Rigorous, Relevant (3R) Implementation Science Hub, funded by the National Institute of Mental Health through an administrative supplement award to the Center for HIV Identification, Prevention, and Treatment Services at the University of California, Los Angeles (grant P30MH058107). Project A was funded by the National Institute of Allergy and Infectious Diseases through an administrative supplement award to the Johns Hopkins Center for AIDS Research (grant P30AI094189). Project B was funded by the National Institute of Allergy and Infectious Diseases through an administrative supplement award to the University of Washington and Fred Hutch Center for AIDS Research (grant P30AI027757). Project C was funded by the National Institute of Allergy and Infectious Diseases through an administrative supplement award to the Tennessee Center for AIDS Research (grant P30AI110527). The funding sources had no role in the design, conduct, or reporting of this manuscript or the studies described herein, nor in the decision to submit the manuscript for publication.

Authors' Contributions

EPR-C facilitated the data collection and analysis approaches. The 3 involved projects contributed primary data (leads RGH and LJ; JJL; and AAA, JMP, and SH). EPR-C, TBL, RGH, JJL, AAA, JMP, CL, and SJL contributed to the analysis. EPR-C and TBL synthesized the data and drafted the manuscript outline. EPR-C, TBL, RGH, JJL, AAA, JMP, and CL contributed to the manuscript draft. All authors read, reviewed, and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

(JMIR Public Health Surveill 2025;11:e85512) doi:10.2196/85512

In “Comparison of Virus Watch COVID-19 Positivity, Incidence, and Hospitalization Rates With Other Surveillance Systems: Surveillance Study” [1], the authors noted one error.

Coauthor ACH was mistakenly linked to the fourth affiliation, which has now been removed from the author. The following affiliation was added:

> *NIHR Health Protection Research Unit in Health Analytics and Modelling, Department of Infectious Disease Epidemiology, School of Public Health, Imperial College London, London, United Kingdom*

This will appear as the seventh affiliation and be attached to ACH, with any subsequent affiliations being renumbered accordingly.

The correction will appear in the online version of the paper on the JMIR Publications website, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

(JMIR Public Health Surveill 2025;11:e88582) doi:10.2196/88582

In "Assessment of Bidirectional and Threshold-Response Associations Between Cognitive Function and Physical Performance: Nationwide Cross-Sectional Study" [1], the authors noted one error in the abstract.

In the original paper, the following information was present:

> *This multicenter study of 20,868 older adults in China analyzed the bidirectional asymmetric and threshold-response associations between cognitive and physical function using logistic or linear regression and restricted cubic spline, with subgroup and interaction analyses.*

This has been revised to the following:

> *This multicenter study of 20,671 older adults in China analyzed the bidirectional asymmetric and threshold-response associations between cognitive and physical function using logistic or linear regression and restricted cubic spline, with subgroup and interaction analyses.*

The correction will appear in the online version of the paper on the JMIR Publications website, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

In “Assessment of Bidirectional and Threshold-Response Associations Between Cognitive Function and Physical Performance: Nationwide Cross-Sectional Study” [1], the authors noted one error in the author information.

In the original paper, a footnote in the author metadata to designate equal contribution was present for authors LX and YH.

The footnote has been added to author HH as well, indicating that HH, LX, and YH contributed equally.

The correction will appear in the online version of the paper on the JMIR Publications website, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Abstract

Background: Online data collection can reach large populations efficiently and cost-effectively. However, the increase in bots and scammers (ie, person- or software-based fraudulent completions) completing online surveys raises data integrity issues and wastes scarce research resources.

Objective: This paper aims to describe case studies and experiences in which bot or scam completions of online surveys occurred within the health behavior field (specifically physical activity and nutrition). Lessons learned and a checklist of strategies to assist researchers before, during, and after data collection to reduce the incidence of and identify bot or scam completions are provided.

Methods: Four diverse case studies are presented from studies that used online recruitment and data collection methods for cross-sectional surveys by parents about children's screen time, cross-sectional surveys by adults about transport-related physical activity, qualitative interviews for a proposed trauma-informed physical activity program for female victim-survivors of intimate partner violence, and the Australian component of a large multicountry prospective study targeting university students. The strategies used to identify and prevent bot or scam online survey completions are explored.

Results: High levels (7%-80%) of suspected bot or scam completions were identified in a number of these studies. Participant characteristics and outcome variables were significantly different between included and excluded participants (eg, excluded responses had a higher percentage of male parents and children, higher social media use, and lower physical activity guideline adherence). The learnings from these case studies and the wider literature are combined to create a checklist of strategies that researchers can use to prevent and identify bot or scam completions. These include strategies before data collection (when creating study collateral), during survey design and development (including the use of inbuilt platform functions and the design of the survey questions and structure), following data collection (indicators of potential bot or scam completions), and recommendations for reporting of bots or scams.

Conclusions: The checklist, based on the included case studies and wider literature, can be used to help researchers who use online recruitment and data collection methods at each stage, from planning and conducting through to analyzing and reporting their findings. Researchers should include several steps to prevent and identify fraudulent survey responses when creating surveys and completing data cleaning. This checklist should also be considered in grant applications and ethics applications. This will provide greater confidence in the research findings and reduce unnecessary waste of research time and resources.

KEYWORDS

scam; bots; survey; online; data integrity; data fabrication; falsification

Introduction

Online data collection is an efficient and cost-effective method to reach a wide audience [1]. However, reports of online surveys being completed by bots (software programs that can complete repeated tasks at speed [2]); by individuals fraudulently claiming to be eligible participants (scammers); and by people completing the survey with malicious intent to sabotage the project or system (bad actors) are becoming widespread and can lead to economic loss, loss of trust, and identity theft [3,4]. In research [2,5-7], these practices raise data integrity concerns, impact the ability to draw accurate conclusions or take appropriate actions based on survey findings, and strain scarce research resources, especially when an incentive (eg, a voucher) is offered for completion. While most survey platforms provide some bot or scam prevention methods [8], these alone may be insufficient [5], and researchers using online methods need practical recommendations to ensure the rigor of their data [9]. The purpose of this paper is to describe case studies and experiences of potential bot or scam completions of online surveys (for either recruitment or data collection purposes) within the health behavior field, specifically physical activity and nutrition; and to provide a checklist of practical strategies for researchers to help reduce and identify bot or scam completions before, during, and after data collection, informed by these case studies and the wider literature [2,5,6,10]. The checklist may also support submissions for journals, grant agencies, and ethics committees so that publications and research funders can take precautions to avoid bot or scam completions.

Ethical Considerations

Ethics approval for the included case studies was obtained from the following institutes: case study 1, ethics approval granted from Deakin University Human Research Ethics–Health (HEAG-H 103_2024); case study 2, ethics approval granted from Deakin University Human Research Ethics (2024/HE000064); case study 3, ethics approval granted from Deakin University Human Research Ethics (2024-209); and case study 4, ethics approval granted from Deakin University Human Research Ethics (2022-311) and Brazil (CAE:63025822.8.1001.5346). Participants were provided with a digital plain language statement outlining the study requirements, privacy and confidentiality of their data and any compensation provided (specific to the case study). Informed consent (digital) was then obtained from participants.

Recent Case Studies

We present 4 recent case studies of surveys conducted in the health (specifically physical activity and nutrition) research field in Australia where bot or scam completions were detected (Textboxes 1-4). Three case studies offered a supermarket voucher to each participant, and 1 case study entered participants into an e-gift card draw. The estimated percentage of nonlegitimate participants and differences in results between the included and excluded participants (where available) are presented for each case study in Textboxes 1-4.

XSL•FO
RenderX

Textbox 1. Case study 1: online recruitment of parents to complete a survey about screen time (Australia).

Population target

- Parents of children aged 8-16 years in Australia.

Recruitment method

- Recruitment was conducted through social media platforms.

Survey platform

- The survey was hosted on Qualtrics (Qualtrics, LLC)

Compensation provided

- Participants received an AUD $10 (US $6.70) supermarket e-voucher

Suspected nonlegitimate completions

- 80% of the responses were identified as nonlegitimate.

Study procedure

Social media (Facebook and Instagram) recruitment for an online survey using Qualtrics commenced in June 2024. Participants completed an initial screening questionnaire, and eligible participants (ie, a parent of a child aged 8 to 16 years living in Australia) provided consent (via online checkbox), then progressed to complete the full survey. Survey completers would receive an AUD $10 (US $6.70) supermarket e-voucher. The survey was closed after 5 days as more than 600 surveys had been completed.

Steps to identify potentially fraudulent responses

The research team examined the Qualtrics embedded data (eg, bot detection variable) and identified mismatched responses (eg, a mismatch between state and postcode) and unlikely responses (eg, a very high number of children, identical or similar dates of birth completed largely sequentially). Emails were sent to participants requesting verification of responses identified as dubious. Suspicious replies were received with standardized responses, font, and format, questionable email addresses (eg, mix of random letters and numbers), and multiple emails from the same "parent" email address. Before reopening the survey for further participant recruitment, additional prevention steps were added, including a reCAPTCHA survey item, a "honeypot" question (a nonsense question that is hidden to people but completed by bots), additional cross-checking questions (eg, participant date of birth check at the start and end of the survey), and specifications that the e-vouchers were limited to an Australian store and that nonlegitimate responses would not receive an e-voucher.

Results

The final sample was 1248 responses, of which 995 (80%) were identified as potentially nonlegitimate and excluded. Including the additional prevention checks slightly improved the proportion of legitimate completions from 16% (before the additional prevention steps) to 25% (after additional prevention checks). There were significant differences in results between the included and excluded participants including the sex of parents (male participant: 37% vs 53%, $P<.01$) and children (male participant: 53% vs children: 60%, $P<.042$), child age at first mobile phone ownership (9.9 vs 8 years, $P<.001$), minutes of social media use per weekday (4 h 19 min/day vs 5 h 44 min/day, $P<.030$), and days per week of meeting physical activity guidelines (3 vs 2.6 days/week, $P<.017$).

XSL•FO
RenderX

Textbox 2. Case study 2: online recruitment for a Brisbane transport and physical activity survey (Australia).

Population target

- Adults aged 18-64 years living in Greater Brisbane, Australia

Recruitment method

- Recruitment was conducted through Facebook advertisements.

Survey platform

- The survey was administered using Qualtrics.

Compensation provided

- Participants received an AUD $10 (US $6.70) supermarket e-voucher.

Suspected nonlegitimate completions

- 59% of the responses were identified as nonlegitimate.

Study procedure

A Facebook campaign recruited Greater Brisbane residents (aged 18-64 years) for an online survey on transport-related physical activity in July 2024. The target was 450 participants within 2 weeks. Survey completers were offered an AUD $10 (US $6.70) supermarket e-voucher. Participants first completed a screening questionnaire to confirm eligibility, provided informed consent (via an online checkbox), and submitted contact details (first name, email, and mobile number) along with the approximate residential address (local government area, postcode, suburb, and nearest cross-street). The campaign generated 1311 complete and 652 incomplete screening responses.

Steps to identify potentially fraudulent responses

The research team used Qualtrics' built-in tools and manual checks based on a combination of the following: mismatched or implausible location data (eg, outside Brisbane, incorrect suburb-postcode pairs, and missing location data); reCAPTCHA issues (eg, low scores or repeated failed attempts); suspicious email addresses (eg, random characters) or landline numbers instead of mobile or cellphone; identical or nearly identical address details submitted consecutively; providing a first name and surname instead of just a first name.

Results

A total of 767 (59%) responses were excluded as possibly fraudulent, mostly due to having a combination of issues identified using the Qualtrics tools and manual checks. This left 544 participants considered probably legitimate, who were then invited to complete the full survey.

XSL•FO
RenderX

Textbox 3. Case study 3: online recruitment for a qualitative study of victim-survivors of intimate partner violence (IPV) about a noncontact cardio-boxing program (Australia).

Population target

- Women victim-survivors of any form of IPV who were aged 18 years or older and living in Australia

Recruitment method

- Recruitment was conducted through social media platforms.

Survey platform

- The survey was hosted on Qualtrics.

Compensation provided

- Participants received an AUD $30 (US $20.10) supermarket e-voucher.

Suspected nonlegitimate completions

- 16% of the responses were identified as nonlegitimate.

Study procedure

Social media platforms (Facebook and Instagram) were used to recruit participants for a brief online interview exploring perceptions of a proposed noncontact cardio-boxing program for women who have experienced IPV. Recruitment began in November 2024.

After watching a brief introductory video on the research project, respondents were asked to complete an initial screening questionnaire. Eligible participants (ie, women with a lived experience of any form of IPV, living in Australia, and older than 18 years with a secure internet connection) then provide consent (via online checkbox) and preferred contact details (ie, text, email, or phone call) to arrange for an online (video) interview. Interview completers would be offered an AUD $30 (US $20.10) supermarket e-voucher. Within 11 days, 25 participants met the inclusion criteria and provided contact information to take part in an interview.

Steps to identify potentially fraudulent responses

The steps included using the bot detection and reCAPTCHA tools within Qualtrics, manually matching postcode to state and cross-referencing those to the GeoIP Estimation data, and identifying suspicious email addresses (ie, combinations of names and numbers) and timing of survey completion.

Results

Following analysis, of the 25 responses, 4 (16%) were deemed to be scam responses, while a further 6 (24%) participants flagged by the system as potential bots proved to be legitimate participants.

XSL•FO
RenderX

Textbox 4. Case study 4: a large multicountry prospective study targeting university students.

Population target

- Undergraduate university students worldwide

Recruitment method

- Recruitment was conducted through university course websites (posted by course or unit coordinators), flyers, and social media platforms.

Survey platform

- The survey was administered using REDCap (Research Electronic Data Capture).

Compensation provided

- Participants were entered into a prize draw to win AUD $100 (US $67) e-gift cards at each data collection time point (Australian cohort).

Suspected nonlegitimate

- 7% of the Australian sample was identified as nonlegitimate (international data collection ongoing).

Study procedure

This large prospective study, involving data collection via online surveys at 4 time points (across 3.5 years), recruited undergraduate university students from 84 universities across 27 countries (worldwide). A wide recruitment campaign for the Australian sample included advertising the study to students at participating universities via course or unit (websites, displaying flyers around the university, and nonpaid social media dissemination [X and Instagram]). Recruitment began at the first study site (university) in Australia in February 2023 (for a duration of 1 teaching semester or trimester). A second wave of recruitment was undertaken the following year (February 2024) to boost the sample size at 5 out of 6 universities. Interested participants completed a brief screening survey to assess eligibility (ie, undergraduate university student, studying in their first year, and at a participating university). Within 4 weeks, a total of 631 participants in the Australian cohort met the inclusion criteria and started or completed the online surveys. However, of these, 111 (17.6%) were suspected bots, scams, or bad actors.

Steps to identify potentially fraudulent responses

The steps included identifying reported fake email addresses; answers in non-English languages; and clearly fake responses (eg, last university enrollment at ≥40 years ago, reporting a net income of over AUD $1 million per month, self-reported occupation as “Microsoft owners,” and self-reported weight and height with unrealistic values).

To address this initial bot attack, additional preventive measures were put in place, including ensuring re-CAPTCHA tools were activated and optimized within the REDCap screening survey, as well as subsequent data collection surveys.

The use of X (formerly Twitter) for recruitment was also paused, because it was suspected that this platform allowed broader (less targeted or more widespread) public access to the survey compared with other recruitment strategies.

Results

Overall, for the Australian cohort, a total of 2869 participants completed the baseline survey; however, 189 (6.9%) were suspected bots. For the global sample (data collection still ongoing), a total of 35,638 (partial) participants have completed the baseline survey, with 178 (0.5%) suspected bots. Because the Australian sites were the first of the global cohort to start recruitment, their learnings were able to be used by the global research team to help prevent or manage bot attacks during recruitment for subsequent sites and countries.

Considerations and Checks to Reduce the Incidence of and Identify Bot or Scam Completions

Based on the learnings from these case studies and the wider literature [2,5,6,10], the following considerations and checks have been compiled to assist researchers when designing and conducting their research to help reduce the incidence of, and identify bot or scam completions. These have been developed into a checklist shown in Multimedia Appendix 1.

Some considerations or checks may be sufficient on their own to suggest a nonlegitimate completion (eg, when the honeypot question is completed), whereas a combination of different checks may be needed to identify a potential nonlegitimate completion (eg, a run of similar start times, *plus* a questionable email address, *plus* similar responses to open-ended questions) to avoid the exclusion of genuine respondents. The following considerations and checklist can be used by researchers to develop a study-specific list of considerations and checks, including hierarchies and combinations of criteria, which can then be applied to each phase of their study to help identify potentially nonlegitimate completions.

Before Data Collection: Creating Study Collateral

Information can be included in the plain language statements, consent forms, and advertisements to help deter bots or scams and indicate how potentially fraudulent data will be dealt with. For example, researchers can reduce the prominence of advertising vouchers or payment as compensation, specify the type of voucher and where it can be redeemed (eg, for a country-specific retailer), state that completions are limited to 1 per household, notify participants that they may be asked to confirm their identity via their listed contact method (eg, email or phone number), and indicate that suspected fraudulent completions will not receive the voucher.

XSL•FO
RenderX

Survey Design and Development 1: Built-In Survey Platform Functions

When creating the survey, enable the built-in bot or scam detection functions of the survey platform. These tools may automatically navigate respondents out of the survey if deemed to be fraudulent (bot or scam) or add a variable to the collected data that can be later reviewed and interpreted as potentially problematic.

In Qualtrics [8], *Bot detection* provides a *Q_RecaptchaScore* (a score of <0.5 is likely to be a bot); and *Prevent multiple submissions* adds a *Q_BallotBoxStuffing* value (a score of 1 is likely to be a duplicate) for each completion. Enabling the *Relevant ID* functions (*Duplicate*, *Duplicate Score*, *Fraud Score*, and *Last Start Date*) helps detect multiple responses by looking at respondents' metadata. The *Duplicate* field will show "True" with the corresponding date and time the last attempt was started in the *Last Start Date* field. *Duplicate Scores* of ≥75 indicate duplicate responses, while *Fraud Scores* of ≥30 indicate the response is both fraudulent and likely a bot. The reCAPTCHA feature, where the participant needs to correctly click the squares containing an item (eg, motorcycles), can also be added to a survey.

In REDCap (Research Electronic Data Capture), reCAPTCHA is also available [11]. Similarly, a similar IP address or geolocation tracking is available through 3 options: set-up of consent forms as e-consent forms, where the IP address is automatically recorded; use of geolocation action tags in survey fields, to identify the longitude and latitude of the survey respondent; and external modules that identify IP address [12]. However, each option has limitations: reCAPTCHA may be passed by sophisticated bots; IP addresses may be falsified with virtual private network services or proxy servers; use of geolocation tags may be blocked by respondents' browsers; and use of external modules is determined by individual REDCap server managers [13].

Survey Design and Development 2: Online Survey Question and Structure

Several precautions can be added to surveys during the design phase to exclude or identify bot or scam completions. These may include the following measures:

- Including a reCAPTCHA variable
- Applying branching logic to exclude ineligible responses from progressing, ensuring that a participant must correctly answer the eligibility question to continue
- Using open-ended questions which provides an additional check as they must type the correct response
- Adopting a 2-step process separating screening and consent form completion from the study survey (eg, eligible participants are sent a unique link to the full survey via their email address, only after responses to the screening questions have been assessed by both the survey platform functions and the researcher)
- Adding automated date and time survey fields, which can be coded to be hidden from respondents (eg, action tags in REDCap can record the respondent's current date and time based on the host REDCap server, and current date and time based on Coordinated Universal Time); discrepancies in timestamps can indicate responses from outside the target region or time zone.
- Repeating questions where the response would not typically change to enable cross-checking (eg, name, date of birth, email, and postcode, in separate consent and survey sections)
- Adding dummy "honeypot" questions (eg, "Please select your favorite option: 1, 2, or 3"), coded to be hidden to humans and only visible to bots. Completion of the question indicates the respondent is nonlegitimate
- Including attention check questions to progress (eg, "Select a color from this list to continue," response options: cat, blue, broccoli)
- Requesting additional contact information to verify participant eligibility

Following Data Collection: Identifying Indicators of Potential Bot or Scam Completions

Researchers should promptly and continuously review their data to identify potential bot or scam completions. The following are factors based on embedded data (eg, IP address), participant responses, and response patterns, which can help identify potentially fraudulent responses:

- Completed responses to the honeypot question (ie, competed by a bot).
- Incorrect geolocation for the study sample (eg, latitude or longitude out of range).
- Built-in bot detection function or variables (eg, Qualtrics *Q_RecaptchaScore*<0.5, *Duplicate Score* of ≥75, *Fraud Score* of ≥30).
- Duplicate IP addresses: however, this may not be a reliable indicator where participants could be at the same location (eg, workplace, school, public library, or internet café) or where multiple responses are permitted from the same address or family or household.
- Similar IP addresses (ie, all but the final sequence of numbers are identical) may indicate repeated submissions from similar sources.
- Several failed attempts at passing a reCAPTCHA test, followed by a successful completion from the same IP address; however, this requires the researcher to examine and compare incomplete and complete surveys.
- Unrealistic survey completion time (eg, less than 10 min when the median time was 33 min).
- Multiple consecutive responses with similar survey start and end time, or in a run of start and end times (eg, a survey with a median completion length of 30 min starts at 5:00 PM and takes 7 min to complete; another survey starts at 5:07 PM, and so on).
- Multiple participants with the same personal details (eg, first name and surname, email address, phone or mobile number, home address).
- Questionable email address or names, often with a similar pattern and completed at a similar time (eg, a participant called Jane Doe provides an email address of john.smith123@...; a run of similar name formats, such as, including a middle initial or extra spaces between names; email addresses contain a random mix of letters and

XSL•FO
RenderX

numbers with similar pattern between participants, such as bgckts541236@... or 74sqwpc.hx54612@...).
- Unusual responses for study context (eg, in studies recruiting parents or perinatal women, this may include an unusually high number of children, particularly over a short or unrealistic time frame, or unrealistic age of childbirth, such as more than 9 children from live births, child birth dates only 6 months apart, child birth at parent age less than 12 years).
- Mismatch between data provided at 2 locations of the participation process (eg, mismatch between date of birth reported in the consent form and survey or state and postcode provided do not match).
- Identical or very similar responses to an open-ended question. This should not be applied to likely common responses (eg, "none," "no benefits," "schoolwork," etc).
- Questionable date format used for date-based responses (eg, including full stops when backslashes are requested or writing the month instead of the number format).
- Providing a landline phone number when a mobile number is requested, or providing landline phone numbers that do not match the area or city they are claiming to live in.
- Providing a full name when only a first name was requested.
- Nonresponse to requested contact information, which would allow researchers to check and confirm details.
- Completed at unusual or unlikely times, such as between 12 AM and 5 AM. Use participant-specific context as needed (eg, consider postnatal women with disrupted sleep patterns, or night shift workers).

Analysis and Write-Up: Reporting of Potential Bot or Scam Completions

Researchers should include a description of any suspected bot or scam completions in reporting their findings using the checklist in Multimedia Appendix 1. This should include how they were identified, the number identified, and reporting confirmation that they were excluded. This provides greater confidence that the participants included and the subsequent findings of the study are legitimate.

Additional Considerations

It is important to note that with increasingly sophisticated bots or scams, not all potential bot or scam completions may be identified, and some legitimate completions may be incorrectly excluded (eg, case study 3). These preventive measures may also inadvertently contribute to the exclusion of some groups, for example, those with low literacy or digital skills. As the technology landscape is rapidly changing, so too are prevention and identification techniques. The use and publication of the checklist in Multimedia Appendix 1 of this paper can lead to more transparency around the experiences of different studies. This may allow for future exploration of variation in fraudulent rates, and possible reasons for these (eg, platform, incentive, or recruitment method). Purpose-designed empirical studies are needed to determine the most effective platform-, methodology-, and population group–specific strategies for preventing and identifying bot or scam completions.

Conclusions

Researchers using online recruitment and data collection methods should consider the checklist of strategies provided to reduce and identify potential bot or scam completions at each stage of their project including in the creation of study collateral, survey design and development, data review, and write-up. Continued exploration and sharing of strategies are needed as technology and bots or scams evolve. Details of the steps planned or taken should be included in grant and ethics applications. While these steps may be time- and resource-consuming, they may help prevent and identify potentially nonlegitimate survey responses and provide greater confidence in the research findings.

Abstract

Background: The COVID-19 pandemic exposed challenges in pandemic management, particularly in real-time data sharing and effective decision-making. Data protection concerns and the lack of data interoperability and standardization hindered the collection, analysis, and interpretation of critical information. Effective data visualization and customization are essential to facilitate decision-making.

Objective: This study describes the development of the PANDEM-2 dashboard, a system providing a standardized and interactive platform for decision-making in pandemic management. It outlines the participatory approaches used to involve expert end users in its development and addresses key considerations of privacy, data protection, and ethical and social issues.

Methods: Development was informed by a review of 25 publicly available COVID-19 dashboards, leading to the creation of a visualization catalog. User requirements were gathered through workshops and consultations with 20 experts from various health care and public health professions in 13 European Union countries. These were further refined by mapping variables and indicators required to fulfill the identified needs. Through a participatory design process, end users interacted with a preprototype platform, explored potential interface designs, and provided feedback to refine the system's components. Potential privacy, data protection, and ethical and social risks associated with the technology, along with mitigation strategies, were identified through an iterative impact assessment.

Results: Key variables incorporated into the PANDEM-2 dashboard included case rates, number of deaths, mortality rates, hospital resources, hospital admissions, testing, contact tracing, and vaccination uptake. Cases, deaths, and vaccination uptake were prioritized as the most relevant and readily available variables. However, data gaps, particularly in contact tracing and mortality rates, highlighted the need for better data collection and reporting mechanisms. User feedback emphasized the importance of diverse data visualization formats combining different data types, as well as analyzing data across various time frames. Users also expressed interest in generating custom visualizations and reports, especially on the impact of government interventions. Participants noted challenges in data reporting, such as inconsistencies in reporting levels, time intervals, the need for standardization between member states, and General Data Protection Regulation concerns for data sharing. Identified risks included ethical concerns (accessibility, user autonomy, responsible use, transparency, and accountability), privacy and data protection (security and access controls and data reidentification), and social issues (unintentional bias, data quality and accuracy, dependency on

XSL•FO
RenderX

technology, and collaborative development). Mitigation measures focused on designing user-friendly interfaces, implementing robust security protocols, and promoting cross-member state collaboration.

Conclusions: The PANDEM-2 dashboard provides an adaptable, user-friendly platform for pandemic preparedness and response. Our findings highlight the critical role of data interoperability, cross-border collaboration, and custom IT tools in strengthening future health crisis management. They also offer valuable insights into the challenges and opportunities in developing IT solutions to support pandemic preparedness.

KEYWORDS

pandemic preparedness and response; COVID-19; cross-border collaboration; surveillance; data collection; data standardization; data sharing; dashboard; IT system; IT tools

Introduction

Background

The COVID-19 pandemic posed considerable challenges to European countries with widespread variation in response capacity. The COVID-19 pandemic revealed shortcomings in coordination, information sharing, and response strategies among countries, leading to fragmented approaches and delayed actions [1-3]. The lack of standardized data collection and analysis methods hindered the ability to assess the situation comprehensively, to allow data sharing and strengthen or facilitate cross-border collaboration, and to make informed decisions [4,5]. In addition, limited resources and infrastructure strained health care systems, exacerbating the impact of the COVID-19 pandemic. Lessons learned from the COVID-19 experience emphasize the critical need for enhanced preparedness and response efforts [6].

In response to the above challenges, the European Union (EU) has mandated the development and implementation of robust measures for pandemic preparedness and response across member states [7]. This mandate highlights the significance of reinforcing coordination and information exchange, as well as strengthening early detection of threats, monitoring and forecasting of diseases and resources (eg, beds and vaccines), rapid risk assessments, and the capacity of evaluating medical countermeasures (eg, therapeutics) and nonpharmaceutical interventions (eg, social distancing measures such as school closures or lockdowns). The aim is that these activities will build capacity to enhance preparedness and response capabilities to future health threats, including pandemics. Recent studies have demonstrated the potential of digital health dashboards to transform public health policy by providing real-time data analytics for rapid decision-making [8].

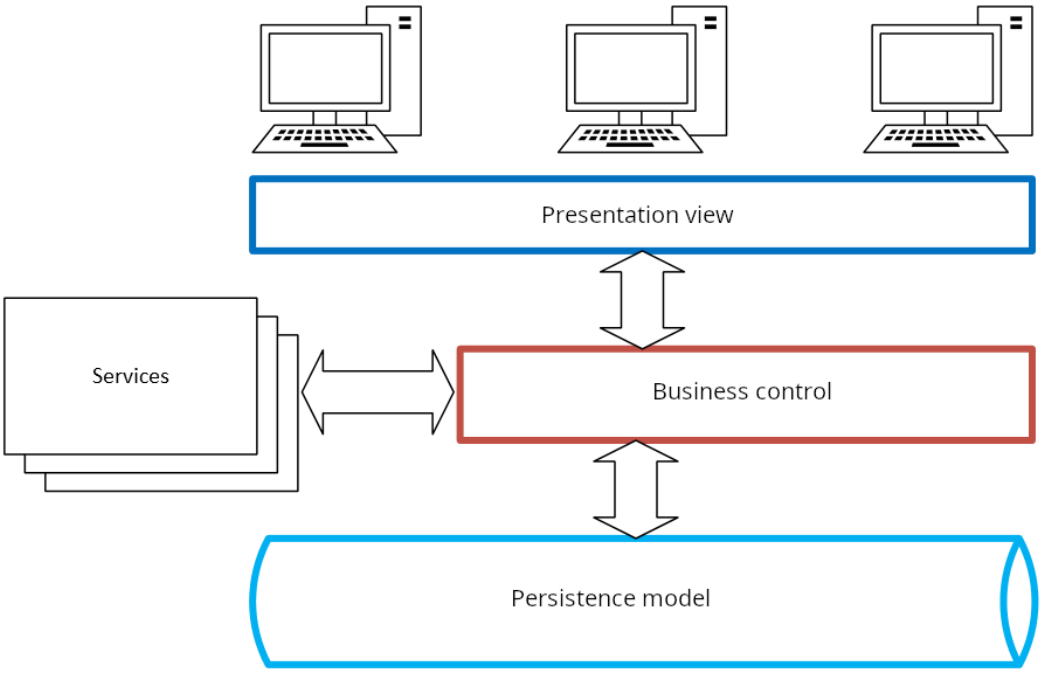
The PANDEM-2 IT system provides an innovative solution to address these objectives by offering a standardized and interactive platform for pandemic preparedness training and response to support decision-making on pandemic management. It also offers adaptability for addressing other potential cross-border threats. The system, which is now developed to an advanced prototype level [9,10], enables pandemic managers and stakeholders to acquire the necessary skills, knowledge, and decision-making capabilities required to respond effectively to future pandemics. Furthermore, it is designed to serve as a prototype that can be further developed or adapted to cater to different training needs. The PANDEM-2 system was tested in a 2-day functional exercise to simulate a pandemic caused by a novel strain of avian influenza. The cross-border exercise was conducted between 2 public health emergency operating centers (National Institute of Public Health & Environment, Netherlands, and Robert Koch Institute, Germany) [11]. Several EU public health and first responder agencies, including the Directorate-General for Health and Food Safety's Early Warning Response System simulation platform, were involved in supporting roles. Qualitative and quantitative data were collected to evaluate the performance of the system and its potential as a cross-border preparedness and response tool for health emergencies. Results indicate that the PANDEM-2 IT system holds potential to become a robust training hub for pandemic management in the future, serving as a valuable resource for continuous learning and preparedness.

Objectives

This study aimed to describe the development and potential of the PANDEM-2 dashboard and to outline the methodologies used in obtaining valuable insights and feedback from end users to further refine its development. It also describes how privacy, data protection, and security risks were considered throughout the design of the system. The lessons learned from the development and implementation of the platform can pave the way for future research and development in pandemic management and response technologies and inform the development of similar IT solutions.

Methods

PANDEM-2 System Architecture



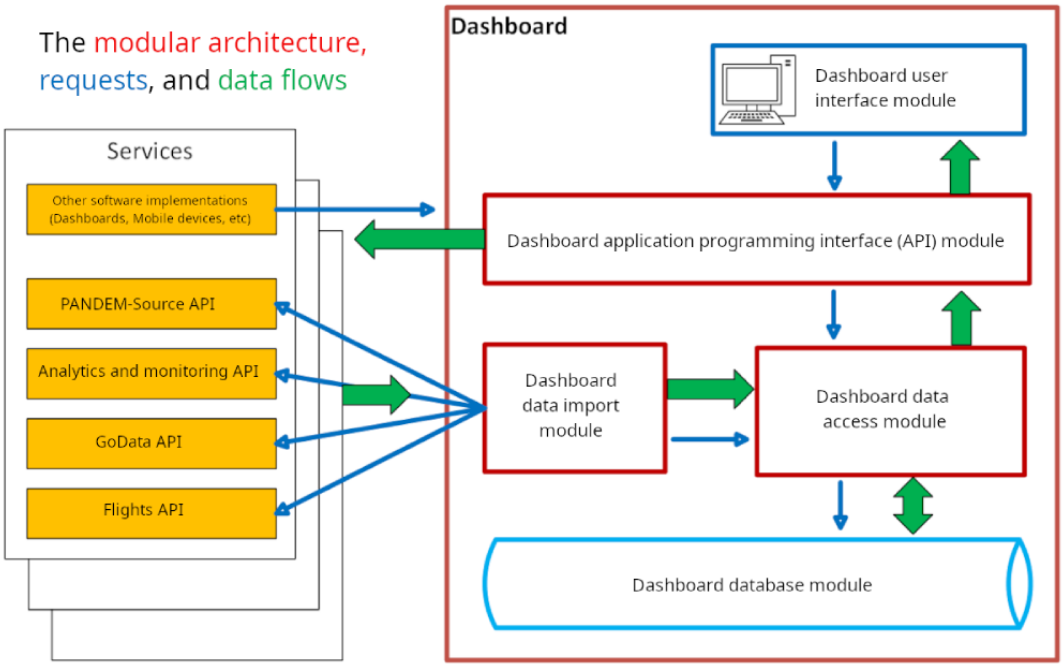
System Design and Components

The PANDEM-2 architecture (Figure 1) is an open-source framework comprising multiple modules and components that are accessed and integrated as web services. Its design and development were guided by the selection of widely supported libraries and adherence to industry-standard development practices and principles. The platform features a multilayered architecture that facilitates communication between its components. The persistence layer, built using MongoDB [12], ensures efficient data retrieval and storage. This layer is accessed through an exposed application programming interface (API) from the NodeJS business layer [13], which facilitates interaction between the MongoDB database and other modules

XSL•FO
RenderX

or external systems. NodeJS is known for its scalability and efficiency and ensures the smooth functioning of the business layer [14]. The presentation layer is developed using the Angular framework [15], which manages the user interface, providing an intuitive and interactive experience for users. Angular was chosen for its robustness, scalability, and extensive library support, which enhances the platform's user-friendliness and maintainability. Angular is a well-maintained framework, with releases every 6 months. Its documentation is comprehensive, containing deprecation, compatibility, and breaking change policies alongside update path guides, ensuring clear upgrades and maintenance. Data visualization within the application is handled by the Highcharts JavaScript library [16]. The use of these stable and well-supported technologies underpins an architectural design that ensures the platform is scalable, adaptable to various presentation contexts, and easy to maintain.

Figure 1. Multilayered architecture of the PANDEM-2 dashboard illustrating the interaction between the different layers, including the persistence layer (MongoDB), business layer (NodeJS), and presentation layer (Angular).



Data Collection and Integration

Data within PANDEM-2 are gathered from various sources via data collectors, which can either be human-operated or automated. The PANDEM-Source module [17], an extract, transform, and load (ETL) pipeline and database was specifically developed for PANDEM-2 to facilitate the continuous collection and integration of heterogeneous surveillance data into a coherent database. PANDEM-Source uses JSON (JavaScript Object Notation)-formatted source definition files to describe each source, including format, monitoring frequency, mapping to PANDEM-2 variables, and coding systems. It performs transcoding by downloading and applying mappings between coding systems, reporting any missing codes or integration errors to a data manager who can update mappings or monitor integration progress. A key challenge was standardizing geographic locations to the Nomenclature of Territorial Units for Statistics (NUTS), a hierarchical system developed by Eurostat that divides the territory of the EU into regions for statistical and reporting purposes [18]. For natural language processing used to detect locations in social media data, we used the GeoNames database, which contains local aliases for geographic locations [19]. To reduce methodological disparities between sources, we prioritized official European Centre for Disease Prevention and Control (ECDC) data where available and relied on existing data collectors like COVID-19 Data Hub [20] when ECDC data were not available. PANDEM-Source allows data managers to tag datasets, enabling the selection of relevant data combinations for export to the PANDEM-2 dashboard. This process, while facilitated by the tool, requires human oversight. To ensure the accuracy of the data acquisition process, manual validation was performed during both the data import and dashboard implementation stages. The declarative syntax used by the tool minimized the risk of errors in data processing. A more formal validation process is currently underway and described in greater detail in a related preprint [21].

The PANDEM-Source module functions as a service with an API providing relevant and preprocessed data to the persistence layer of the dashboard. Data are then processed, exposed through a specific API, and made accessible to the front-end of the dashboard, as well as other interested data publishers (Figure 2).

XSL•FO
RenderX

Figure 2. Dashboard modular architecture demonstrating the flow of data from external sources into the PANDEM-2 dashboard, showing how data is processed through various modules and application programming interfaces (APIs).

The business layer in the dashboard collects data from external modules, such as the World Health Organization GoData implementation [22] and also from the Flights module [23] and the Modelling and Analytics module developed internally as part of the project. It processes these data, performing validations, adaptations, and enrichment based on formulas, to prepare them for display in the presentation layer.

Security Aspects of the PANDEM-2 Dashboard

The PANDEM-2 dashboard infrastructure is secured using Amazon Web Services (AWS) Cloud Security [24]. The AWS environment is monitored using AWS CloudWatch and CloudTrail, ensuring General Data Protection Regulation (GDPR) compliance [25]. Several other AWS services were used to enhance privacy and control network access, including Amazon GuardDuty for continuous threat monitoring [26] and AWS Secret Manager and Key Management Services for data protection [27]. Data are encrypted in transit with Transport Layer Security across the AWS services, and secure sockets layer and transport layer security certificates, are managed with AWS Certificate Manager. A summary of the PANDEM-2 security aspects can be found in Multimedia Appendix 1. The project only hosted publicly available aggregated or simulated data, which addressed data protection concerns for the duration of the project.

Dashboard Design and Development

Exploratory Research and Design Rationale: Why a Dashboard Approach?

A dashboard is a visual display of key analytical indicators arranged on a single screen, enabling real-time monitoring and quick assessment [28]. The goal is to provide stakeholders with relevant analyses to anticipate issues and make decisions in domains with complex multivariate data. For example, a study by Franklin et al [29] modeled the real-time status of a hospital's emergency department as a dashboard to support rapid clinical decision-making and improve throughput. However, the growing use of dashboards has raised concerns about the cognitive effort required to extract actionable information, particularly for users with limited analytic skills [30]. Data storytelling has been proposed as a more intuitive way to communicate information that motivates decision-making [31]. Stakeholders, however, determined that maintaining and updating multiple specific decision narratives would be overly complex. Therefore, we chose a dashboard approach for its flexibility and adaptability across various public health scenarios, including surveillance and training. In addition, a key design requirement was the ability to customize the dashboard view and generate reports, which was seen as a more scalable and sustainable solution compared to data storytelling, given the diverse decision-making needs of different stakeholders. The primary users of the PANDEM-2 dashboard are public health officers and medics typically trained in data analysis.

Review of Existing Dashboards

Responses to the ongoing pandemic provided opportunities to review public health indicators, visualization approaches used, and the design decisions made by different organizations. To gain insights into these aspects, we conducted a review of publicly available dashboards in April and May 2021, operating under the assumption that these reflected the information needs of public health agencies and could be analyzed without an imposition on end users (Multimedia Appendix 2). This review included dashboards recommended by collaborating partners based on their initial user requirements, as well as publicly accessible COVID-19 projects under development (Multimedia Appendix 3). The review assessed the available dashboards, focusing on their aims, target users, and content. We also collated data sources for each dashboard, along with their breakdowns by population, time, location, granularity, and visualization approaches. This analysis provided insights into

XSL•FO
RenderX

how organizations prioritized information and the data views expected by experts. It also highlighted different data interaction models and how data artifacts were aggregated, filtered, modified, and recorded. While the data sources identified during this review were considered for inclusion in the PANDEM-2 database, consortium members' own data eventually proved to be more suitable, especially as larger organizations and governments began openly sharing their information.

Data Visualization Catalog

Capturing and storing visualizations for viewing or referencing during the design process was challenging due to their volume and complexity. Initially, screenshots of each visualization, along with related data, were added to a document (Multimedia Appendix 4). However, as the document grew, this approach became impractical and difficult to reference. To overcome this challenge, a data visualization catalog was created. The catalog was specifically developed for annotating and uploading data visualizations during the design phase of the project. The visualizations became searchable using keywords related to graph types, data types, or indicator types. The catalog served as a directory of existing public health visualization approaches, which the project team could consult during the participatory design process. It is important to note that the Vizualisation Catalogue was used solely as a development tool during the design phase and is not part of the final application.

User Requirements and Participatory Design

Gathering of User Requirements

The design and development of the PANDEM-2 dashboard began with collecting user requirements from members of the project consortium, outlining the necessary functionalities and features to meet users' needs. Participants represented a wide range of domains, including universities, national public health institutes, the Italian Red Cross, the Austrian Red Cross, the National Institute of Medical Emergency (Portugal), a leading institute for trend and technological analysis, and MedTech health organizations. Each consortium partner appointed a contact person to gather internal requirements and communicate them to the project's technical team.

These designated representatives participated in initial user forums that were held during the project's inception, aimed at gathering user requirements from domain experts and capturing their needs and preferences for features in pandemic management software (Multimedia Appendix 5). The group was diverse in age, experience, and gender, with participants ranging from recent postdoctorates to professionals with >30 years of experience, and included software designers, data scientists, epidemiologists, microbiologists, physicians, first responders, and project managers. They also represented a wide geographic spread, including Romania, Italy, Portugal, France, Germany, the Netherlands, Belgium, Sweden, Finland, and Ireland. This diversity ensured a wide range of expertise and perspectives, thus reducing potential design biases.

The requirements gathering process involved 2 workshops held between February and April 2021. During these workshops, users described their ideal dashboard for pandemic management and identified essential visual features for the dashboard. These requirements were then compiled into a comprehensive list and organized into functional units. The participatory design surveys were conducted as part of this process, providing interactive design prototypes and collecting feedback from users on key functionalities (Multimedia Appendix 6).

Generation and Analysis of User Stories

User requirements were assigned to different groups within the technical team, who analyzed and converted them into user stories. A user story describes a feature from the end-user's perspective, detailing how it provides value [32] (eg, "As a policy advisor or health care professional, I want to see cases stratified by age, sex, time, and severity to monitor clusters and track the virus spread over time").

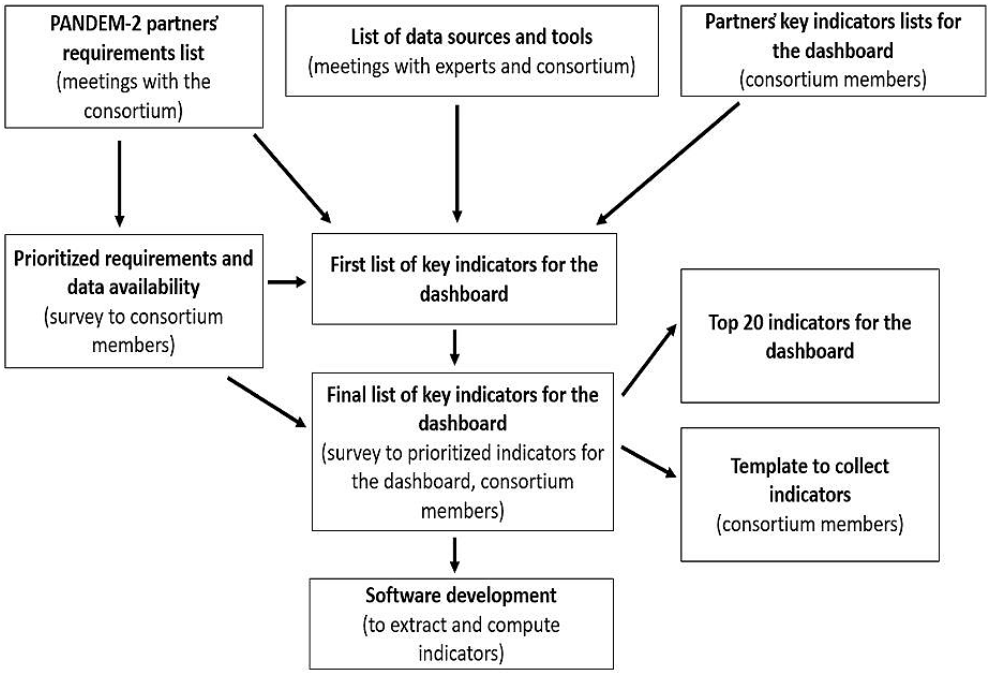
By exploring user requirements and generating user stories, the technical team identified common needs, consolidated similar requests, and clarified key functionalities for the PANDEM-2 system. Each user story generated focused on a primary indicator query and was linked to the initial requirements for traceability. It defined query resources for user interactions, enabling data filtering, aggregation, new data creation, and record management. In addition, each user story considered the time-related and geographic aspects of the indicator within the application. Multimedia Appendix 7 provides an example of a user story.

Prioritization and Refinement of Key Variables and Indicators

To refine and prioritize user requirements for the dashboard, a prioritization process was undertaken. This involved a data availability and prioritization survey, which was conducted with the consortium members using the initial requirements generated in the Gathering of User Requirements section. A matrix was created, mapping all necessary variables and indicators required to fulfill the identified needs. This was followed by an assessment of the priorities and availability of these variables in open and restricted data sources. Users were invited to provide insights into their institution's data availability, including details about the level of information, reporting periodicity, data format, and the geographic level at which the data were accessible (municipal, regional, or national). The questionnaire covered various aspects, such as level of priority, data availability within their institution, the level of detail of publicly available data, adherence to the European Surveillance System (TESSy) format, and the pathogens for which data were collected (Multimedia Appendix 8).

The list of requirements was further divided into 14 variable categories, and each item on the list was classified as either an observation, a characteristic, an indicator, a resource, a document, or a referential. These terminologies are defined in Textbox 1.

XSL•FO
RenderX



Textbox 1. Definitions of variable categories used in the PANDEM-2 dashboard.

- Observation: Any variable or item that reflects a measurement or observation reported by a data source. These variables are typically numeric and represent concepts like the number of people or resources, or could include nonnumeric items, such as statements (eg, tweets) published by individuals.
- Indicator: Specific observations used to monitor particular questions. They can be categorized as either calculated values with associated methodologies and formulas or directly reported by users.
- Characteristic: Any variable or item which describes or categorizes an observation. It is always linked to variables of the observation type, such as the country, date, or variant of the observed cases.
- Referential: A specific type of characteristic distinguished by having a unique code that can be mapped to other characteristics. For example, municipalities serve as a referential, each possessing a unique code and linking to a country.
- Resources: A specific type of referential that concerns resources needed to handle pandemics. They play an important role in PANDEM-2 for resource modeling features (eg, nurses per bed or material resources). They are associated with observations like the number of available resources.
- Document: Refers to any generic term for a record or written material.

The methods used for defining key indicators and data sources, as outlined earlier, culminated in a final variables list that encompasses both open data sources and data contributed by partners (Multimedia Appendix 9). Alongside this list, data formats and an ETL process were specified to facilitate seamless integration with PANDEM-Source. To support the ETL process, a collaborative effort led to the development of a Microsoft Excel template to accommodate specific data needs for most consortium members. Furthermore, relevant heterogeneous data sources for effective pandemic management, such as Next Generation Sequencing–Laboratory data, social media data, and participatory surveillance data, were identified and corresponding ETL processes were devised for inclusion in the PANDEM-2 database.

After receiving the initial list of requirements and the prioritization feedback, the technical team began further refinement of the requirements. The process was guided by the concept of a minimal viable product (MVP), which focuses on prioritizing essential features to maximize learning with minimal effort [33]. Although the PANDEM-2 system is a prototype, the MVP approach helped in determining where efforts should be concentrated and which requirements should be given priority during the implementation process. Each group in the technical team looked at the requirements list and the prioritization process and created an MVP list. Subsequently, with participation from all Public Health Agencies and first responder partners in the biweekly web-based workshops, the initial requirements, the prioritization list, and the MVPs were combined and deliberated upon. The process of gathering and refining user requirements is illustrated in Figure 3. This process underpinned the development of the PANDEM-Source software used to extract and compute indicators, which were visualized on the PANDEM-2 dashboard. At the end of this prioritization process, a list of key indicators was generated.

Figure 3. Process used to gather partners' requirements list and prioritize partners' key indicator lists for developing the dashboard's core features.

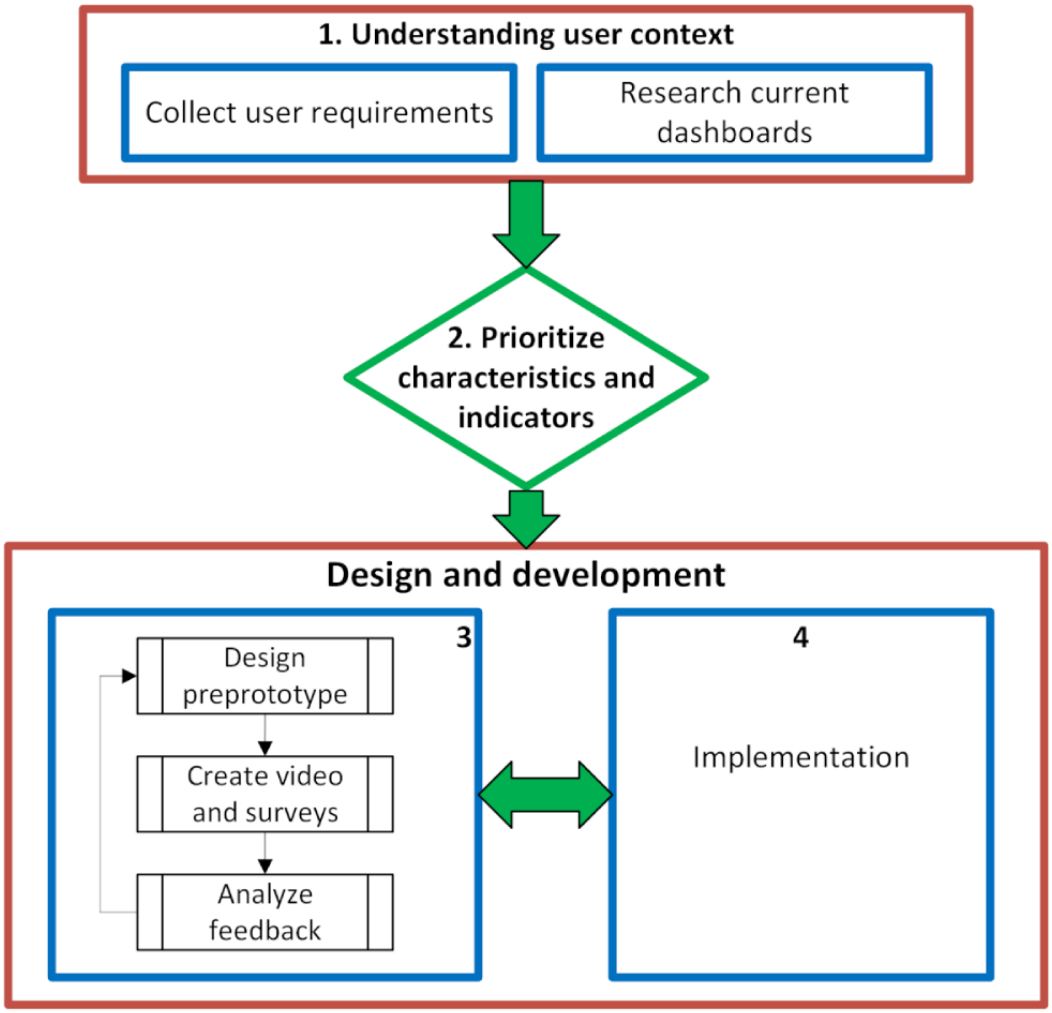
RenderX



Prototype Design, Participatory Feedback, and Iterative Improvements

The design of the PANDEM-2 dashboard followed an iterative process involving a participatory design approach, with user feedback incorporated throughout the design stages. Participatory design represents a design approach in which the people destined to use the system being designed play a critical role in its design [34]. Generally, participatory design is conducted in face-to-face settings where users are engaged in recording requirements and teasing out functionalities that are necessary to implement them. However, due to the COVID-19 pandemic, these physical meetings were not possible to organize. The participatory design process was therefore adapted to the pandemic context and involved several asynchronous methods, as illustrated in Figure 4. The adapted process allowed relevant stakeholders to participate and enabled collaboration across multiple teams. The analytical components of the dashboard were then designed based on the outcomes of this collaboration and are presented as follows:

1. Understanding the context of use by gathering insights from various stakeholders to understand end-user requirements and identify COVID-19 public dashboards for analysis
2. Prioritization of dashboard characteristics and indicators
3. Asynchronous participatory design (APD) process that involved weekly asynchronous interactions with users. Interactive design prototypes along with video documentation and feedback forms were sent to consortium members, who explored the designs and provided feedback. The primary objective of the APD process was to enable users to interact with a preprototype platform, explore potential interface designs, and provide feedback. This process involved targeted questionnaires, which aimed to explore what graphical representations and interactions were beneficial to users for their respective roles. Participants were presented with a range of potential functionalities linked to priority indicators, which included visual analytics components and interaction models, such as the ability to filter and switch between different data views. Participants shared their feedback on the structure of the pages, the data presented, the data visualizations that were used on each page, and the interactions with those data visualizations. Through this process, users provided feedback on elements to be added, removed, or modified within different components in the system. This feedback was then integrated into subsequent designs.
4. In parallel to the above step, the design prototypes were sent to the software team, who carried out the implementation of designs and improvements toward the final prototype.

XSL•FO
RenderX

Figure 4. Development workflow, including asynchronous participatory design, detailing the iterative feedback process used to incorporate user input into the PANDEM-2 dashboard design. AVG: average.

Impact Assessment

The implementation of ethical, privacy, data protection, and social principles was an integral part of the PANDEM-2 project. The process was led by Trilateral Research, a research and innovation organization specializing in applied ethics, privacy, and data protection in technology development. The project team actively engaged with end users both within and outside the project consortium to identify and mitigate potential risks arising from the tool's development. Following relevant guidance, including the Information Commissioner's Office Privacy Impact Assessment Code of Practice [35] and International Organization for Standardization and International Electrotechnical Commission standard for privacy impact assessments [36], the process mapped information flows, assessed potential risks within the system, and provided recommendations to mitigate the risks. A diverse group of stakeholders were involved in the process, participating in 2 workshops conducted in November 2021 and May 2023. There were 20 participants in each of the workshops, representing a wide geographic spread, including Romania, Italy, Portugal, France, Germany, the Netherlands, Belgium, Sweden, Finland, and Ireland. Those that partook in the workshops came from universities (UCLouvain and University of Galway), national public health institutes (Institute of Public Health in Romania, Public Health Agency of Sweden, the National Institute for Public Health and the Environment in the Netherlands, the Robert Koch Institute, the Portuguese National Emergency Medicine Institute, and the Finnish Institute for Health and Welfare), as well as other organizations such as the Italian and Austrian Red Cross, the Fraunhofer Institute for Technological Trend Analysis, and software companies specializing in health, Epiconcept, and development, Clarisoft. Roles of those taking part included software design and development, data science, epidemiology, microbiology, infectious disease specialists, doctors, researchers, first responders, pandemic managers, and project managers. Notably, participants included a former adviser to the World Health Organization on health security and a former head of the Chemical, Biological, Radiological and Nuclear threat unit for Belgian defense. The initial workshop aimed to raise awareness of ethical, privacy, data protection, and social principles requiring consideration during the development and deployment of the PANDEM-2 system and tools. It also focused on mapping data flows within the PANDEM-2 system and identifying related risks or opportunities. In addition, the workshop explored privacy, social, and ethical issues and opportunities to be considered in different pandemic scenarios, both in the preparedness and response

XSL•FO
RenderX

phases. Possible mitigations for the identified risks were also discussed. The second workshop involved an open and collaborative discussion, allowing stakeholders to contribute insights on mitigation measures, necessary actions, and final recommendations for both project stakeholders and end users.

Ethical Considerations

The PANDEM-2 project adhered to GDPR regulations and Horizon 2020 guidelines. Ethical approvals were obtained from the relevant institutional review boards of all consortium partners involved in data collection and processing. These approvals ensured that the project complied with the highest ethical standards, protecting participants' rights and ensuring the responsible handling of personal data. Informed consent was obtained from all participants before their involvement in the stakeholder engagement activities. The consent procedures ensured that participants clearly understood the nature of the study, the use of their data, and their rights, including the ability to withdraw at any time. Participants were also informed that their data would be used for research purposes only. All personal data were anonymized or pseudonymized to protect participants' identities. Data were securely stored on password-protected servers, accessible only to authorized personnel. Participant identifiers were removed or replaced with pseudonyms to ensure anonymity in the research outputs, preventing any risk of reidentification. No financial compensation was provided to participants. Participation was entirely voluntary, and participants had the right to withdraw from the study at any time without any negative consequences. No identifiable images of participants are included in the study materials or outputs.

Results

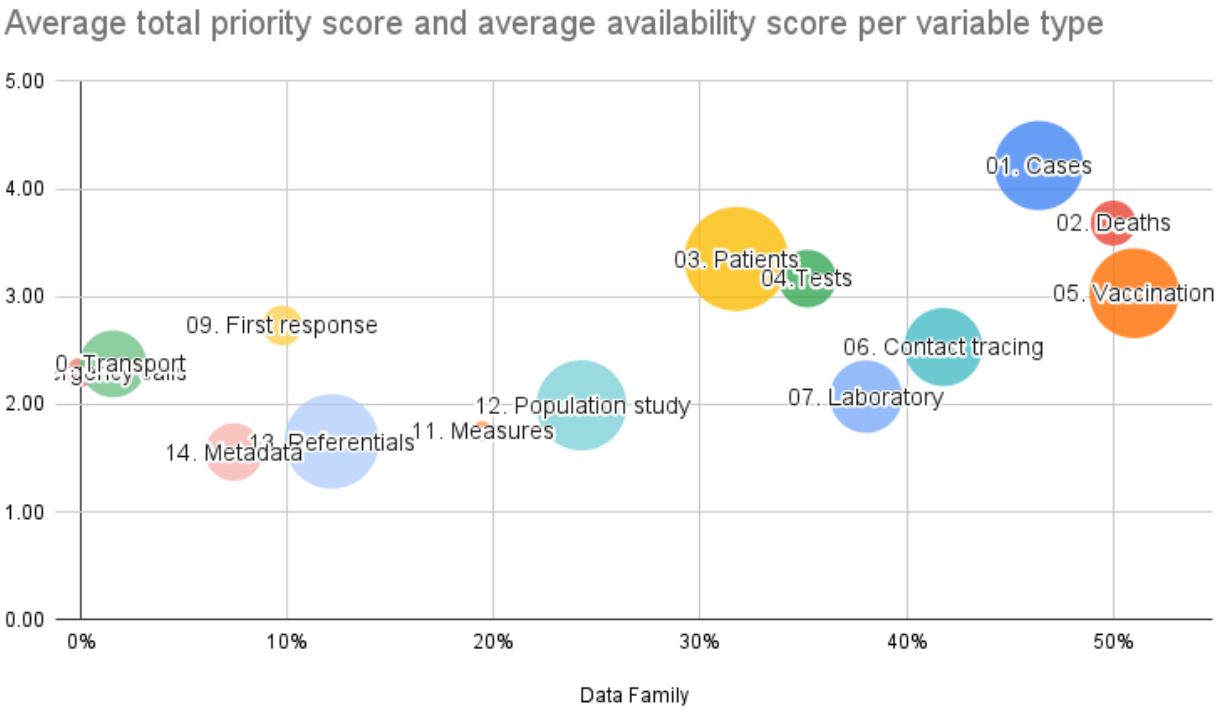
System Architecture and Data Integration

Implementation and Configuration

The dashboard was implemented and hosted on the Amazon Cloud as a central data management system at the EU level, accessible to all national health institutes across Europe. To address challenges with semitransparent data access, whereby some but not all data from different institutions can be shared with others, the architecture is not only open access but also adaptable. An adaptable architecture allows for both isolation of data between groups of countries and on-demand installation or deployment in a single health institute.

The dashboard offers flexibility in its configuration, allowing customization in 2 main areas. First, user experience and user-interface attributes, which encompass elements related to user experience and user interface. This involves tailoring aspects such as the language used for interface elements, the design of graphical features, and the overall visual style. Users can personalize the appearance of the dashboard to align with their preferences and needs by adjusting these attributes. Second, internal functional parameters that deal with the technical aspects of the dashboard's operation can be customized. This includes details on how different modules within the system access APIs and specific technical information relevant to the system's functioning. The administration module of PANDEM-2 serves as the control center for managing these parameters, granting users the ability to fine-tune the dashboard's functions and adapt it to their specific requirements.

Data Sources and Key Indicators



Responses to the data availability and priority survey are shown in Figures 5 and 6, and tables 1 and 2. The 9 participant institutions were questioned about 103 variables classified by groups. For each variable, the respondent answered a series of questions about availability, priority, and format of the associated information. On the basis of these answers, data availability scores were calculated and color-coded, ranging from low (red) to high (green; Figure 5). The variables identified as most relevant were cases, vaccination uptake, deaths, hospital resources, and hospital admissions. Figure 6 shows that the most important variable categories were also the categories with the most available data. Higher priority categories are toward the top of the graph, while high availability categories are toward the right. This observation highlights the importance of prioritizing and ensuring accessibility to critical data categories to support effective pandemic preparedness and response efforts.

XSL•FO
RenderX

Figure 5. Survey results highlighting the availability and prioritization of key data variables for the dashboard (AVG; X). AVG: average; ICU: intensive care unit; N°: number of; PPE: personal protective equipment; Rt:; X: specific pathogen of the pandemic.

Variable type	Variables	# AVG Institution availability score	# AVG Publicly availability score	# AVG of total priority
01. Observation	Confirmed cases	2.3	1.7	6.9
	N° of infected patients per bed type (clinic care, ICU, ventilator)	1.8	1.1	5.0
	People fully vaccinated	1.8	1.1	4.8
	Vaccination status	1.8	1.0	4.0
	People that have received at least 1 dose	1.6	0.9	4.0
	N° of deaths by X	1.7	0.3	4.0
	Suspected cases (possible, probable, and unclassified)	1.6	0.9	3.9
	N° of deaths	2.6	1.3	3.9
02. Characteristic	Cases per (age, sex, comorbidities)	2.2	1.0	4.7
03. Indicator	Incidence rates (last week, two weeks, month)	1.8	0.9	5.4
	Incidence rates (age, sex, comorbidities, variant)	1.1	0.4	5.0
	Rt number	0.6	0.6	4.8
	Positivity rate	1.4	1.4	4.7
	Vaccination progress (proportion of vaccinated, overall, by age and risk group)	1.8	1.2	4.3
04. Resources	Emergency staff	0.3	0.0	4.6
	Vaccination resources (staff, centres, supplies)	1.0	0.8	4.4
	Hospital staff type, eg, intensive care, emergency care, etc	0.8	0.4	4.2
	PPE (stock, type, and need)	0.7	0.6	4.0
	Bed type (ICU, regular clinical wards, emergency)	0.4	0.7	4.0
	Beds/Room occupancy and types, eg, isolation	0.8	0.4	3.8
Grand Total		**1.4**	**0.8**	**4.5**

Figure 6. Comparison of priority versus availability of variable categories, showing the alignment between prioritized variables and their availability across institutions.

Most of the data were reported on a weekly or daily basis, indicating a commitment to timely and up-to-date information (Table 1). A significant proportion of the data were collected and recorded by various institutions and from data sources related to COVID-19. There was limited recording of pandemic-related data before the COVID-19 pandemic. There were also variations in data granularity, reporting frequency, geographic coverage, or other specific details related to the COVID-19 information being collected. On average, only 9.7% (10/103) variables were available in the TESSy [37] format and 26.2% (27/103) only in a different format, a format used by the TESSy (Multimedia Appendix 10).

XSL•FO
RenderX

Table 1. Data reporting frequency and types of pandemic-related data available, highlighting the frequency of reporting (daily, weekly, or monthly) and the prevalence of COVID-19 data from various sources (n=115).

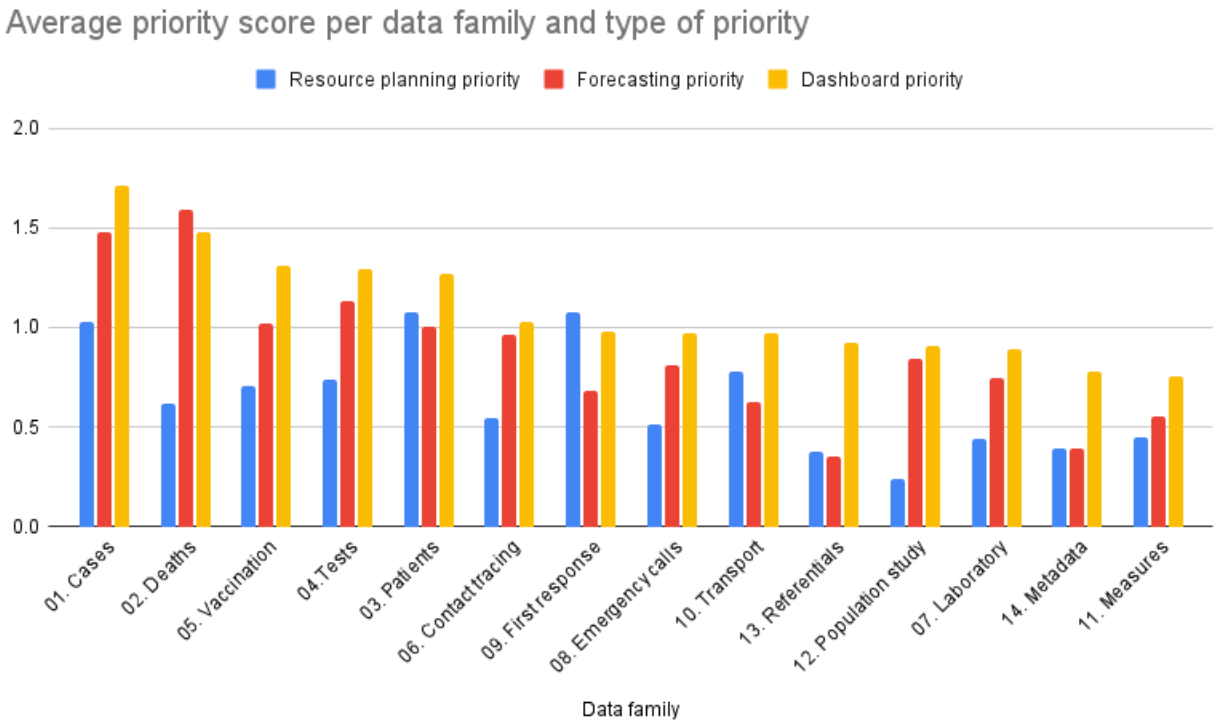
Data category	Reporting variables or items, n (%)
Periodicity	
Weekly	17 (14.7)
Daily	14 (12.1)
Others[a] (specify in comments)	8 (6.9)
Monthly	2 (1.7)
Pathogens	
COVID-19	17 (14.7)
Others (specify in comments)	13 (11.3)
Influenza and COVID-19	8 (6.9)
Influenza	1 (0.8)

[a]The "others" option refers to any reporting frequencies that were neither daily, weekly, nor monthly, which participants were asked to provide qualitatively through comments.

The survey also identified several data gaps, as shown in Table 2. Among these, 2 areas of particular significance were contact tracing and deaths. It was evident that these areas lacked sufficient information despite their high priority in the survey. In addition, there was also a noticeable lack of information concerning resource availability, despite its recognized importance in pandemic management.

Table 2. Data gaps identified during data availability survey, showing critical pandemic-related data, such as contact tracing and deaths that were insufficiently available despite high priority.

Variable category	Average public availability gap
Deaths	1.1
Contact tracing	0.9
Cases	0.8
Laboratory	0.6
Patients	0.5
Vaccination	0.5
Tests	0.3
Referential	0.2
Population study	0.1
Metadata	0.1
First response	0.1
Transport	0.0
Emergency calls	0.0
Measures	0.0



The public availability gap is a metric quantifying the specific types of data accessible at a detailed level but not disclosed publicly. Each participant provided their estimation of variable availability within their institution and at the public level, to the best of their knowledge. The assigned scale attributes 4 as the highest value to individual level, 3 to municipality, 2 to regional, and 1 to country level. In instances where data were unavailable or unknown, a score of 0 was assigned. The data availability gap is determined by calculating the difference between the average availability score at the institution level and at the public level.

Figure 7 illustrates the findings regarding the variables that users prioritized for resource planning, forecasting, and the dashboard. To calculate the priority score for these purposes, participants were asked to rate the importance of each variable from 0 to 3 for the 3 purposes, with 0 being the lowest and 3 being the highest. The results were averaged by variable category. In most cases, dashboard variables held a higher level of importance compared to forecasting or resource planning variables. The spikes observed in the resource planning and forecasting areas highlight the data points of utmost priority for those domains, with particular significance placed on the ability

XSL•FO
RenderX

to forecast deaths and to perform resource planning for patient care at the hospital and first response level.

Figure 7. Prioritization of variable categories for resource planning, forecasting, and the dashboard, showing importance ratings assigned to various data categories by participants.

At the end of the data and indicator prioritization process, a template to collect variables and indicators from nonopen sources (or partner-restricted data) was created.

Dashboard Design and User Engagement

Insights and Outcomes From Dashboard Review

The review of existing dashboards provided several insights that influenced the design of the PANDEM-2 dashboard. The data visualizations within the reviewed dashboards highlighted the prioritization of information by various organizations and identified the data views expected by experts. This review also revealed different data interaction models useful in public health domains and how data artifacts were aggregated, filtered, changed, and recorded. Insights gained from this review helped shape the decision to use consortium members' data as the primary data source, as these proved to be more comprehensive and reliable than many external sources. The review also informed the design features and visualization approaches adopted in the PANDEM-2 dashboard.

Prototype Design and Features

Multimedia Appendix 11 visually illustrates the design of a PANDEM-2 dashboard page. The key components on each page of the dashboard include the following:

1. Overview explanation component. This component includes a page title and provides an explanation of the indicator and the data presented on the page. It serves as a brief summary to provide context and understanding.
2. Indicator cards. These cards display high-priority data related to the indicator. They offer a quick snapshot of the current state of the pandemic, allowing users to grasp important information at a glance. The cards also feature an information button that provides additional details about the data being shown. The highlighted figures show a comparison between the most recent 7 days and the preceding 7 days. The highlighting provides an instant visual understanding of how important indicator variables such as admissions and intensive care unit admissions are changing over time.
3. Map. The map component offers a geographical perspective on the pandemic situation. Users can choose the specific information they wish to view on the map, such as cases, vaccination rates, or other relevant metrics. They can also segment the map by NUTS regions, providing a more localized view.
4. Graphs. The dashboard includes multiple graphs that present detailed information about the indicator. These graphs allow users to explore and filter the data according to their preferences. This feature enables a deeper analysis of the pandemic trends and patterns.
5. User-interface functionality. Users can access the PANDEM-2 system using the interface in the presentation layer. This interface offers multiple possibilities to display and filter information, build reports based on displayed graphical elements and comparisons between different data, and export these reports in many predefined formats, including images, tables, and web service-specific formats.

XSL•FO
RenderX

The final design framework of the PANDEM-2 dashboard was structured to provide an intuitive and interactive experience for users. Each indicator view was conceptualized as a dedicated page, comprising various relevant components. Abstract components were developed that could be adapted to each indicator page, ensuring a unified design and interaction experience across pages. This approach allowed users to intuitively understand the interactions and functionality across different pages once they had become familiar with the system on one page.

Together, these components enhance the accessibility and usability of the PANDEM-2 dashboard, empowering users to gain insights into the pandemic data through both high-level summaries and detailed visualizations. More illustrations of initial and final dashboard designs are shown in Multimedia Appendix 12.

Participatory Design Feedback

The participatory design process led to several modifications and improvements in the PANDEM-2 dashboard prototype. The number of responses to each of the APD feedback forms ranged from 4 to 9.

Feedback from the APD process highlighted the importance of data visualization in diverse formats, combining different data types, and analyzing data across various time frames. Users expressed their interest in generating custom reports and exploring data alongside government interventions (countermeasures):

> *The addition of countermeasures on the emotion/sentiment timelines is good. However, the countermeasures would be easier to see or understand, if they were all on the top part of the graph with the name of each intervention placed next to the line [on the left or right side of the graph]. Now it's difficult to check back to the figure legend below and tell one shade of grey from another. Now there's also a false impression that a countermeasure is somehow linked to the emotions on the same level of the graph* [for example, social distancing with anticipation and disgust]

Because of the feedback received, the final prototype incorporated various features that catered to the specific needs of the stakeholders, such as customizable dashboard views and report generation capabilities. The design also addressed the cognitive effort required to extract actionable information, ensuring that the dashboard remained user-friendly and accessible to all users, regardless of their analytical skills. This feedback proved invaluable for the technical team, offering insights into the preferred indicators and formats for their presentation. In addition, the feedback offered the technical team an understanding of how end users intended to use the data beyond the dashboard, including saving reports, downloading visualizations, and obtaining underlying data. When asked about saving outputs from the dashboard, participants expressed a desire for flexibility, with various preferences emerging. Users wished to save the current state of the page to share with others, download images or PDFs of the page, obtain the data within the page, or capture images of specific sections of the page.

Regarding epidemiological and resource modeling, participants expressed the desire to save the model used, the input parameters for scenario runs, visual outputs, data outputs in alternative formats, and high-level indicators.

Participants' feedback also shed light on data reporting challenges, particularly in terms of disparities in reporting levels and time intervals and the need for standardization across organizations. For instance, a participant highlighted how delays in testing workflows in Finland resulted in challenges when reporting cases and tests:

> *Due to unavoidable delays in testing workflow [sampling, sample shipping and processing, analysis, registration of results] it may not be realistic to report tests and cases 'this week.' In reality [in Finland], numbers of cases and tests from this week cannot be reported before Wednesday [COVID-19] or Friday [other viruses in infectious diseases register] next week. Sentinel surveillance may have even longer delays.*

The APD process further brought to light the complexity of data in public health situations, emphasizing the significance of considering interdependencies. It highlights that the system developed serves as a decision support tool and that the role of public health officials remains crucial in making informed decisions based on the presented information. One participant's feedback from Germany highlighted a specific example of complexity in data representation related to counting beds versus assessing capacity:

> *In Germany we do not really count the beds but the capacity. This is because to be able to add a new patient you need a bed, a room, ventilation, staff etc, or do you mean capacities with the term "bed"?*

This inquiry highlights the importance of clarity and precision in defining data elements to ensure accurate interpretation and decision-making within the tool. Finally, through their engagement with an expanding collection of interactive designs, users were able to identify gaps in the available indicators and provide specific requests for additional information, such as excess mortality data. This iterative process was instrumental in ensuring continuous and active user involvement throughout the project, enabling their valuable contributions to the design and development of the PANDEM-2 system.

Impact Assessment Findings and Mitigation Strategies

The impact assessment process identified 10 potential risks, all of which were deemed to have a low to medium likelihood of occurring. In total, 4 (40%) of the risks were ethical, 2 (20%) regarded privacy and data protection, and 4 (40%) related to social factors. These are summarized in Textbox 2 and reported in more detail elsewhere [38].

XSL•FO
RenderX

Textbox 2. Summary of the identified risks categorized into ethical, privacy and data protection, and social factors.

Ethical risks

- Accessibility and inclusivity: risk of excluding individuals with certain needs.
- User autonomy: risk of limiting end-users' control over their use of the training platform.
- Responsible use: risk of incorrect or unethical use of the training platform.
- Transparency and accountability: risks associated with the ability to account for actions taken or decisions made during the development of the training platform.

Privacy and data protection risks

- Security and access controls: risks relating to the protection of digital information from unwanted actions or unauthorized users, based on commonly accepted security frameworks, such as the confidentiality, integrity, and availability model.
- Data reidentification: risk associated with the correlation or linking of anonymous datasets with other data sources—especially those that have been collected by the state

Social risks

- Unintentional bias: risks associated with biased algorithms, biased data sources, and bias in training content that may lead to systematic errors that create prejudiced or unintended outcomes.
- Data quality and accuracy: risks associated with the ability to make informed decisions based on accurate information.
- Dependency on technology: risk of heavy reliance on the IT platform for critical operations, processes, or decision-making.
- Collaborative development: risk of inadequate collaboration with end users or public health authorities in the development and postproject stages to understand training needs and enhance the platform's capabilities.

The risks were effectively mitigated through several measures throughout the project. Design considerations extended beyond functionality to inclusivity and accessibility. The user interface was designed to accommodate multilingual users, providing options in both English and Romanian with provisions for translation into additional languages. Accessibility for individuals who are visually impaired was ensured through the selection of a color-blind–friendly palette. To facilitate ease of use, user-friendly training materials and guides were developed, offering clear instructions for system navigation. Supplementary features such as tooltips and contextual help were integrated, further enhancing the user experience. In addition, transparency was prioritized through the provision of accessible data sources and modeling assumptions used in the development process. Security was a paramount concern, prompting the adoption of Amazon Cloud, a reputable cloud computing service known for its robust security measures. The commitment to open collaboration and adaptability was evident in the decision to offer all components of the dashboard as open-source software. This approach encourages wider use, fosters adaptability, and invites collaboration across diverse contexts. Furthermore, a comprehensive developer guide in English was provided, serving as a valuable resource for future developers interested in building upon the PANDEM-2 platform or creating similar tools. End-users' feedback was continuously obtained and integrated to ensure the platform's suitability to diverse user needs.

To enhance the accuracy and relevance of training content, public health authorities' expertise was used in content development, and active end users engaged in patient surveillance and treatment assessed the training materials. This collaborative approach guarantees that the training content accurately reflects current information, best practices, and public health guidelines. Training exercises were based on scripts generated by public health authorities, adding objectivity and minimizing subjective biases or arbitrary preferences. These actions collectively enhance the accuracy and scientific validity of the training content.

Discussion

Principal Findings

The PANDEM-2 project aimed to develop an IT prototype system that offers a standardized and interactive platform for pandemic preparedness training and response to support decision-making on pandemic management. This paper outlined the development and potential of the PANDEM-2 dashboard, including methodologies used to gather users' insights to enhance its design and steps taken to identify and address potential risks associated with the technology.

The COVID-19 pandemic brought about an unprecedented surge in pandemic-related data at national, EU, and global levels, presenting a valuable opportunity to identify crucial data needs for effective pandemic response. PANDEM-2 leveraged user surveys to identify essential data requirements, not only for the ongoing pandemic but also for potential future health threats. Despite this increase in data, significant challenges emerged due to data availability, diverse data sources, nonstandardized formats, varying granularity, and data sharing restrictions among EU member states. These obstacles hindered timely data exchange for a coordinated EU-wide response and hampered cross-border response efforts. Addressing these data challenges became a central concern throughout the PANDEM-2 project, and consequently it emerged that it is imperative to proactively anticipate and address data requirements for potential future pandemics.

XSL•FO
RenderX

The EU initiated measures to address data sharing gaps through Regulation 2022/2731 on serious cross-border threats to health [39]. The Commission's responsibility includes defining mechanisms for data exchange, adhering to personal data protection rules and information exchange security. In addition, Article 5 of Regulation 2022/2730 on serious cross-border threats to health specifically refers to the development of the Union health crisis and pandemic plan "to promote effective and coordinated response to cross-border health threats at Union level" [40]. Specifically, article 5, point 5, states, "In order to ensure the operation of the Union preparedness and response plan, the Commission shall conduct stress tests, exercises and in-action and after-action reviews with Member States and update the plan as necessary."

The development process of PANDEM-2 aligns with these measures, both in terms of data sharing and exercises. Lessons learned in the development of the platform offer insights into data analysis, sharing, and reporting methods, effectively supporting public health actions and control measures. The PANDEM-2 platform's design, built on an open architecture and open data sources, ensures security, stability, extensibility, and flexibility, allowing it to adapt to evolving data needs and data sharing practices.

The PANDEM-2 platform is also a training platform, designed to facilitate both national and cross-border simulation exercises. A simulation exercise is a form of training or evaluation of capabilities involving the simulation of an emergency [41]. Operationally, there is the potential for the PANDEM-2 dashboard to be deployed at regional, subnational, national, and EU levels to conduct simulation exercises aimed at stress-testing pandemic response capacity. A recent large-scale functional exercise involving 2 public health emergency operating centers within the PANDEM-2 consortium (the Robert Koch Institute in Germany and the National Institute for Public Health and the Environment in the Netherlands) supports this position. The aim of this exercise was to explore the coordinated response to a large-scale pandemic due to a novel strain of avian influenza in Europe with the objective of testing and evaluating the functionalities of the PANDEM-2 IT system and associated tools. During the 2-day exercise, participants received 44 injects to develop the scenario and provide specific tasks to complete within their country's context. A manuscript outlining the implementation of this exercise is currently under review [11]. Evaluation of the exercise comprised both qualitative (hot-wash group interviews and after-action interviews) and quantitative (questionnaires and interviews), and feedback indicated that the PANDEM-2 dashboard met or exceeded their technical requirements in terms of user experience. Moreover, participants agreed that the dashboard addresses a current gap in national and cross-border training capacity for pandemic preparedness and response.

Alongside addressing data requirements, effective methods for data presentation need to be considered. The PANDEM-2 platform's participatory design approach emphasizes the importance of involving end users in the design of a system. Through this interactive and iterative approach, users can define system requirements, share domain expertise, and identify high-priority indicators for pandemic management. This approach within the PANDEM-2 platform enabled the creation of a design framework that offers adaptability and scalability, ensuring consistent interactions even as indicators evolve.

The participatory design approach also supported the effective knowledge transfer among end users and the technical team. This was crucial to enable the design team to understand the requirements of diverse and specialized domains and to facilitate the design of novel technical solutions within those domains. Ongoing research endeavors should be directed toward enhancing user engagement with intricate software in specialized areas, such as epidemiological and resource models, balancing user-friendly interfaces with necessary complexity, and exploring efficient techniques for presenting voluminous datasets and findings.

Data storytelling has become one such technique for enhancing user engagement and is often seen as an intuitive way to drive decision-making and reduce the risk of information overload. The participatory design process revealed that managing multiple decision narratives would add unnecessary complexity. The dashboard approach chosen provides flexibility across public health scenarios like surveillance and training. The ability to customize views and generate reports makes it a more scalable solution, especially for our primary users, public health officers, and medics trained in data analysis, who require more in-depth exploration than storytelling offers. The dashboard includes filtering, tagging, and prioritization features to address information overload, but managing complex data while meeting the needs of expert users remains a challenge. The participatory design process helped refine key indicators to present concise, relevant information, but balancing exploration and clarity is an ongoing effort in systems like PANDEM-2.

The identification of high-priority indicators and the possibility of consolidating them into a singular variable that captures the status of a pandemic merits in-depth investigation. This strategy could streamline decision-making processes and yield immediate insights into the dynamic nature of the pandemic across its various stages.

Summary

During the project, challenges related to data standardization across consortium members became evident, particularly due to the lack of data in the TESSy format. In addition, many countries had regional divisions that differed from those used by the ECDC (NUTS). End-user experts also highlighted the critical role dashboards play in pandemic preparedness and response. The findings underscore the importance of making data for these indicators accessible for public health purposes.

The project's commitment to responsible innovation and user-centric principles was demonstrated through its robust impact assessment process, which prioritized key elements such as privacy-by-design and adherence to GDPR as well as regulations governing health technology development. This iterative process ensured that the platform remained relevant and user-friendly. Transparency stands as a core value of the PANDEM-2 project, demonstrating its commitment to openness and accountability. All project resources have been made publicly available for interested parties to access and review on

XSL•FO
RenderX

the project website [42] and the European research platform Cordis [43], where stakeholders can find comprehensive information about data sources used, project procedures, and methods.

While the PANDEM-2 dashboard holds promise for effectively managing real-time data during future pandemics, successful integration with existing IT systems within public health agencies will be a necessary step. In the interim, the dashboard stands as an innovative training platform, providing member states the opportunity to assess their pandemic preparedness capacity through collaborative cross-border exercises developed by the PANDEM-2 project. Despite the limitations encountered during the project, our approach and findings provide valuable insights through open-access materials and tools to support public health agencies in EU member states to better prepare for upcoming pandemics.

To ensure comprehensive and transparent reporting of the development process, this study followed the Guidelines for Intervention Development checklist, documenting each stage of the dashboard's design and stakeholder engagement (Multimedia Appendix 13) [44].

Acknowledgments

This project has received funding from the European Union's Horizon 2020 research and innovation program (grant 883285). The material presented and views expressed here are the responsibility of the authors only. The EU Commission takes no responsibility for any use made of the information set out. The authors would like to acknowledge the contribution of the PANDEM-2 public health agencies and first responder partners for their valuable input to the design and development process. This publication has emanated from research supported in part by a grant from Science Foundation Ireland (grant 12/RC/2289_P2; Insight SFI Centre for Data Analytics).

Abstract

Background: The 2022 mpox outbreak in the United States disproportionately affected gay, bisexual, and other men who have sex with men (GBMSM). Uptake of mpox testing may be related to symptomology, sociodemographic characteristics, and behavioral characteristics.

Objective: This study aimed to describe suspected mpox symptoms and testing uptake among a sample of GBMSM recruited via the internet in the United States in August 2022.

Methods: We conducted a rapid internet-based mpox survey from August 5 to 15, 2022, among cisgender men 15 years and older who had previously participated in the 2021 American Men's Internet Survey. We estimated the prevalence of suspected mpox symptoms (fever or rash or sores with unknown cause in the last 3 mo) and uptake of mpox testing. We calculated adjusted prevalence ratios (aPRs) and 95% CIs for associations between participant characteristics and suspected mpox symptoms and summarized characteristics of GBMSM reporting mpox testing. Among symptomatic GBMSM who did not receive mpox testing, we described testing self-efficacy, barriers, and facilitators.

Results: Of 824 GBMSM, 126 (15.3%) reported at least 1 mpox symptom in the last 3 months; 58/126 (46%) with rash or sores, 57 (45.2%) with fever, and 11 (8.7%) with both. Increased prevalence of suspected mpox symptoms was associated with condomless anal sex (CAS; aPR 1.53, 95% CI 1.06 - 2.20). Mpox testing was reported by 9/824 GBMSM (1%), including 5 with symptoms. Most GBMSM reporting mpox testing were non-Hispanic White men (7/9 vs 1 Black and 1 Hispanic or Latino man), and all 9 lived in urban areas. Most reported having an sexually transmitted infections test (8/9), 2 or more partners (8/9), CAS (7/9), and group sex (6/9) in the last 3 months. Of those tested, 3 reported living with HIV and all were on treatment, whereas the remaining 6 men without HIV reported current pre-exposure prophylaxis (PrEP) use. Of symptomatic GBMSM who did not report mpox testing, 47/105 (44.8%) had low mpox testing self-efficacy. Among those with low self-efficacy, the most common barriers to testing were not knowing where to get tested (40/47, 85.1%) and difficulty getting appointments (23/47, 48.9%). Among those with high testing self-efficacy (58/105, 55.2%), the most common facilitators to testing were knowing where to test (52/58, 89.7%), convenient site hours (40/58, 69%), and low-cost testing (38/58, 65.5%).

Conclusions: While all GBMSM who reported testing for mpox were linked to HIV treatment or PrEP, those with symptoms but no mpox testing reported fewer such links. This suggests targeted outreach is needed to reduce structural barriers to mpox services among GBMSM in rural areas, Black and Hispanic or Latino GBMSM, and GBMSM living with HIV. Sustaining and scaling community-tailored messaging to promote testing and vaccination represent critical interventions for mpox control among GBMSM in the United States.

Introduction

Human mpox is an orthopox virus first identified in the Democratic Republic of the Congo and endemic to regions of Central and Western Africa, which has caused localized outbreaks for decades [1]. mpox is classified into 2 clades; of the two, clade I mpox is associated with more severe symptoms and is highly lethal, with an estimated 10% mortality rate and several thousands of cases annually in Central Africa, including a 2023‐2024 outbreak in the Democratic Republic of the Congo [2]. While clade I mpox has not been observed outside the African continent, clade II mpox has been occasionally reported internationally, often linked to travel [3]. Although clade II infections are associated with a much lower mortality rate, they have resulted in increasing global morbidity, including a global outbreak in 2022 [3]. From 2022 to 2024, there have been 95,000 confirmed cases of clade II mpox globally, including several deaths, predominantly affecting gay, bisexual, and other men who have sex with men (GBMSM) [1].

The first case in the 2022 mpox outbreak was identified in the United States on May 17, 2022, triggering a nationwide response to identify and monitor new cases and deliver the mpox vaccine [4]. As of March 5, 2024, approximately 32,000 mpox cases have been reported in the United States [1], and over 90% of cases in the United States have occurred among cisgender men, the majority of whom had recent sexual contact with a man [5].

As elsewhere, the 2022US mpox outbreak and its disproportionate impacts on GBMSM have been attributed to connected sexual networks. Moreover, the US mpox outbreak demonstrated disparities in infections associated with structural determinants of health such as racism: communities of color reported higher burdens of infections, but lower uptake of testing and vaccines [1,6]. In studies of testing for sexually transmitted infections (STIs) and COVID-19, lower socioeconomic status has been associated with reduced testing uptake [7,8]. However, few studies to date have examined how structural determinants may have shaped mpox testing in a large, national sample of MSM [9,10].

Beyond structural factors, engagement in mpox screening and testing services may be driven by individual factors, particularly risk perception and behavioral indication for mpox tests [11]. For example, GBMSM who report regular condom use have been found to have lower engagement in testing for HIV [12] and bacterial STIs [13]. Condom use and engagement in other sexual behaviors associated with mpox (such as group sex) [14,15] may therefore be associated with increased engagement in mpox testing.

New infections have slowed significantly since the peak of the outbreak [1,16], but equitable testing remains key to contract tracing, treatment, and linkage to vaccination programs. Understanding potential barriers and facilitators to mpox testing during the peak of the 2022 outbreak can inform strategies for future mpox or other STI outbreaks. The current work aims to fill knowledge gaps around these barriers and facilitators by describing suspected mpox symptoms and testing from an mpox study among a sample of prior participants in the American Men's Internet Survey (AMIS).

Methods

Recruitment

The AMIS mpox study was an internet-based survey conducted from August 5 to 15, 2022 in GBMSM aged 15 years and older who had participated in AMIS 2021. Methods for the annual AMIS have been described elsewhere [17]. Annual AMIS participants were recruited via social media and deemed eligible if they identified as cisgender male, aged ≥15 years, had ever had sex with a man, and lived in the United States. For the mpox study, the sampling frame included GBMSM who had completed the AMIS 2021 survey cycle, had sex with a man in the past year, and had consented to be recontacted for future research (N=2999).

Ethical Considerations

This study received ethical approval from the Emory University Institutional Review Board (IRB00047676). All activities were conducted consistent with US Centers for Disease Control and Prevention policies and regulations. All participants provided informed consent to participate and were not compensated. All study data were deidentified.

Procedures

Potential participants (ie, all AMIS 2021 participants who had consented to be recontacted for future research, N=2999) were contacted via email with an invitation to participate and a secure survey link. Potential participants were contacted up to twice and provided electronic informed consent after eligibility screening. The internet-based survey included questions in English about demographics, sexual behavior, substance use, HIV and STI testing and diagnosis, HIV pre-exposure prophylaxis (PrEP) use, and mpox knowledge, symptoms, testing, diagnosis, vaccination, stigma, and behavior change.

Measures

We measured participant age, race or ethnicity (non-Hispanic White, non-Hispanic Black, Hispanic or Latino, other), US census region (Northeast, Midwest, South, or West), urbanicity based on 2013 National Center for Health Statistics classification [18], health insurance (none, private, public, other), self-reported HIV status, current antiretroviral therapy use (among people living with HIV, [19]) and current PrEP use (among those without HIV).

Participants reported, in the past 3 months, their number of sexual partners (1 or ≥2), participation in group sex, bathhouses or sex clubs, or sex parties, and any illicit or injection drug use. They also reported condomless anal sex (CAS) in the past 12 months, CAS with partners of a different HIV status in the past 3 months, HIV testing in the past 12 months, and STI testing in the past 3 months.

Outcomes

We assessed symptoms suggesting mpox by asking: "In the past three months, have you had a (1: fever or 2: new rash/sores on the skin) and didn't know the cause?" For GBMSM reporting rashes, we asked their location and pain severity (rated 0‐10),

XSL•FO
RenderX

and whether, after GBMSM first noticed the rash or sores, they changed in appearance, number, or location.

We measured mpox testing by self-report. For GBMSM reporting no mpox testing, we assessed agreement (4-point Likert scale) with the statement: "If I thought I had mpox, I could get a test if I wanted it." GBMSM who strongly or somewhat agreed were considered to have high mpox testing self-efficacy, and those who strongly or somewhat disagreed as having low self-efficacy. We also asked participants what made it easy (for those with high self-efficacy) or difficult (for those with low self-efficacy) to get a test; parallel response options included location, eligibility, appointments, using one's own provider, site times, privacy, and cost.

Statistical Analysis

We calculated frequencies for participant characteristics, symptoms suggesting mpox, and mpox testing. We calculated unadjusted prevalence ratios (PRs) and 95% CIs for associations between participant characteristics and symptoms suggesting mpox. Factors found to have a significant association (α<.05) with symptoms were included in a multivariable model to calculate adjusted prevalence ratios (aPRs). The final model included age, race or ethnicity, PrEP use, STI testing, and CAS. We assessed model fit using Hosmer-Lemeshow test, which has been recommended for use with binomially distributed data [20]. We used frequencies to summarize the characteristics of GBMSM reporting mpox testing. Among symptomatic GBMSM who did not report mpox testing, we summarized testing self-efficacy, barriers, and facilitators. All analyses were performed in Stata 15.1 (StataCorp) [21].

Results

Sample Characteristics

Of 2999 GBMSM in the sampling frame, 824 completed the mpox study survey for a response rate of 27.5%. The majority of mpox study participants were aged ≥40 years (478/824, 58%), non-Hispanic White (581/824, 70.9%), residents of urban areas (770/824, 93.4%), and had private health insurance (564/824, 68.6%, Table 1). In the last 3 months, a minority reported CAS with a partner of a different HIV status (220/824, 26.7%), group sex (238/824, 29.1%), or attending a sex club (147/824, 19.7%), or sex party (111/824, 14.9%). Just over two-thirds (575/824, 69.8%) reported past-year HIV testing, and around half (408/824, 49.6%) reported STI testing in the last 3 months. Most (720/824, 87.4%) were not people living with HIV and 44.7% of these (316/720, 44.7%) were currently using PrEP; of 104 people living with HIV in the sample, 99 (96.1%) were currently on HIV treatment.

[a]STI: sexually transmitted infection.

[b] ART: antiretroviral therapy.

[c] One participant with HIV did not provide information on ART use.

[d]PrEP: HIV pre-exposure prophylaxis.

[e]CAS: condomless anal sex.

Prevalence of Symptoms Suggesting mpox and Associated Factors

In total, 126/824 (15.3%) participants reported at least 1 mpox symptom in the last 3 months (Table 2): 58/126 (46%) with rash or sores, 57 (45%) with fever, and 11 (9%) with both. In unadjusted analyses, there was decreased prevalence of symptoms suggesting mpox among participants aged ≥40 years versus 15 - 24 years (PR 0.48, 95% CI 0.28 - 0.82) and among Hispanic or Latino versus non-Hispanic White participants (PR 0.44, 95% CI 0.20 - 0.97), and increased prevalence among participants reporting current PrEP use (PR 1.48, 95% CI 1.05 - 2.09), recent STI tests (PR 1.40, 95% CI 1.01 - 1.95), and CAS in the last 12 months (PR 1.64, 95% CI 1.14 - 2.35). In our adjusted model, we failed to reject the Hosmer-Lemeshow null hypothesis (Hosmer-Lemeshow $\chi_8^2$5.01; P=.76), indicating adequate model fit [20]. In adjusted analyses, prevalence of symptoms suggesting mpox remained lower among GBMSM aged ≥40 years versus 15 - 24 years (aPR 0.49, 95% CI 0.28 - 0.83), and higher among those reporting CAS (aPR 1.53, 95% CI 1.06 - 2.20).

[a]mpox: mpox.

[b]PR: prevalence ratio.

[c]aPR: adjusted prevalence ratio.

[d]Not applicable.

[e]REF: reference.

[f]ART: antiretroviral therapy.

[g]PrEP: HIV pre-exposure prophylaxis.

[h]The model with PrEP use was restricted to individuals without HIV, and included all listed covariates except HIV status.

[i]No PR reported given 100% of symptomatic people living with HIV reported current antiretroviral therapy use.

[j]STI: sexually transmitted infection.

[k]CAS: condomless anal sex.

Uptake of mpox Testing

Among 126 symptomatic GBMSM, 114 (90.5%) did not report mpox testing; their characteristics mirrored those of the overall sample (Table 2). mpox testing was reported by 9 participants (1%, Table 2), including 5 with reported symptoms. Most GBMSM reporting mpox testing were non-Hispanic White (7/9 vs 1 Black and 1 Hispanic or Latino man) and all 9 lived in urban areas. Most reported STI testing (8/9), 2 or more partners (8/9), CAS (7/9), and group sex (6/9) in the last 3 months. Three were people living with HIV, all on treatment; the remaining 6 without HIV reported current PrEP use.

Among 69 GBMSM experiencing recent rashes or sores with unknown cause, most located them on hands or arms, feet or legs, and genitals or pelvic area (Table 3). Over half (31/50, 62%) rated their pain as ≤2 on a 10-point scale. Most (38/69, 55%) reported no changes over time; the most common reported change was worsening appearance of rash or sores (22/69, 32%).

XSL•FO
RenderX

Table . Rash or sore location, severity, and changes among men having sex with men in the United States reporting new rashes or sores in the last 3 months (n=69).

		Experienced new rash or sores with unknown cause, last 3 months (n=69), n (%)
Location of rash		
	Hands or arms	26 (37.7)
	Feet or legs	24 (34.8)
	Genitals or pelvic area	19 (27.5)
	Chest	14 (20.3)
	Face	13 (18.8)
	Anus	10 (14.5)
	Mouth	7 (10.1)
Severity of rash or sores		
	0: no pain at all	10 (20)
	1 - 2	21 (42)
	3 - 4	11 (22)
	5 - 6	4 (8)
	7 - 8	4 (8)
	9 - 10: the worst pain possible	0 (0)
Changes in rash or sores		
	No changes	38 (55.1)
	Worsening appearance	22 (31.9)
	Increased number of rashes or sores in the same location	11 (15.9)
	Rashes or sores in new locations	7 (10.1)

Of the 126 symptomatic GBMSM, 105 (83%) did not report mpox testing and were offered questions about testing self-efficacy and barriers and facilitators to testing (Table 4). Among GBMSM with high testing self-efficacy (58/105, 55%), common facilitators to testing were knowing where to test (90%), convenient site hours (69%), and low-cost testing (38/58, 66%). Among those with low testing self-efficacy (47/105, 45%), the most common barriers to testing were not knowing where to get tested (40/47, 85%) and difficulty getting appointments (23/47, 49%).

Table . Characteristics of gay, bisexual, and other men who have sex with men with symptoms suggesting mpox who did not take up mpox testing (n=105).

Barriers or facilitators to testing	Low testing self-efficacy[a] (n=47), n (%)	High testing self-efficacy (n=58), n (%)
(Not) knowing where to get tested	40 (85.1)	52 (89.7)
Getting an appointment	23 (48.9)	29 (50)
Getting tested at own doctor	17 (36.2)	24 (41.4)
Convenience or testing site hours	11 (23.4)	40 (69)
(Not) knowing who is eligible	10 (21.3)	29 (50)
Cost considerations	7 (14.9)	38 (65.5)
Privacy considerations	6 (12.8)	19 (32.8)

[a] Assessed using the statement: “If I thought I had mpox, I could get a test if I wanted it.” Participants who strongly or somewhat agreed were considered to have high mpox testing self-efficacy, and those who strongly or somewhat disagreed as having low self-efficacy.

Discussion

Principal Findings

Our findings show that a large proportion of GBMSM with symptoms suggesting mpox did not access mpox testing and mpox testing was low or zero among GBMSM in rural areas and GBMSM who were younger, Black, Hispanic or Latino, or people living with HIV.

Compared with non-Hispanic White participants, we observed low levels of mpox testing among Black and Hispanic or Latino GBMSM in this study. While this likely reflects our overall sample, which was primarily non-Hispanic White, it is worth noting that this finding aligns with broader disparities not only in mpox cases and vaccine delivery, but also with the majority of US vaccine doses administered to date to non-Hispanic White individuals [1]. Our findings may reflect structural challenges with communication and knowledge of access to and locations of testing, laboratory capacity, and stigma [22]. As others have noted, additional data are needed to ensure equitable access to and communication on mpox testing, including routine collection of demographic data through testing programs [23,24].

There was no reported testing among GBMSM in rural or nonurban areas in our study. While few participants in our study were from rural areas, this parallels findings from an internet-based study also conducted in August 2022, which found that GBMSM in rural areas had lower perceived susceptibility to and severity of mpox, compared with urban GBMSM [25]. The authors of the earlier manuscript found further disparities in rural GBMSM's perceptions of mpox vaccine benefits and in their intention to be vaccinated, amidst potentially inadequate vaccine supply. Our findings likely reflect broader challenges with public health infrastructure in rural areas [26] and increased availability of HIV and STI services in urban areas, which may have facilitated linkages to mpox testing. While there are opportunities to leverage these services for mpox testing, given only half of potentially symptomatic GBMSM were engaged with PrEP and STI services, additional outreach may be needed.

Testing uptake was also low among GBMSM living with HIV. While only about 1 in 5 participants in our study were people living with HIV, we agree with others that tailored interventions can better serve this community with services, including mpox testing, postexposure prophylaxis for mpox exposure, and vaccination [27]. Current US surveillance data suggest that around 40% of mpox diagnoses were among people living with HIV [1]. Given recent evidence that suggests severe mpox in the context of advanced immunosuppression may be an AIDS-defining condition [28], structural interventions to improve access to mpox testing among people living with HIV, such as integrating mpox testing into routine care for people living with HIV, are critical to ensure early identification and treatment of new mpox cases.

We found that the most symptoms suggesting mpox in our sample were rashes or sores, most commonly in the arms, legs, and genitals. Rashes in the arms and legs were reported at a similar rate in our study as has been shown in broader US surveillance data; however, we saw less frequent rashes in the genitals and face [5]. In our study, rashes and sores were reported to be generally mild and commonly did not change after they were first observed. This may explain the relatively low uptake of mpox testing among potentially symptomatic GBMSM, because GBMSM with mild symptoms suggesting mpox may not have felt they needed a test or been eligible for testing at that time [5]. During clinical encounters with GBMSM (eg, STI testing), providers should continue to counsel GBMSM to seek mpox testing and vaccine if they develop unexplained rash or other symptoms consistent with mpox.

Limitations

A key limitation of these analyses is the small sample of GBMSM in our study who reported mpox testing (n=9), precluding advanced statistical analyses comparing the characteristics of GBMSM who tested for mpox with those who did not. Furthermore, we are unable to draw generalizable conclusions based on the characteristics of these 9 individuals. We recruited a convenience sample that is subject to selection bias; our respondents were predominantly non-Hispanic White, elderly, and privately insured and may have increased access to mpox testing services—the sample is thus unlikely to represent all GBMSM in the United States. Our use of self-reported data and recall period of 3 months for most outcomes may have introduced recall bias; furthermore, we are unable to confirm whether those with symptoms suggesting mpox indeed had acquired mpox. Given symptoms were reported in the last 3 months, in some cases, participant responses may have reflected symptoms before the first US mpox case on May 17, 2022. We were also not able to place individuals' locations at the time of symptom onset or testing, which may have affected testing uptake given the nonuniform roll-out of testing nationwide. Regarding symptoms, we only included items assessing the presence of fever and rash or sores; we did not inquire about other symptoms commonly reported among mpox cases such as malaise, headache, nausea or vomiting, pain, itching, or bleeding. Low mpox testing prevalence in this sample may be attributed to perceptions that symptoms, such as fever or rash, were unrelated to mpox and therefore did not require testing. Our findings also reflect the timing of data collection (August 2022); access to mpox testing and other services likely changed as the US outbreak response evolved. For example, testing uptake could have been limited due to sustained increases of telehealth services after the COVID-19 pandemic, particularly among wealthier, insured patients such as the GBMSM who comprised the majority of our sample [29]. Furthermore, access to testing over the course of the outbreak likely varied by geographic location, something we were unable to fully assess in this analysis.

Conclusions

Similar structural barriers that have long been known to increase the risk of other STIs were rapidly replicated during the mpox outbreak in 2022. Sustained disparities fostered by racism, stigma, and limited access to health care in rural settings contribute to ongoing morbidity and mortality for GBMSM and predispose many communities to unexpected new outbreaks and epidemics such as mpox. While the epidemiology of mpox

XSL•FO
RenderX

continues to evolve, transmission risk remains present and characterizing optimal public health interventions for mpox is critical to both prevent future outbreaks and more rapidly respond if they occur.

Abstract

Background: Parents play a pivotal role in supporting transgender and gender diverse (TGD) youth. Yet only 35% of TGD youth describe their home as a gender-affirming place. Lack of parental support contributes to recent findings that TGD youth are approximately three times more likely to attempt suicide than their cisgender peers. In contrast, parents' affirmation of their children's gender identity significantly improves their mental health outcomes, by reducing anxiety, depression, and suicidality.

Objective: Addressing the urgent need for effective, scalable interventions, this study evaluates a novel digital approach: short, animated storytelling videos. We hypothesized that our 2.5-minute video intervention would reduce antitransgender stigma, or transphobia, and improve attitudes toward gender diverse children among US parents.

Methods: We recruited 1267 US parents, through the Prolific Academic (Prolific) online research platform, and randomized them into video intervention or control groups. We measured transphobia using the Transgender Stigma Scale, and attitudes toward transgender children using the gender thermometer, before and after watching the video. We compared outcomes between the two groups using 2 × 3 ANOVA. Both groups were invited to return 30 days later for follow-up assessment, before being offered posttrial access to the intervention video, which portrayed an authentic conversation between a mother and her transgender child.

Results: Single exposure to a short, animated story video significantly reduced transphobia and improved attitudes toward transgender children among US parents, immediately post intervention. We observed a significant group-by-time interaction in mean Transgender Stigma Scale scores ($F_{2,1}$=3.7, P=.02) and significant between-group changes when comparing the video and control groups from baseline to post intervention (F_1=27.4, P<.001). Effect sizes (Cohen d) indicated small to moderate immediate changes in response to the 2.5-minute video, though the effect was no longer observed at the 30-day follow-up. Gender thermometer scores revealed significant immediate improvements in the attitudes of participants in the video intervention arm, and this improvement was sustained at the 30-day time point.

Conclusions: Short, animated storytelling is a novel digital approach with the potential to boost support and affirmation of transgender children, by offering authentic insights into the lived experiences of TGD youth. Repeated exposures to such interventions may be necessary to sustain improvements over time. Future studies could test a series of short, animated storytelling videos featuring the lived experiences of several TGD youth. Evaluating the effect of such a series could contribute to the fields of digital health communication and transgender health. Digital approaches, such as short, animated storytelling videos, that support empathy and acceptance of TGD youth could foster a more inclusive society in which every child can thrive.

Introduction

Optimal health outcomes for transgender and gender diverse (TGD) youth depend on the support and affirmation of their parents, as well as other adults with whom they interact [1-5]. Yet, even in their own homes, only 35% of TGD youth feel they are in a gender-affirming place [6]. Lack of parental support contributes to recent findings that TGD youth are 2.7 - 3.5 times more likely to attempt suicide than their cisgender peers [7,8]. Simple, gender-affirming acts, such as consistently respecting a child's pronouns in the home, can dramatically reduce the percent of TGD youth who attempt suicide from 21% to 12% as in a 2023 US national survey [6]. However, reducing stigma toward TGD youth, among adults, remains challenging [9,10]. Stigma acts as a broader social mechanism that contributes to transphobia (prejudice against individuals who defy traditional gender norms) [9,11]. Recent findings indicate that, even within their own homes, only 35% of TGD youth report feeling that they are in a gender-affirming place, with parental transphobia being a key contributing factor [6]. Lack of adult support and affirmation remains one of the leading causes of poor mental health outcomes in TGD youth [2-5,12,13].

This public health problem is aggravated by a growing climate of general societal intolerance in the United States. A record number of anti-LGBTQ (lesbian, gay, bisexual, transgender, queer) bills (more than 400) were introduced across US state legislatures in 2023 [14]. These environmental factors contribute to an alarmingly high rate of suicidality among TGD youth: the 2023 US National Survey on the Mental Health of LGBTQ+ Young People reported that 48% of transgender girls, 56% of transgender boys, and 48% of nonbinary youth had seriously considered attempting suicide in the past year [6]. Overall, TGD youth are 3.5 times more likely to attempt suicide than their cisgender peers [8]. Simple gender-affirming acts from adults, such as consistently respecting a child's pronouns, have been associated with a dramatic reduction in the percent of TGD youth who attempt suicide from 21% to 12% [6]. Even before the COVID-19 pandemic, a scoping review published in the *Journal of Adolescent Health* identified an urgent need for innovative interventions to reduce transphobia toward TGD youth [15]. Pandemic lockdowns, through a loss of community and school support, further threatened the mental health of TGD youth, who found themselves isolated and unsupported [16-18].

Research on transphobia reduction in schools highlights the need for interventions to reduce stigma among all parents, not just those of TGD youth [19]. Not only does affirmation from the general parent community positively impact TGD children directly, it also makes it easier for the parents of TGD children to adopt gender-affirming attitudes toward their children, when these prevail in the broader parent community [20,21]. Importantly, a parent's journey toward acceptance and support of their TGD child begins with them as a member of the general parent community [22]. Only once they have truly accepted the TGD identity of their child will they identify as "a parent of a TGD child." So, efforts to promote acceptance and reduce transphobia in the general parent population supports TGD youth in two ways: (1) a more accepting general parent population will model acceptance for the parents of TGD youth, and (2) a more accepting general parent population results in gender-affirming interactions with TGD youth in school or social settings, thereby creating a more accepting environment in which all children can thrive [19-22].

A significant body of research suggests that social contact-based interventions may be the most effective way to reduce stigma [23-26]. Grounded in intergroup contact theory, this research suggests that exposure to the stories and experiences of transgender individuals can effectively reduce transphobia toward them [27-31]. A known stumbling block of this approach is the selection bias that limits exposure to the stories of TGD youth, since prejudiced individuals generally avoid intergroup contact [30]. Disseminating the stories of TGD youth to the general public, on the platforms where they readily consume information, still presents a major challenge.

In the postpandemic era, social media has become a primary source of health information for the public [32]. A 2021 scoping review in the *Lancet Digital Health* described social media as a "crucial communication tool" for public health [33]. Social media has proven effective for reaching broader and more varied audiences, including hard-to-reach populations [32]. As such, social media presents a powerful, emerging pathway for scaling the stories of TGD youth to the public.

Short, animated storytelling videos, disseminated via social media, emerged as a powerful digital approach to engaging diverse audiences around the world, during the COVID-19 pandemic [34]. Harnessing the appeal of human stories, enhanced with compelling soundtracks, this novel digital approach is easily shareable and thus readily scalable via social media [34,35].

This study investigated the effect of a short, animated storytelling video on transphobia in a sample of US parents. Our hypothesis was that exposure to the authentic narratives of TGD youth, animated to protect their identities, could effectively reduce transphobia and improve attitudes toward gender diverse children, thereby boosting affirmation and support for TGD youth, among parents in the general public.

Methods

Participants and Recruitment Procedure

From January to February 2024, we enrolled parents from the general US population using Prolific Academic, a crowdsourcing platform frequently used to recruit participants in online psychology and medical research [36]. Prolific supports high-quality data collection by ensuring consistency in demographic responses over time, screening for bots, blocking participants who hide their location, and assigning anonymous unique participant IDs [37,38]. For this trial, we recruited

XSL•FO
RenderX

English-speaking parents, aged 18 - 50 years, with at least one child, who were residing in the United States. Participants were recruited through the Prolific Academic platform. Before the initiation of this study, all participants reviewed a detailed information sheet, outlining the rationale for this study as well as all study procedures, and potential risks and benefits of taking part in this study. Those who agreed to participate were directed to complete this study's procedures on Qualtrics, a secure online data-collection platform.

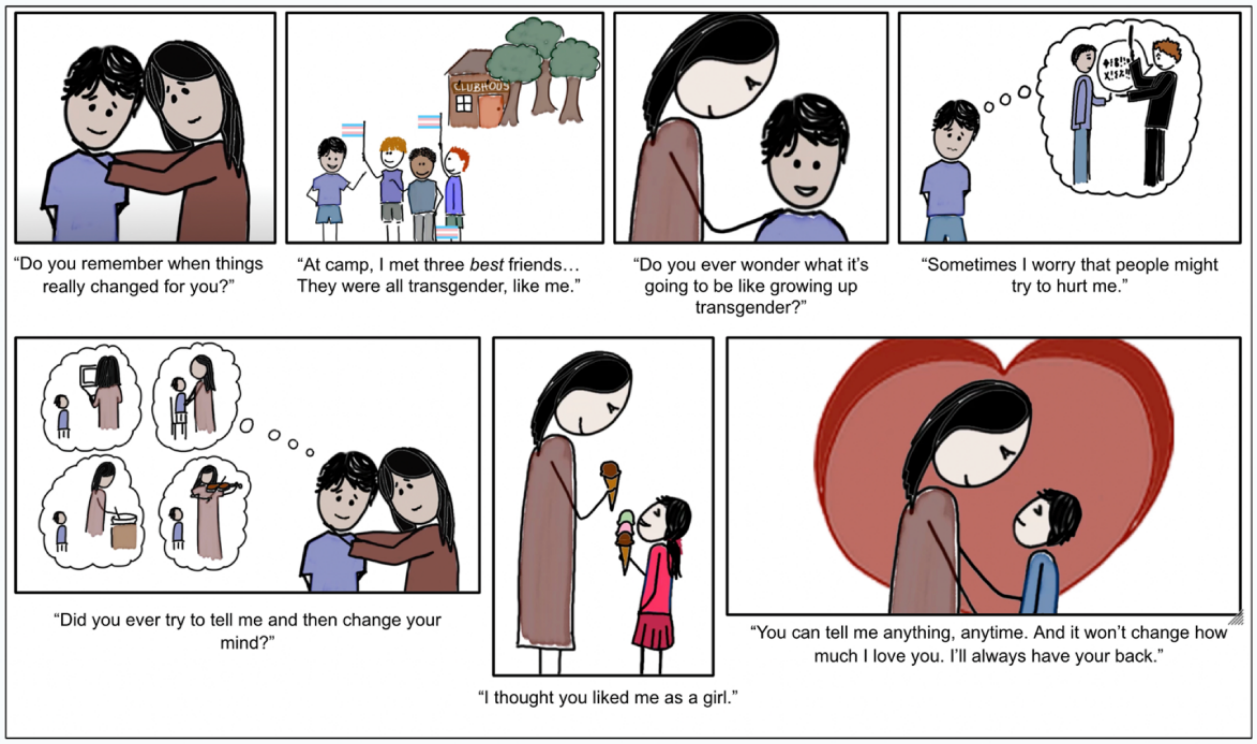
Ethical Considerations

This study, which involved human participants, was performed in accordance with the ethical standards laid down in the 1964 Declaration of Helsinki and was approved by the Stanford University internal review board (IRB-#72761) on January 21, 2024. We followed the CONSORT (Consolidated Standards of Reporting Trials) guidelines [39], and this study was registered (#159248) with AsPredicted, a clinical trial registry created in 2015 by the Wharton School at the University of Pennsylvania [40].

Informed consent was obtained from all participants prior to enrollment in this study. Participants were provided with an information sheet that contained a detailed description of this study's purpose, procedures, potential risks, and benefits. The information sheet was reviewed and approved by the Stanford IRB. Participants were informed that participation was voluntary and that they could withdraw at any time without penalty. The consent process was facilitated by Prolific Academic, the academic recruitment platform through which participants were recruited. Participants were paid US $2.40 for participation in this short study, at 2 time points and in accordance with the payment recommendations of Prolific Academic. Participants were assured that their responses would remain confidential and that any identifying data would not be shared with the research team by Prolific. The informed consent process was reviewed and approved by the Stanford IRB (#72761) ensuring compliance with ethical research standards.

Randomization and Study Design

After consenting to take part in this study, participants were randomly assigned to one of two groups: short, animated storytelling video intervention group or a control group that received a simple fact sheet about TGD youth. We used a baseline survey to collect demographic information and we administered validated questionnaires to assess transphobia and attitudes toward TGD youth. We conducted the first round of surveys immediately post exposure to the short, animated storytelling intervention. Follow-up assessments, using the same surveys, were conducted 30 days later. To ensure accuracy and validity of the results, we included attention checks (eg, "For this question, please select the answer 'Neither agree nor disagree.'") and excluded participants who failed these. We also used a timer to confirm that participants in the control group read the TGD fact sheet and that those in the intervention group viewed the short, animated storytelling video before proceeding to the next screen. Each participant received US $2.40 for completing this study.



Intervention

Our novel, digital intervention used a short, animated storytelling video to capture an authentic prerecorded conversation between a mother and her transgender child. We chose this video because it follows the principles of social contact-based interventions, which foster identification and emotional engagement. A significant body of research suggests that these principles have proven effective in reducing stigma and transphobia by exposing viewers to the real-life stories and experiences of marginalized individuals [23-30,41]. In the conversation featured in our intervention, a mother asks her son to recall experiences related to his gender identity, including his early hesitations to confide in her that he was transgender. The child then asks his mother about her worries, and she shares these candidly. The identities of the speakers are concealed at all times, and we received written permission to use the audio recording from the speakers. The scenes and characters used to represent the speakers were drawn by hand on a Wacom tablet, by our coauthor (MA), and edited by the Educational Technology Group at Stanford Medicine. Figure 1 shows selected scenes and quotations from the intervention video.

The short, animated video tested in this trial can be previewed on YouTube [42].

RenderX

Figure 1. Selected scenes and quotations from the short, animated storytelling intervention video shown to reduce transphobia in US parents in this online, randomized controlled trial.

Instruments

The primary outcome was transphobia toward TGD youth, which was measured using the total score of the Transgender Stigma Scale (TSS) developed by Madera et al [43]. We adjusted the wording of the scale items to assess attitudes toward transgender children (eg, "Boys who act like girls should be ashamed of themselves," and "Children should play with toys appropriate to their own sex"). The TSS is scored along a 5-point Likert scale ranging from "strongly disagree" (1) to "strongly agree" (5). Higher scores indicate greater transphobia. The TSS is highly reliable and has a Cronbach α of 0.89 [43].

As secondary outcome, we measured attitudes toward TGN children, using the "gender thermometer," a tool we previously developed to assess attitudes regarding sexual orientation and gender diversity [27]. The thermometer provides the following prompt: "Using a scale from zero to 100, please tell us about your personal feelings toward transgender boys or girls. As you do this task, think of an imaginary thermometer. The warmer or more favorable you feel toward the group, the higher the number you should give it. The colder or less favorable you feel, the lower the number. If you feel neither warm nor cold toward the group, rate it 50." We asked respondents about their attitudes toward (1) boys or girls and (2) transgender boys or girls. Higher ratings indicate more positive attitudes toward the group and lower ratings indicate less positive attitudes. Researchers in the fields of political science and psychology have frequently used feeling thermometers to assess attitudes toward diverse groups, including sexual minorities [44].

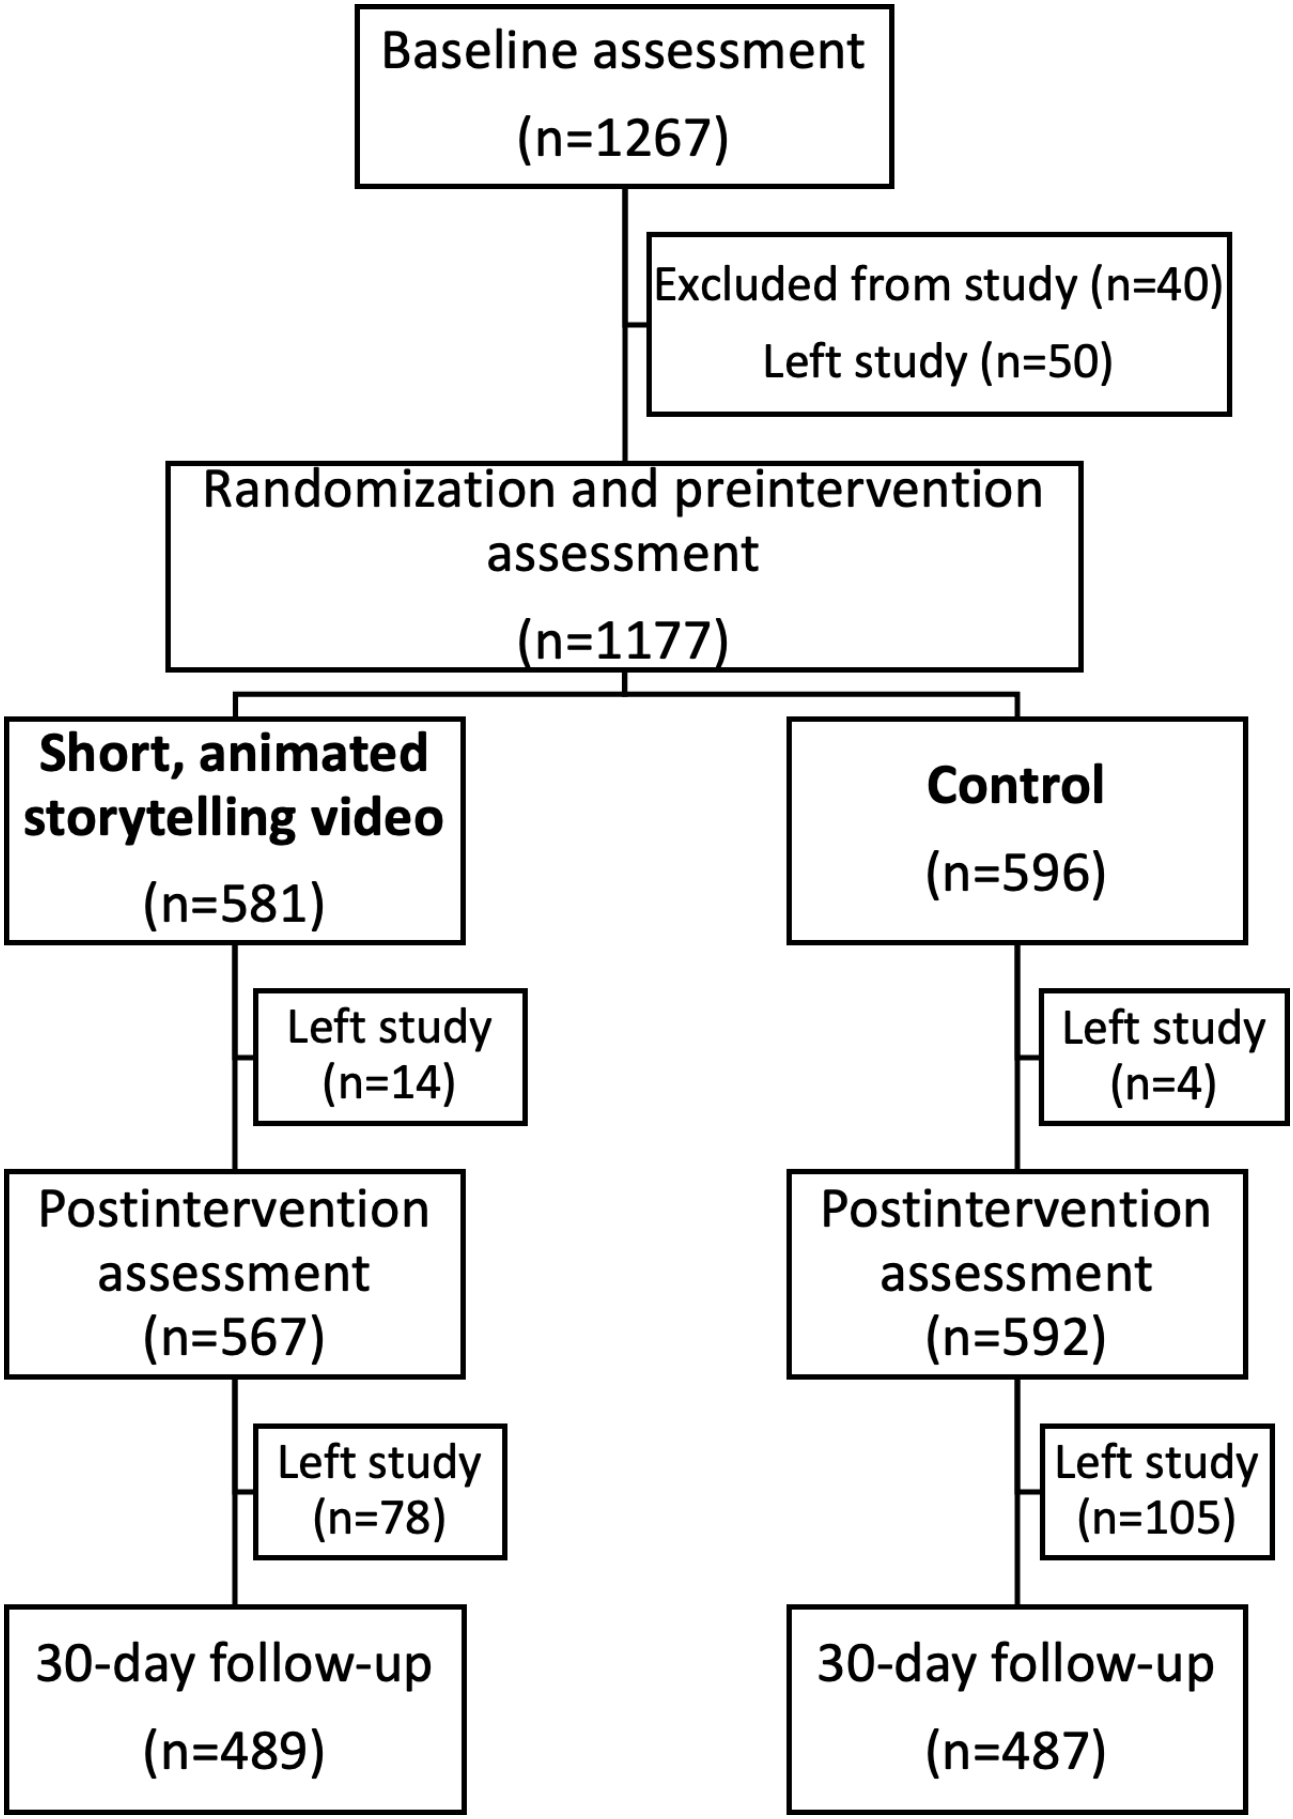
Analysis

The main outcome measures were changes in total TSS scores and gender thermometer scores, from baseline to post intervention and from baseline to 30-day follow-up. We calculated our sample size based on our previous studies [27,45-48]. We used Pearson chi-square and one-way ANOVA tests to compare sociodemographic characteristics between the short, animated storytelling video intervention and control groups. We used repeated-measures ANOVA tests to compare the mean transphobia score between the groups at 3 time points. Next, we used a one-way ANOVA test to compare changes from baseline scores, at post intervention, and at 30-day follow-up. We used independent *t* tests (2-tailed) to compare gender differences at baseline. Data were analyzed using SPSS (version 29.0; IBM Corp) [49].

Results

Sample Characteristics

We recruited 1267 US parents, through the Prolific Academic online research platform. In total, 1177 parents completed the preintervention assessment after we excluded 40 (3%) who failed attention tests and 50 (4%) who left this study. Of these, 1159 (98%) completed the postintervention assessment and 976 (83%) completed the 30-day follow-up assessment. Figure 2 shows the design and flow of this study.



Sociodemographic characteristics and completion rates did not differ significantly between groups (Table 1), nor did baseline characteristics differ between follow-up completers and noncompleters. Mean participant age was 39 (SD 6.9; range 20 - 50) years. More than half of participants self-identified as

XSL•FO
RenderX

female (n=653, 56%), 510 (43%) male, and 14 (1%) transgender or nonbinary. Overall, 110 (9%) participants self-identified as Hispanic, 192 (16%) non-Hispanic Black, 789 (67%) non-Hispanic White, 57 (5%) non-Hispanic Asian, 8 (1%) non-Hispanic Native American, and 18 (2%) other (Table 1).

Intervention Effects

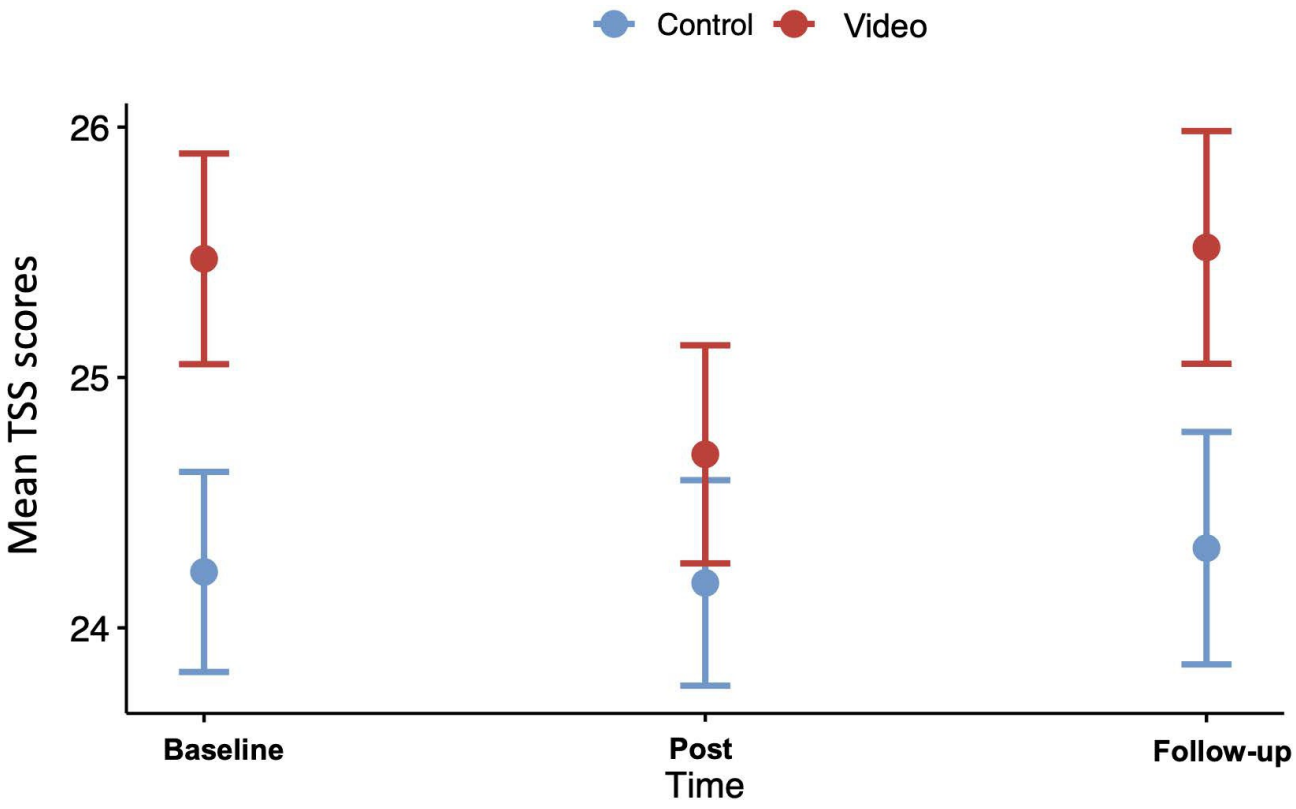
We observed significant differences in outcomes between this study's groups. Figure 3 presents mean TSS scores of this study arms at 3 time points, showing that the control arm changed minimally across time points, in contrast to the short, animated storytelling video intervention arm, which showed a strongly significant decrease in transphobia immediately post intervention. This effect was no longer evident at 30 days post intervention. A 2 × 3 group-by-time ANOVA showed a significant group-by-time interaction in mean TSS scores ($F_{2,1}$=3.7, *P*=.02). One-way ANOVAs revealed significant between-group changes between the short, animated storytelling video and control groups from baseline to post intervention (F_1=27.4, *P*<.001), but not from baseline to the 30-day follow-up.

Figure 4 presents mean gender thermometer scores, by study arm, over time. Figure 4A shows changing attitudes toward transgender boys or girls. Attitudes of participants in the short, animated storytelling video intervention arm improved significantly over time and this improvement was sustained at the 30-day time point. In contrast, we observed a slight improvement in the control arm, which was not significant, and showed a subsequent rebound at the 30-day follow-up.

We did not find a 2 × 3 group-by-time interaction. However, independent *t* tests showed a significant difference between the changes from baseline to post intervention between short, animated storytelling video intervention and control groups (change of 2.2, SD 9.7 vs 0.8, SD 6.5; *t*=3, t_{df}=1151 *P*=.003). We did not observe an effect of the intervention on attitudes toward cisgender boys or girls (Figure 4B).

XSL•FO
RenderX

Figure 3. Mean scores on the TSS between short, animated storytelling video intervention (n=588) and control (n=598) groups at 3 time points in our online RCT measuring the effect of a short, animated storytelling intervention on transphobia in US adults. Follow-up surveys completed after 30 days; higher scores indicate greater transphobia; TSS (range 10 - 50). Repeated measure ANOVA (*P*=.02). RCT: randomized controlled trial; TSS: Transgender Stigma Scale.



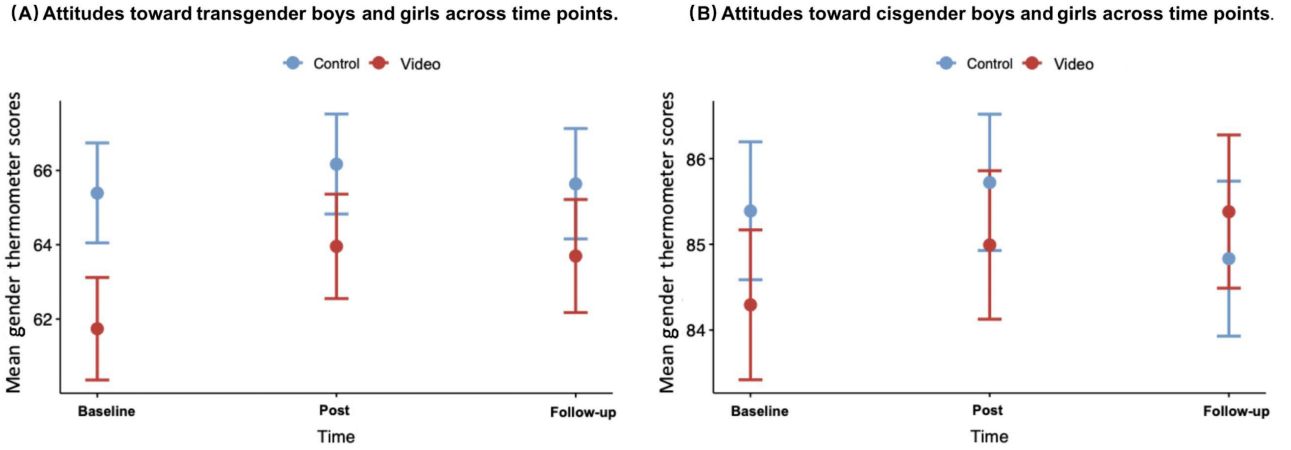


Figure 4. Gender thermometer scores toward (A) transgender children and (B) cisgender children, at 3 time points in our online RCT measuring the effect of a short, animated storytelling intervention on transphobia in US adults. Follow-up surveys completed after 30 days; higher scores indicate more favorable attitudes; gender thermometer (range 0 - 100). RCT: randomized controlled trial.

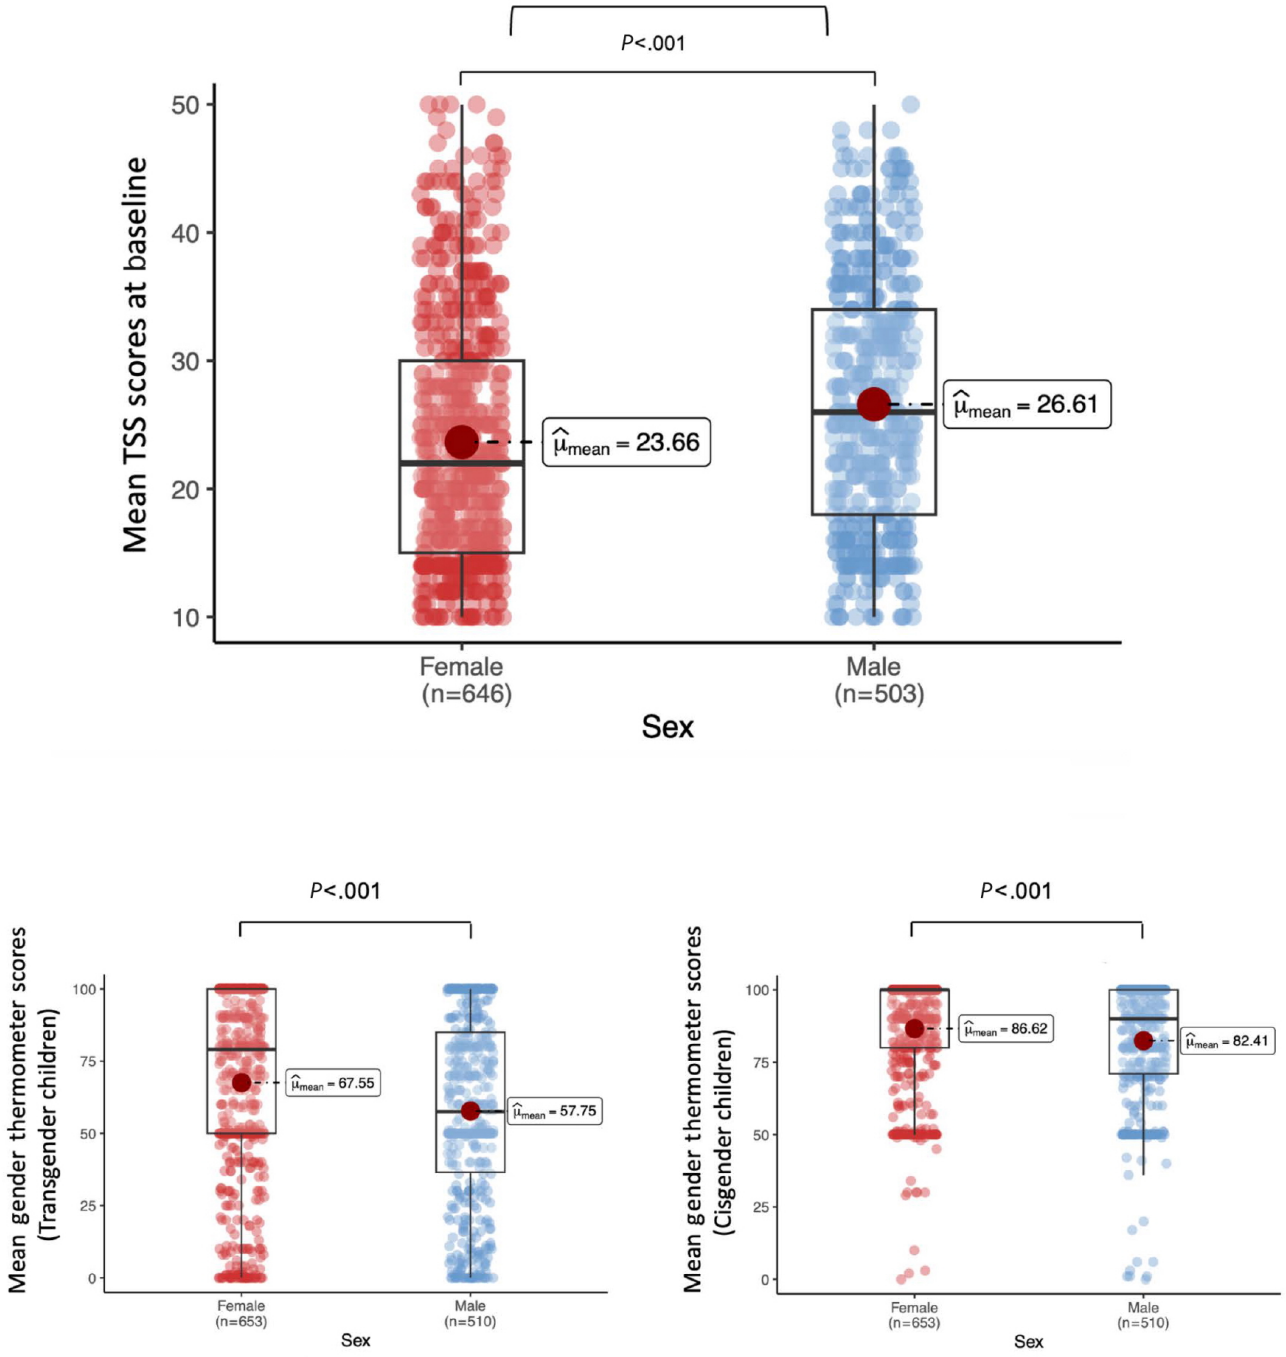

Participant Gender Differences

Figure 5 presents baseline differences between men and women on the TSS (26.6, SD 9.7 vs 23.7, SD 9.8; independent *t* tests: *t*=5.1, *t*df=1161, *P*<.001) and on the gender thermometer both for transgender boys or girls (57.7, SD 32 vs 67.5, SD 33.1, *t*=5.1, *t*df=1161, *P*<.001) and cisgender boys or girls (82.4.7, SD 21 vs 86.6, SD 19.7, *t*=3.5, *t*df=1161 *P*<.001). The observed baseline differences between men and women remained constant across time points in both study groups.

XSL•FO
RenderX

Figure 5. Gender differences (TSS and gender thermometer) at baseline in our online RCT measuring the effect of a short, animated storytelling intervention on transphobia in US adults. Higher scores indicate greater transphobia; TSS (range 10 - 50). Higher scores indicate more positive attitudes; GT (range 0 - 100). GT: gender thermometer; RCT: randomized controlled trial; TSS: Transgender Stigma Scale.

Discussion

In this study, we conducted a large-scale, randomized, controlled experiment to document the potential of a novel, digital approach—short, animated storytelling—to reduce transphobia and improve attitudes toward TGD youth among US parents. Within our study population, we observed significantly reduced transphobia and significantly improved attitudes toward TGD youth, immediately after viewing the 2.5-minute short, animated storytelling video intervention. The effect of this short video was no longer evident one month after the intervention, suggesting that repeated, short exposures to similar short, animated storytelling video content may be necessary to sustain transphobia reductions and improvements in attitudes over time. One potential approach is to develop and disseminate a series of short, animated storytelling videos featuring the authentic lived experiences of several TGD young people. This scalable, digital approach could be implemented through a smartphone-based ecological momentary intervention. Evaluating the effect of such a series could be a meaningful future research direction in the fields of both digital health communication and transgender health.

During the COVID-19 pandemic, our coinvestigator (MA) developed the short, animated storytelling approach, a novel digital modality for scaling health information worldwide. Early short, animated storytelling COVID prevention videos reached

XSL•FO
RenderX

more than 15 million people via social media within 4 months [35]. High voluntary public engagement with short, animated storytelling content was also documented in randomized, controlled trials [50,51]. As short, animated storytelling videos have proven effective for engaging diverse adult audiences, they present a potentially promising new method for engaging the public in the stories of TGD youth. The findings of this study support the potential for using short, animated storytelling to reduce transphobia and elicit empathy. Animation also protects the identities of the TGD storytellers—an important consideration, since many of these young people still live in "stealth" [52].

Intergroup contact theory, and recent research grounded on this theory, support the stigma-reducing potential of social contact with TGD individuals [27,28,30,31,53,54]. To date, interventions designed to reduce transphobia have been difficult to scale broadly to the public because (1) they involve face-to-face or online synchronous interactions, (2) they involve a significant time commitment and some form of active "opting in," thereby self-selecting for people who already have low stigma, or (3) they lack the production value needed to make them highly engaging—one of the keys to scalability [55]. The short, animated storytelling video tested in this study packages a theory-driven approach to stigma reduction (the sharing of human stories) in a readily scalable form of health message (short, animated videos that can be shared via social media) to overcome a critical health challenge (lack of support and affirmation for TGD youth). Anecdotally, and supporting the potential for easy scalability, one participant in our study sent a message to the research team:

> *As the father of a child with 2 trans friends, this video is amazing and I showed it to my daughter, who is 8 and she completely loved it. She asked if we could send it to her friends' parents, who called us and thanked us. So I wanted to let you know this was helpful and well thought. I can't thank you enough!*

In this study, we also observed significant differences in baseline transphobia between men and women. Aligned with prior research, men in our study scored significantly higher on transphobia than did women, and these differences persisted across time points [11,56]. Other researchers have proposed that threatening gender norms can trigger a perceived loss of social status among men more than women [57]. Men may also be more likely to feel that transgender individuals pose a threat to their own gender identity and masculinity [58]. Future interventions could include story-based content that is tailored toward men. Featuring the stories of fathers, who are supporting of and affirming to their transgender children, may be particularly important. We also note that, to date, much of the research on family support of TGD youth focuses on parents, but there is an emerging body of research on the attitudes of other family members (eg, grandparents and siblings) toward transgender youth. If parents are not supportive, these other family members may be able to play a vital role in protecting transgender youth and the approach described here could also work with a wider range of target audiences.

A limitation of this study is the fact that our sample was recruited via an online research platform, suggesting that the sample may not be entirely representative of the general population in the United States. However, considering the intended, digital dissemination route for our intervention (social media), we feel this population is similar enough to our target population to allow us to gain some meaningful insights and draw relevant conclusions.

Our findings highlight the important role of authentic storytelling, packaged in scalable, accessible digital formats, for reducing transphobia toward TGN youth. These results also add to the growing field of research on short, animated storytelling, an innovative digital approach to rapidly scaling health information worldwide. Finally, these findings underscore the potential for light-touch, scalable video content to improve attitudes toward TGN youth within our society. Simply put, adults can be critical determinants of better health outcomes for TGD youth, simply by affirming their right to live and express themselves. Using authentic storytelling to engage and elicit empathy, and social media to broadly reach adults across demographics, we have the potential to catalyze a shift toward affirmation and support within society—a shift that could help children of all gender identities to survive and thrive.

Acknowledgments

This study was funded by the Department of Psychiatry, Columbia University Vagelos College of Physicians & Surgeons and the Stanford Center for Digital Health. The funders played no role in study design, data collection, analysis and interpretation of data, or the writing of this paper. We wish to thank the parent and child, who courageously shared their story in the intervention video, with the hope of contributing to a more accepting environment for gender diverse children.

Abstract

Background: Women and sexual minority individuals have been found to be at higher risk for experiencing poor sleep health compared to their counterparts. However, research on the sleep health of sexual minority women (SMW) is lacking in China.

Objective: This study aimed to examine sleep quality and social support for Chinese women with varied sexual identities, and then investigate the in-depth relationships between sexual identity and sleep.

Methods: This was a cross-sectional web-based survey. All participants completed a structured questionnaire containing a set of sociodemographic items referring to the social-ecological model of sleep health, the Pittsburgh Sleep Quality Index, the Social Support Rating Scale, and social relationships and environment domains of the World Health Organization Quality of Life-abbreviated short version. Pearson correlation coefficients were used to examine the relationship between sleep quality and social support as well as the two domains of quality of life. Structural equation modeling analysis was used to explore the social-ecological relationships.

Results: A total of 250 cisgender heterosexual women (CHW) and 259 SMW were recruited from July to September 2021. A total of 241 (47.3%) women experienced poor sleep quality and the rate was significantly higher in SMW than in CHW (55.2% vs 39.2%, $P<.001$). Around one-fifth of SMW reported low levels of social support, which was significantly higher than that of CHW (21.6% vs 5.6%, $P<.001$). Pearson correlations showed that overall sleep quality was significantly negatively associated with social support with weak correlations ($r=-0.26$, $P<.001$). The final structural equation modeling analysis with satisfactory fit indices identified 6 social-ecological pathways, showing that alcohol use, objective support, utilization of support, and perceived social relationship and environment quality of life played important roles in the sleep quality of individuals from their sexual identity.

Conclusions: SMW experienced poorer sleep quality compared to CHW. Further research is recommended to address the modifiable factors affecting sleep and then implement tailored sleep improvement programs.

Introduction

Sleep is a crucial element that significantly impacts health across all populations. As a modifiable behavior, sleep is strongly linked to health and well-being [1], and abnormal sleep has been proven to be significantly associated with an extensive range of adverse health-related outcomes [2,3]. Consequently, sleep health is increasingly recognized as a public health issue that concerns everyone [4,5]. Sleep quality is widely used to evaluate sleep health and includes both objective and subjective aspects of sleep [6]. Many studies have shown that women generally experience poorer sleep quality than age-matched men, possibly due to the influence of sex steroids over sleep [7,8]. Although research on sleep health among vulnerable populations has gradually increased, most studies have been limited to racial or ethnic minorities [7,9-12], and knowledge of sleep health among sexual minority populations is relatively scarce [13].

To date, only 3 reviews have been published on the sleep health of sexual minorities, with all being narrative reviews that contain a very limited number of studies [14-16], reflecting the fact that relevant research is still in its infancy. Overall, these reviews

XSL•FO
RenderX

suggest that sleep health constitutes an unmet health need for sexual minorities, and sleep health disparities related to sexual identity have been widely documented. Consistently, existing studies have recognized that sexual minority individuals experience significantly worse sleep quality than their cisgender and heterosexual peers. Furthermore, women and sexual minority individuals reported more sleep difficulties than did men or heterosexual participants [17], and sexual minority women (SMW) were more likely to report a higher prevalence of poor sleep quality than heterosexual women regardless of race/ethnicity [18-20], especially those in less supportive environments [21]. Additionally, SMW were more vulnerable to experiencing sleep disturbances than both sexual minority and heterosexual men [22], indicating that the sleep health of SMW deserves more attention.

The current evidence on sleep health among sexual minority Chinese is very limited; it remains an understudied area of research. So far, there are only 3 relevant studies, 2 of which are based on the analysis of data from nationwide school-based surveys of adolescents [23,24] and college students [25], indicating that sexual minority status was significantly associated with poor sleep quality. Notably, there is only 1 study that specifically investigated the sleep and discrimination experienced by lesbian, gay, and bisexual individuals in Hong Kong [26], and the results showed that discrimination experienced was associated with greater sleep disturbance, which in turn led to poorer physical and mental health conditions.

Health-related research on sexual minority Chinese also exhibits significant gender disparities, manifested by a substantially higher focus on the male sexual minority population than on female groups [27]. A recently published scoping review that mapped all the scientific literature and gray reports on the health needs of women with same-sex attraction in mainland China determined that Chinese sexual minority women have multiple unmet health needs [28], such as substance abuse, concerning mental health, and sexual and reproductive health. However, little is known about their sleep health, which is a crucial health issue that deserves more attention.

Research on factors affecting sleep has received more attention in recent years [29,30]. Grandner et al [31,32] initially proposed the social-ecological model of sleep health that integrated possible determinants of sleep and sleep-induced health outcomes from a global perspective. This model has been applied to studies in different populations [9,33,34] but has not yet been applied to sexual minority populations. Regarding the determinants of sleep, this model considers from a socio-ecological perspective that sleep may be determined by multiple causes at 3 levels, including the individual level, social level, and societal level.

Individual-level factors contain all aspects directly related to individuals' sleep such as genetics and sleep-related behaviors. A growing body of literature suggests that alcohol use has detrimental effects on sleep [35] by reducing sleep quality [36]. Meanwhile, there is also comprehensive evidence that the pooled association between alcohol use and sleep disorders was not significant [37], suggesting that the relationship between alcohol use and sleep needs further investigation. Similarly, smoking has been identified as another sleep determinant [38], with smokers being more vulnerable to poorer sleep quality [39]. In China, a review targeting sexual minority women concluded that the prevalence of smoking and alcohol use among minority women was much higher than among general women [28]. Therefore, alcohol use and smoking status need to be considered along with sexual identity when exploring individual-level factors that affect sleep quality.

Social-level factors influencing sleep could be socioeconomic status, ethnicity, and social support. Ethnic minorities and individuals from disadvantaged economic backgrounds generally report lower sleep quality [12,13]. In addition, a review of sleep research concluded that financial hardship is associated with poor sleep health in the general population [16]. Notably, many studies have confirmed that social support is a key factor affecting sleep [40,41], with greater social support associated with better sleep outcomes [42-45], while having strained relationships was linked to more troubled sleep [46]. Compared with heterosexual populations, social support has unique functions in sexual minority individuals, but they reported receiving less support [47]. Therefore, when exploring social-level factors affecting sleep quality, conditions such as ethnicity, education, employment, and economic status need to be considered in addition to social support.

Regarding societal-level factors affecting sleep, geography, physical environment, and other aspects of the environment could be grouped into this category [32], and environmental factors may positively or negatively impact sleep [48]. A cohort study also found a link between declining social relationship quality and poor sleep quality [49]. The societal-level factors are closely linked to everyone's livelihood, and therefore it is worth exploring whether individuals are local residents or new migrants to their current residence and whether they are cohabitating with others. The abovementioned factors involved in the social-ecological model might have direct or indirect impacts on sleep, but the associations among these factors have not been fully studied.

Despite the evident vulnerability of women and sexual minorities to poor sleep, there has been little research on their sleep health. Meanwhile, in China, research on the sleep health of sexual minorities, although gradually receiving attention in recent years, is still very limited, and there is currently no research specifically on the sleep of sexual minority women. To help eliminate inequalities in sleep health, a more diverse and inclusive sample, including women of different sexual identities, is greatly needed. Therefore, this study aimed to examine the sleep quality and social support in Chinese adult women, compare them between SMW and cisgender heterosexual women (CHW), then investigate the in-depth relationships between sexual identity and sleep using structural equation modeling (SEM) in the Chinese context.

Methods

Participants and Recruitment

This was a web-based cross-sectional study. The Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) checklist [50] was used for reporting the study findings. Eligible participants were Chinese women who: (1) were at least 18 years old, (2) self-identified as female or were assigned female gender at birth, and (3) were able to read and understand Mandarin Chinese.

Generally, the minimum sample size for SEM is 200 [51,52], and the sample size needs to be more than 25 times the number of parameters as a rule of thumb [53]. In this study, based on the hypothesized model, it is evident that 10 variables are expected to be entered into the SEM model validation, thus the minimum sample size is 250.

Convenience sampling and respondent-driven sampling methods were used to recruit this relatively hidden population [54,55], by releasing the study poster via 4 popular nongovernmental organizations and encouraging respondents to help recruit potential peers through their network of connections. Details regarding the recruitment procedure have been previously reported [56].

In this study, 524 questionnaires were collected between July and September 2021, of which 15 were excluded for being cisgender men, adolescents, or invalid data. Finally, a total of 509 (97.1%) adult women were enrolled in the study with no missing data.

Ethical Considerations

This study was approved by the Human Research Ethics Committee of the University of Hong Kong (reference number EA210325) on July 8, 2021. Electronic written consent was obtained for each study participant. Data were collected using an online survey platform (Wenjuanxing), and no compensation was provided. All information collected during the study was kept anonymous and strictly confidential.

Measures

Pittsburgh Sleep Quality Index

The Pittsburgh Sleep Quality Index (PSQI) is a commonly used measure of individuals' sleep quality [14,57]. It includes 19 self-rated items, and they generate 7 component scores with an average weight of 0 - 3 points. The Chinese version of the PSQI has been previously validated [58,59] and was used in this study. Specifically, the seven components are: (1) subjective sleep quality, (2) sleep latency, (3) sleep duration, (4) habitual sleep efficiency, (5) sleep disturbances, (6) sleeping medication use, and (7) daytime dysfunction. The sum of the 7 component scores yields 1 global score, ranging from 0 to 21 points, and higher scores represent poorer sleep quality. A global PSQI score >5 indicates poor sleep quality [6,57].

Social Support Rating Scale

The Social Support Rating Scale (SSRS) is a 10-item scale specially designed for the Chinese population with sound reliability and validity [60]. It includes three dimensions of social support: (1) subjective support, (2) utilization of support, and (3) objective support. The full-scale score and dimension scores are the sum of the scores of each item, with higher scores indicating higher levels of social support [61,62]. In addition, a total score of 22 or below could be classified as low level, 23 - 44 as medium level, and 45 - 66 as a high level of social support [63].

World Health Organization Quality of Life – Abbreviated Short Version

The World Health Organization Quality of Life – Abbreviated Short Version (WHOQOL-BREF) is a generic quality of life (Qol) measure comprising 4 domains, and the psychometric properties of its Chinese version have been confirmed [64-66]. According to the social-ecological model of sleep [32], social relationships and environment could be considered as the societal-level factors affecting sleep, but there is little evidence of associations between sleep and these factors. Thus, this study used the social relationship domain and environment domain of the WHOQOL-BREF as societal-level factors of sleep for investigation. Each domain score can be transformed into a score ranging from 4 to 20, with higher scores representing better Qol [64,67].

Sociodemographic Information

All participants completed a set of sociodemographic items that were widely reported in previous studies referring to the social-ecological model of sleep health [31,32], including individual-level factors (sexual identity, age, smoking status, alcohol use status, drug use status), social-level factors (ethnicity, education, employment, income, number of friends, social support, relationship status, bed-sharing situation), and societal-level factors (local resident or not, duration in current residence, cohabitation situation, social relationship and environment Qol).

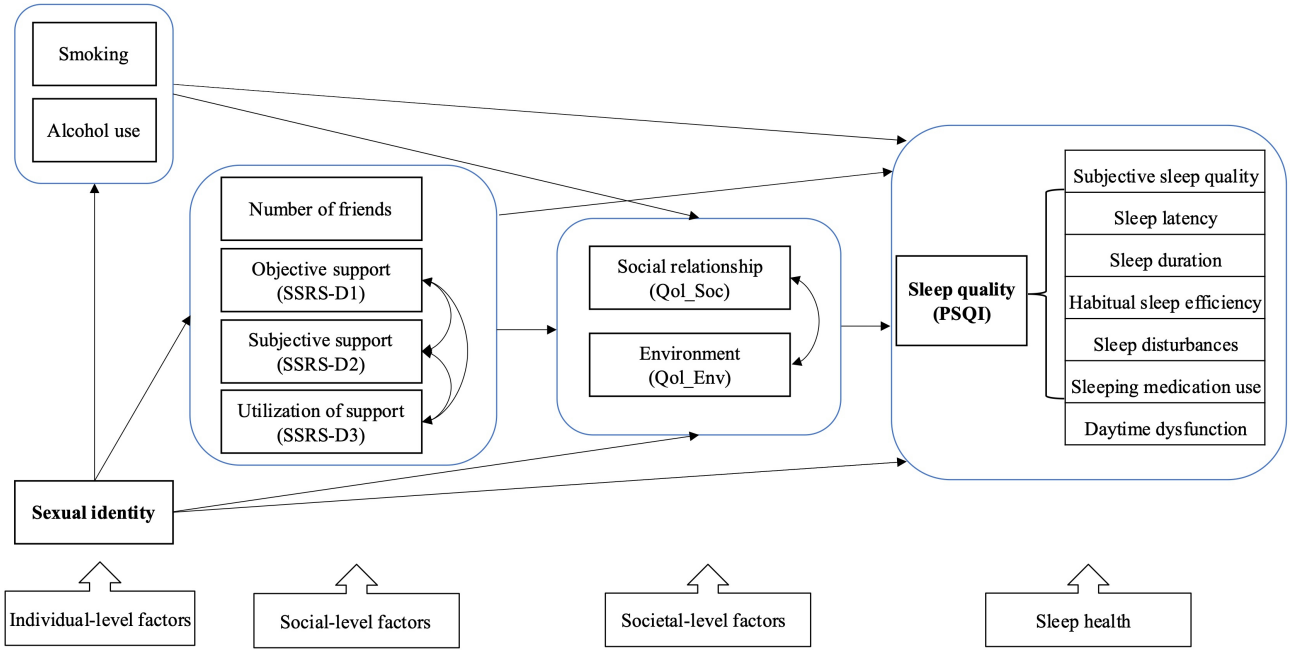
Statistical Analysis

Descriptive statistics were reported on participants' demographic characteristics, sleep quality, and social support. Independent *t* tests and χ^2 tests were conducted for comparisons between SMW and CHW. Cohen *d* effect size was calculated [68].

Social-Ecological Factors Identification

Pearson correlation coefficients were used to examine the relationship between sleep quality and social support as well as the 2 domains of quality of life, and the correlations were defined as strong (≥0.5), moderate (≥0.3 and <0.5), or weak (<0.3) [68]. Then, independent *t* tests, 1-way ANOVA, and multiple linear regressions were performed to identify factors significantly associated with sleep quality.

Structural Equation Modeling Analysis



Based on the factors identified previously (which will be further detailed in the Results section), with reference to the socio-ecological model of sleep, the following factors with significant coefficients were simultaneously entered into the SEM analysis, including sexual identity (binary), alcohol use (binary), and smoking (binary) (identified as individual-level factors); the number of friends (categorical) and social support

XSL•FO
RenderX

(continuous) (identified as social-level factors); and social relationship Qol (continuous) and environment Qol (continuous) (identified as societal-level factors). Sleep quality was treated as the latent construct using the 7 domains of the PSQI measure.

The hypothesized model for socioecological influences on sleep based on the social-ecological model of sleep is shown in Figure 1.

Figure 1. Hypothesized model for socioecological influences on sleep (based on the social-ecological model of sleep). PSQI: Pittsburgh Sleep Quality Index; Qol: Quality of life; Qol_Env: Environment domain of Qol; Qol_Soc: Social relationship of Qol; SSRS: Social Support Rating Scale; SSRS-D1: objective support; SSRS-D2: subjective support; SSRS-D3: utilization of support.

All identified variables and the 7 components of sleep quality were included in the SEM model to test the hypothesized relationships among the previously listed variables. Standardized coefficients (β), standard errors, and associated *P* values are reported for all paths of the final model. Model goodness of fit was evaluated using chi-square (χ^2), root mean square error of approximation (RMSEA), comparative fit index (CFI), Tucker-Lewis index (TLI), and standardized root mean square residual (SRMR). The model fit was considered adequate [69,70] when RMSEA (90% CI) ≤0.08, CFI ≥0.90, TLI ≥0.90, and SRMR ≤0.05.

Data were analyzed using SPSS version 28.0 (IBM Corp), and the SEM analysis was performed using Mplus 8.6 software [71]. All significance tests were 2-tailed, and findings with *P* values <.05 were considered statistically significant.

Results

Participant Characteristics

Table 1 presents the sociodemographic characteristics of the 509 women. Approximately half of the participants (259/509, 50.9%) were SMW, and 250 (49.1%) were CHW. The mean age of the overall sample was 25.57 years (SD 5.77), ranging from 18 to 56 years old. Details regarding the sexual orientation and gender identity of participants have been previously reported [56]. Notably, SMW had higher rates of substance use than CHW, and the rates of smoking and alcohol use showed significant differences (27.4% vs 4%, *P*<.001; 73.7% vs 56%, *P*<.001; respectively). Nine participants in total (1.8%) had a history of recreational drug use (4 used cannabis and 5 used methamphetamine), 7 of whom were SMW.

Sleep Quality and Social Support

A total of 241 (47.3%) women experienced poor sleep quality and the rate was significantly higher in SMW than in CHW (55.2% vs 39.2%, *P*<.001). Similarly, independent *t* tests showed that SMW experienced significantly worse overall sleep quality than CHW (*P*<.001). There were statistically significant differences in subjective sleep quality, sleep latency, habitual sleep efficiency, sleep disturbances, and daytime dysfunction between CHW and SMW (Table 2). In addition, 81.5% (415/509) of all participants reported medium levels of social support. Around one-fifth of SMW reported low levels of social support, which was significantly higher than that of CHW (21.6% vs 5.6%, *P*<.001). Table 2 shows that SMW reported significantly lower support in all aspects than CHW (*P*<.01).

Associations Between Social-Ecological Factors and Sleep

The correlations among sleep quality (PSQI total score and seven component scores) and social support (SSRS total score and three domain scores), social relationship Qol, and environment Qol are reported in Table 3. The total sleep quality was significantly negatively associated with social support and all domains with weak correlations (r ranged from −0.15 to −0.26, P<.001), and it was significantly negatively linked with social relationship Qol (r=−0.38, P<.001) and environment Qol (r=−0.39, P<.001) with moderate correlations.

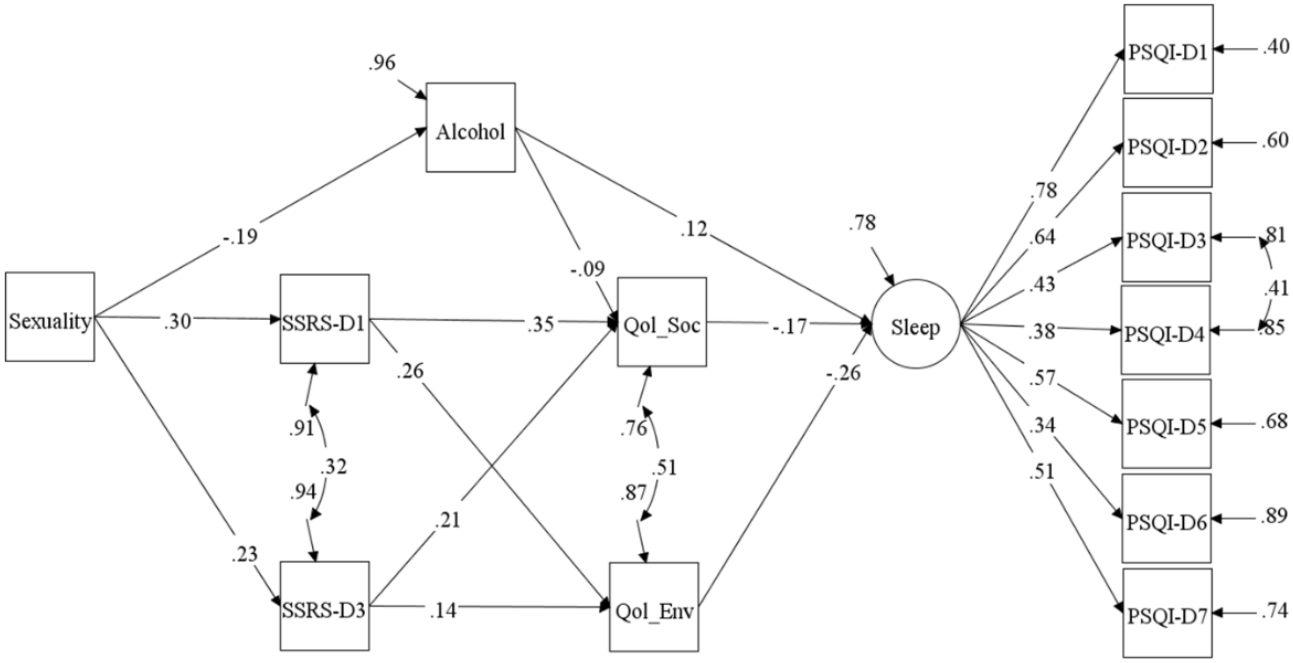
[a]PSQI: Pittsburgh Sleep Quality Index.

[b]SSRS: Social Support Rating Scale.



Comparisons of overall sleep quality between different socioecological groups are shown in Table S1 in Multimedia Appendix 1, with significant differences in sleep quality between people with different sexual identities, smoking status, alcohol use status, number of friends, and perceived social support (all *P*<.01). Table S2 in Multimedia Appendix 1 presents the multiple linear regression model of all the significant variables on sleep quality, and SEM was then performed among all these significant variables.

Model Testing

The full initial model including smoking and number of friends failed because these 2 variables were neither directly nor indirectly correlated to sleep in the model and were therefore not included in subsequent model analyses. Contrary to the hypothesized model, none of the aspects of social support were found to have a direct relationship with sleep quality. Furthermore, the model involving the subjective support domain of social support (SSRS-D2) showed no direct or indirect association of this domain with sleep and it was therefore also removed. The final model was then proposed and illustrated in Figure 2, exhibiting robust fit indices (χ^2_{51}=118.80; RMSEA=0.051, 90% CI 0.039-0.063; CFI=0.948, TLI=0.921, SRMR=0.040).

RenderX

Figure 2. Final structural equation model of this study. Correlations and paths with nonsignificant *P* values are not depicted. PSQI: Pittsburgh Sleep Quality Index; PSQI-D1: subjective sleep quality; PSQI-D2: sleep latency; PSQI-D3: sleep duration; PSQI-D4: habitual sleep efficiency; PSQI-D5: sleep disturbance; PSQI-D6: sleeping medication use; PSQI-D7: daytime dysfunction; Qol: quality of life; Qol_Soc: social relationship of Qol; Qol_Env: environment domain of Qol; SSRS: Social Support Rating Scale; SSRS-D1: objective support; SSRS-D3: utilization of support.

All model standardized coefficients (β), their standard errors, and associated *P* values are reported in Table 4. There were 6 significant paths from sexual identity (sexuality) to sleep quality in the final SEM model. Specifically, alcohol use (β=0.12, *P*=.01), social relationship Qol (β=−0.17, *P*=.004), and environment Qol (β=−0.26, *P*<.001) were direct predictors of sleep quality. Although social support did not directly influence sleep, it may indirectly influence sleep by a ecting the perceived social relationship Qol and environment Qol (β range 0.14 - 0.35, *P*<.01).

Discussion

Principal Findings

This study was the first to explore the social-ecological pathways from sexual identity to sleep quality. Few studies worldwide have examined the sleep health of SMW, and this investigation was the first to examine the sleep health of Chinese women with diverse sexual identities. This study showed SMW reported significantly worse overall sleep quality relative to CHW, which is consistent with existing reviews [14-16] and findings among Chinese youth [24,25]. Compared with the pooled PSQI mean score of the general Chinese population from a recent meta-analysis [72], our study populations reported higher total scores on the same standardized PSQI scale (5.92 vs 4.32), implying that the female population in this study experienced noticeably poorer sleep quality. Furthermore, compared with the percentage of Korean sexual minority adults (lesbian, gay, and bisexual) reporting poor sleep quality (33.8%) [73], the rate of SMW reporting poor sleep quality in our study (55.2%) was higher, indicating that sleep in SMW requires more attention and improvement.

This study also found that the proportions of current smokers and alcohol users were significantly higher among SMW than those among CHW, which is consistent with findings in China and overseas [28,74]. A scoping review summarized that some Chinese SMW regard smoking and drinking as a means of interacting with other SMW in specific social gatherings. It is also reported that smoking and drinking were the main strategies they used as a sexual minority to cope with marital stress and feeling isolated [28]. These also echo our findings on the mental health of this sample population, where we have found that SMW indeed significantly experienced more psychological symptoms [56]. A national survey conducted in the United States revealed higher rates of substance use disorders among sexual minority adults compared to heterosexual adults, with SMW showing the highest rates [75], suggesting that substance use among women, especially SMW, needs to be given attention as a public health issue.

Alcohol is one of the most commonly used psychoactive substances in different social communities around the world. A growing body of literature has confirmed that alcohol use has deleterious effects on sleep by reducing sleep duration and sleep quality [35,36], which has also been documented in sexual minority men [76] and is consistent with this study. However, a meta-analysis of cohort studies indicates that the relationship between alcohol consumption and sleep disorders is conditional, with pooled analyses finding that general drinking and the incidence of sleep disorder were significantly correlated, while heavy drinking was not [37]. Another review concluded that alcohol use has a bidirectional relationship with sleep continuity disturbance [77]. For instance, insomnia symptoms were

XSL•FO
RenderX

associated with subsequent heavy drinking; conversely, heavy drinking was associated with subsequent insomnia symptoms [78]. Nevertheless, both comparative analyses and the final SEM in this study revealed that drinking alcohol was significantly associated with poor sleep quality compared to not drinking alcohol, suggesting that both alcohol use and sleep in women deserve more attention and tailored intervention. Considering the limitations of the cross-sectional design used in this study, which could not provide evidence of causal relationships between drinking and sleep quality, more longitudinal studies with further subdivision of alcohol use are warranted in the future.

The adverse effects of smoking on sleep are well documented, as evidenced by the fact that smokers are more likely to experience sleeping difficulties, longer sleep latency, and poorer sleep quality [38,39,79], and similar findings were observed in the all-female population included in this study. The possible mechanism regarding the effects of smoking on sleep may be that smoking triggers depression or sleep-related breathing problems, which can lead to poor sleep quality [79]. However, a meta-analysis that included only cohort studies showed that, despite the significant correlation between smoking and the prevalence of insomnia, the difference between smokers and nonsmokers was very small (odds ratio 1.07) [80]. This may partly explain why the smoking variable that differed in between-group comparisons in our study was no longer associated with sleep quality in our final SEM. Future studies should record and subdivide smoking status and use prospective study designs to further explore the relationship between smoking and sleep across sexual identities.

The correlation between social support and sleep has been extensively studied in different populations [42,43,45] but its exploration in sexual minorities remains scarce. Therefore, the strength of this study is to fill this gap by examining the association between social support and sleep quality among Chinese women with diverse sexual identities. Consistent with previous research [49], overall social support was significantly and negatively associated with each component of sleep quality in the current study sample. Moreover, sexual minority individuals generally experience a higher level of poor social relationships, especially in the relatively traditional Chinese culture, where such groups are often invisible and therefore perceive more discrimination and stress [27,28,56]. However, findings from a study of 3 generations showed that feeling stigma was statistically significant in predicting a sleep disorder diagnosis among sexual minority individuals [81].

A mediation analysis of Chinese college students nationwide found that the relationship between sexual orientation and sleep quality was independently and in series mediated by interpersonal relationships and depressive symptoms, and this effect was more robust in men than women [25]. These interpersonal difficulties were related to their perceived stress associated with sleep difficulties. Our findings align with previous studies that found that sexual minority status is significantly associated with poor sleep quality [23], and social support has both direct and indirect correlations with sleep quality [42]. The relationships manifested in this study were that sexual identity was significantly associated with inadequate levels of social support, which in turn was significantly associated with poor levels of quality of life in terms of social relationships and environment, all of which were associated with poor sleep quality. Therefore, the lack of social support for sexual minority women is a significant public health issue, as is their poor sleep health, which deserves more attention.

Our correlation findings suggest that there may be more complex pathways from sexual identity to sleep among Chinese women with different sexual identities. Therefore, based on the holistic perspective proposed by the social-ecological model of sleep [32], this study explored and demonstrated the socioecological pathways from sexual identity to sleep quality for the first time using the multivariate SEM analysis method, providing a comprehensive evidence reference for promoting sleep health. The results of the final fitted model with satisfactory fit indices showed that starting from sexual identity, the following factors played important roles in women's sleep quality: alcohol use; objective social support and utilization of support; and social relationship and environment Qol. Our findings demonstrated the important roles of socioecological factors on sleep quality among women with different sexual identities. Therefore, future research should consider not only modifiable individual-level factors but also the potential influence of social- and societal-level factors when developing and implementing sleep promotion interventions. In particular, future interventions targeting sleep quality in sexual minority women may benefit from incorporating strategies that improve their social support, alcohol use, and the quality of their living environment.

This study has several limitations. First, due to the cross-sectional design, it was not possible to determine the explicit causal relationships among variables, so further research using longitudinal designs is needed. Second, despite the diversity of sexual identities, our sample was an all-female population (self-identified as female or assigned female at birth), so the results might not be generalizable to the broader Chinese sexual minority population. There has also been research indicating that bisexual people [82], those with less education [83], and those who are economically disadvantaged [16] may be more likely to suffer from sleep disorders than other groups. Hence, future studies with more diverse and representative samples including individuals from varied socioeconomic backgrounds are warranted. Third, the social-ecological model of sleep used in this study is only the upstream end of sleep research, and the downstream effects, namely the effects of sleep on specific health outcomes, have not been expanded upon in this study. Therefore, further research is recommended to comprehensively explore sleep and holistic health across diverse populations.

Conclusion

Overall, this study contributes to the existing literature by including SMW and expanding knowledge on sleep health in this population. By exploring socioecological pathways from sexual identity to sleep quality, this study provides a comprehensive understanding of factors that affect sleep health at different levels. These contextual and modifiable factors, based on the socioecological model of sleep, are layered and may interact with one another, providing guidance for future

XSL•FO
RenderX

interventions. In addition, the pathways from sexual identity to sleep identified in this study are complex and multidisciplinary; thus, all stakeholders and sleep professionals across disciplines are encouraged to collaborate and contribute to sleep improvement programs tailored for sexual minority individuals.

Acknowledgments

We are grateful to all the participants for sharing their experiences with us. We also thank TrueSelf Shenzhen, Period Pride China, Wuhan LGBT Center, and r&B bisexual community, as well as all those who shared this survey with their friends, for their contribution to the questionnaire distribution.

Abstract

Background: Immunization Information Systems (IIS) and surveillance data are essential for public health interventions and programming; however, missing data are often a challenge, potentially introducing bias and impacting the accuracy of vaccine coverage assessments, particularly in addressing disparities.

Objective: This study aimed to evaluate the performance of 3 multiple imputation methods, Stata's (StataCorp LLC) multiple imputation using chained equations (MICE), scikit-learn's Iterative-Imputer, and Python's miceforest package, in managing missing race and ethnicity data in large-scale surveillance datasets. We compared these methodologies in their ability to preserve demographic distribution, computational efficiency, and performed G-tests on contingency tables to obtain likelihood ratio statistics to assess the association between race and ethnicity and flu vaccination status.

Methods: In this retrospective cohort study, we analyzed 2021 - 2022 flu vaccination and demographic data from the West Virginia Immunization Information System (N=2,302,036), where race (15%) and ethnicity (34%) were missing. MICE, Iterative Imputer, and miceforest were used to impute missing variables, generating 15 datasets each. Computational efficiency, demographic distribution preservation, and spatial clustering patterns were assessed using G-statistics.

Results: After imputation, an additional 780,339 observations were obtained compared with complete case analysis. All imputation methods exhibited significant spatial clustering for race imputation (G-statistics: MICE=26,452.7, Iterative-Imputer=128,280.3, Miceforest=26,891.5; *P*<.001), while ethnicity imputation showed variable clustering patterns (G-statistics: MICE=1142.2, Iterative-Imputer=1.7, Miceforest=2185.0; *P*: MICE<.001, Iterative-Imputer=1.7, Miceforest<.001). MICE and miceforest best preserved the proportional distribution of demographics. Computational efficiency varied, with MICE requiring 14 hours, Iterative Imputer 2 minutes, and miceforest 10 minutes for 15 imputations. Postimputation estimates indicated a 0.87% - 18% reduction in stratified flu vaccination coverage rates. Overall estimated flu vaccination rates decreased from 26% to 19% after imputations.

Conclusions: Both MICE and Miceforest offer flexible and reliable approaches for imputing missing demographic data while mitigating bias compared with Iterative-Imputer. Our results also highlight that the imputation method can profoundly affect research findings. Though MICE and Miceforest had better effect sizes and reliability, MICE was much more computationally and time-expensive, limiting its use in large, surveillance datasets. Miceforest can use cloud-based computing, which further enhances efficiency by offloading resource-intensive tasks, enabling parallel execution, and minimizing processing delays. The significant decrease in vaccination coverage estimates validates how incomplete or missing data can eclipse real disparities. Our findings support regular application of imputation methods in immunization surveillance to improve health equity evaluations and shape targeted public health interventions and programming.

Introduction

The usage of large datasets obtained from surveillance data and Immunization Information Systems (IIS) has held a vital role in recognizing and comprehending the extent of health disparities and inequities within a population [1,2]. Previous research has shown that there is an association between race and ethnicity and vaccine acceptance and uptake [3-5]. However, as exemplified by the COVID-19 pandemic, race and ethnicity fields in public health surveillance systems and health records are historically underpopulated, thereby limiting a full understanding of the extent of vaccine inequities [2,6,7]. Missing data can affect the capability to effectively describe vaccine coverage and may introduce bias into epidemiologic analyses, particularly when attempting to estimate and address racial and ethnic health inequities, further compromising public health decision-making and resource allocation.

Studies exploring racial and ethnic inequalities traditionally omit individuals with missing demographic information or classify them as "unknown" [8-11]. However, this can miscalculate vaccine coverage rates when stratified by race and ethnicity, leading to biased analyses between different racial and ethnic groups. This selection bias dampens the capacity to accurately measure the true vaccine uptake among underserved populations that are more likely to have racial and ethnic data missing in surveillance datasets [2,12-14]. Multiple imputation for missing data, alternatively, has been shown to be a better method for eliminating missing data and preserving the greatest amount of data [13]. The theoretical foundation and technique for multiple imputation was established by D B Rubin, who developed the structure for managing missing data through the formation of multiple probable datasets [15]. This central process undertakes the innate ambiguity of missing values by generating multiple, complete, and reasonable datasets [16-18].

Following multiple imputation, classic likelihood ratio tests cannot be implemented as is because the final estimates do not come directly from a single model, and as a result, require modification to account for the uncertainty introduced by the imputation process. The multiple imputation likelihood ratio test, developed by Li et al [19] and Meng et al [20], or stacked multiple imputation, introduced by Chan et al [21,22], provides frameworks for hypothesis testing that properly incorporate both within-imputation and between-imputation variability.

Multiple imputations using chained equations (MICE) builds upon Rubin's initial work to handle multifaceted and specific datasets; it is a statistically sound method for managing missing data and has been used in the context of medical research and large, national datasets [23,24]. MICE uses the distribution of the original data to estimate values that signify the ambiguity of the true missing value. This can yield unbiased approximations after an adequate number of imputations, which is contingent on the quality of the dataset.

Machine learning (ML) is increasingly being used to reconcile missing data by offering robust and sophisticated solutions for improving data quality. Different ML techniques use various mathematical processes based on decision trees to predict a specified outcome, all with varying levels of accuracy [25-28]. Similar to traditional MICE, the accuracy and performance of machine learning algorithms to impute missing data rely heavily on the type of missing data being evaluated.

When compared with various ML techniques, MICE had less bias and similar standard errors for parameter estimates, with additional studies demonstrating that combining MICE with ML yields less biased results [26]. Miceforest is a combination of classical epidemiological techniques and ML algorithms. This algorithm uses MICE with light gradient boosting, a tree-based algorithm, to provide a flexible and powerful solution that remains efficient and reliable for managing missing data [29-31].

Recent public health pandemics and outbreaks have emphasized the importance of reliable approaches to missing data in surveillance systems. Studies have demonstrated that imputation methods significantly affect results, with incidence estimates and measures of disparity varying by method, and multiple imputation demonstrating more consistency and efficacy than single or complete case approaches [2,32,33].

Recent attempts have explored Bayesian Surname and Geocoding and Bayesian Improved Surname and Geocoding (BISG) methods to reconcile missing race and ethnicity data in large public health datasets [2,34-36]. While this approach has demonstrated practicality in particular circumstances, its suitability for state-level immunization registries is imperfect. Specifically, name-based imputations can present systematic bias in racially and ethnically diverse populations [37]. Statewide immunization registries contain various naming conventions and regional uniqueness; reliance on a name-based imputation can bolster misclassification bias and lead to misguided epidemiological analyses. As a result, approaches such as multiple imputation using observed covariates may be more suitable for IISs [38-40].

IISs present unique missing data challenges because they are a birth-to-death registry, making them temporally complex. Missing data patterns may vary by birth cohort due to evolving reporting requirements, provider participant rates, state-specific reporting requirements, use of multiple providers, and technology advancements.

However, this research addresses a critical gap identified in the surveillance literature, where, despite the widespread recognition of missing data challenges, few studies have systematically evaluated imputation approaches specifically designed for immunization data. To date, there is little published peer-reviewed literature on methods to address missing data in IIS. A 2024 cross-sectional study improved race and ethnicity data in the NYS laboratory reporting system by integrating IIS data, while Russ et al [41] enhanced IIS completeness by incorporating external records and applying logistic multiple imputation and random forest techniques [42].

This study builds upon established multiple imputation methodologies while addressing the complexities of IIS data structures by adapting recent advancements in handling missing data in EHRs to the specific challenges of population-based immunization surveillance. In this study, we investigate racial and ethnic disparities in flu vaccine uptake in the West Virginia

XSL•FO
RenderX

IIS for the 2021‐2022 flu season. We sought to address potential bias due to missing race and ethnicity data through multiple imputation and test the efficiency and accuracy of 3 established methods to address missing data in IIS and the implications of imputations on flu vaccination coverage data.

Methods

Overview

In this retrospective cohort, patient data for the 2021‐2022 flu vaccination (June 1, 2021, to June 30, 2022) was obtained from the West Virginia Statewide Immunization Information System (WVSIIS). Geo-demographic data, such as urbanicity and Social Vulnerability Index (SVI) status, were calculated using county address data obtained from the IIS. For the purposes of our analysis, urbanicity was defined as a county being either "metropolitan" or "rural." In accordance with the Federal Office of Rural Health Policy (FORHP), counties that had a population of 50,000 or more were considered "metropolitan" and counties with less than 50,000 were considered "rural." County population was obtained from the West Virginia 2020 US Census [43,44]. SVI is calculated by the Centers for Disease Control and Prevention (CDC) and the Agency for Toxic Substances and Disease Registry (ATSDR) at the census tract and county level and represents the potential negative effects of external stresses, such as housing, socioeconomic, and minority statuses have on a community [45].

After a preliminary data cleaning process on a clone of the WVSIIS database, where patients who were marked as deceased, inactive, or retained out of state address were removed, there were a resulting 2,302,036 records with a 2021‐2022 flu vaccine coverage rate of 26%. 15% of records were missing patient race (n=347,633), and 34% (n=780,339) of records were missing patient ethnicity. We addressed missing race and ethnicity data by using 3 different multiple imputation approaches to assess the stability and reliability of our findings.

We first implemented Stata 17's (StataCorp LLC) MICE using the mi impute chained command. Stata allows us to identify individual imputed datasets and pool results, excluding the original dataset with missing values.

We then used the Python scikit-learn's Iterative-Imputer algorithm. Iterative Imputer operates similarly to MICE by using available data in other features to estimate missing values. The imputation is performed in an iterative, round-robin manner, with a regressor to predict the missing values [46].

We applied the Python Miceforest package, which is designed for performing MICE using random forests. Rather than assume a linear relationship between variables, miceforest can capture complex, non-linear patterns and imputes values iteratively, unlike traditional MICE [33].

With each imputation method, we created 15 imputed datasets to stabilize our variance estimates [47,48]. We jointly imputed patient race and ethnicity using age, sex, urbanicity, SVI, county, and flu vaccination status. Selection of these covariates was based on the work done by Zhang et al [40], and the considerable missingness present in other potentially informative variables.

Once missing data had been reconciled, postimputation estimates were applied to WVSIIS flu vaccination data for the 2021‐2022 flu season.

We performed G-tests on contingency tables to obtain likelihood ratio statistics to assess the association between race and ethnicity and flu vaccination status. For MICE, we pooled across individual imputed datasets, and G-test statistics were averaged across imputations. In addition, we calculated between-imputation variance to evaluate the stability of results. Pooling was used in lieu of stacking to accommodate the computational requirements of the statewide immunization data's size. No pooling was required of Iterative-Imputer and Miceforest because they produce a single imputation result.

To assess the proportion estimate, we calculated vaccination proportions with 95% CIs using the Wilson score interval method. This method offers improved coverage properties than the standard normal estimate.

Sensitivity analyses examined vaccination disparity statistical significance, consistency, comparison of G-statistics to determine variances in effect sizes, and whether CIs for vaccination proportions overlap.

The primary engine for Iterative-Imputer, Miceforest, and all postimputation analyses was executed in Python 3.11 using pandas, scipy.stats, and matplotlib. The evaluation framework was intended to manage the multilevel configuration of Stata's MICE while preserving uniformity with Iterative-Imputer and Miceforest. All Python computations were performed on a cloud-based computing cluster with 16-core processors and 128 GB of RAM.

Ethical Considerations

This study consisted of secondary analysis of deidentified data from WVSIIS. The original data collection was conducted as part of state-mandated public health surveillance under W Va Code R § 64-7-6.6, which requires immunization data collection for all individuals residing in West Virginia. As such, it was not subject to institutional review board (IRB) review [49]. The secondary analysis did not involve direct interaction with human candidates and was determined not to constitute human candidate research, qualifying for exemption from IRB review and not requiring informed consent. This study met the jurisdiction requirement for IRB exemption, given the nature of the data used. The data used were compiled for public health surveillance and did not contain personal designations. Consent to access and analyze the data was permitted by the West Virginia Division of Immunization Services. All analyses met the terms of related federal, state, and international data privacy regulations. No compensation was provided or applicable, and no images or materials containing identifiable individual information are included in the manuscript or supplementary files.

Results

MICE

347,633 race categories that were previously missing were imputed after completing MICE. There were 16.5% additional

XSL•FO
RenderX

White records, 16.8% additional Black records, 16.3% additional Asian records, 18.5% additional Indigenous records, 16.8% additional Native Hawaiian or Pacific Islander records, 17.4% additional Multiracial records, and 15.3% additional other records after imputations (Table 1).

780,339 ethnicity categories that were previously missing were imputed after completing MICE. There were 52.4% additional Hispanic or Latino records and 40.5% additional Not Hispanic or Latino records after imputations (Table 1).

After MICE, individual demographics remained proportional to the original dataset distributions (Figures 1 and 2 and Table 2). A chi-square test illustrated that there was a statistically significant difference between the complete case and MICE estimates (P<.001; Table 3). Overall computational time was approximately 14 hours.

For the 2021 - 2022 flu season, the complete case analysis flu vaccine coverage rate was 26%. After MICE, West Virginia had an overall flu vaccine coverage rate of 19%. Flu vaccine coverage rates decreased when stratified by race and ethnicity when compared with a complete case analysis, with the most significant decreases observed in non-Hispanic (NH) White (5%), NH Black (4%), Hispanic or Latino (6%), Asian (7%), Native Hawaiian or Pacific Islander (6%), and Other (19%; Table 4 and Figure 3). After reconciling missing race and ethnicity, an additional 63,984 individuals were included in the analysis that were previously excluded from stratified analyses.

Likelihood ratio tests were used to determine the impact of race and ethnicity on vaccine uptake. Using MICE, race was significantly associated with flu vaccination status (G-statistic range=26,365.427 - 26,612.980; pooled G-statistic=26,452.66; P<.001), with considerable between-imputation variance (4103.38; Table 5). This denotes good stability with a coefficient of variation of 0.24%. For ethnicity, the MICE model also denoted a significant impact (G-statistic range=1055.287 - 1,205.254; pooled G-statistic=1142.23; P<.001), also with substantial between-imputation variance (1277.885) and a moderate coefficient of variation of 3.13% (Table 5). Both of MICE's G-scores demonstrate a large effect.

Table . Assessment of West Virginia Statewide Immunization Information System race and ethnicity demographics using complete case analysis and 3 imputation methods—multiple imputation using chained equations, Iterative-Imputer, and Miceforest.

Variable	Missing, %	Complete case	MICE[a]	Iterative-Imputer	Miceforest
Race	15%				
White, n (%)		1,519,326 (77.7)	1,793,167 (77.8)	1,527,855 (66.4)	1,792,102 (77.8)
Black, n (%)		65,716 (3.36)	77,767 (3.38)	391,756 (17.0)	78,624 (3.42)
Asian, n (%)		14,334 (0.73)	16,886 (0.73)	24,003 (1.04)	16,813 (0.73)
Indigenous, n (%)		7110 (0.36)	8561 (0.37)	7110 (0.31)	9399 (0.41)

[b]MICE: multiple imputation using chained equations

[c]Not applicable.

Iterative-Imputer

347,633 race categories that were previously missing were successfully imputed after completing the Iterative-Imputer. There were 0.26% additional White, 142.5% additional Black, 50.4% additional Asian, 0% additional Indigenous, 95.2% additional Native Hawaiian or Pacific Islander records, 10.6% additional Multiracial, and 0% additional Other records after imputations (Table 1).

Like MICE, 780,339 ethnicity categories that were previously missing were imputed after completing Iterative-Impute r. There were 0% additional Hispanic or Latino and 4.5% Not Hispanic or Latino records after imputations (Table 1).

After the Iterative Imputer, individual demographics did not remain proportional to the original dataset distributions (Figures 1 and 2 and Table 2). A chi-square test illustrated that there was a statistically significant difference between the complete case and the Iterative-Imputer estimation (*P*<.001; Table 3). Overall computational time was 2 minutes.

For the 2021 - 2022 flu season, the complete case analysis flu vaccine coverage rate was 26%. Using Iterative-Imputer, after imputations, West Virginia had an overall flu vaccine coverage rate of 19%. Flu vaccine coverage rates decreased when stratified by race and ethnicity when compared with a complete case analysis, with the most significant decreases observed in NH White (3%), NH Black (13%), Native Hawaiian or Pacific Islander (4%), and other (15%; Figure 3 and Table 4). After reconciling missing race and ethnicity, an additional 63,984 individuals were included in the analysis that were previously excluded from stratified analyses.

Likelihood ratio tests were used to determine the impact of race and ethnicity on vaccine uptake. Applying Iterative Imputer, race was significantly associated with flu vaccination status (G-statistic=128,280.27, *P*<.001), demonstrating a massive

XSL•FO
RenderX

effect (Table 5). For ethnicity, the Iterative-Imputer model produced a nonsignificant result (G-statistic=1.68, *P*=.195; Table 5).

Miceforest

347,633 race categories that were previously missing were imputed after completing Miceforest. There were 16.5% additional White records, 17.9% additional Black records, 15.9% additional Asian records, 27.7% additional Indigenous records, 26.0% additional Native Hawaiian or Pacific Islander records, 13.6% additional Multiracial records, and 15.1% additional Other records after imputations (Table 1).

780,339 ethnicity categories that were previously missing were imputed after completing Miceforest. There were 76.1% additional Hispanic or Latino records and 39.8% additional Not Hispanic or Latino records after imputations (Table 1).

After Miceforest, individual demographics remained proportional to the original dataset distributions (Figures 1 and 2 and Table 2). A chi-square test illustrated that there was a statistically significant difference between the complete case and Miceforest estimates (*P*<.001; Table 3). Overall computational time was 10 minutes.

For the 2021 - 2022 flu season, the complete case analysis flu vaccine coverage rate was 26%. Using miceforest, after imputations, West Virginia had an overall flu vaccine coverage rate of 19%. Flu vaccine coverage rates decreased when stratified by race and ethnicity when compared with a complete case analysis, with the most significant decreases observed in NH White (5%), NH Black (4%), Hispanic or Latino (7%), Asian (7%), Native Hawaiian or Pacific Islander (7%), and Other (18%; Figure 2 and Table 4). After reconciling missing race and ethnicity, an additional 63,984 individuals were included in the analysis that were previously excluded from stratified analyses.

Likelihood ratio tests were used to determine the impact of race and ethnicity on vaccine uptake. Using Miceforest, race was significantly associated with flu vaccination status (G-statistic=26,891.53; *P*<.001), demonstrating a large effect (Table 5). For ethnicity, the Miceforest model remained robust and was significantly associated with flu vaccination status (G-statistic=2185.01; *P*<.001; Table 5).

Discussion

Principal Findings

Our results highlight that the imputation method can profoundly change research findings. For race, all 3 methods show highly significant results and conclude that there are significant race disparities in flu vaccination after addressing missing data. G-tests performed on race and ethnicity and flu vaccination contingency tables showed consistent evidence of significant racial disparities across all imputation methods (*P*<.001). However, for ethnicity, Iterative-Imputer failed to distinguish any significant disproportions, while MICE and Miceforest found strong associations.

Of the 3 methods used to address missing data, we found that MICE and Miceforest had the best model fit and effect sizes. MICE and Miceforest were able to reconcile missing data with little bias, produced more stable and reliable imputations, and retained better preservation of original data relationships, producing similar conclusions; subsequently allowing for more sophisticated post hoc analyses. Iterative Imputer exhibited the most substantial deviations from the complete case analysis. While the majority of race and ethnicity categories retained proportions similar to those observed before imputation, the Black race category had a notable 142% increase post-Iterative-Imputer. Though all methods identify disparities for race, Iterative-Imputer suggests effects that are 5 times stronger than MICE and Miceforest (Iterative-Imputer G-statistic=128,280; MICE G-statistic=26,453; Miceforest G-statistic=26,892). Alternatively, Iterative-Imputer suggests no significant (*P*=.19) ethnicity disparities, while MICE and Miceforest distinguish strong disparities. Iterative-Imputer's results suggest that the model may be overfitting that data, intensifying present correlations, or generating false patterns in the imputed dataset. The significant change within a singular racial and ethnic group carries several potential implications: it may lead to neglecting crucial health disparities or greatly overvaluing disparities.

While MICE and Miceforest demonstrated more reliable and moderate effect sizes, the most striking difference between MICE and Miceforest was overall computational time. Large population surveillance-based datasets can be computationally expensive to impute [50]. While traditional MICE and Miceforest were proportionally similar to the complete case analysis and had similar G-statistics, the computational load was a significant limitation for further epidemiological analyses. Since Stata 17 operates locally, executing MICE required approximately 14 hours, using between 92% and 98% of the total central processing unit (CPU) capacity of the local system. In contrast, as Iterative-Imputer and Miceforest were processed on a cloud-based drive, the total computational time was reduced to under 10 minutes. Cloud-based computing extends several advantages, including enhanced scalability, reduced dependence on local servers, and the capability to allocate computational jobs efficiently [51,52]. As datasets become larger and more complex, they require larger memory and CPUs become necessary, and consequently, there will be computational limitations. By divesting resource-intensive tasks to the cloud, researchers and public health officials can alleviate processing constraints, enabling analogous performance of multiple tasks and minimizing downtime. This improved efficiency not only accelerates analyses but also improves overall productivity by removing lengthy processing delays.

Compared with the complete case analysis, the imputed dataset was 45% larger, and the estimated 2021 - 2022 flu vaccination coverage rate decreased from 26% to 19%. This resulted in distinct divergences in vaccination rates from those seen in the complete case analysis. Stratified flu vaccination coverage rates declined across all racial and ethnic categories following imputation. This is both expected, due to denominator inflation, and consistent with existing literature, which suggests that enhancements in data completeness often uncover underlying racial inequities [2,6-8,10,14,53].

XSL•FO
RenderX

In addition, the presence of the "Other" category may be artificially influencing the race missingness rate. Reports indicate that the increasing size of the "Other" category may be influenced by individuals choosing not to disclose their race, varying cultural perceptions of race, or vaccine providers selecting "Other" rather than leaving the race field blank [54,55]. Those who select the "Other" category get combined into a single, dissimilar category that does not reflect accurate identities and makes results for this group difficult to accurately decipher.

These findings align with the broader imputation literature, which demonstrates that not only does reconciling missing race and ethnicity data reveal under-reported disparities, but that imputation methodology can significantly influence the magnitude of these inequities. Similar patterns have been observed in findings from Labgold et al [2], Dorabawila et al [42], and Russ et al [41], where imputing missing race and ethnicity revealed greater disparities in health outcomes than previously understood, but the severity of these inequities fluctuated contingent upon parameters placed on the imputation method. This is consistent with theoretical bases proposing that the creation and assumptions of statistical models and algorithms can either dilute or intensify disparities, conditional on how missingness is managed and whose data are omitted [2,30,39,56]. The absence of demographic data in IISs carries significant public health implications. Missing data limits our capability to correctly assess and monitor vaccination coverage, potentially leading to an incomplete or inaccurate understanding of disparities in vaccination rates among different vulnerable groups. Consequently, public health interventions and policies may be based on flawed assumptions, undermining their effectiveness. Moreover, the inability to identify and address disparities hinders efforts to promote equity within communities. Poor data quality can also result in inefficient allocation of resources, both human and financial, further exacerbating inequities. Finally, inadequate data can erode public trust in health systems, as decisions based on incomplete information may be perceived as unreliable or inequitable. However, Miceforest successfully imputed missing values in a large public health dataset in the most time-efficient manner, and therefore, we were able to mitigate potential bias and increase our statistical power in our analyses. By allowing more complete and representative datasets, Miceforest encourages more equitable vaccination surveillance and permits fuller public health decision-making in a timely manner. State public health departments can use this technique to augment incomplete data to identify vaccine coverage gaps more accurately, concentrate on programming and resource allocation in underserved communities, and assess whether interventions are aiding populations who need it most. Our findings emphasize how multiple imputation is not only a statistical solution but a means for progressing equity in immunization programs and interventions.

There were several limitations to our approach. Due to high levels of missingness of variables in the dataset, there were limited informative variables for the imputations. The WVSIIS population denominator is higher than the census population, which can skew flu vaccination rates lower than they are. Race and ethnicity are self-reported, and they may not reflect the reality of demographic distribution in the state, especially with growing nuances of racial and ethnic identity.

Data are the foundation of all effective public health interventions, and missing data can reduce our comprehension of vaccination coverage, recognizing disparities, and creating successful public health programs. Without properly addressing missing data, vulnerable groups continue to be underserved. As demonstrated, different methods for reconciling missing data result in different assumptions regarding the data and the process. However, using Miceforest to reconcile missing demographic data poses a potential solution, offering a flexible, fast, and iterative approach that can improve data completeness while preserving underlying distributions and mitigating potential bias.

Future efforts should validate imputation values against other population-based surveillance systems, such as census data and claims data. In addition, because our imputations focused on one state's IIS, supplementary efforts should examine the performance of various multiple imputation methods across more diverse populations and geographies and examine the optimal frequency for updating imputation models. Further, based on our results, we recommend several suggestions for enhancing both the epidemiological approach and practice in immunization surveillance. Though more resource-intensive, preventing missing data initially is the most effective measure to handle missing data, especially for surveillance data that necessitates system-wide resolutions. This can be achieved through standardized race and ethnicity data collection protocols and data collection training in state IISs. Imputation should be a temporary answer for a larger, systematic problem. Public health agencies should be transparent in the imputation methods used in reports and present both complete case and imputed estimates to demonstrate the impact of missing data on vaccine equity reports.

Conclusions

Both MICE and Miceforest offer flexible and reliable approaches for imputing missing demographic data in IISs, outperforming Iterative-Imputer with regard to bias mitigation and distributional accuracy. These findings highlight that imputation method selection can greatly affect research outcomes, with repercussions for both statistical validity and public health decision-making and trust. While MICE and Miceforest yielded comparable effect sizes and preserved demographic proportions, MICE's substantial computational demands limit its scalability for large datasets, while Miceforest's ability to leverage cloud-based computing enhances efficiency by offloading resource-intensive tasks, enabling parallel execution, and minimizing processing delays.

Addressing missing data is both a methodological necessity and a public health imperative when handling large surveillance data. By improving data completeness and analytical precision, multiple imputation methods such as Miceforest can help illuminate disparities, reveal disparities, inform resource allocation, and promote equity in immunization and public health programs.

Abstract

Background: Reporting of notifiable infectious diseases was overall impacted by the COVID-19 pandemic. This could affect disease surveillance and thus, outbreak detection, as it is based on historical data. For effective outbreak detection, it is crucial that communicable disease control professionals can rely on accurate and valuable alarm thresholds to ensure timely and adequate response to potential outbreaks.

Objective: In this study, we take the first steps in the development of a methodology that adjusts for the impact of the COVID-19 pandemic on the number of notifications of notifiable infectious diseases and provides corrected alarm thresholds for outbreak detection. We identify which infectious diseases were affected by the COVID-19 pandemic, assess the duration of these effects, and explore potential correction methods to improve outbreak detection.

Methods: We analyzed cases of 25 notifiable infectious diseases reported from 2015 - 2023 in the Netherlands. Negative binomial regression was used to calculate the incidence rate ratios for each period: pre-COVID-19 pandemic, COVID 2020, COVID 2021, COVID 2022, and post-COVID-19 pandemic. To address the decrease in notifications during the COVID-19 pandemic, we tested 3 correction methods: (1) recoding COVID-19 years as missing; (2) imputing with the last pre-COVID-19 pandemic observation; and (3) imputing the historical moving average.

Results: Between 2015 - 2023, a total of 74,990 notifications were reported in the Netherlands, of which 9,836 notifications (13%) occurred during the COVID-19 pandemic. Malaria, typhoid fever, hepatitis A, meningococcal infection, paratyphoid fever, Q-fever, shigellosis, measles, mumps, and pertussis had significantly lower notifications during the COVID-19 pandemic, but the duration and magnitude of the effect differed among the infections. The effect of the COVID-19 pandemic on the notifications of malaria (incidence rate ratio [IRR] 0.17, 95% CI 0.08 - 0.36) and typhoid fever (IRR 0.12, 95% CI 0.02 - 0.55) was only seen in 2020, while the notifications for measles (IRR 0.34, 95% CI 0.15 - 0.75) and pertussis (IRR 0.34, 95% CI 0.20 - 0.60) were still significantly lower in the post-COVID-19 pandemic period. In addition, the newly calculated alarm thresholds showed a noticeable difference compared with the original unadjusted alarm thresholds. However, the variation among the 3 different corrected alarm thresholds was not substantial.

Conclusions: During the COVID-19 pandemic, notifications of 10 infectious diseases declined significantly. The duration of this decline varied among infections, highlighting the need for pattern-specific adjustments. Our study demonstrates that accounting for the reduced notifications impacts alarm threshold calculations for outbreak detection. We therefore recommend amending the alarm thresholds to account for this impact to ensure reliable outbreak detection, so that communicable disease control professionals can act in a timely and data-driven manner. The next step in the development of the "pandemic-proof" methodology is to determine which correction method is most suitable. Further validation by communicable disease control professionals is essential to assess the applicability of the adjusted alarm thresholds for outbreak detection.

Introduction

In the Netherlands, it is mandatory under the Dutch Public Health Act for all medical doctors and laboratories to notify certain infectious diseases to the public health services (PHS), who then report it to the National Institute for Public Health and the Environment (RIVM) [1]. Among others, the RIVM is responsible for the surveillance of those notifiable infectious diseases at the national level and the PHS at a regional level. A critical aspect of surveillance is outbreak detection, for which various methods establish an alarm threshold for the number of notifications that signal for a potential outbreak detection [2-6]. Regarding these methods, robust historical data are essential for optimizing alarm thresholds accuracy. This allows communicable disease control professionals to implement preventive actions or control measures in a timely manner, and at the same time minimizing false positive signals, to effectively interrupt transmission and thus contain an outbreak.

The COVID-19 pandemic had an impact on the notifications of other infectious diseases. Several countries worldwide reported less notifications than expected during the pandemic on all types of infectious diseases, not only respiratory infections [7-16]. Nonpharmaceutical interventions (NPIs) that were implemented to decrease the transmission of SARS-CoV-2 most likely influenced the transmission of other infectious diseases, especially respiratory infections. Some studies suggest that SARS-CoV-2 was in competition with other respiratory infections, which suppressed the transmission of the lesser dominant respiratory infection [17-19]. In addition, the pandemic disrupted health care systems and altered health-seeking behavior, resulting in underdiagnosing and underreporting and thus, a decrease in notifications of other infectious diseases [20].

Since outbreak detection thresholds are based on historical data and considering reports of the impact of the COVID-19 pandemic on notifications of other infectious diseases globally, it is essential to investigate what the effect of the COVID-19 pandemic was on the number of notifications. This includes investigating which infectious diseases were affected and the duration of these effects, and whether these trends align with the aforementioned hypothesized causes. This is crucial for understanding the impact of the COVID-19 pandemic on outbreak detection, as it still remains unknown. To our knowledge, no previous studies have been conducted on how to adjust for the impact of the COVID-19 pandemic on the historical data and thus, establish accurate alarm thresholds for outbreak detection. The development of a methodology that adjusts for the impact of the COVID-19 pandemic on the number of notifications of notifiable infectious diseases requires a stepwise approach: first identifying which infectious diseases were affected by the COVID-19 pandemic, then developing a novel methodology, and finally validating the novel methodology for its applicability in effective outbreak detection. This future "pandemic-proof" methodology will provide corrected historical averages and alarm threshold as indicators of changes in infectious disease trends, to monitor and signal for upcoming infectious disease outbreaks.

In this study, we focus on the first steps of this process toward a "pandemic-proof" methodology by examining which infectious diseases were affected by the COVID-19 pandemic, the duration of these effects, and exploring approaches to correct for them in outbreak detection. The validation of any correction method is beyond the scope of this study, as it first requires a comprehensive understanding of the impact of the COVID-19 pandemic on infectious disease notifications, as well as of the potential correction methods for addressing this.

Methods

Study Design and Data Sources

To determine which notifiable infectious diseases were affected by the COVID-19 pandemic on the number of notifications in the Netherlands, we used anonymized routinely collected data on all 45 notifiable infectious diseases from the database "Osiris" collected by National Institute of Public Health and Environment. Notifiable clusters of infections, such as Methicillin-resistant Staphylococcus aureus clusters, were left out of the dataset. All notifications (except COVID-19 pandemic) between January 2015 and December 2023 based on the date of disease onset were included. In addition, information on age, sex, region (the regional distribution is the PHS catchment area), and type of infection for each notification was extracted from the database. Infectious diseases with lacking historical data (eg, notifiable since 2019 or later on) were excluded from the analysis (n=4). Furthermore, we also excluded infectious diseases that were only notified 20 times or less during the entire study period (n=16). We investigated the notifications of 25 infectious diseases.

Definition of Study Periods

To investigate the duration of the COVID-19 pandemic effect, we split our study period into different periods: pre-COVID-19 pandemic, COVID 2020, COVID 2021, COVID 2022, and post-COVID-19 pandemic. Pre-COVID-19 pandemic was defined as January 2015-February 2020, as the first case in the Netherlands was reported at the end of February 2020 and the first national NPIs were implemented mid-March. COVID 2020 was defined as March 2020-December 2020, COVID 2021 included the whole year of 2021, COVID 2022 was defined as January 2022-August 2022 and post-COVID-19 pandemic was defined as September 2022-December 2023. We chose September 2022 as the ending date of the COVID-19 pandemic, as the COVID-19 stringency index was at its lowest for the Netherlands and all NPIs were not in place anymore [21]. Since then, there were no NPIs implemented in the Netherlands.

Hypothesis Development

First, we hypothesized what the potential impact of the COVID-19 pandemic was on the number of notifications and trends for every notifiable infectious disease. We based our hypotheses on 4 factors: effect of NPIs (eg, physical distancing and travel bans), variants of SARS-CoV-2 interference (competing between infections), demographic determinants (ie, region, age, and gender), health care use and access to diagnostics. All factors were reviewed by the team with extensive knowledge on infectious disease control (BvD,

XSL•FO
RenderX

infectious disease epidemiologist; SR, medical doctor in communicable disease control; CHMvJ, epidemiologist; and AT, professor and medical doctor in communicable disease control) and discrepancies were discussed until consensus was reached. The latter potential factor (access to diagnostics) was additionally reviewed by a microbiologist. The effect of the NPIs was leading in this decision-making, whether we expected an effect on the notifications or not (Multimedia Appendix 1).

Statistical Analysis

For the descriptive analysis, we calculated the age, sex, and region distribution for each infection in each study period (pre-COVID-19 pandemic, COVID 2020, COVID 2021, COVID 2022, and post-COVID-19 pandemic). To examine which infectious diseases were affected and the duration of these effects, we performed negative binomial regression to determine the incidence rate ratios (IRR) and their respective 95% CI, using pre-COVID-19 pandemic as reference period. The included months of the reference period corresponded to the respective months of the investigated study period to account for seasonality. For example, the COVID 2020 period was compared with the historical months March until December from the years 2015 - 2019. We defined the impact of the COVID-19 pandemic on infectious disease notifications as a significantly lower IRR than the pre-COVID period, with the effect beginning in the COVID 2020 period, as we considered that substantial effects of the pandemic should be visible in that period. Effects that emerged later are more difficult to directly attribute to the COVID-19 pandemic.

Threshold Recalibration

For the exploration of recalibrating the alarm threshold, we reviewed literature and expert opinions on the correction for the decrease in notifications. The correction was integrated into an alarm threshold for outbreak detection, which is mostly based on the method of Stroup that focuses on the moving average [3]. The moving average for a month is calculated by the means of the preceding, current, and upcoming month of the last 5 years, with a corresponding moving SD and moving SE. For example, the moving average of July 2021 is calculated by the means of the months June, July, and August of the years 2016 - 2020. If there was an outbreak in one of those months (defined as: moving average+[2*SD]), the number of cases was set back to the moving average of that month. Thus, we calculated the alarm threshold with the moving average that is corrected for outbreaks, from now on called baseline. The original alarm threshold itself is calculated as: baseline+(1.96 * SQRT[SD^2+SE^2]).

After assessing which notifiable infectious diseases were affected, we tested the following 3 methods for correction: (1) treating disease counts as missing during the correction period; (2) replacing disease counts with the last value (outbreak corrected) for the same month in the year preceding the correction period; and (3) replacing disease counts with the baseline value (as mentioned above) for the same month in the year preceding the correction period. We calculated new thresholds for infectious diseases impacted by the COVID-19 pandemic, focusing on those with a decrease in notifications, and only for the corresponding affected period. We used the original alarm threshold method (as described above), as a reference. We refer to this further on as the unadjusted threshold method, as it is not corrected for a decreased number of notifications.

Ethical Considerations

We used anonymized notification data collected by the RIVM in accordance with the Dutch Public Health Act. The Medical Ethics Committee of Radboudumc declared that an ethical approval was not required for this study, as the study did not fall under the scope of the Medical Research Involving Human Subjects Act.

Results

Overview

In the entire study period (2015 - 2023), 74,990 notifications were reported of the 25 included infectious diseases. Of those 74,990 notifications, 73% (n=54,430) were notified in the pre-COVID-19 pandemic period, 13% (n=9836) during the COVID-19 pandemic, and 14% (n=10,724) in the post-COVID-19 pandemic period. Notification numbers and characteristics for each notifiable infectious disease are provided in (Multimedia Appendix 2). We found no difference regarding age, sex, or region distribution between the periods.

Affected by the COVID-19 Pandemic

We hypothesized that the notifications of Creutzfeldt-Jakob disease, Q-fever, hantavirus, listeriosis, and psittacosis were not affected by the COVID-19 pandemic (Multimedia Appendix 1). For all other 20 notifiable infectious diseases, we expected a decrease in notifications due to implementation of the NPIs (egsimilar transmission routes), interference of other infections, changing demographics, change in health care seeking behavior or use of diagnostics.

Based on the IRRs, we found that the number of notifications of 11 infectious diseases was significantly affected by the COVID-19 pandemic (Table 1 and Figure 1). However, the duration of affected months differed. In Figure 1, we present the IRRs per COVID-19 period for all infectious diseases, indicating whether a significant effect was found and how this effect evolved over time.

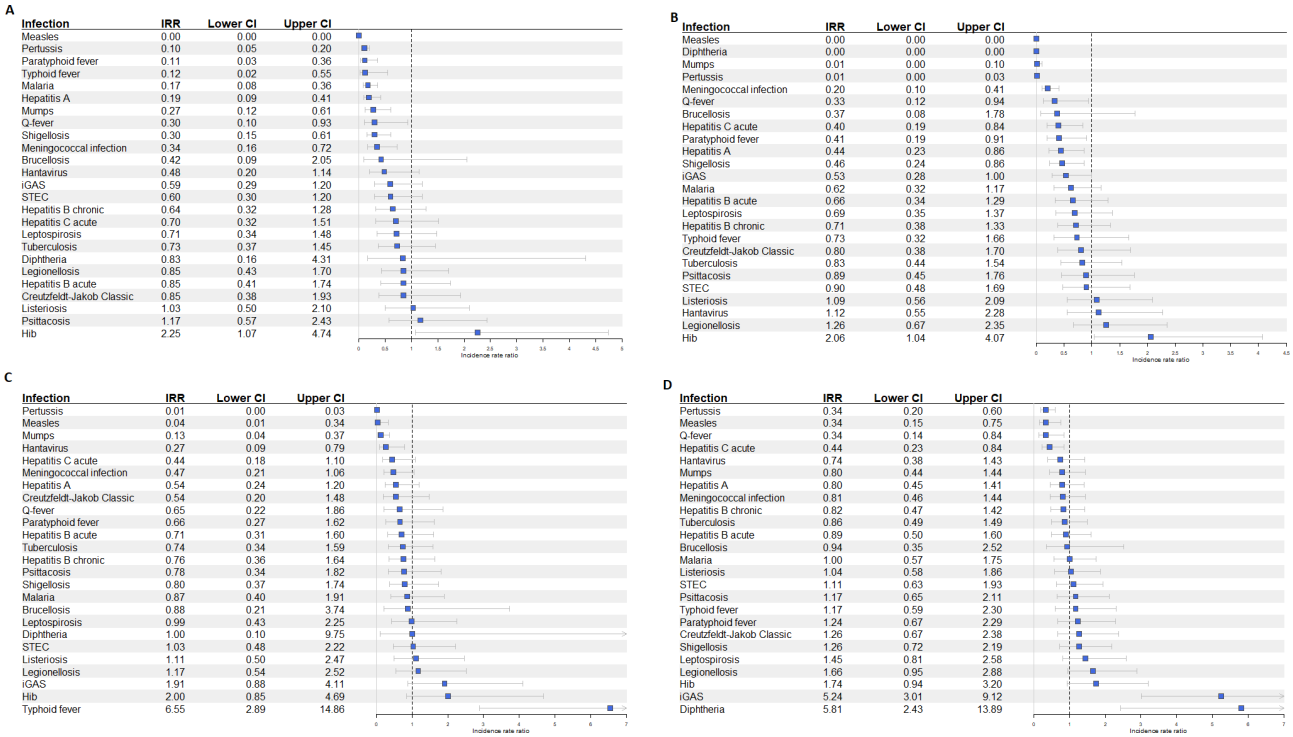

Figure 1. Incidence rate ratios for 25 notifiable infectious diseases plotted by the COVID-19 pandemic periods (2020, 2021, 2022 and post-COVID-19 pandemic), with the pre-COVID-19 pandemic period (January 2015-February 2020) as reference, the Netherlands. Hib: *Haemophilus influenzae* type b; iGAS: invasive group A streptococcal; STEC: Shiga toxin-producing *E. coli*.

Malaria (IRR 0.17, 95% CI 0.08 - 0.36) and typhoid fever (IRR 0.12, 95% CI 0.02 - 0.55) were significantly less notified during COVID 2020 and were back on pre-COVID-19 pandemic levels in 2021 (Figure 2). Typhoid fever was in the COVID 2022 period significantly more reported compared with the pre-COVID-19 pandemic period, which was related to a large outbreak (IRR 6.55, 95% CI 2.89 - 14.86) [22]. Infectious disease notifications affected in 2020 and 2021 were hepatitis A, meningococcal infection, paratyphoid fever, Q-fever, and shigellosis. *Haemophilus influenzae* type b (Hib) was also affected in 2020 and 2021; however, contradictory to other infections, the number of notifications increased significantly in those periods (IRR 2.25, 95% CI 1.07 - 4.74 and IRR 2.06, 95% CI 1.04 - 4.07, respectively). This significant increase was not reported in the COVID 2022 period (Figure 2).

XSL•FO
RenderX

Figure 2. IRRs for 25 notifiable infectious diseases for each COVID-19 pandemic period compared with pre-COVID-19 pandemic period (January 2015-February 2020): (A) COVID 2020 period; (B) COVID 2021 period; (C) COVID 2022 period; and (D) Post-COVID-19 pandemic period, the Netherlands. Hib: *Haemophilus influenzae* type b; iGAS: invasive group A streptococcal; IRR: incidence rate ratio; STEC: Shiga toxin-producing *E. coli*.

Mumps, measles, and pertussis were affected during the entire duration of the COVID-19 pandemic, with significantly less notifications reported (Table 1). Furthermore, the notifications for measles and pertussis continued to be low in the post-COVID-19 pandemic period as well (IRR 0.34, 95% CI 0.15 - 0.75 and IRR 0.34, 95% CI 0.20 - 0.60, respectively). Our hypotheses on whether we expected an effect of the COVID-19 pandemic on the notifications did not match with the found effects for Q-fever and Hib.

Our hypotheses on whether we expected an effect of the COVID-19 pandemic on the notifications did not match with the found effects for Q-fever and Hib.

Not Affected by the COVID-19 Pandemic

Based on our definition of the impact of the COVID-19 pandemic, we found no effect on the notifications of the other 14 infectious diseases: legionellosis, brucellosis, diphtheria, hepatitis B acute, hepatitis B chronic, leptospirosis, listeriosis, psittacosis, Shiga toxin-producing *E. coli*, tuberculosis, Creutzfeldt-Jakob disease, hantavirus, hepatitis C acute, and invasive Group A streptococcal disease. However, we expected an effect in ten of them (Multimedia Appendix 1). Our hypotheses for hantavirus, listeriosis, psittacosis, and Creutzfeldt-Jakob disease were correct.

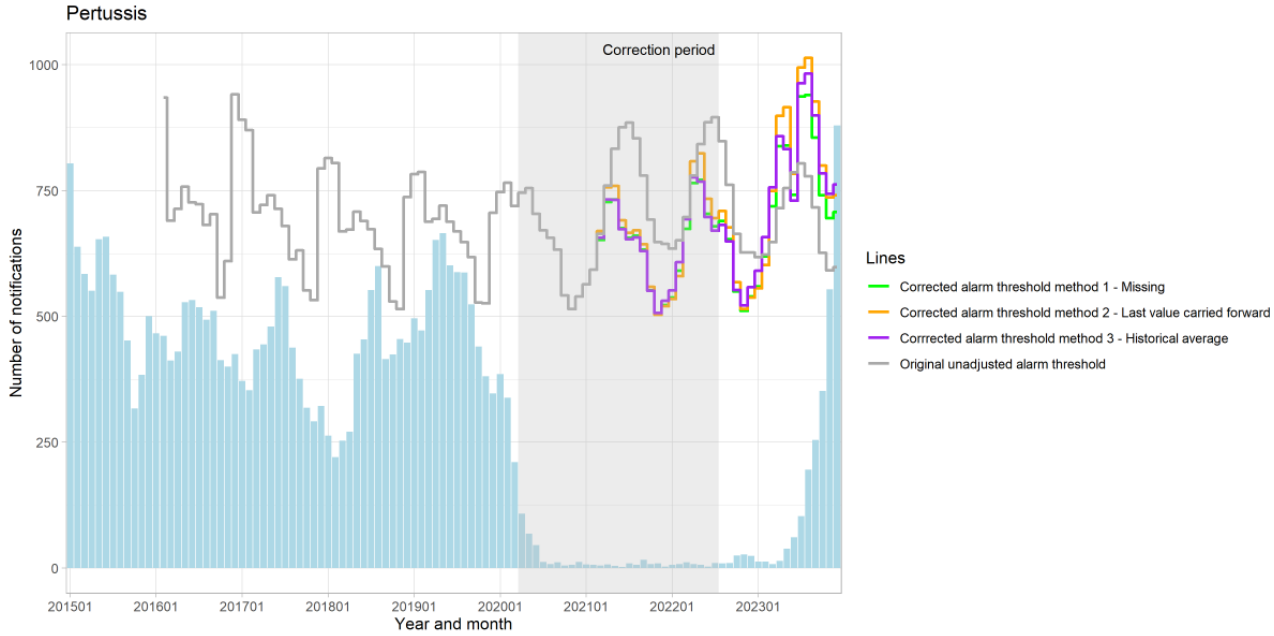
Correcting for the Impact of COVID-19 Pandemic

As the notifications of malaria, typhoid fever, hepatitis A, meningococcal infection, paratyphoid fever, Q-fever, shigellosis, mumps, measles, and pertussis were significantly less during the COVID-19 pandemic, we calculated their adjusted alarm thresholds for each correction method. The alarm thresholds for outbreak detection do not require adjustment for Hib, as Hib notifications increased during the COVID-19 pandemic, and correcting for outbreaks is standard practice in the original method.

The results of the different correction methods are presented in (Figures 3 and 4, Multimedia Appendices 3-10). We found that there is a difference in the number of notifications between the unadjusted and corrected alarm thresholds for exceeding the alarm threshold; however, no clear difference was observed between the different corrected alarm thresholds. The difference in the number of exceedances of the alarm threshold per method compared with the original unadjusted method was only seen for malaria and mumps (Multimedia Appendix 11). We observed that the corrected alarm thresholds are influenced by the duration and magnitude of the effect of the COVID-19 pandemic, as well as the number of notifications. Over the observed study period, we highlight 2 noteworthy results.

XSL•FO
RenderX

Figure 3. Number of monthly notifications of pertussis with the unadjusted threshold and 3 corrected threshold methods for outbreak detection, the Netherlands, January 2015-December 2023.



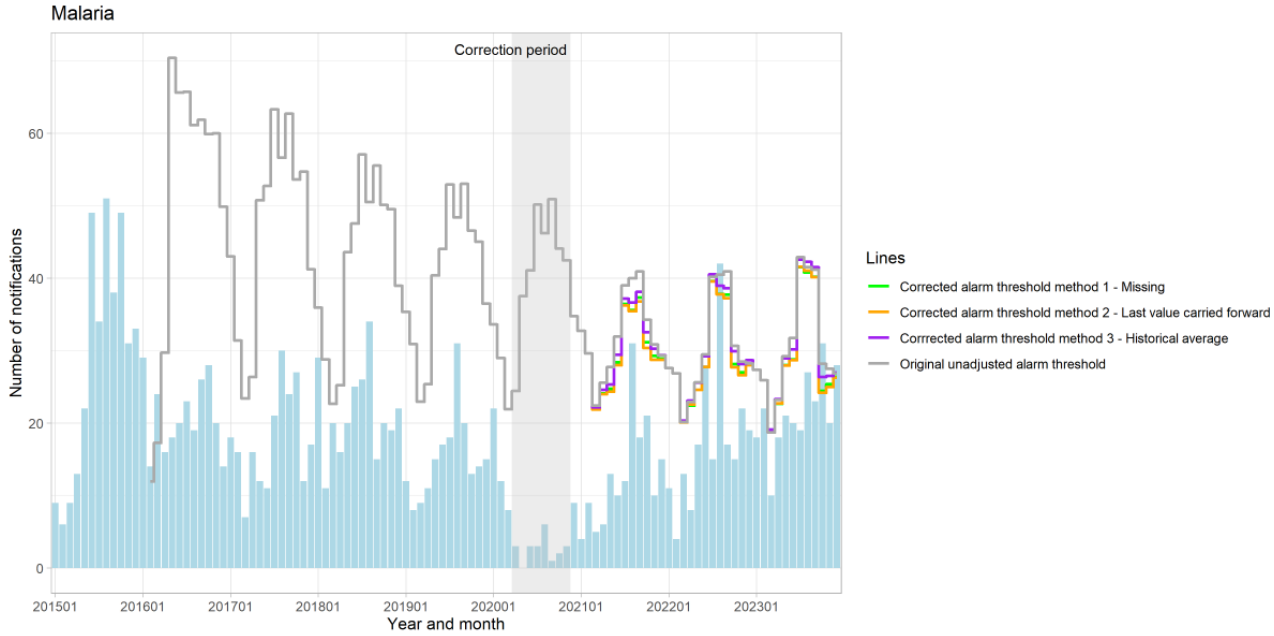


Figure 4. Number of monthly notifications of malaria with the unadjusted threshold and 3 corrected threshold methods for outbreak detection, the Netherlands, January 2015-December 2023.

First, we found that the corrected alarm thresholds for hepatitis A, measles, mumps, paratyphoid fever, and Q-fever were generally higher than their original unadjusted alarm thresholds. The alarm thresholds for typhoid fever showed minimal variation across methods. In contrast, the corrected alarm thresholds were at some points in time lower than the unadjusted alarm thresholds for pertussis, meningococcal infection, and shigellosis. For instance, during the COVID-19 pandemic, the corrected alarm thresholds for pertussis were lower, with a difference of 200 notifications compared with the unadjusted alarm threshold (Figure 3 and Multimedia Appendix 12). This indicates that the correction already impacts the alarm thresholds during the COVID-19 pandemic.

Second, the length of the correction period also varies depending on the duration of the effects of the COVID-19 pandemic on specific disease notifications, which in turn influences the corrected alarm thresholds. Malaria, for example, was only corrected for the period March-December 2020 during which notifications significantly decreased (Figure 4 and Multimedia Appendix 13). As the correction period is longer, the immediate effect of the correction seems more visible compared with a shorter correction period, such as seen with pertussis (Figure 3 and Multimedia Appendix 12). Furthermore, the disparity between the unadjusted and corrected thresholds seems to gradually diminish earlier over time, compared with the infectious diseases with a longer correction period.

XSL•FO
RenderX

Discussion

Principal Findings

This study shows that the COVID-19 pandemic had a significant impact on the notifications of other infectious diseases, and therefore on the surveillance and especially a noteworthy effect on the alarm thresholds for outbreak detection. To take timely preventive actions and implement control measures to contain outbreaks, an accurate alarm threshold for outbreak detection is essential. Malaria, typhoid fever, hepatitis A, meningococcal infection, paratyphoid fever, Q-fever, shigellosis, measles, mumps, and pertussis had significantly lower notifications during the COVID-19 pandemic, but the duration of the effect differed among the infections. Only measles, mumps, and pertussis were affected during the whole duration of the COVID-19 pandemic, and for measles and pertussis, this effect continued in the post-COVID-19 pandemic period. Interestingly, the notifications of Hib increased significantly during the COVID-19 pandemic. In addition, the newly calculated alarm thresholds for infectious diseases with decreased notifications showed a noticeable difference compared with the unadjusted alarm thresholds. However, the variation among the 3 different corrected alarm thresholds was not substantial.

Comparison With Previous Work

Decrease in notifications of malaria, typhoid fever, hepatitis A, meningococcal infection, paratyphoid fever, shigellosis, measles, mumps, and pertussis was expected based on the hypotheses. This was already observed in other countries for malaria, hepatitis A, meningococcal infection, shigellosis, measles, mumps, and pertussis [7-13,15]. In our study, the notifications of Q-fever unexpectedly decreased, while this concerns a zoonotic disease, and the presence of *Coxiella burnetii* in the reservoir in the Netherlands was unlikely to be affected by the COVID-19 pandemic and the NPIs. Furthermore, the number of notifications of the other 14 investigated infectious diseases showed no impact from the COVID-19 pandemic. However, other studies reported a decrease in notification numbers of brucellosis, hepatitis B (acute and chronic), hepatitis C, legionellosis, leptospirosis, listeriosis, and tuberculosis, possibly due to differences in surveillance systems and case definitions [7,8,10,11,13].

Surprisingly, we found a significant increase in the Hib notifications during COVID 2020 and 2021. We expected that Hib would decrease, as it has a similar transmission route as SARS-CoV-2, and therefore, the NPIs could have impacted Hib transmission as well. Besides, other studies described a decrease in Hib notifications during the COVID-19 pandemic [11,23,24]. According to the study of Steens et al [25], the observed increase in incidence in the Netherlands could be explained by methodological, behavioral, biological, or vaccine-related factors; however, the conclusive reason still remains unknown.

In exploring the post-COVID-19 period, we found that the number of notifications for measles and pertussis remained significantly lower compared with the pre-COVID-19 period. This prolonged effect on the notifications was also observed in Poland [26]. This is most likely due to the prolonged unintended effects of NPIs, leading to reduced circulation of these infectious diseases [27]. It highlights the importance of a robust surveillance system, as a resurgence of cases is likely to occur in the future. In the Netherlands, we have experienced a pertussis outbreak in early 2024, exceeding pre-COVID-19 levels (data not shown).

Our study shows that correcting for the impact of the COVID-19 pandemic on the decreased notifications of other notifiable infectious diseases has an effect on the alarm threshold for outbreak detection. The levels of the original unadjusted alarm thresholds differed from the other alarm threshold methods, which were corrected for the decrease in notifications. Other studies that observed a significant decrease in their notifications briefly mention the impact for surveillance; however, none of them propose a concrete solution [11,28]. To our knowledge, this is the first study that investigates whether correction for the decrease in notifications has an effect on outbreak detection and investigates multiple correction methods. Based on our findings, the initial difference among the investigated alarm threshold methods was not evident. This could be explained by the delayed effect of the correction, as it calculates with historical values and could appear visibly later on in the period of 2025 - 2027. Nevertheless, the effect was already strongly visible for the infectious diseases with high notification numbers and a longer correction period, such as pertussis. This underlines the need for pattern-specific corrections. However, implementing a different outbreak detection method for every infectious disease would be too complex in a PHS setting and would require more data points than are available, especially for infectious diseases with low notification numbers. We therefore propose a general methodology that incorporates pattern-specific corrections based on the timing of impact. For example, the alarm threshold for malaria would only be corrected for the COVID 2020 period, while the alarm threshold for pertussis will be corrected for the whole COVID-19 pandemic period. The next step will be the validation by communicable disease control professionals to assess the applicability of the corrected alarm thresholds for outbreak detection.

The significant and prolonged effect of the COVID-19 pandemic on notifiable infectious diseases underlines the necessity of correction for the decrease in notifications. As it is important for communicable disease professionals to act validly in a timely manner. Not correcting for the decrease of notifications during the COVID-19 pandemic could lead to false positive exceedances of the alarm threshold, thereby consuming time and other resources of communicable disease control professionals. The findings also suggest that certain outbreaks could potentially go undetected, and consequently, no action would be taken, with all its associated consequences. Furthermore, as for pandemic preparedness, data-driven decision and policy-making is crucial. Consequently, a robust surveillance system is a necessity. This study shows that correction for a decrease in notifications affects outbreak detection for other infectious diseases, even during an ongoing pandemic. In conclusion, it is recommended to account for periods of underreporting or reduced notifications to ensure reliable outbreak detection. Future work should explore which correction method is the most appropriate for outbreak detection in the PHS setting.

Limitations

One of the limitations of this study is the inability to determine the factors driving the decrease in notifications based on this analysis. We hypothesized that the NPIs had an effect on the notifications, as the interference of the SARS-CoV-2 variants, possible shift in demographic determinants, and difference in health care use and access to diagnostics during the COVID-19 pandemic. We did not have any data on vaccination status, health care usage, and number of diagnostic requests; therefore, we could not identify if the notifications were affected by one of these factors specifically. However, we did not see any difference in the distribution of demographic determinants among the notifications. Other studies suggest that the decrease is likely due to a combination of factors [7,10,11]. In addition, exploring the causes of this decrease was beyond the scope of this study.

Another limitation is that we had a simplified definition for the post-COVID-19 pandemic period. We defined September 2022 as the end of the COVID-19 pandemic in the Netherlands, as the COVID-19 Stringency Index was at its lowest. One could argue that the post-COVID-19 pandemic period started later on, which could lead to underestimating the effect in the post-COVID-19 pandemic period. An alternative approach is to evaluate whether the monthly value is significantly below the historical average, similar to the methodology used for outbreak correction. As it will correct for short-term effects, this could create an alarm threshold that is more sensitive, which can be preferred in infectious disease control. Furthermore, assessing a monthly or even weekly correction approach would be valuable during a future pandemic, as it allows continuous adjustments for the ongoing impact rather than defining it retrospectively. This option was not assessed in our study, as we believe it would require more data and a prolonged study period. However, we recommend including this in future validation studies to further develop the “pandemic-proof” methodology.

Finally, we did not perform an interrupted time-series analysis for determining the trend of the notifications, as seen in other studies. This analysis required more data points than were available for some infectious diseases. Nevertheless, the negative binomial regression proved to be a robust alternative, as it accounts for zero notifications. To assess sensitivity, we compared the IRR between the pre-COVID-19 pandemic period and the entire COVID-19 pandemic period (2020 - 2022) and found no notable differences to the IRRs of the individual COVID-19 pandemic periods. Our main focus was to identify which infectious diseases were affected and the duration of these effects, which was adequately addressed using the negative binomial regression.

Conclusions

The COVID-19 pandemic and the related pandemic measures are likely to have had a considerable effect on the notifications of other infectious diseases, affecting both surveillance and outbreak detection. The length of the effect also differed among the infectious diseases, necessitating pattern-specific corrections. Our study shows that correcting for the decrease in notifications has an effect on the alarm thresholds for outbreak detection. Further research is required to determine which correction method is most suitable and applicable for effective outbreak detection, to ensure communicable disease control professionals act in a timely and data-driven manner.

Acknowledgments

The authors acknowledge Dr M Nabuurs-Franssen for providing expert insights on the impact of the COVID-19 pandemic on healthcare access and diagnostic use. The authors also extend their gratitude to Dr R Akkermans and Dr R Pijnacker for their valuable statistical advice. In addition, they would like to thank the National Institute of Public Health and Environment for providing the data. The authors acknowledge the research infrastructure provided by the Dutch Collaborative Academic Practice for Public Health Infectious Diseases. This project was funded by the Ministry of Health, Welfare and Sport of the Dutch Government within the program "Strengthening infectious disease control and pandemic preparedness of the regional Public Health Services." The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript. The artificial intelligence language model ChatGPT was used exclusively to enhance the manuscript’s readability and to correct linguistic and spelling errors.

Abstract

Background: Research has shown that perceptions of a mental health need are closely associated with service demands and are an important dimension in needs assessment. Perceived and unmet mental health needs are important factors in the decision-making process regarding mental health services planning and resources allocation. However, few prediction tools are available to be used by policy and decision makers to forecast perceived and unmet mental health needs at the population level.

Objective: We aim to develop prediction models to forecast perceived and unmet mental health needs at the provincial and health regional levels in Canada.

Methods: Data from 2018, 2019, and 2020 Canadian Community Health Survey and Canadian Urban Environment were used (n=65,000 each year). Perceived and unmet mental health needs were measured by the Perceived Needs for Care Questionnaire. Using the 2018 dataset, we developed the prediction models through the application of regression synthetic estimation for the Atlantic, Central, and Western regions. The models were validated in the 2019 and 2020 datasets at the provincial level and in 10 randomly selected health regions by comparing the observed and predicted proportions of the outcomes.

Results: In 2018, a total of 17.82% of the participants reported perceived mental health need and 3.81% reported unmet mental health need. The proportions were similar in 2019 (18.04% and 3.91%) and in 2020 (18.1% and 3.92%). Sex, age, self-reported mental health, physician diagnosed mood and anxiety disorders, self-reported life stress and life satisfaction were the predictors in the 3 regional models. The individual based models had good discriminative power with C statistics over 0.83 and good calibration. Applying the synthetic models in 2019 and 2020 data, the models had the best performance in Ontario, Quebec, and British Columbia; the absolute differences between observed and predicted proportions were less than 1%. The absolute differences between the predicted and observed proportion of perceived mental health needs in Newfoundland and Labrador (−4.16% in 2020) and Prince Edward Island (4.58% in 2019) were larger than those in other provinces. When applying the models in the 10 selected health regions, the models calibrated well in the health regions in Ontario and in Quebec; the absolute differences in perceived mental health needs ranged from 0.23% to 2.34%.

Conclusions: Predicting perceived and unmet mental health at the population level is feasible. There are common factors that contribute to perceived and unmet mental health needs across regions, at different magnitudes, due to different population characteristics. Therefore, predicting perceived and unmet mental health needs should be region specific. The performance of the models at the provincial and health regional levels may be affected by population size.

Introduction

Mental disorders are prevalent and have a considerable impact on the people who experience them, as well as families, communities and society as a whole. To enhance the provision of timely and appropriate mental health services for people who are in need, effective health services planning should be adaptable and responsive to the changing needs and emerging opportunities. Research has shown that many people living with a mental disorder do not receive the services due to the barriers of availability, accessibility, and acceptability [1]. On the other hand, many people with symptoms of mental disorders that do not meet clinical criteria may also benefit from intervention and these people may actively seek treatment to prevent the symptoms from escalating to the level of a disorder [2]. These phenomena reflect different types of mental health care needs and the extent to which the mental health needs are being met.

Mental health need is difficult to define. Bradshaw [3] proposed six need types: (1) normative (presence of a mental disorder diagnosis), (2) felt (subjective perception of a mental health problem), (3) expressed (demand for mental health service), (4) comparative (population inequities in mental health), (5) medical (treatable disease), and (6) social (restoring quality of life). There is evidence to suggest that perceptions of a mental health need (felt need) are closely associated with service demands [4] and are an important dimension in needs assessment [5]. Data-driven evidence about perceived and unmet mental health needs at provincial, state and regional, or county levels can be very helpful in building the business case of demand [6]. However, population health data about perceived and unmet mental health needs have not been well adopted for this purpose [7].

Unmet health need is “the absence of sufficient or appropriate care and services.” [8] These needs are commonly assessed as being for information, medication, counseling or therapy, or another type of help. A need is considered to be fully met when a person receives help meeting all their expectations. In other cases, the help may only partly fulfill the need, or no support is provided at all and the need is unmet [9]. Based on 2012 Canadian Community Health Survey (CCHS)–mental health, 17.3% of Canadians aged 15 years and older reported having mental health needs in the past year, and about one-third of those with a mental health care need reported that it was unmet [9,10]. Addressing unmet needs is important, as people with untreated anxiety or depression are at higher risk of experiencing poor outcomes including persistence of symptoms, delayed recovery, poor personal and occupational functioning, and recurrence of these problems [11]. Unmet health care need has been identified to be an important indicator of health care access within various health care systems [12,13], and is a form of inefficiency that has economic implications, according to Mental Health Commission of Canada [14]. Both perceived and unmet mental health needs constitute the central part of demand which is a critical element in the process of health resources allocation.

Decision makers and health service planners have detailed information about existing mental health resources including available infrastructure, services and workforce at the provincial and regional levels. To allocate and use these resources efficiently, the magnitude of mental health needs and unmet needs in the community is critical information in the decision-making process. The ability to closely monitor and forecast the trends of perceived and unmet needs in populations can greatly facilitate this decision-making process. The objective of this study was to develop prediction models for estimating and forecasting perceived and unmet mental health needs at the provincial and health regional levels in Canada.

Methods

Study Design

For the objective of this study, data from the 2018, 2019, and 2020 CCHS and Canadian Urban Environment (CANUE) were used. CCHS is an annual national population health survey conducted by Statistics Canada to gather data on health status, health care use, and health determinants at the health region levels of geography. The CCHS covers the household population from 12 years of age and older living in the 10 provinces and 3 territories. The CCHS sample is selected using different frames according to the age group. For the adult population (18 y and older), the sample of households is selected from an area frame. For the youth population (12 to 17 y old) a list frame is used to select persons. The area frame used by the Labour Force Survey is used as a sampling frame for the adult population. The Labour Force Survey uses a 2-stage sample design. In the first stage, a sample of primary sampling units, corresponding to geographical regions called clusters, is selected. In each selected primary sampling unit, a sample of dwellings is drawn at the second stage. To sample persons for the youth population between the ages of 12 and 17 years, the CCHS uses a list frame created from the Canadian Child Benefit files. The sample for the youth population is selected from a list of individuals. For adult participants, 1 person is selected per household using varying probabilities taking into account the age and the household composition. Each year the CCHS collects information on approximately 65,000 Canadians (60,000 aged 18 y and older and 5000 aged 12 to 17 y) [15]. The CCHS uses 2 separate computer-assisted interviewing applications to collect data, 1 for telephone interviews (computer-assisted telephone interviewing) and 1 for personal interviews (computer-assisted personal interviewing). Approximately 25% of these completed cases were conducted in person using computer-assisted personal interviewing, and the other 75% were conducted over the phone using computer-assisted telephone interviewing. Starting in 2015, the CCHS undertook significant redesign in sampling and the content [15]. Data about the outcome variables of the proposed study (perceived and unmet mental heath needs) were not collected in 2015, 2016, and 2017 CCHS, therefore, we will analyze the 2018, 2019, and 2020 CCHS data.

CANUE is a Canadian Institutes of Health Research–funded collaboration that focuses on developing robust methods for producing measures of urban form that capture a wide range of characteristics for every postal code in Canada [16]. It has produced a unique repository of standardized metrics of urban, suburban, and rural characteristics. CANUE shares a range of data that can be directly linked with population health surveys

XSL•FO
RenderX

through postal codes, including neighborhood-level material and social deprivation [17], marginalization [18], and walkability. CANUE is updated every 5 years. The most recent CANUE update was in 2016. The CANUE data can be obtained from CANUE consortium at no costs for research, and is linkable to the CCHS by postal codes.

Perceived and Unmet Mental Health Needs

In the CCHS, perceived and unmet mental health needs were measured by the Meadows et al [19] Perceived Needs for Care Questionnaire (PNCQ). The PNCQ was designed and field tested for the Australian National Survey for Mental Health and Wellbeing which was commissioned by the Federal Government of Australia [19]. The PNCQ assessed four types of help for problems with emotions, mental health, or the use of alcohol or drugs: (1) information about problems, treatments, or services; (2) medication; (3) counseling or therapy; and (4) other mental health services. Respondents were asked which types of help they had received in the past 12 months. For each type received, they were asked if they felt they had received enough. For each type of help not received, they were asked if they felt it was needed. Based on the PNCQ, the following binary outcome variables can be derived: [9,20]

- *Perceived mental health needs:* having reported "yes" to a perceived need of any type of help.
- *Unmet mental health needs:* For any type of help for which a respondent had a perceived need, having reported not receiving any or enough of that type of help. Interrater reliability of the PNCQ (κ value) was 0.62 [19]. Validity testing using homo-method agreements and hetero-method agreement demonstrated that the PNCQ has good discriminative validity [19]. The PNCQ has been used to assess perceived and unmet mental health needs in a number of population health surveys conducted in Australia [19], Canada [21], the United States [22], and the Netherlands [20].

Candidate Predictors

Overview

Guided by the Andersen Health Behavior model [23], we selected potential predictors from the core component of the CCHS which are consistently administered over time in all provinces and territories. This ensured that health regions can readily ascertain the predictor profile of their regions to make an estimation and prediction when PNCQ is not administered in the CCHS.

From the CCHS core component, we selected the predisposing factors (sex, gender, age, marital status, race or ethnicity, rural or urban residence, first official language spoken, immigration, household food security, self-reported life stress, work stress, life satisfaction, and sense of belonging), enabling factors (educational level, household income, employment status, and insurance coverage), and need factors (general health, comorbid physical conditions, self-reported mental health, mood, and anxiety, and primary care service use). Mental health problems such as depression, anxiety, and psychological distress are not part of the core component; data about these variables are not available in every CCHS and for every province and territory. Therefore, these variables were not selected. A number of studies have shown that health behaviors (smoking [24], problematic substance use [25,26], and physical inactivity [27,28]) are associated with depression, anxiety, and psychological distress. We selected these health behaviors from the core component as candidate predictors. From the CANUE, neighborhood-level social and material deprivation [17], marginalization [18], and walkability will be selected as enabling factors.

Model Development

The 2018 CCHS data were used to develop the prediction models. Given the vast geographic area of Canada, we developed the models by regions: Atlantic region (Newfoundland and Labrador, Prince Edward Island, Nova Scotia, and New Brunswick), Central region (Ontario and Quebec), Western region (Manitoba, Saskatchewan, Alberta, and British Columbia). For each region, we developed prediction models for perceived and unmet mental health needs through the application of regression synthetic estimation developed by the UK's Office of National Statistics [29], which is a type of small area estimation methodology. The same methodology has been used to estimate state and area-level prevalence of severe mental illness in the United States [30]. The regression synthetic estimation method involves several steps: (1) The development of a prediction model of the outcome at the individual level. (2) The coefficients derived from the foregoing model are used with a parallel set of predictors on the area level, using data obtained from CCHS, and coded using the same categories as used to estimate the individual-level model and to compute national and area-level estimates. (3) Internal and external validation.

To develop the predictive models for the outcomes at the health region level, multilevel, random intercept binary logistic regression models were used to analyze the perceived and unmet need for mental health services (level 1) nested within health regions (level 2). A backward selection method was used to identify the model with the best calibration and discrimination. The decisions of model selection were initially based on the changes in the values of Akaike information criterion and Bayesian information criterion [31].

Because the goal of models was to assist decision makers and service planners to estimate perceived and unmet needs at the population level (not to be used by clinicians to identify high risk individuals), we focused more on the calibration of the model, instead of discrimination, when it came to model performance. Discrimination is the ability of a prediction model to separate those who experienced the outcome events from those who did not, by predicting higher versus lower probabilities, respectively. We quantified this by calculating the area under the receiver operating characteristics curve, which is equal to the C statistic. Calibration measures how closely predicted outcomes agree with actual outcomes. For this, we used the calibration slope by which a value of 1 indicates perfect model calibration with data; less than 1 is overconfident and greater than 1 is underconfident [32]. Additionally, we used calibration plots to visually compare the mean predicted risk of the outcomes versus the observed risk (the cumulative fraction

XSL•FO
RenderX

of events) by decile risk groups so that the overall calibration and the areas with over or under prediction can be identified.

The second step was synthetic estimation of the proportions at the population level with perceived and unmet mental health needs, which consisted of 2 stages. First, population proportions for predictor variables that were used in the initial modeling were estimated. For instance, if 5 household income categories are used in the initial modeling (<CAD $30,000, CAD $30,000 - $49,000, CAD $49,000 - $60,000, CAD $60,000 - $80,000, and CAD $80,000+; <US $21,175.80, US $21,175.80-$34,587.14, US $34,587.14-$42,351.60, US $42,351.60-56,468.80, and US $56,468.80+, respectively), the population proportion of participants in each of the same 5 income ranges were estimated from the CCHS. The regression coefficients were then applied to the corresponding proportions in the dataset, and to calculate the logit estimates for each province, which were then converted into probabilities, giving the predicted proportions of perceived and unmet mental health needs in the province. These procedures were repeated with data aggregated at the provincial and health regional levels. All analyses were conducted using bootstrap weights provided by Statistics Canada to account for the unequal sampling probabilities and design effects.

Validation

As internal validation, we used CCHS-2018 data to compare the predicted proportions (step 2 above) and the observed proportions. To ensure the validity of the predictive models, it is also important that the developed models are externally validated in related but independent populations. As external validation, we applied the developed synthetic models in CCHS-2019 and CCHS-2020, to examine the performance of the models, to investigate how the pandemic may affect the performance of the models by comparing the model predicted (synthetic) proportions and the observed proportions. Additionally, we randomly selected 10 subprovincial health regions from over 100 across the country. We applied the regional models directly to the health regions and compared the observed and predicted proportions of perceived and unmet mental health needs. All analyses were conducted using the bootstrap weights provided by Statistics Canada to account for the sampling and design effects of the CCHS.

Ethical Considerations

This is a secondary data analysis using the deidentified data collected by Statistics Canada. The data analysis was carried out at one of the Research Data Centers across the country, located on the campus of Dalhousie University. Researchers who conducted data analysis had to go through security clearances and become “deemed employees” of Statistics Canada. The results were vetted by data analysts of the Research Data Center to ensure privacy and confidentiality. CCHS participants gave informed consent to Statistics Canada for use of their data in accordance with the Statistics Act and no compensation was provided to the CCHS participants. For these reasons, ethics review was waived by the health research ethics committee of Dalhousie University.

Results

Overview

The 2018 CCHS data were used to develop the prediction models. The demographic and socioeconomic characteristics of the participants in the 2018 CCHS are presented in Table 1. In the 2018 CCHS, 17.82% reported perceived mental health need and 3.81% reported unmet mental health need. In 2019, the proportion of perceived and unmet mental health needs was 18.04% and 3.91%, respectively; in 2020, the proportion of perceived and unmet mental health needs was 18.1% and 3.92%, respectively.

Predicting Perceived Mental Health Need

The individual based models with the best performance for predicting perceived mental health need are in supplemental tables (Tables S1 [Atlantic region], S2 [Central region], and S3 [Western region] in Multimedia Appendix 1). Sex, age, self-reported mental health, physician diagnosed mood and anxiety disorders, and self-reported life stress and life satisfaction were the predictors in the 3 regional models. Perceived work stress and household food insecurity were in the models for the Atlantic and Central regions, but not for the Western region. However, immigrants, smoking, or problematic drinking and material deprivation were predictors in the models for the Atlantic and the Western region, not for the Central region. The individual based models had good discriminative power with C statistics over 0.83 (Tables S4-S6 in Multimedia Appendix 1) and good calibration by comparing observed and predicted proportions.

Converting the individual based models into synthetic estimation models, the predicted proportion of perceived mental health need in each province was estimated. The absolute difference between the observed and predicted proportions in 2018 was less than 1% for all provinces (Tables 2-4), except Saskatchewan (3.37%). This is not surprising as the models were developed using the 2018 CCHS data. To validate the models, we applied the synthetic models directly in 2019 and 2020 data. The extent to which the predicted or synthetic estimates agree with observed proportions varied by regions (Tables 2-4). The models had the best performance in Ontario and British Columbia (absolute difference <1% in both 2019 and 2020), followed by Quebec (absolute difference=1.54% in 2019 and 0.54% in 2020). The models for Nova Scotia, New Brunswick, Saskatchewan, and Alberta had 1 absolute difference being less than 1% and the other greater than 2%. The absolute differences between observed and predicted proportions in Newfoundland and Labrador (−4.16% for perceived needs in 2020) and Prince Edward Island (4.58% for perceived needs in 2019) were larger than those in other provinces. When applying the models in the 10 selected health regions, the data showed that the model performed well in health regions in Ontario (first 2 digits with 35) and in Quebec (first 2 digits with 24), supported by the relatively small absolute differences between observed and predicted proportions (Table 5). Health region 1304 had the largest absolute differences in 2019 and 2020.

Predicting Unmet Mental Health Need

The individual based models with the best performance for predicting unmet mental health need are in Tables S7 (Atlantic region), S8 (Central region), and S9 (Western region) in Multimedia Appendix 1. As seen from the tables, sex, age, marital status, self-reported mental health, self-reported life stress, and low sense of belonging to the community were the common predictors in the models for the 3 regions. Household income was a predictor only in the model for Central region; professional diagnosed mood disorders, problematic drinking, and smoking and social deprivation were the factors specific for the model for the Atlantic region. The individual based models had good discriminative power with C statistics over 0.77 (Tables S10-S12 in Multimedia Appendix 1) and good calibration by comparing observed and predicted proportions.

The individual based models were converted into synthetic estimation models, and the predicted proportion of perceived mental health need in each province was estimated (Tables 2-4). The data demonstrated that the models for unmet mental health need performed well in most of the provinces with the absolute difference between observed and predicted proportions being less than 1%, except for Prince Edward Island, Nova Scotia, and Saskatchewan. When applying the models in the 10 selected health regions, the data showed that the models calibrated well with data in all selected health regions with absolute difference between observed and predicted proportions being less than 1% (Table S13 in Multimedia Appendix 1).

Discussion

Principal Results

The 3 waves of CCHS showed that the proportion of the Canadian population that perceived the need for mental health care was between 17.82% and 18.1%, and about 4% reported unmet mental health need. This study demonstrated the feasibility of integrating individual and community level data to build informative synthetic models for perceived and unmet mental health care needs at the population level. The models performed well in predicting the outcomes at both the provincial and health regional levels, particularly in populous provinces such as Ontario, Quebec, and British Columbia. The absolute differences between the observed and predicted proportions of perceived and unmet mental health needs in Ontario, Quebec, and British Columbia were less than 1%. For the rest of the provinces, the results showed that the models at provincial and health regional levels predicting unmet mental health needs had better calibration than the models predicting perceived mental health need.

Limitations

This study had several limitations. First, although the predictors in the models were associated with the outcomes, causal inferences cannot be made. The goal of the prediction models is to identify a key set of factors that in combination are best predictive of the outcomes. The models are not to test hypothesis or make inferences about etiology. Second, the relationships between the selected factors and the outcomes are complex. The logistic regression model is a linear function. Although we found no evidence of interactions among the selected predictors, nonlinear relationships between some predictors and the outcomes are still possible. Future studies may test if models using machine learning techniques have better performance. Third, the selection of candidate predictors was limited by what CCHS collected. It is possible that other factors are associated with the outcomes of this study, but were not measured in CCHS, therefore could not be examined in this study. Finally, the models appeared to perform well at regional and provincial levels. Relatively large absolute differences between predicted and observed proportions of perceived and unmet needs were observed in some health regions (eg, health region 1304). Caution should be exercised for using them at the health region level.

Comparison With Prior Work

The CCHS used a nationwide representative sample of the Canadian household population. However, we found that a model developed for the whole population performed well only in the most populous provinces such as Ontario and Quebec, but not in the rest of the provinces. Developing models for specific regions appeared to be a better approach. The regional models have some common predictors, including sex, age, self-reported mental health, physician diagnosed mood and anxiety disorders, self-reported life stress and life satisfaction for perceived mental health need, and sex, age, marital status, self-reported mental health, self-reported life stress, and low sense of belonging to the community for unmet mental health need. These factors have been found to be significantly associated with mental health problems [33] in the literature. On the other hand, the coefficients associated with these factors varied by regional models and these models also contained predictors that are regionally specific. This finding indicates that there are common factors in the mechanisms underlying perceived and unmet mental health needs across geographic regions and populations. The extent to which these factors influence perceived and unmet mental health needs may differ due to the population characteristics of these provinces and regions. The differences in population characteristics and the distribution of the outcomes across the regions may also contribute to the finding that the models contained region specific predictors.

We have not found studies on predicting perceived and unmet mental health needs at the population level. Therefore, a direct comparison with previous studies is not possible. There are several studies predicting county or state level suicide and severe mental illness. For example, Kandula et al [34] modelled county-level suicide risk in the United States using county-level predictors derived from 8 different databases of different sources (government programs, health surveys, or private organizations). For some predictors such as the prevalence of major depressive episode, only state-level estimates were available and these estimates were extrapolated to the counties [34]. Hudson [30] explored the utility of regression synthetic estimation model that incorporated individual data from the National Comorbidity

XSL•FO
RenderX

Survey, census and hospital administrative data to predict state-level prevalence of severe mental illness. The advantages of these population risk prediction models are the use of community level predictors from existing sources or published research and the ability of adapting the models in local context. Notably, our study used the regression synthetic estimation modeling approach. We used CCHS data. The use of a single data source may improve the efficiency of data analysis, data access, and eventually of the decision-making process.

One critical element of building risk prediction models is assessing model performance and model validation. This is to ensure that the developed model is accurate and has good performance in different populations or at different time periods. In this study, we developed the models using the 2018 CCHS data, and validated the models using the data from 2019 and 2020 CCHS. Furthermore, we validated the models in a random sample of health regions. These models were designed to estimate population proportions and to identify regions with high levels of mental health need and unmet mental health need; these models were not to be used by clinicians to identify high-risk individuals. Therefore, the focus of model performance assessment can be different. Kandula et al [34] used symmetric proportional error (observed deaths–predicted deaths)/(observed deaths+predicted deaths) to quantify model calibration. Hudson [30] calculated the absolute difference between the predicted and observed prevalence of severe mental illness. In this study, we calculated the absolute difference between the observed and model predicted proportions of perceived and unmet mental health needs. The absolute difference indicates the extent to which the model prediction deviates from the observed value. However, there is no consensus about what an optimal threshold of absolute difference should be. There may be other indicators that are useful for assessing the performance of population level models. Consultations with policy and decision makers (ie, end users of the models) would be helpful to understand what indicators are informative about model performance, and the level of the model error that is acceptable.

The results of this study are expected to have implications for population mental health planning. Few would deny that resources allocation should be partly driven by needs, and needs assessments typically require the knowledge of potential changes in prevalence estimates and in local population profiles, for example, their demographics, diagnoses, and mental health services use. The prediction models developed by this study will allow decision makers and mental health services planners to forecast the proportions of perceived and unmet mental health needs in the years to come at the provincial (state) and health regional (county) levels based on the potential changes in local population profiles. Such profile changes may be estimated using health administrative data and national population census data. Additionally, region-specific estimates can help categorize health regions—for example, regions with relatively stable mental health needs especially those that remained in the highest or lowest groups, or regions in which the largest year-to-year changes are observed—and hence help identify areas with a greater need of preventive resources, or conversely identify areas where interventions seem to be effective.

Conclusion

In conclusion, accurate forecast of perceived and unmet mental health needs in the population can allow policy and decision makers and mental health services planners to categorize regions or communities that are at high need and to monitor changes so that they may mobilize resources and interventions to the right populations and the right places at the right time. Regularly collected population health data such as those from the CCHS are readily accessible to policy and decision makers and mental health services planners. The models are particularly useful for service planners at the health regional level because population health surveys usually do not contain sufficient numbers of participants at the health regional level. Future studies are needed to identify methods to improve prediction for regions with small numbers of residents.

Abstract

Background: High response rates are needed in population-based studies, as nonresponse reduces effective sample size and bias affects accuracy and decreases the generalizability of the study findings.

Objective: We tested different strategies to improve response rate and reduce nonresponse bias in a national population–based COVID-19 surveillance program in England, United Kingdom.

Methods: Over 19 rounds, a random sample of individuals aged 5 years and older from the general population in England were invited by mail to complete a web-based questionnaire and return a swab for SARS-CoV-2 testing. We carried out several nested randomized controlled experiments to measure the impact on response rates of different interventions, including (1) variations in invitation and reminder letters and SMS text messages and (2) the offer of a conditional monetary incentive to return a swab, reporting absolute changes in response and relative response rate (95% CIs).

Results: Monetary incentives increased the response rate (completed swabs returned as a proportion of the number of individuals invited) across all age groups, sex at birth, and area deprivation with the biggest increase among the lowest responders, namely teenagers and young adults and those living in more deprived areas. With no monetary incentive, the response rate was 3.4% in participants aged 18 - 22 years, increasing to 8.1% with a £10 (US $12.5) incentive, 11.9% with £20 (US $25.0), and 18.2% with £30 (US $37.5) (relative response rate 2.4 [95% CI 2.0-2.9], 3.5 [95% CI 3.0-4.2], and 5.4 [95% CI 4.4-6.7], respectively). Nonmonetary strategies had a modest, if any, impact on response rate. The largest effect was observed for sending an additional swab reminder (SMS text message or email). For example, those receiving an additional SMS text message were more likely to return a completed swab compared to those receiving the standard email-SMS approach, 73.3% versus 70.2%: percentage difference 3.1% (95% CI 2.2%-4.0%).

Conclusions: Conditional monetary incentives improved response rates to a web-based survey, which required the return of a swab test, particularly for younger age groups. Used in a selective way, incentives may be an effective strategy for improving sample response and representativeness in population-based studies.

Introduction

In population-based studies, a high response rate from a representative sample may reduce nonparticipation bias, increase the generalizability, and improve the accuracy of study estimates [1]. However, achieving this goal is challenging, both due to the difficulty in contacting and then engaging eligible participants [2]. For example, UK Biobank, a population-based

XSL•FO
RenderX

cohort study with stored biological samples from half a million participants aged 40 - 69 years in the United Kingdom, achieved an overall response rate of 5.5% [3], which was lower in men, younger people, and those living in more deprived areas [4]. The impact of nonresponse and nonrepresentativeness on the generalizability of disease prevalence and incidence rates in the UK Biobank has been widely debated [5,6].

It is important to address low or falling response rates to reduce the likelihood of systematic biases that may affect study estimates [7]. While weighting is commonly applied to correct for differential participation, it may fail to correct bias if the responders in a particular subgroup of the population are not representative of that subgroup as a whole. Furthermore, weighting to correct for observed biases worsens precision (reducing the effective sample size) [8].

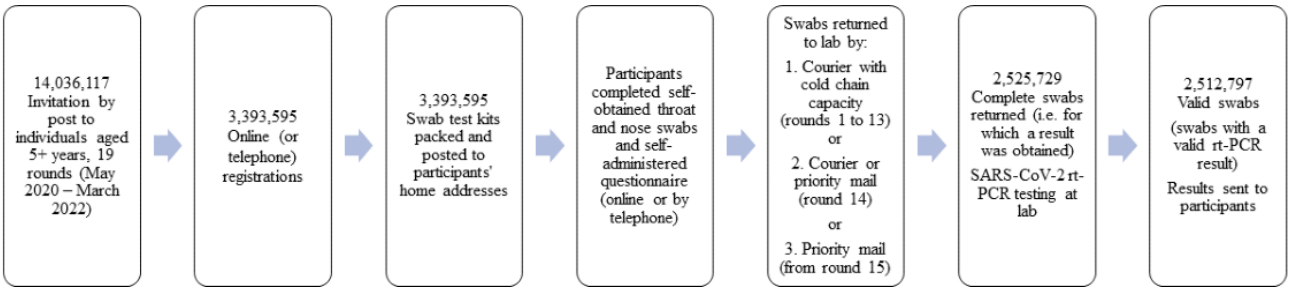
Systematic reviews that have evaluated interventions to increase response rates in surveys have concluded that monetary incentives are more effective than nonmonetary incentives [9-11], although findings were inconsistent concerning web-based surveys in educational research [12]. Some studies have found incentives can increase response among under-represented sociodemographic groups, such as those with low incomes, those with low education, single parents, and minority ethnic groups, potentially reducing nonresponse bias [13], while others show mixed results [9].

Other strategies that have been shown to improve response rates in surveys have included the use of SMS text message reminders to enhance the contact method of letters and emails [14,15], using alternative motivational statements in invitation letters [16], and changing the font color of text [17]. In a United Kingdom–based study investigating the effects of augmenting the contact strategy of letters and emails with SMS text messages for a web questionnaire, the findings indicated that SMS text messages did not help to significantly increase response rates overall, although some subgroups benefited from them, such as younger panel members and those with an irregular response pattern [15].

The Real-time Assessment of Community Transmission-1 (REACT-1) study was one of the largest population surveillance studies in the world. Across 19 rounds between May 1, 2020 and March 31, 2022, it provided timely prevalence estimates of SARS-CoV-2, the virus that causes COVID-19, from random cross-sectional samples of the population in England [18,19].

Response rate varied between 11.7% and 30.5% and, like in many population surveys, varied across demographic groups [19]. For financial reasons, we could not issue more than 845,000 invitation letters by mail, so we could only achieve the minimum desired sample size adopted from round 12 (May 20 to June 7, 2021) of 100,000 by improving response [18]. The observed nonresponse biases meant REACT-1 was under-representing groups with lower vaccination rates and where COVID-19 prevalence was highest; thus, we were likely underestimating the true population prevalence despite our attempts to correct for such biases by use of weighting on known demographic variables [20,21]. Here we present results of experiments nested within the REACT-1 study to test the effectiveness of different strategies to increase response rates and participation of groups with a lower propensity to take part.

Methods



The REACT-1 Study

Methods for the study, including sample size calculations, are described in detail elsewhere [18,19]. In summary, at approximately monthly intervals, between 395,020 and 841,227 people were sent personalized invitations by mail to take part. For children (5-17 years old), the invitation was sent to or via the parents or guardians. Individuals aged 5 years and older were randomly sampled from the National Health Service (NHS) list of patients in England (with near-universal population coverage) across all 316 Lower Tier Local Authorities [18,19]. This list includes the name, address, date of birth, and sex of everyone registered with a general practitioner in England. Invitees who registered (most digitally, some by telephone) for the study received a kit by mail with instructions on how to take a throat and nose swab and send it for SARS-CoV-2 testing using reverse transcriptase polymerase chain reaction (rt-PCR). Swabs were transferred to laboratories for processing, initially being picked up by courier with cold chain capacity (rounds 1-13 and part of 14) or sent by priority mail (part of round 14 and subsequent rounds). Participants were also asked to complete a self-administered web-based or telephone questionnaire [18,19].

Over the 19 study rounds, we sent out 14,036,117 invitations, 3,393,595 registrations were made, and 2,525,729 completed swabs were returned (ie, for which a laboratory result was obtained) (Figure 1). Of these swabs, 2,512,797 (99.5% of completed swabs returned) were considered valid for analysis in REACT-1 (swabs with a valid rt-PCR result) [19]. A swab with a valid rt-PCR result was a swab for which a “cycle threshold” (Ct) value could be obtained. Therefore, not all swabs tested by the lab were considered valid. Overall, 12,932 (0.5% of completed swabs returned) were considered invalid and rejected. Reasons included inadequate sample volume, contamination during sample collection, inappropriate sample storage, or inappropriate sample transportation. All analyses in this paper are based on completed swabs returned (ie, for which a laboratory result was obtained, n=2,525,729), thus including swabs for which a Ct value could not be obtained but excluding swabs returned unused.

XSL•FO
RenderX

Figure 1. REACT-1 study process over 19 rounds of data collection: England, May 1, 2020 to March 31, 2022. Overall, across 19 rounds, we report the number of invitations sent, the number of participants registered, the number of swab test kits sent out, the number of completed swabs returned (ie, for which a laboratory result was obtained) and the number of valid swabs (swabs with a valid rt-PCR result). REACT-1: REal-time Assessment of Community Transmission-1; rt-PCR: reverse transcriptase Polymerase Chain Reaction; SARS-CoV-2: Severe Acute Respiratory Syndrome CoronaVirus 2.

All the experiments carried out to improve response rate were randomized trials, enabling an unbiased assessment of the impact of the changed survey procedure compared to a control group. Due to funding constraints, initial experiments focused on approaches which would not materially affect the survey budget, before turning to an experiment with monetary incentives.

Swab Reminder and Tailored Letter or SMS Experiments

In each round of REACT-1, those registering for a swab test were, where necessary, sent at least one reminder to complete the swab test and return it, to maximize the number of swabs returned. In round 3 (July 24 to August 11, 2020) we conducted an experiment to establish the optimal use of email and SMS text message swab return reminders, with participants randomly allocated to the experimental conditions (Table 1).

Table . Round 3 swab reminder experimental conditions, England, July 24 to August 11, 2020.

Condition	Reminder on day 4 after swab test kit received	Reminder on day 6 after swab test kit received	Reminder on day 8 after swab test kit received	Sample, n
Control group	Email (SMS if no email address)	SMS	None	11,194
Experimental group A	SMS	Email (SMS if no email address)	None	11,154
Experimental group B	Email (SMS if no email address)	SMS	Email (SMS if no email address)	96,337
Experimental group C	SMS	Email (SMS if no email address)	SMS	96,305

The tailored letters or SMS experiments are summarized in Table 2. Further details are available in Multimedia Appendix 1. The experiments tested whether it was possible to increase participation by different types of conditions (Textbox 1).

Table . Rounds 9, 11, and 12 registration invitation letter experimental conditions and rounds 10 and 12 SMS registration reminder experimental conditions, England, February 4 to June 7, 2021.

Age and letter or SMS type	Additional content for experiment (actual additional content used in bold text)	Sample, n
Round 9[a] (≥70 years)		
Standard invitation letter Adult	None	37,037
Experiment invitation letter A	"**It is still important to take part in this study if you have received a vaccination from COVID-19 or expect to be vaccinated in the near future**. Your participation will help DHSC assess the impact of the vaccines on COVID-19 infection rates." As well as a new sub-heading "**COVID-19 Testing Study: Take part to help measure COVID-19 infection rates among those aged 70 and over**."	37,037
Experiment invitation letter B	As per Experiment Letter A with additional line "**Older people are a vulnerable group, so we need your help to monitor prevalence**. It is still important to take part in this study if you have received a vaccination from COVID-19 or expect to be vaccinated in the near future."	37,036
Round 9 (5 - 12 years)		
Standard invitation letter Child (addressed to parent)	None	24,009
Experiment invitation letter C	**"We need to know how many children and young people have COVID-19, and how easily the new variant spreads amongst them."**	24,009
Experiment invitation letter D	As per Experiment Letter C with new sub-heading **"COVID-19 Testing Study: Take part to help measure how easily COVID-19 spreads among children and young people."**	24,008
Round 9 (all)		
Standard registration reminder letter	Blue text used	306,012
Experiment registration reminder letter E	Red text used	305,041
Round 11[b] (≥18 years)		
Standard invitation reminder letter	None	178,828
Experiment invitation reminder letter A	New content asking participants to take a test to help prevent the spread of COVID-19 and explaining that taking part would help the Government work out the best way to manage the pandemic. Also mentioned testing for new variants, that the study compared people who had been vaccinated with those who had not, and that taking part would help inform the vaccine strategy and help to avoid lockdowns.	178,809
Round 12[c] (all)		
Standard invitation final reminder letter	Double-sided	169,845
Shorter invitation final reminder letter	Single-sided	342,191
Round 10[d] (all)		
Standard SMS first reminder	Unchanged **"The study is closing soon, please register by 18 March if you want to take part."**	50,000

XSL•FO
RenderX

Age and letter or SMS type	Additional content for experiment (actual additional content used in bold text)	Sample, n
Experiment first SMS reminder	New SMS content "**Taking part will help inform decisions about the best time to lift restrictions**."	430,283
Round 11 (all)		
Standard SMS second reminder	Unchanged "**The study is closing soon, please register by 3pm on 22 April if you want to take part**."	127,028

[a]Round 9 (Feb 4-23, 2021)

[b]Round 11 (Apr 15 to May 3, 2021)

[c]Round 12 (May 20 to Jun 7, 2021)

[d]Round 10 (Mar 11-30, 2021)

Textbox 1. Types of conditions tested in the tailored letters or SMS experiments.

- Using additional content in the invitation letter, tailored for the oldest and youngest age groups.
- Using color, additional content, and varying the length of the reminder letter.
- Using additional content in the SMS reminder.

Incentives Experiment

In round 15 (October 19 to Nov 5, 2021), conditional incentives (£10 [US $12.5], £20 [US $25.0], or £30 [US $37.5] gift vouchers for returning a completed swab test) were tested in a randomized controlled trial for all age groups except 5 - to 12-year-olds.

The process for obtaining consent in REACT-1 for children was undertaken differently based on participant age at the time of the invitation [18]. For 5 - to 12-year-olds, the parent or guardian was contacted via letter and asked to consent on behalf of the child. Therefore, we did not include the 5 - to 12-year-olds in the trial, as the sampled child would not be making the decision to take the swab test, and their parent would be incentivized, raising ethical and reputational concerns. For 13 - to 17-year-olds, the parent or guardian received a letter addressed to them, asking them to pass on an enclosed invitation letter addressed to their sampled child if they agreed for their child to take part in the study. As such, children aged 13 - 17 years were able to decide whether to consent to the study and take the swab test. In addition, those aged 13 to 15 years were asked at registration to confirm the name of the parent or guardian who had given them permission to take part. This was not required for those aged 16 - 17 years, as in UK health research, the Health Research Authority states that young people over 16 are presumed capable of giving consent on their own behalf [22].

Participants were randomly allocated to experimental and control groups: (1) £10 (US $12.5) conditional incentive (n=10,900), (2) £20 (US $25.0) conditional incentive (n=10,900), (3) £30 (US $37.5) conditional incentive (only for 18 - to 32-year-olds) (n=1750), and (4) control group (n=23,500). Further details of the sample size calculations are available in Multimedia Appendix 1.

XSL•FO
RenderX

The £30 (US $37.5) incentive was limited to the 18‐ to 32-year-olds because the response rate in REACT-1 was lowest among this age group. Also, there is evidence that incentives can be more effective among younger age groups [23]. Those in this age group were of particular interest as they were less likely to be vaccinated, had more social contact (and therefore were more likely to be at risk of infection), and had been particularly impacted by the pandemic (in terms of well-being, education, and employment) [21,24]. It was decided to test offering a larger (£30 [US $37.5]) incentive to this age group (and not the other age groups) to overcome their higher reluctance to take part and to better represent this group in the achieved sample. Based on the same rationale, we oversampled younger age groups to maximize the statistical power we had to detect an increase in the response rate due to the use of incentives among these groups.

The primary outcome was overall swab response rate, ie, the number of completed swabs returned (referred to as swabs returned forthwith) as a proportion of the number of invitations sent. For those invited, we knew age, sex at birth, and score from an area-level index of multiple deprivation, the Index of Multiple Deprivation (IMD) 2019 [25]. Participants were classified by quintiles of the deprivation score based on their residential postcode.

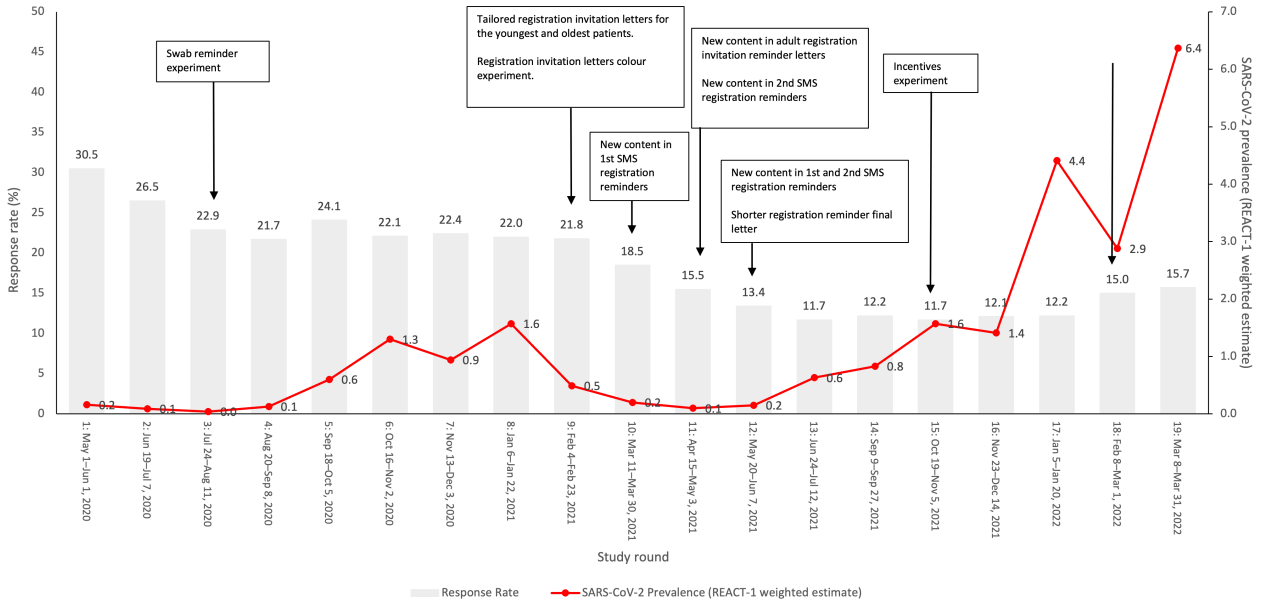
We used COVID-19 vaccination status (the proportion who had received at least one vaccine dose) as a proxy for attitudes to health behaviors and health care access, hypothesizing that REACT-1 responders would be more likely to be vaccinated than those who did not, indicating a responder bias. Thus, the difference in vaccination status at registration between the experimental and control groups was used as a crude indicator of how incentives might improve response rates in individuals less likely to participate in research, beyond sociodemographic characteristics. We also compared the COVID-19 vaccination status of those who returned a swab with the achieved population vaccination rate for that age group as a whole. To obtain information on dates of received COVID-19 vaccine doses, participant study data were linked to their NHS records from NHS Digital (now NHS England) on COVID-19 vaccination events [26] using their unique NHS number and other personal identifiers. This was only possible for study participants who had consented to data linkage. The source of vaccination data for the population vaccination rates was the NHS National Immunization Management System [27].

Ethical Considerations

The study was ethically approved by the South Central-Berkshire B Research Ethics Committee (IRAS ID: 283787). Participants provided informed consent when they registered for the study, and all data were handled securely in accordance with a detailed privacy notice. Collected data were deidentified; the data used in this study were anonymous and did not contain any personally identifiable information. Participants had the ability to opt out anytime during the research period. The study did not provide any specific compensation other than the monetary gift vouchers for returning a completed swab test as set out in the study's incentives experiment described above.

Statistical Analysis

Data analysis was conducted using IBM SPSS Statistics (version 28). As the incentives experiment was skewed toward younger age groups, swab response rates for sex at birth and area deprivation (IMD) were calculated with age-standardized weighting using 2021-based population estimates for England [28]. The percentage point difference (95% CI) and independent 2-tailed *t*-tests were used to show the absolute difference in swab response rates between the experimental and control groups and were also used to show the absolute difference in vaccination rates at registration between the experimental and control groups. Using multivariable logistic regression, we tested the impact of each of the incentive conditions on swab response rate by age, sex at birth, and area deprivation (relative response rate [RRR] with 95% CI). The reference group was the no-incentive condition—eg, the response rates for females in the £10 (US $12.5), £20 (US $25.0), and £30 (US $37.5) incentives groups were compared to females in the no-incentive group (£0 [US $0.0]). We tested interaction terms for age, sex at birth, and area deprivation by incentive (incentive*age, incentive*sex at birth, and incentive*IMD), which can be interpreted as testing whether the estimated effects of incentives on swab response rates differ by each of these 3 covariates.



Results

Overview

Overall, 24.2% (3,393,595/14,036,117) of invitees registered for the study, and 74% (2,512,797/3,393,595) of those registered returned valid swabs, giving an overall response rate for the REACT-1 study (number of valid swabs/number of invitations) of 17.9% (2,512,797/14,036,117) [19]. Whilst the rate at which registered participants returned valid swabs remained relatively stable across rounds (range 67.2%-78.9%), response rates varied more widely, ranging from 11.7% in rounds 13 (98,233/841,227) (June 24 to July 12, 2021) and 15 (100,112/859,184) (October 19 to November 5, 2021) to 30.5% in round 1 (120,620/395,020) (May 1 to June 1, 2020, during the first lockdown in England) (Figure 2). The following groups were relatively underrepresented: younger people, men, ethnic minorities, and those living in the most deprived areas (comparing achieved sample profiles with population profiles) (Table S1 in Multimedia Appendix 2).

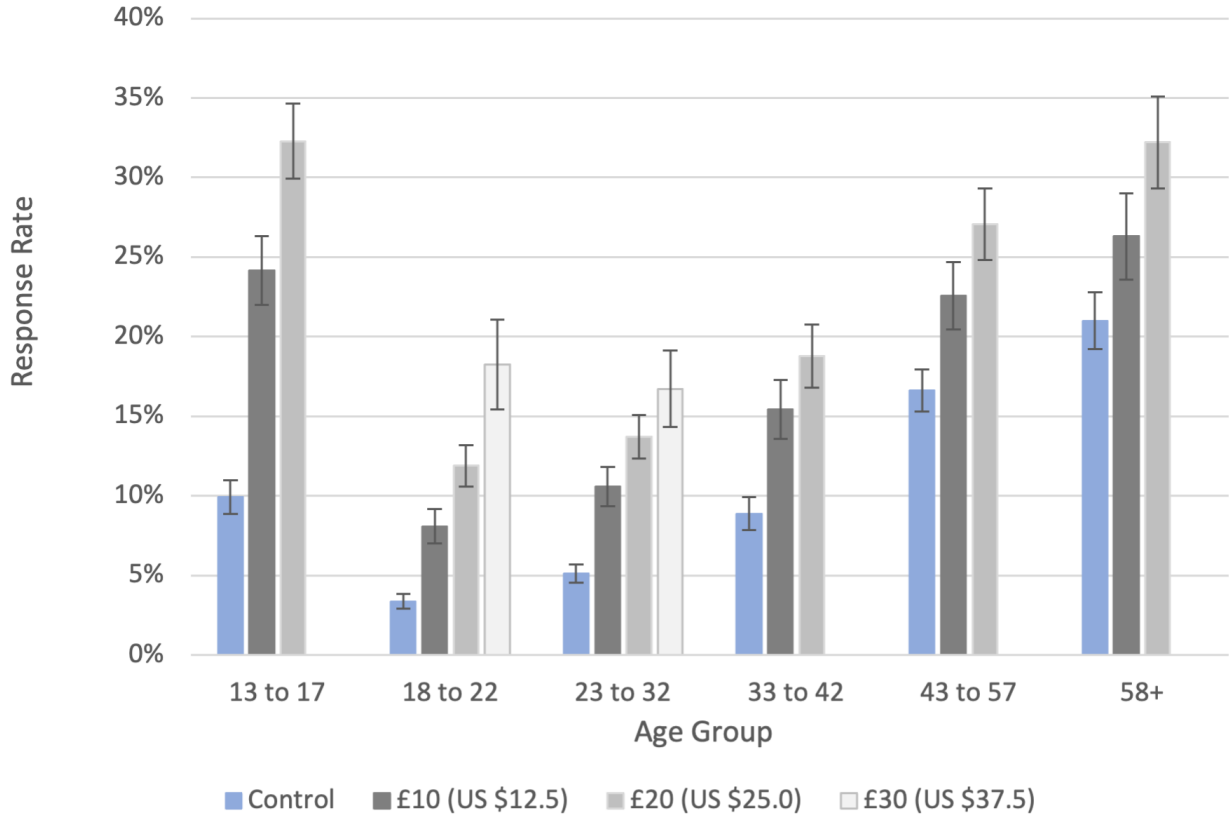
Figure 2. REACT-1 study timeline over 19 rounds of data collection showing response rates, SARS-CoV-2 prevalence (weighted), and timing of experiments to improve response. England, May 1, 2020 to March 31, 2022. REACT-1 Response Rate: number of valid swabs returned/number of invitations. We report weighted SARS-CoV-2 swab-positivity prevalence for individuals aged 5 years and older from all rounds of the REACT-1 study. REACT-1: REal-time Assessment of Community Transmission-1; SARS-CoV-2: Severe Acute Respiratory Syndrome CoronaVirus 2.

Swab Reminder and Tailored Letter or SMS Experiments

Table S2 in Multimedia Appendix 2 summarizes the results of the swab reminder and tailored letter or SMS experiments. Sending an additional reminder (email or SMS) to those who registered resulted in a small increase in response rate: those receiving a third swab reminder (experimental groups B and C) were more likely to return a completed swab compared to those receiving the standard Email-SMS approach (group B vs control: 73% vs 70.2%, percentage difference 2.8% [95% CI 1.9%-3.7%]; group C vs control 73.3% vs 70.2%, percentage difference 3.1% [95% CI 2.2%-4%]).



In round 9 (February 4-23, 2021), both experimental invitation letters A and B had a small but positive impact on response rate in participants aged ≥70 years of 0.9% (95% CI 0.2%-1.5%) and 1.2% (95% CI 0.6%-1.8%) percentage difference, respectively, compared to the standard invitation letter. For participants aged 5 - 12 years, experiment letter C generated a slightly higher response rate compared to the standard letter (16.6% vs 15.9%; percentage difference 0.7% (95% CI 0.1%-1.4%)). In round 11 (April 15 to May 3, 2021) and round 12 (May 20 to June 7, 2021), the experimental invitation reminder letters had a small positive impact on response rate compared to the standard letters: round 11 (new content), 5.6% vs 5.4%, percentage difference 0.2% (95% CI 0%-0.3%); round 12 (shorter), 2.3% vs 1.6%, percentage difference 0.8% (95% CI 0.7%-0.8%). We saw no effect on response rate for any of the other nonmonetary strategies (Table S2 in Multimedia Appendix 2).

Incentives Experiment

The conditional monetary incentives increased the response rate across all age groups but were particularly effective among the lowest responding groups, those aged 13 - 17 years and 18 - 22 years (Figure 3 and Tables S3 and S4 in Multimedia Appendix 2). Table 3 shows the RRR for each incentive level by age, sex at birth, and area deprivation. The higher the monetary value of the incentive, the higher the response rate. For example, in participants aged 18 - 22 years, the response rate in the control group was 3.4% (95% CI 2.9%-3.8%), increasing to 8.1% (95% CI 7.0%-9.2%), 11.9% (95% CI 10.6%-13.2%), and 18.2% (95% CI 15.4%-21.1%) with £10 (US $12.5), £20 (US $25.0), and £30 (US $37.5) incentives, respectively. The largest relative increase was with the £30 (US $37.5) incentive in 18 - to 22-year-olds (RRR 5.4 [95% CI 4.4-6.7]) (Table 3). All incentive conditions led to a greater increase in response rate in younger age groups. The £20 (US $25.0) incentive led to a greater increase in the more deprived areas, RRR 2.7 (95% CI 2.2-3.3) for the most deprived quintile and RRR 1.8 (95% CI 1.6-2.1) for the least deprived.

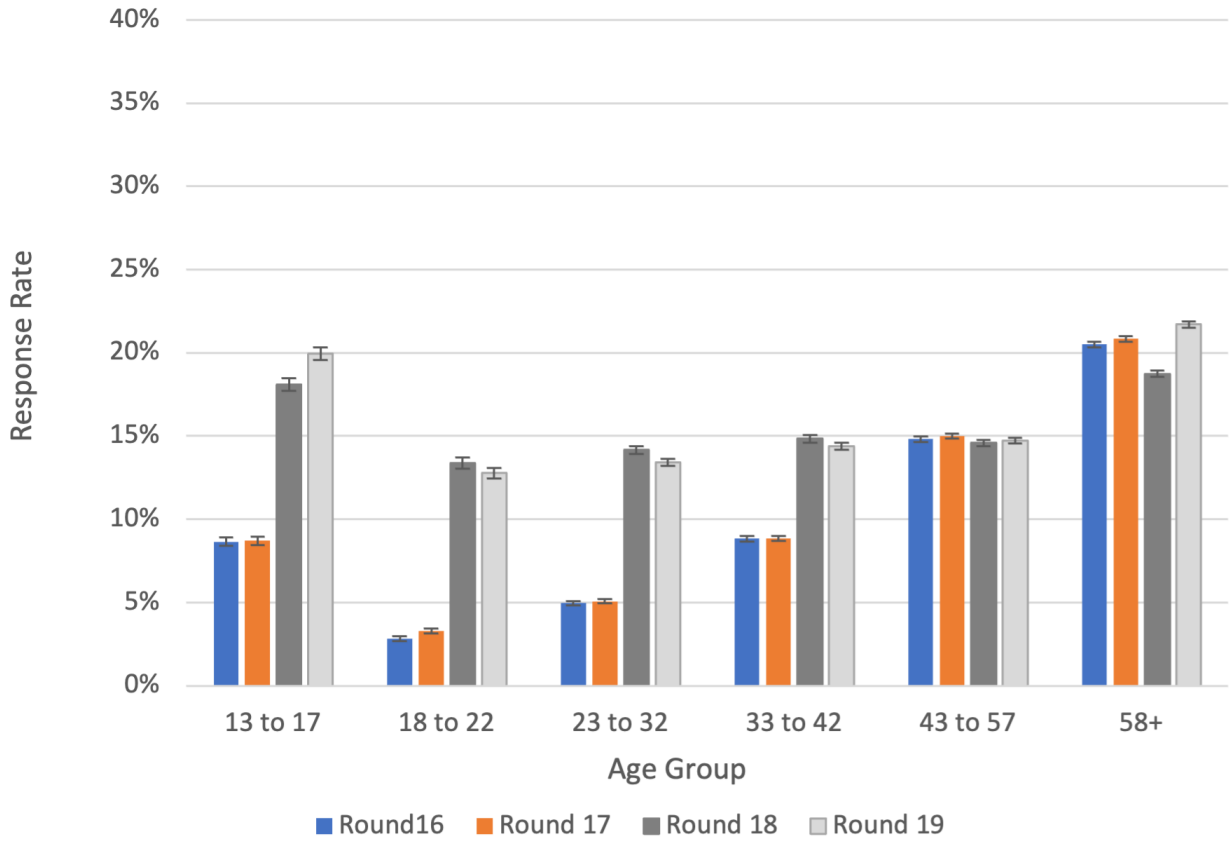
[b]Reference group, ie, the reference group for each row is the no incentive condition. For example, the RRR for female £10 (US $12.5), female £20 (US $25.0), and female £30 (US $37.5) is versus female £0 (US $0.0). *P* value for main effect of incentive on response rate for all row comparisons <.001.

[c]Not applicable

[d]Age-standardized weighting applied to calculate swab response rate with the control group totals used as the sample profiles.



Following the results of the selective use of incentives in round 15, they were introduced in rounds 18 (Feb 8-Mar 1, 2022) and 19 (Mar 8-Mar 31, 2022). For returning their completed test, those aged 13 - 17 and 35 - 44 years were offered a gift voucher worth £10 (US $12.5), while those aged 18 - 34 years were offered a voucher worth £20 (US $25.0). In these final 2 rounds, this had the effect of increasing the swab response rate in these groups and was associated with less variation in response rate by age (Figure 4), suggesting that the selective use of incentives reduced participation bias by age.

Table S5 in Multimedia Appendix 2 shows the effective sample sizes and sample efficiency for each round of REACT-1. The effective sample size measures the size of a (unweighted) simple random sample that would achieve the same precision (standard error) as the design used. The efficiency of a sample is given by the ratio of the effective sample size to the actual sample size. Rounds 18 and 19, where selective use of incentives was used, saw the fourth and second highest (respectively) effective sample sizes of any REACT-1 round, and the highest sample efficiency for any REACT-1 round.

Overall, vaccination rates were higher in REACT-1 participants than in the general population (Tables S6 and S7 in Multimedia Appendix 2). For example, by October 24, 2021, just over 3 quarters of 18 - to 22-year-olds had received at least one vaccine dose nationally (Table S6 in Multimedia Appendix 2) [29], lower than the 84.0% (95% CI 78.1%-88.6%) in the round 15 (October 19-November 5, 2021) control group for that age (Table S7 in Multimedia Appendix 2). With the incentives that proportion declined to 82.1% (95% CI 76.0%-86.8%), 73.9% (95% CI 68.6%- 78.7%), and 75.9% (95% CI 67.9%-82.5%) for £10 (US $12.5), £20 (US $25.0), and £30 (US $37.5), respectively, suggesting that the selective use of incentives reduced participation bias in relation to vaccination status as a proxy for health behaviors.

Figure 4. Swab response rates and 95% CIs for round 16 (November 23 to December 14, 2021), round 17 (January 5-20, 2022), and rounds 18 (February 8 to March 1, 2022) and 19 (March 8-31, 2022) in which incentives were used selectively, England. Note: Incentive amounts used in rounds 18 and 19: £10 (US $12.5) for 13- to 17-year-olds and 35- to 44-year-olds, £20 (US $25.0) for 18- to 34-year-olds, and no incentives for other age groups.

Discussion

Principal Findings

In this large population-based study of the prevalence of SARS-CoV-2 infection in England, we tested several measures to increase response rates and reduce nonresponder bias. We found that changes to the wording of letters, timing, and numbers of reminders made only limited differences to response rates, with a maximum increase in response rate of 3.1 percentage points for additional swab reminders sent to people who had already registered for the study. Sending an additional reminder, regardless of its form (SMS or email), increased response. This is consistent with other studies in the literature [30]. These reminder strategies may have helped slow, but did not halt, the decline in response rates over time observed during REACT-1. Nonetheless, these findings informed the swab reminder strategy and invitation letter wording in later rounds. In contrast, the offer of a financial incentive conditional on the return of a completed swab made a more substantial difference of up to 22.3 percentage points and was particularly effective in those with a lower propensity to respond: younger age groups and those living in more deprived areas. Similarly, incentives increased the return of completed swabs by unvaccinated individuals so that COVID-19 vaccination rates were more in keeping with those in the general population at the time. Thus, the selective use of incentives may reduce nonresponder bias in relation to factors of interest in population health research beyond sociodemographic characteristics.

The selective use of incentives was subsequently adopted from round 18, making the achieved sample more representative by age, with a reduction in age-based variation in response rates. Previous research suggests that ethnic minorities [31], individuals living in more deprived areas [32], those in urban areas [33], and the youngest and oldest age groups [34,35] are the least likely to respond in general population surveys. Using incentives selectively allowed us, at modest cost, to increase recruitment among such groups and hence increase the effective sample size; thus, in round 18, the effective sample size was over 10,000 greater compared to round 17, even though we received circa 7000 fewer swabs. We were able to reduce the number of invitations sent out while achieving a similar number of completed swabs returned as in earlier rounds when response rates were higher.

Using incentives selectively has been tried in UK social surveys previously and is common practice in the United States, where studies show they are cost-effective, improve response, and reduce bias [11,13,23,36]. From an ethical perspective, in the selective use of (versus universal) incentives, it was important to consider not only issues of equity but also cost and the public interest in continuing to obtain high-quality data, covering all sectors of society, to monitor the spread of a serious disease. This needs to be balanced against the possible disappointment of some participants who learn others are being offered a (larger)

XSL•FO
RenderX

incentive. These considerations might apply to many population-based surveys. We accept that the argument for using incentives selectively may have been more persuasive in the context of REACT-1, a study to measure the spread of SARS-CoV-2 during the pandemic, the policy responses to which had far-reaching consequences for the way of life of every person in England.

Both unconditional and conditional financial incentives have been shown to significantly increase response rates to both postal and web-based surveys [37,38]. Although unconditional incentives appear to have the largest effect, the conditional approach is more cost-effective [37,38]. Unconditional incentives have been used in social surveys in the United Kingdom, and in experiments in how to increase response rates [39,40]. Unconditional incentives were not an option for REACT-1 due to the constraints of the survey budget.

Limitations

In terms of limitations, it was not possible to ascertain the extent to which noncontact (ie, the intended recipient did not receive the invitation letter) accounted for nonresponse. Such situational factors, for example, not informing their general practitioner of a change in address or having moved with no forwarding address (shown to be greater for young adults and lower socioeconomic groups) [32] will not be affected by the experimental conditions; therefore, our estimates of effect are likely conservative, as invitations sent out do not necessarily mean that invitations were received. In addition, the unique circumstances of carrying out such assessments of response rates during a global pandemic may not "read across" to other less pressing issues.

Conclusions

We achieved small improvements in response rates by varying the number, order, and content of invitations and reminders but much larger effects were seen through the use of monetary incentives. Lessons learnt from the REACT-1 study may help inform the design and implementation of future population-based surveys where the intent is to obtain as representative a sample as possible and to reduce nonresponse bias at reasonable cost. The results suggest selectively using incentives with younger and more deprived individuals may be justifiable to achieve these ends.

Abstract

Background: Social network data are essential and informative for public health research and implementation as they provide details on individuals and their social context. For example, health information and behaviors, such as HIV-related prevention and care, may disseminate within a network or across society. By harmonizing egocentric and digital networks, researchers may construct a sociocentric-like "fuzzy" network based on a subgroup of the population.

Objective: We aimed to generate a more complete sociocentric-like "fuzzy" network by harmonizing alternative sources of egocentric and digital network data to examine relationships between participants in the Neighborhoods and Networks (N2) cohort study. Further, we examined network peer effects of the status-neutral HIV care continuum cascade.

Methods: Data were collected from January 2018 to December 2019 in Chicago, Illinois, United States, from a community health center and via peer referral sampling as part of the N2 cohort study, comprised of Black sexually minoritized men and gender expansive populations. Participants provided sociodemographics, social networks, sexual networks, mobile phone contacts, and Facebook friends list data. Lab-based information about the HIV care continuum cascade was also collected. We used an experimental approach to develop and test a fuzzy matching algorithm to construct a more complete network across social, sexual, phone, and Facebook networks using R and Excel. We calculated social network centrality measures for each of these networks and then described the HIV care continuum within the context of each network. We then used Spearman correlation and a network autocorrelation model to examine social network peer effects with HIV status and care engagement.

Results: A total of 412 participants resulted in 2054 network connections (ties) across the confidant and sexual partner social networks (participants=387; ties=445), peer referral network (participants=412; ties=362), phone contacts (participants=273;

XSL•FO
RenderX

ties=362), and Facebook network (participants=144; ties=1383), reaching the entire study sample in one fully connected "fuzzy" network. Results from the individual networks' autocorrelation model suggest there are no peer effects on status-neutral HIV care engagement. Results from the final fuzzy-like sociocentric network autocorrelation model, adjusted for HIV serostatus, suggest that participants who were proximate to network members engaged in HIV care were significantly more likely to be engaged in care (ρ=0.128, SE 0.064; *P*=.045).

Conclusions: Using alternative sources of network data allowed us to fuzzy match a more complete network: fuzzy matching may identify hidden ties among participants that were missed by examining alternative sources of network data separately. Although sociocentric studies require significant resources to implement, more complete sociocentric-like networks may be generated using a fuzzy match approach that leverages egocentric, peer referral, and digital networks. Enriching offline networks with digital network data may provide insights into characteristics and norms that egocentric approaches may not be able to capture.

Introduction

Social epidemiology is the "branch of epidemiology concerned with the way that social structures, institutions, and relationships influence health." [1] Within social epidemiology, social network models focus on how social networks can influence attitudes and knowledge surrounding health as they are a powerful force for influencing health behaviors [2,3]. As health information and behaviors can disseminate within a network, or across society [4], network science, a set of theories and methods for examining social relationships, has garnered interest among researchers, including social scientists and public health researchers, who are seeking to describe social phenomena [2,5-8]. Within network science, there is a fundamental dichotomy between sociocentric and egocentric network characterization [8]. Sociocentric study designs collect information about a "complete" network among members of a population or cohort of interest, whereas egocentric studies focus on the network of contacts that immediately surround a focal individual (ego) and often collect information from subgroups sampled from a larger population [1,9].

Sociocentric approaches are one of many frameworks for examining social network data; however, they are often perceived by researchers as the "gold standard" of network science in that they presumably include all nodes and ties within a network. The complexity and resource demands of collecting such data have led social scientists to use egocentric study designs, which are considered more pragmatic in that their elicitation can be more easily worked into traditional survey data collection. Despite their pragmatism, however, egocentric networks are limited as they intentionally ignore potential connections between ego networks and they tend to represent only a subsample of an existing network [5]. Given these tensions between the resource demands of sociocentric network data collection and the limits of egocentric network data collection, there is a need to find alternative sources of network data that could be collected from individuals without knowledge of who else is in the network and could be used to locate "hidden" connections among members of a focal population.

Individuals are often thought to have upwards of 1500 connections; crafting an egocentric survey design to capture all personal networks or a sociocentric approach to include all individuals bound within a network would be burdensome and analytically complex, although not impossible [10]. One way of bolstering traditional egocentric research and circumventing the steep demands of sociocentric designs is by incorporating digital epidemiology, which includes digital methods and data. Digital data includes mobile phone network data, data derived from the internet, and social media network data [11]. In the United States, cell phone and internet use are ubiquitous, with 97% and 95% of US adults owning a cell phone [12] and using the internet [13], respectively. Further, the majority of US adults frequent social networking websites such as YouTube (83%) and Facebook (68%) [14].

By harmonizing egocentric and digital networks, researchers may construct a "fuzzy" network based on a subgroup of the population. Although this more complete network would not be a "pure" sociocentric network as described by Laumann's boundary specification [10,15], it could offer hidden ties that a purely egocentric network could not unveil. Deterministic linkage, a technique used to link records that may be less than a 100% match, could be used to triangulate egocentric data from multiple sources (eg, digital and phone networks) into a fuzzy network [16]. This matching compares all records of one dataset to another and creates matching pairs using prespecified linkage specifications such as phoenetic name and age, which are then manually validated to ensure a true match. Social network researchers could use deterministic linkage algorithms to explore if a study participant's nominated tie (ie, alter) could be another participant in the study (ie, ego) [16]. Including additional types of networks such as mobile phonebook networks and online social networks could further aid the construction of a more complete network of a subgroup of a population with variable tie typologies that together may provide a more expansive understanding of social influence.

XSL•FO
RenderX

Using fuzzy matching and digital networks to generate connections across egocentric networks could provide insights into "hidden" relationships and social influence dynamics that are commonly excluded due to the limitations of egocentric approaches. Thus, our aim was to construct a fuzzy sociocentric-like network using egocentric confidant and sexual networks, peer referral ties, and digital networks (mobile phone and Facebook contacts), then to identify correlations between each of these networks and the fuzzy sociocentric-like network and status-neutral HIV care engagement among a cohort of Black sexually minoritized and gender expansive people (SGM) in Chicago [17]. This group is a relatively underreached group that continues to experience HIV-related health disparities at a disproportionate rate; approximately 1 in 3 Black sexually minoritized men are estimated to be diagnosed with HIV by age 50 if current rates persist [18,19]. As pre-exposure prophylaxis (PrEP) can reduce HIV acquisition by up to 99% [4-10], and antiretroviral treatment (ART) effectively eliminates forward transmission of HIV [11,12], together they can effectively end the HIV epidemic among Black SGM. However, Black SGM are not being reached by or using PrEP and ART at optimal rates to curb this HIV epidemic. Black SGM experience poor HIV-related outcomes in the United States due to historical and structural barriers and intersectional discrimination [20-23], which have manifested as reduced access to PrEP and ART. Although supportive social relationships are shown to promote PrEP and ART uptake [24], there is scant research that examines personal networks to identify the role of social networks on status-neutral HIV outcomes. A status-neutral approach proposes the same engagement approach for HIV prevention and care, regardless of HIV serostatus, and focuses instead on the common final state of engagement in HIV prevention (ie, PrEP) or care (ie, ART) activities [25].

Previous studies have suggested that social networks may be leveraged to surmount health disparities [26-31]; thus, this experimental approach is novel and important in reaching health equity for this marginalized group. Given that the data in the present study were collected 6 years ago, harmonization provides an opportunity to enhance their relevance and applicability by integrating them into a fuzzy-like sociocentric network. At the time that these data were collected, they were cutting edge, and despite 6 years passing since the collection of this data, HIV-related disparities in Chicago have exhibited stability over time, suggesting that the information derived from this dataset may still be applicable. To our knowledge, this robust dataset is the most updated and comprehensive social network dataset of Black SGM available since the uConnect cohort in Chicago [28], and it presents a unique opportunity for secondary analyses on a persistent health disparity (HIV) that disproportionately impacts Black SGM. For example, although HIV diagnoses in Chicago decreased by 7.7% from 2018 to 2022, Black non-Hispanic people (46.7% vs 47.1%) and men who have sex with men (60% vs 60.7%) continued to disproportionately comprise the same percentage of new HIV diagnoses while transgender women experienced an increase in new HIV diagnoses by 12.2%. This necessitates a better understanding of how networks may play a role in HIV prevention and care. Thus, the aim of this paper was to generate a more complete sociocentric-like "fuzzy" network by harmonizing alternative sources of egocentric and digital network data to examine relationships between participants in the Neighborhoods and Networks (N2) cohort study. Further, we aimed to examine the network peer effects of the status-neutral HIV care continuum cascade using our sociocentric-like "fuzzy" network.

Methods

Study Sample and Recruitment

Data were collected at baseline from January 2018 to December 2019 from the Chicago site of the multisite N2 cohort study, a prospective longitudinal study. Participants were recruited from a community health clinic and via peer referral in the South Side of Chicago, Illinois, United States. The community health clinic provides next-generation testing and notification, integrated biobehavioral HIV prevention, and community mobilization with the aim of eliminating new HIV transmission in the United States by 2041. The recruitment strategy was designed to leverage clients of the clinic and participants from existing research projects. We used a probabilistic variant of peer referral sampling that allowed participants to refer up to 6 members of their social networks. Participant inclusion criteria were the following: (1) Black or African American racial identity, (2) 16 years old or older, (3) assignment of male sex at birth, (4) residency in the Chicago Metropolitan Statistical Area (MSA), (5) having at least one sexual encounter with a cisgender man or transgender woman in the past year, (6) willingness to wear a GPS device, and (7) intention to remain in the Chicago MSA during the course of the study (~2 years). Additional information about the parent N2 study can be found elsewhere [32]. Given that the data in this study were collected 6 years ago, this analysis provides an opportunity to enhance their relevance by integrating them into a fuzzy-like sociocentric network. This paper was prepared using the Strengthening the Report of Observational Studies in Epidemiology (STROBE) guidelines [33].

Data Collection

A study team member trained in quantitative and network data collection obtained written informed consent from participants and then collected data using interviewer-administered computer-assisted assessments in a private room at the study site. We collected the following data from each participant: sociodemographics, confidant and sexual partner information, mobile phone contact lists, and Facebook friends lists.

Sociodemographic data about the participant and each confidant and sexual partner included first name, last name, gender identity (cisgender man, cisgender woman, transgender or another gender expansive identity), race (Black or not Black), Latine ethnicity (Latine, not Latine), and age (in years). Sociodemographic data were collected using a network inventory using Qualtrics. We downloaded participants' phone contact information and Facebook network information. We attempted the download of phone contacts and Facebook friends one time, and if the download was not successful then we considered that participants' data to be missing at random.

Analysis

Overview

We developed and tested a fuzzy matching algorithm (ie, deterministic linking algorithm) with a set of identifiers that provided a match result across confidant, sexual, phone contact, and Facebook networks. We used R (version 12.1.402; R Foundation for Statistical Computing [34]) and Microsoft Excel (Microsoft Corp) for data analysis and matching. The boundaries of the final complete sociocentric-like fuzzy network were only those participants enrolled in the N2 cohort study and did not include those individuals that participants may have named as being in their social networks. We describe the following characteristics for each of the networks: connected components (number of unique networks within the larger network), network density (proportion of nodes that are connected relative to all potential connections), degree (average number of nodes that a node reports knowing added to average number of nodes who also know the node), diameter (maximum distance between the furthest pair of nodes), radius (maximum shortest distance between pairs of nodes), betweenness centrality (how often a node acts as a bridge along the shortest path between two nodes), and characteristic path length (average shortest distance for all possible pairs of network nodes). We conducted an ANOVA to assess the differences in mean betweenness centrality based on HIV care cascade outcome (ie, not using PrEP, using PrEP, not virally suppressed, virally suppressed).

Matching Confidants With Sexual Partners

To identify confidants who were also sexual partners, we collected these data separately. Thus, participants named up to 5 people they considered to be their closest social network members using the prompt, "Who is the person you most talk to about things that are important to you?" Participants also named up to 5 people with whom they had sex with in the past 6 months. Participants indicated whether they had sex with a confidant and if a sexual partner was also a confidant. Egocentric network members included those who were confidants or sexual partners.

Matching Social Network Members With Participants Enrolled in N2

We adapted a previously used deterministic linkage algorithm [16]. We first phoneticized first and last names to standardize names in the instance of incorrect or multiple spellings of names. Thus, each name was given a unique phonetic code. We then used a *for loop* in R to match each social network member with each participant (dyad) based on the following selection criteria: phoneticized first name (both individuals have the same phoneticized first name), phoneticized last name (both individuals have the same phoneticized last name), gender identity (both individuals are homophilous on gender), race (both individuals within the pair being matched are homophilous on race), Latine ethnicity (both individuals within the pair being matched are homophilous on Latine ethnicity), and age (both individuals within the pair being matched are within 5 years of each other, $age_i \pm 5$ years to age_j).

Following a similar algorithm as in previous work, we created an autoscoring algorithm ranking the certainty of each dyad being compared [35]. We then manually reviewed each potential match of dyads to identify whether social network members named in the inventory could be matched to participants enrolled in the study. We decided that if dyads fit the following criteria, they were the same person: both members of the potential dyadic match (1) had the same phoneticized first name, phoneticized last name, or phoneticized first and last name; (2) were either both cisgender women, were both cisgender men, were both transgender-identified, or one member of the potential match dyad was transgender-identified and another member of the potential match dyad was a cisgender man; (3) were both Black or were both not Black; (4) and were within 5 years of age. We decided to match individuals who were indicated as being transgender with those who were indicated as being a cisgender man because we recognized that not all individuals may be "out" with their social networks and because gender can be fluid, and great strides in gender identity can be made in a short time. In addition, we considered a match on Latine identity to contribute toward the manual match algorithm; however, if both members of a dyad were not Latine, this did not negate the potential match.

Identifying Ties Between Participants Using Peer Referral Ties

We identified ties between participants using the peer referral ties during enrollment. Thus, we could see which participants were referred by an existing participant in the study.

Matching Participants Based on Mobile Phone Contact Data

We identified matches between participants' phone contact data and other participants in the study based on the phone number provided at baseline data collection.

Matching Participants Based on Facebook Friends Lists

Facebook data were cleaned using Python (including the packages *beautifulsoup4.9.3*, *soupsieve2.2.1*, and *pandas1.2.4*) to parse through the files each participant's information was stored in. The only available information for a Facebook friend was their display name—there was no additional identifying information for friends lists such as an identifier or URL. For this reason, we assumed any common Facebook friend was one held in common between participants, rather than assuming that 2 different people with the same name had friendships among the study population.

Network Peer Effects on HIV Engagement in Care Analysis

We investigated if there was an association between individuals' HIV-related care and their network members' engagement in status-neutral HIV-related care using a multistep process. We first identified the participant's HIV serostatus (ie, 0=not living with HIV; 1=living with HIV) and their network members' mean serostatus (ie, proportion of members living with HIV). We then identified the participant's engagement in status-neutral HIV-related care (ie, 0=not engaged in care or not using ART/PrEP; 1=engaged in care or virally suppressed or using PrEP) and their network members' mean engagement. For both of these outcomes (ie, HIV serostatus and engagement in

XSL•FO
RenderX

status-neutral HIV-related care), we conducted the following steps:

- Step 1: Spearman correlation to examine binary correlations between an individual's outcome and the mean of their network's outcome.
- Step 2: Unadjusted linear regression to examine associations between an individual's outcome and the mean of their network's outcome.
- Step 3: Quadratic Assignment Procedure (QAP) correlation to examine the relationship between an individual's outcome and the mean of their network's outcome. This allowed for the identification of the product-moment correlation between the adjacency matrices of graphs for an individual's outcome and the mean of their network's outcome [36]. We used the R environment packages *igraph* [37] and *statnet* [38] to use the *gcor*() function for analysis.
- Step 4a: Linear Network Autocorrelation Model (LNAM) to examine the relationship between an individual's outcome and the mean of their network's outcome [39-41]. This model "assumes that social influence occurs when individuals are exposed to a behavior by their network contacts." [42] We used the R environment package *sna* and the *lnam*() function [43].
- Step 4b: LNAM to identify the social cross-sectional peer effects of a participant's engagement in status-neutral HIV-related care within each of the networks, adjusting for their social network members' HIV serostatus. We used the R environment package *sna* and the *lnam*() function [43].

The network autocorrelation model assumes continuous dependent variables; however, our outcome variables are binary. Because there is no established statistical model that can account for the network autocorrelation for the Bernoulli distribution of the error term, we used the LNAM. This model assumes a normal distribution of error terms with a null value and variance in the identity matrix. Due to this limitation, we added the supplemental analysis of conducting logistic regression as we could not adjust for the limitation of not accounting for potential network autocorrelation. Within the network autocorrelation model [39,44-46], we specified the network effects model, that is defined in the following formula:

$$y=\rho Wy+X\beta+\varepsilon,\varepsilon\sim N(0,\sigma 2I)$$

in which y is a vector for values of our outcome variable (ie, engagement in status-neutral HIV-related care), and X is a matrix of values for the N actors. The β term is a vector of regression coefficients, ρ is a scalar estimate of the autocorrelation parameter, and W is a matrix of weights, which is the allocation of peer effects among network members (eg, engagement in HIV-related care). We also fit the multiple network autocorrelation model [40],

We also fit the multiple network autocorrelation model [40]

which was adjusted to include HIV serostatus (Xβ), as our unadjusted model does not include HIV serostatus Xβ.

Network Visualization

We used Cytoscape to visualize participants' peer referral ties; sexual, social, phone contact, and Facebook networks; and the final fuzzy match networks [47].

Ethical Considerations

The N2 cohort study protocol for the Chicago site was approved by the Biological Sciences Division/University of Chicago Medical Center Institutional Review Board (IRB16-1419) and Columbia University (AAAS7654). Written informed consent was obtained from the study participants. Participants were compensated US $150 for their time and US $20 for each person they referred to the study. A Certificate of Confidentiality from the National Institute of Health was obtained to protect study participants' privacy.

Results

Overview

A total of 412 Black SGM enrolled in the N2 cohort study. Of participants, 387 provided confidant and sexual network data, 273 provided mobile phone contact data, and 144 provided Facebook data. Of these networks, the Facebook network had the highest number of undirected ties (n=1383; undirected means that if one person in the network reported knowing the other, then they were considered to know each other, regardless of the direction of the tie), the fewest connected components, the highest density (13.4% of all potential ties), highest degree (n=19.21), and lowest network diameter (n=5), network radius (n=3), and average characteristic path length (length=2.28). The fuzzy match network consisted of 400 unique nodes and 12 isolates. There was a total of 2054 undirected edges in one centralized component after removing isolates. Its density was 0.026, with an average degree of 10.27. The network diameter was 9, the radius was 5, and the characteristic path length was 3.49. An overview of each of the networks, including nodes, undirected ties, and other network characteristics, can be found in Table 1.

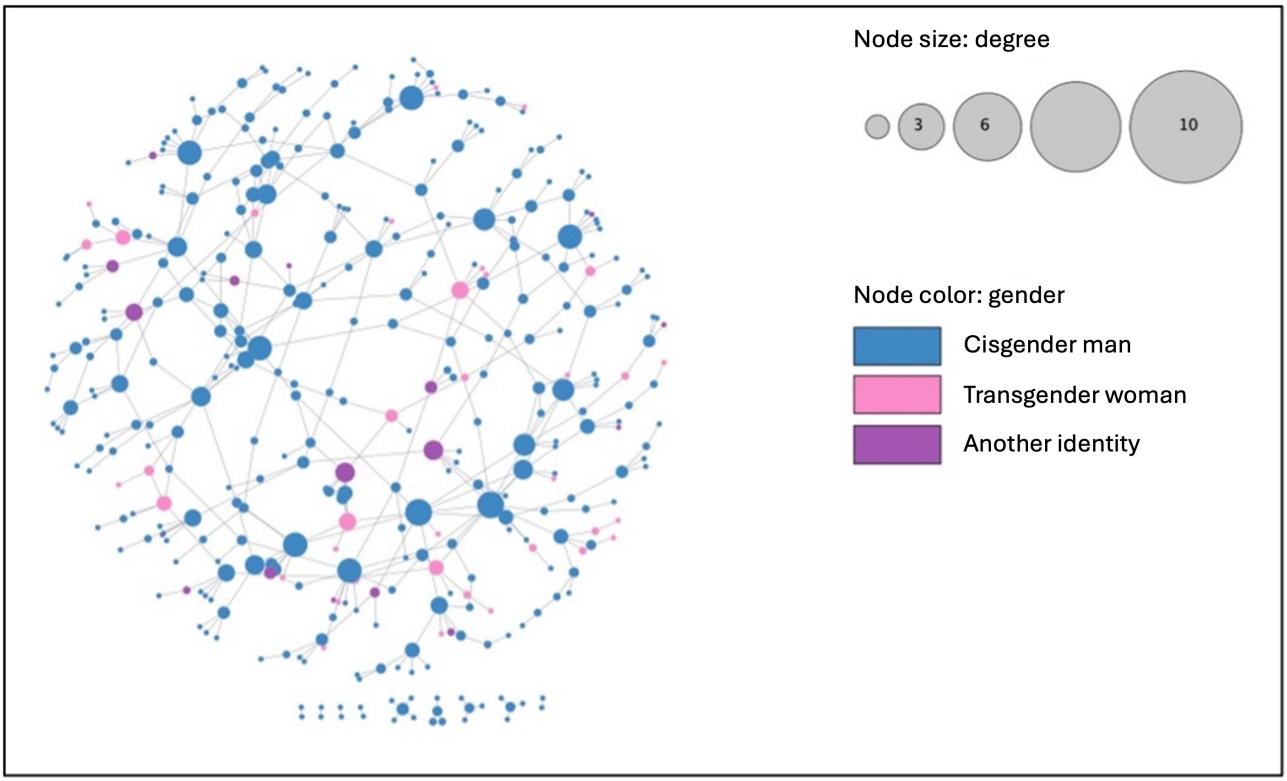
Matching Social Confidants With Sexual Partners



Of 412 participants, 387 completed the social network inventory. Participants named up to 5 social network alters (n=1036; mean 2.73, SD 1.32) and 5 sexual partner alters (n=1017; mean 2.57, SD 1.58). We identified an overlap of 136 confidants who were also sexual partners, for a total of 1917 unique alters.

Matching Social Network Members With Participants Enrolled in N2

There were a total of 1917 unique alters. When considering that 412 participants were enrolled in the N2 study, this means that there was a potential of 169,332 directional matches our analyses could identify (ie, A knowing B is treated as separate from B knowing A; between 412 participants, there are 84,666 potentially unique ties as 412 × 411 = 169,332). We found that there were 8020 potential "fuzzy" matches. Upon manual validation, we found that there were 445 undirected ties between the 379 nodes in this network. There were 10 connected components, and the network density was 0.007, indicating it was a sparse network. Average degree was 2.42 and betweenness centrality was 0.028. The network diameter was 19 steps, the radius was 11 steps, and the characteristic path length was 7.77 steps. The egocentric network can be observed in Figure 1. There was no statistical association between betweenness centrality and the HIV care cascade (F_3=0.242; P=.87).

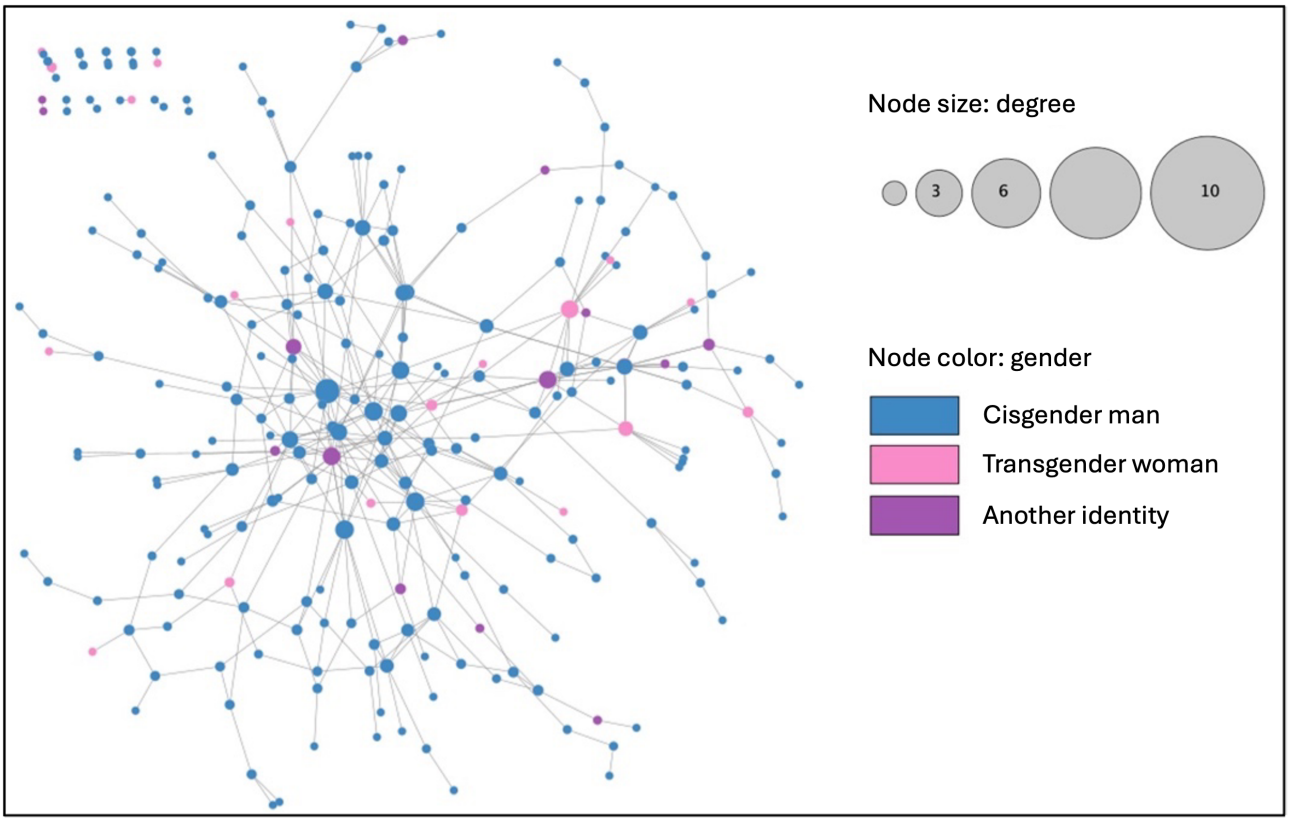
Identifying Ties Between Participants Using the Peer Referral Sampling Chain

We identified 363 unique ties between 344 participants from the peer referral ties. There were 19 connected components (ie, 19 seeds), and the network density was 0.012. The average degree was 1.99 and betweenness centrality was 0.080. The network diameter was 18 steps, the radius was 9 steps, and the characteristic path length was 7.64 steps. The peer referral tie network is visualized in Figure 2 using a *yFiles* hierarchic layout to display the chain [48]. There was no statistical association between betweenness centrality and the HIV care cascade (F_3=2.00; P=.11).

Figure 2. Peer referral tie network of Chicago Black sexually minoritized and gender expansive people from the Neighborhoods and Networks (N2) cohort study (n=344), yFiles hierarchic layout.

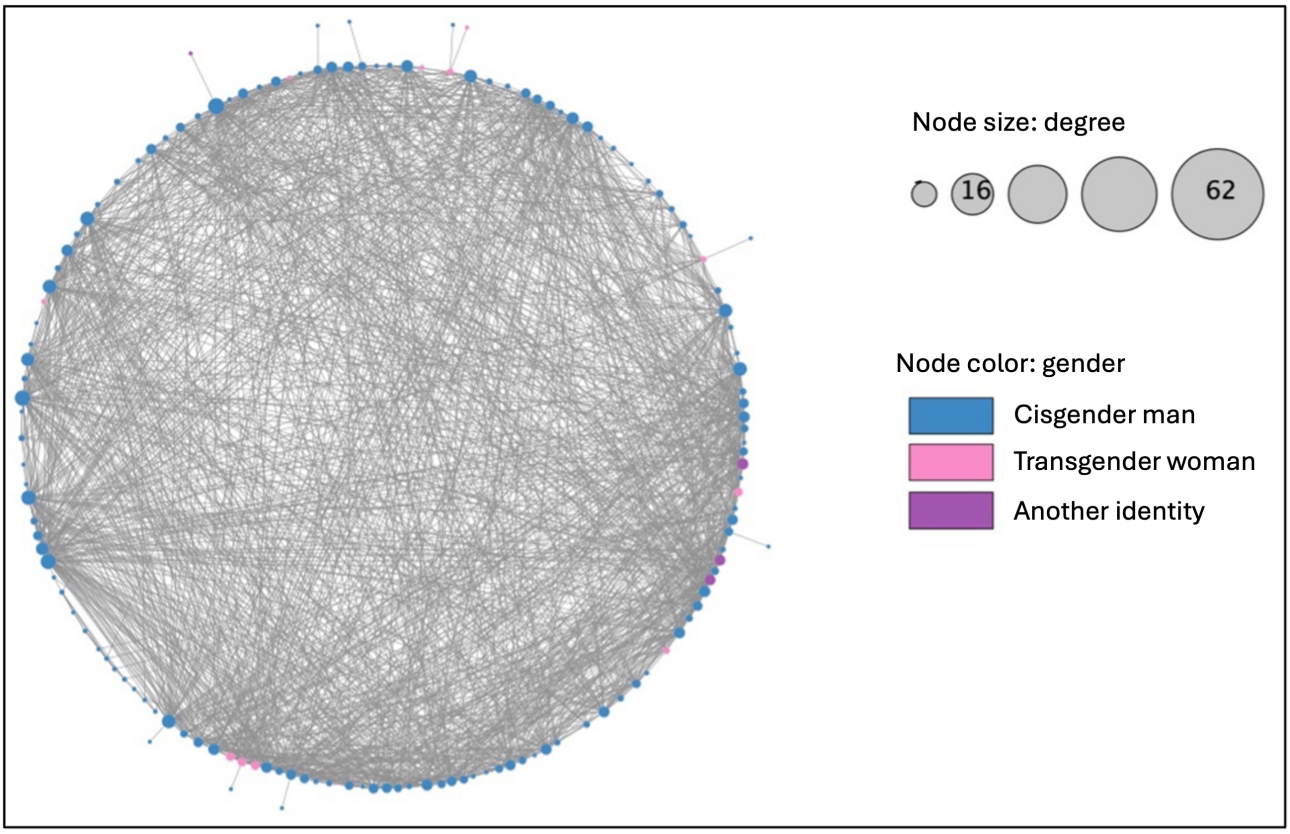


Matching Participants Based on Mobile Phone Contact Data

Of the participants, 294 provided consent to share their mobile phone contact data. There were 95,831 phone number entries, of which 51,671 were valid phone numbers (ie, in a 10-digit format). We found that there were 416 unique ties among 270 participants from the mobile phone contact data. Figure 3 displays a visualization of the mobile phone contact network. The average degree was 3.18 and betweenness centrality was 0.03. There was no statistical association between betweenness centrality and the HIV care cascade (F_3=1.03; P=.39).

XSL•FO
RenderX

Figure 3. Phone contact network of Chicago Black sexually minoritized and gender expansive people from the Neighborhoods and Networks (N2) cohort study (n=245), edge-weighted spring embedded layout by edge-betweenness.



Matching Participants Based on Facebook Data

We downloaded the Facebook friends list of 144 participants. Due to refusal and interruptions in the download process, we were not able to download data for 268 participants. There were a total of 18,255 Facebook friendship ties, posts, and comments. Among these, we identified 1383 undirected ties between N2 participants. There was one connected component with a density of 0.134. The average degree was 19.21 and betweenness centrality was 0.009. The network diameter was 5 steps, the radius was 3 steps, and the characteristics path length was 2.28 steps. The Facebook-only network is visualized in Figure 4. There was no statistical association between betweenness centrality and the HIV care cascade (F_3=1.194; P=.31).

Fuzzy Match Network Description

Once all networks were combined, we identified 400 participants who were included in the fuzzy-like sociocentric network. There were 2054 unique ties among participants. The density of our fuzzy match network was 0.025, and there was one connected component. The average degree was 10.21 and betweenness centrality was 0.006. The network diameter was 9 steps, the radius was 5 steps, and the characteristic path length was 3.49 steps. The fuzzy match sociocentric network is visualized in Figure 5. There was a statistically significant difference between betweenness centrality and the HIV care cascade (F_3=5.837; P<.001). We conducted a post hoc comparison using the Tukey Honestly Significant Difference test and found that the not virally suppressed group had higher betweenness centrality measures relative to the group not using PrEP (Diff=0.006, 95% CI 0.002 to 0.009; P<.05); the PrEP-using group had lower betweenness centrality measures relative to the not virally suppressed group (Diff=−0.005, 95% CI −0.009 to −0.007; P<.05); and the virally suppressed group had lower betweenness centrality relative to the not virally suppressed group (Diff=−0.005, 95% CI −0.009 to –0.001; P<.01). The other 3 conditions were not statistically significant (P>.05).

Findings of the Correlation, Quadratic Assignment Procedure Correlation, Regression Models, and Network Autocorrelation Models

We found a low correlation and QAP correlation between HIV status and care engagement between participants and their network members (Table 2). Only the regression model for engagement in care was found to be statistically significant; participants had a 2.07 higher odds ratio (95% CI 1.09 - 3.97; *P*=.03) of engagement in care with higher network-level engagement in care. None of the unadjusted linear network autocorrelation models were significant when examining HIV status and care engagement for each of the different networks (Table 2, models a-e). For the linear network autocorrelation models adjusted for HIV status (Table 2, models f-j), HIV status had a significant negative association with care engagement for all network models: confidant and sexual (β=−0.268, SE 0.048; *P*<.001), peer referral (β=−0.281, SE 0.049; *P*<.001), phone contact–only (β=−0.231, SE 0.056; *P*<.001), Facebook-only (β=−0.252, SE 0.079; *P*=.001), and the combined sociocentric network (β=−0.256, SE 0.047; *P*<.001). Results from the linear network autocorrelation model for the combined sociocentric network adjusted for HIV status showed that care engagement had network clustering. Thus, participants who were proximate to network members who were engaged in care were significantly more likely to be engaged in care (ρ=0.128, SE 0.064; *P*=.045).

Discussion

Principal Findings

Sociocentric network study designs are resource heavy to conduct and primary data collection is difficult. To address this gap, we aimed to develop and test a matching algorithm consisting of multiple types of nonsociocentric networks. We generated a fuzzy matched sociocentric-like network based on the egocentric social networks, egocentric sexual networks, peer referral ties, egocentric mobile phone contact data, and Facebook network present within the N2 cohort study of Black SGM. In addition to analyzing a fuzzy match algorithm, we found that sociocentric networks and digital networks have high utility in unveiling hidden connections. More specifically, we found that in the "fuzzy" network, bridging (ie, betweenness centrality) differed based on the HIV care cascade and engagement in HIV-related care had an autocorrelative effect; these findings were not identified in the partial networks. To our knowledge, this is one of the first studies to harmonize multiple networks to construct a larger fuzzy network, to examine the peer effects of network-level, status-neutral HIV care at the individual level, and to prioritize Black SGM social networks. Our methods and findings are novel and contribute toward the fields of social and digital epidemiology by introducing a fuzzy matching algorithm that can identify hidden ties among participants within different types of networks to better understand the larger sociocentric network.

The initial peer referral chain identified 362 existing ties within our network; however, by including alternative types of networks such as social networks and sexual partner networks, phone contact data, and Facebook friends lists, we were able to identify a total of 2054 undirected ties among 400 participants. The egocentric network quintupled the network degree and doubled density while introducing an additional >50 participants into the network. Whereas the peer referral network had 19 connected components, the final and more complete network brought together these networks into one connected component. In addition, the network diameter decreased from 18 to 9. This means that, while the most distant pairs of nodes required 18 steps at maximum to reach each other, this number halved to 9 steps in the fuzzy match network. In addition, the network radius decreased from 9 to 5, meaning it did not take more than 5 steps for anyone in the network to reach someone else. The characteristic path length, or what Milgram (1967) [49] referred to as "degrees of separation," also halved from 7.64 to 3.49 steps from the peer referral ties to the fuzzy network. Although the Chicago MSA is indeed a small world, and our population may be too homophilous for a pair of individuals to be selected at random, our findings support the idea of the "small world problem" or the probability that 2 random people selected from a larger population will know each other. Our findings support

XSL•FO
RenderX

the need for study designs using peer referral to include additional estimators to account for the interdependence of participants, as these networks may not be as apparent. Further, our study supports the utility of using a fuzzy match algorithm to construct a larger sociocentric network based on other networks, which scientists may collect at a lower burden. Our findings must be interpreted with caution as the network autocorrelation parameter was small. In real-world settings, this may suggest that there is weak social influence within the fuzzy-like network, networks are diverse or mixed and have low homophily, or individual variability may be more important than network influence.

The digital data networks identified the most ties and had superior network density, degree, diameter, radius, and characteristic path length relative to the egocentric confidant and sexual networks and the peer referral network. Interestingly, the characteristic path length of the Facebook network, 2.28 steps, is lower than reported in another study, which found pairs of random people on Facebook to have a characteristic path length of 4 steps [50]. Although our study included mobile phone contact networks and Facebook networks, future studies may have better success in identifying networks using other types of digital networks based on their priority population. For example, studies prioritizing people aged 18 - 29 years may have success using Instagram as 78% of people in the 18 - 29 year age group use Instagram, which is higher than other age groups (59% of people aged 30 - 49 years, 35% of people aged 50 - 64 years, and 15% of people aged ≥65 years) [14]. If studies hope to reach Black populations, TikTok or Instagram may be the best social networking sites as 49% of US Black adults report using TikTok (relative to 28% of White adults, 49% of Hispanic adults, and 29% of Asian adults) and 46% report using Instagram (relative to 43% of White adults, 58% of Hispanic adults, and 57% of Asian adults). In addition, after the COVID-19 pandemic stay-at-home orders in the United States, social media platforms became an online "home" for many SGM [51,52]; however, further study on social media use by young (ie, 16 - 34 years old) Black SGM is warranted.

Our findings suggest that, while we did not identify differences in betweenness centrality based on a participant's HIV care cascade in the partial networks, we did so in the fuzzy-like network. More specifically, we found that participants who were virally suppressed had lower betweenness centrality measures relative to individuals in the other HIV care cascades (ie, people who did not use PrEP, people who used PrEP, and people who were not virally suppressed). This means that, relative to individuals who are HIV-negative or not virally suppressed, participants who are virally suppressed appear to be a bridge in the network less often. This could be due to their lower likelihood to engage in behaviors with enhanced vulnerability to HIV such as condomless sex [53], which could also reduce their network connections. People who are virally suppressed may also be embedded in clinical networks instead of other social, sexual, or other community networks, as they are engaged in their HIV-related care. People who are virally suppressed may not only have smaller networks but also have networks that are more closely knit, which could reduce their bridging. Alternatively, people living with HIV may also experience stigma from HIV-negative people, which could reduce their network bridging potential. Additionally, research can explore the relationship between bridging or betweenness centrality and HIV care cascade outcomes.

Our findings must be considered within their context. There is a dearth of studies comparing influence in digital and in-person networks, and it is difficult to ascertain whether endogenous influence and social norms can be transmitted through digital or in-person interactions. Additionally, the weight social media influencers and content creators may have on social norms surrounding health and how social media algorithms "push" specific content through are largely unexplored. Further, we were unable to ascertain which relationships may be more important to intervene on. Finally, within social epidemiology and social network studies, the contextual factors of the sample as well as the geographic setting are important to consider as findings may (or may not) apply to other marginalized populations or geographic settings. For example, Black SGM in Chicago, Illinois, experience intersectional discrimination [20-23] and health disinvestment within their communities [54], which negatively impact health outcomes including HIV-related outcomes. Within this population, social norms may influence access to resources, support, and other opportunities [55-58]. These findings may translate to other Black SGM born in the United States, but may not translate to Black SGM born elsewhere who migrated to the United States or Black SGM living in cities with a more robust health infrastructure. Future studies could explore these topics.

Sociocentric data, the "gold standard" of social network data, are difficult to collect due to resource demands and complex study designs. However, constructing sociocentric networks from digital data may surmount challenges such as limitations in data collection as asking participants to list everyone that they know may be subject to measurement issues like recall bias. Although our inclusion of digital data expanded the breadth of our sociocentric network, the depth, or the influence of individuals in digital networks, is unknown. In addition, although we found that the inclusion of digital data resulted in a model that found statistical significance in HIV-related behaviors, it is unclear if this model is more precise or accurately describes the data. Thus, to see if the quality or strength of digital networks may be similar to that of in-person networks, future studies identifying the quality of these ties are needed. Another way to do so could be to analyze a behavior that is more susceptible to network structure, such as direct interactions among participants (eg, likes, comments, reactions). Although our findings support the collection of additional network data, from an ethical perspective, this may increase the likelihood that a participant may be identified as part of a network that one may not want to be identified with. These concerns must be considered in study designs.

Limitations

Network analyses are often not perceived to be generalizable because they are representative of one network at a given time point; however, we argue that the purpose of this analysis is not to generalize our findings to the larger population but rather to explore novel fuzzy matching methods to enrich social network

XSL•FO
RenderX

research by identifying opportunities to harmonize multiple types of data to triangulate a more robust and complete network. Differentiating selection from peer effects in this analysis may manifest differently based on the mechanisms at play and the networks being considered—for this, Simulation Investigation for Empirical Network Analysis (SIENA) models may allow for the distinguishing between these 2 mechanisms. In addition, participants were asked to provide their perceptions of the sociodemographic information of their network members. Race and ethnicity are complicated social identities that can be incorrectly perceived by others. This could introduce misclassification as participants may incorrectly estimate their network member's sociodemographic information and introduce bias into our findings by creating incorrect linkages between participants and creating errors in the network structure [9]. This could then trickle down and impact our tests of differences and associations and, if nonrandom, create confounding effects. Because the majority of participants felt close or very close (>80%) to their social members, we believe that misclassification bias may be minimized. A future study could also assess the accuracy of this fuzzy matching analysis. This type of data validation could include a brief survey or interviews with a random sample of the network to authenticate relationships. Another limitation is the number of participants for whom we were able to download complete Facebook data (n=144, 35%). If we were able to include Facebook data from additional participants, we could have potentially constructed a larger fuzzy network. However, because we were able to identify participants who did not provide their Facebook data from the Facebook friends lists of current participants, we believe this bias may be minimized. Future studies can opt to collect less Facebook data, such as only collecting friendship networks, instead of collecting data on group membership, comments, and other Facebook interactions. Finally, we used a cross-sectional linear network autocorrelation, a model that assumes continuous dependent variables, to analyze binary variables. The use of this model assumes that associations are linear, which may not hold for binary variables that constrain probabilities within the (0,1) range. The use of the linear network autocorrelation model may introduce misestimation of effect sizes due to nonlinearity, predictions outside the valid probability range, and heteroskedasticity. To address this bias, we have added supplemental analyses of unadjusted logistic regressions to test the effects of the network exposure to HIV serostatus and engagement in care. To establish peer effects, longitudinal data and a robust set of covariates could be used instead. Our findings may not be capturing peer effects, but rather homophily in the select effect (ie, participants deliberately seek others similar in their HIV care to be friends with). As our study was a pilot approach, our findings on autocorrelative effects may be interpreted with caution as they are marginally significant correlations.

Although not a limitation, a notable feature of this analysis was the time intensity of the match between participants and the social alters and sexual partners listed by other participants. This match of respondents to social network members and sexual network members generated over 8000 potential matches. We manually validated each match to determine if it was a true match or a false-positive match. This was a time-consuming analysis that unveiled <1% of ties of the final network. A machine learning algorithm, if trained appropriately, may alternatively be used to identify matches.

Conclusions

Digital networks, which we operationalized as phone contact and Facebook networks, were the most productive in identifying ties and may be best to characterize social networks. Our experimental approach identified opportunities to characterize networks more thoroughly and accurately. Future studies can explore how to operationalize and examine the influence of ties across various networks. In addition, there are added benefits to including digital networks to egocentric networks as they can identify hidden ties. There are clearly differential impacts of digital data networks on health and HIV outcomes; future studies could more thoroughly assess these networks. Thus, fuzzy matching may be an effective means to identify hidden ties among participants within different types of egocentric and digital networks to better understand the larger sociocentric network, including among vulnerable populations.

Abstract

Background: As more humanitarian relief organizations are beginning to use electronic medical records in their operations, data from clinical encounters can be leveraged for public health planning. Currently, medical data from humanitarian medical workers are infrequently available in a format that can be analyzed, interpreted, and used for public health.

Objectives: This study aims to develop and test a methodology by which diagnosis and procedure codes can be derived from free-text medical encounters by medical relief practitioners for the purposes of data analysis.

Methods: We conducted a cross-sectional study of clinical encounters from humanitarian clinics for displaced persons in Mexico between August 3, 2021, and December 5, 2022. We developed and tested a method by which free-text encounters were reviewed by medical billing coders and assigned codes from the *International Classification of Diseases, Tenth Revision* (*ICD-10*) and the *Current Procedural Terminology* (*CPT*). Each encounter was independently reviewed in duplicate and assigned *ICD-10* and *CPT* codes in a blinded manner. Encounters with discordant codes were reviewed and arbitrated by a more experienced medical coder, whose decision was used to determine the final *ICD-10* and *CPT* codes. We used chi-square tests of independence to compare the *ICD-10* codes for concordance across single-diagnosis and multidiagnosis encounters and across patient characteristics, such as age, sex, and country of origin.

Results: We analyzed 8460 encounters representing 5623 unique patients and 2774 unique diagnosis codes. These free-text encounters had a mean of 20.5 words per encounter in the clinical documentation. There were 58.78% (4973/8460) encounters where both coders assigned 1 diagnosis code, 18.56% (1570/8460) encounters where both coders assigned multiple diagnosis codes, and 22.66% (1917/8460) encounters with a mixed number of codes assigned. Of the 4973 encounters with a single code, only 11.82% (n=588) had a unique diagnosis assigned by the arbitrator that was not assigned by either of the initial 2 coders. Of the 1570 encounters with multiple diagnosis codes, only 3.38% (n=53) had unique diagnosis codes assigned by the arbitrator that were not initially assigned by either coder. The frequency of complete concordance across diagnosis codes was similar across sex categories and ranged from 30.43% to 46.05% across age groups and countries of origin.

Conclusions: Free-text electronic medical records from humanitarian relief clinics can be used to develop a database of diagnosis and procedure codes. The method developed in this study, which used multiple independent reviews of clinical encounters, appears to reliably assign diagnosis codes across a diverse patient population in a resource-limited setting.

KEYWORDS

refugee; population health; disaster medicine; humanitarian clinic; electronic health record; Fast Electronic Medical Record; fEMR

Introduction

The global population of forcibly displaced persons, including refugees, asylum seekers, and internally displaced persons, has surpassed 100 million people [1]. Both human-made and natural disasters can break down traditional centers of health care delivery, which may leave displaced persons with gaps in medical care [2]. Displaced persons who leave their countries of origin are often highly mobile between the time of displacement and resettlement [1], which can create challenges for continuity of care, including management of chronic medical conditions, provision of psychiatric and mental health services, and prevention and treatment of communicable diseases.

Humanitarian organizations that provide medical care for displaced persons do so with few resources, limited technological infrastructure, and high patient and staff turnover [3]. Staff turnover may pose serious challenges to maintaining continuity of care for displaced persons. Health information, if properly leveraged, can guide public health interventions for these populations [4,5]. More humanitarian relief organizations are transitioning their operations from paper to electronic medical records, but clinical documentation in ad hoc relief clinics is typically not standardized, nor conducive to analysis [2]. Specifically, clinicians working in resource-limited settings, particularly in disaster response scenarios, may not have time to consistently document all aspects of history-taking and the physical examination, and they may not themselves formally assign *International Classification of Diseases, Tenth Revision* (*ICD-10*) codes to patient encounters [4,5]. Quality of care in these settings can be greatly enhanced if data from clinical documentation can be effectively analyzed and interpreted [6,7]. Electronic health records designed for austere environments may also be an untapped resource to enhance population health and guide public health interventions, for example, by contributing to systems of syndromic surveillance for early warning of infectious disease outbreaks in humanitarian settings [7-9].

Past research has evaluated the ability for free-text clinical documentation to be analyzed with high efficiency, both by manual review and using natural language processing [10,11]. Studies using machine learning methods have used free-text clinical documentation, mostly from high-income settings, to categorize symptom presentations and classify diagnosed chronic diseases [11,12]. However, few studies have evaluated free-text clinical documentation in humanitarian relief settings where clinicians are under particularly high time pressures and operate with limited resources. There is a growing recognition that clinical documentation from humanitarian relief settings could provide much-needed data to measure the outcomes and improve the performance of humanitarian action [13]. To address this gap, we developed and tested a methodology of assigning medical diagnosis codes to free-text medical records collected from a humanitarian clinic at the Mexico-US border.

Methods

Study Design

We conducted a cross-sectional study of clinical encounters from humanitarian clinics for displaced persons at the Mexico-US border between August 3, 2021, and December 5, 2022. There has been a rise over the past decade in the number of displaced persons who transit through the Rio Grande Valley, which is situated near the Eastern coast of the Mexico-US border. Volunteer clinicians with Global Response Medicine, an international humanitarian relief organization, documented medical encounters using Fast Electronic Medical Record (fEMR), a digital medical record system specifically designed for disaster response [14]. Details of a similar clinical operation are separately described [15]. We created a program in which trained volunteer medical coders reviewed free-text medical records from this clinical site and assigned *ICD-10* and *Current Procedural Terminology* (*CPT*) codes. Our analysis included all the encounters with completed medical triage in the camp (ie, the patient registered in the electronic system) and which were assigned a medical diagnosis by the coders.

Ethical Considerations

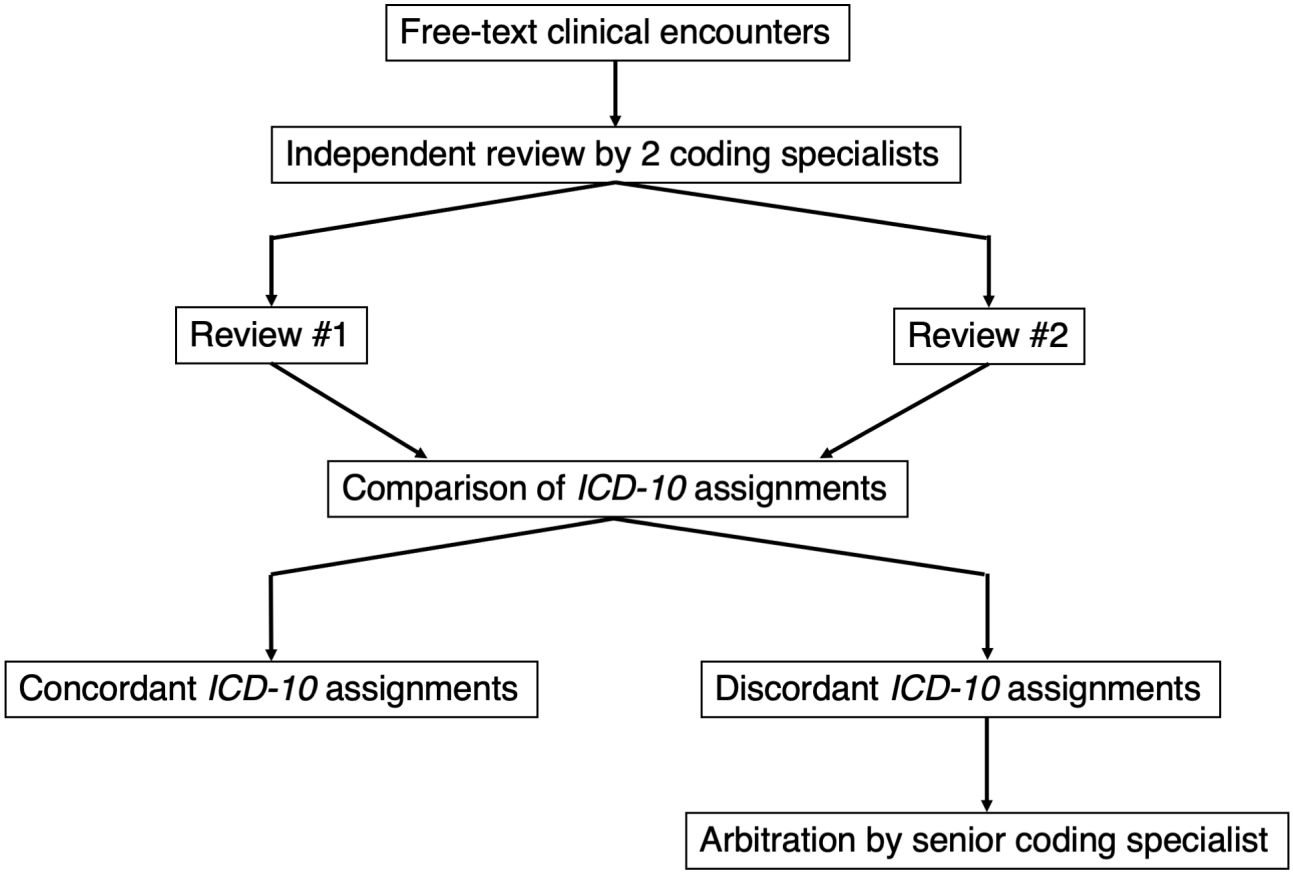
All fEMR records used in this study were deidentified and made Health Insurance Portability and Accountability Act–compliant to protect patient privacy. Informed consent and participant compensation for research were not possible as all data were deidentified. No research participant was recruited for this study as it was a review of medical records. We did not use machine learning, artificial intelligence, language models, or any similar technology for the purposes of information gathering, analyses, content creation, manuscript writing, or manuscript editing. This study was approved by the fEMR board of directors and the Mass General Brigham Institutional Review Board (2022P003273).

Training of Medical Coders

Coders underwent a rigorous onboarding process before participating in the project. As a prerequisite, they were required to achieve a score of 70% accuracy or higher on a structured entry examination, as determined by experienced medical coders who designed the training. This examination used a subset of medical records from the study dataset to assess the coder's ability to accurately interpret and assign codes in alignment with the project's standards. In addition, all coders were required to complete training in Health Insurance Portability and Accountability Act to ensure compliance with patient privacy and data security regulations.

To support coders in their tasks and ensure uniformity in the coding process, they were provided with access to a

XSL•FO
RenderX



comprehensive set of resources. These resources included detailed instructions on the coding process, examples of coded records, and a manual specifically tailored to the unique aspects of the dataset used in this study. This preparation was designed to standardize the approach across coders, reducing variability and enhancing the reliability of the coding process.

Assignment of Diagnosis Codes

To ensure consistency and reliability in the assignment of *ICD-10* and *CPT* codes, a structured process was developed for the assignment of coders. All coders were randomly assigned blocks of 100 clinical records to review and code. Each block was to be completed within 30 days of assignment. Once a coder submitted their completed block, they were assigned the next available block of 100 records in the dataset. This approach minimized the potential for systematic biases related to the order of record review, such as rater fatigue. Importantly, there were no penalties for exceeding the 30-day completion period, nor incentives for finishing ahead of schedule, ensuring that coders could focus on accuracy rather than speed.

Each record was independently reviewed by 2 coders who assigned *ICD-10* and *CPT* codes in a manner blinded to each other. We compared the codes for concordance, which we defined as an exact match in both the *ICD-10* codes. When discrepancies were identified, the arbitration process was initiated. Specifically, a third, more experienced coder, who had undergone additional training in advanced medical coding, reviewed the original free-text record along with the codes assigned by both initial coders. This coder then independently determined the final coding assignment based on established guidelines and standards for *ICD-10* and *CPT* coding. The final arbitration was documented along with necessary notes detailing the rationale for code selection to facilitate quality assurance and reproducibility in future applications of the process (Figure 1). Quarterly team calls were conducted to review coding processes and provide clarification on complex cases. In addition, team members engaged in ongoing, near-daily discussions through a dedicated group chat platform to address questions and ensure consistency in coding practices.

Figure 1. Workflow for assignment of *ICD-10* codes to free-text clinical encounters from humanitarian relief clinics in Mexico, 2021-2022. *ICD-10*: *International Classification of Diseases, Tenth Revision*.

Statistical Analysis

We evaluated the content of the encounters by measuring the mean, median, and IQR of words in each free-text encounter. We measured concordance between coders by calculating the proportion of encounters assigned the same *ICD-10* diagnosis code. We separately analyzed encounters in which both coders assigned a single diagnosis, both coders assigned multiple diagnoses, and at least 1 coder assigned multiple diagnoses. In cases of multiple diagnoses, we measured complete concordance (defined as all identical diagnoses), partial concordance (defined as at least 1 identical diagnosis), and complete discordance (defined as no identical diagnoses). We used chi-square tests of independence to compare concordance across single-diagnosis and multidiagnosis encounters. We determined the most common diagnoses and analyzed concordance stratified by patient characteristics using chi-square tests of independence for comparison across age, sex, and country of origin. We also

XSL•FO
RenderX

used chi-square testing to compare concordance across encounters with different lengths of free-text documentation. We used R 2024.04.2 for all calculations.

Results

From an original sample of 8546 encounters, we found that 99.0% (n=8460) were assigned at least 1 *ICD-10* code and therefore met inclusion criteria for analysis. These represented 5623 unique patients and 2774 unique diagnosis codes (Table 1). The diagnoses included communicable and noncommunicable illnesses (Table 2). The most common diagnoses included management of hypertension, diabetes mellitus, headaches, and encounters to receive prescription refills for chronic conditions. Common diagnoses that were likely related to infectious diseases during this study period included cough, fever, and urinary tract infection. The mean word count for free-text encounters was 20.5 words, with a median of 14 (IQR 2 - 28) words per encounter. A sample of the free-text clinical documentation and diagnosis code assignments are shown in Table 3. There were 58.78% (4973/8460) encounters where both coders assigned 1 diagnosis code, 18.56% (1570/8460) encounters where both coders assigned multiple diagnosis codes, and 22.66% (1917/8460) encounters with a mixed number of codes assigned.

Table . Concordance of assigned *International Classification of Diseases, Tenth Revision* (*ICD-10*) diagnosis codes across demographic variables in free-text clinical encounters from humanitarian relief clinics in Mexico, 2021 - 2022 (N=8460 encounters).

Characteristic	Proportion	Complete concordance	*P* value
Assigned diagnosis codes, n (%)			<.001
Single, both coders	4973 (58.78)	3096 (62.26)	
Multiple, both coders	1570 (18.56)	215 (13.69)	
Mixed, single and multiple	1917 (22.66)	N/A[a]

Table . Sample free-text clinical encounters with assigned *International Classification of Diseases, Tenth Revision* (*ICD-10*) codes from humanitarian relief clinics in Mexico, 2021-2022.

Sex	Age group (years)	Country of origin	Free-text clinical documentation	Coder 1 diagnoses	Coder 2 diagnoses	Arbitrator diagnoses
Male	30-39	Mexico	"Sore throat × 7 days, green mucous, has been taking paracetamol × 7 days. Fever past 2 days. Last tylenol taken 11 pm. No allergies. Taking 2 other medications but can't identify. Note HR. Double checked."	J35.1, J02.9, R50.9	Z00.00	J35.1, J02.9, R50.9
Male	40-49	Honduras	"Pain and swelling in R eye and R neck and R side of head. Sun makes it worse. More than 1 year. Took ibuprofen."	H10.31, R05.9	I10, H10.31	H10.31, I10
Female	60-69	Honduras	"Pt reports being seen here Tuesday for her foot pain and given pain medications at that time that have been working. Pt instructed to continue taking those meds PRN."	R53.1, M79.673, R03.0	R53.1, M79.671	R26.89
Male	40-49	Nicaragua	"Cough productive of yellow phlegm and cold x4 days, afebrile 35.1 here, throat pain, no body aches, no vomiting or diarrhea, no sick contacts. large tonsils without exudates or erythema, lungs clear, nontoxic."	J11.1, R05.9	J11.1, J35.1	R05.8, J00, R07.0
Female	40-49	Haiti	"Patient with diabetes and no insulin for 8 days. previously on metformin but didn't tolerate secondary to nausea. now feels bad with blurred vision and headache. also has h/o ovarian cysts and some abdominal pain. PMH: DM, ovarian cysts."	E11.9, N83.209, Z79.84	E08.620, E11.9	E11.9, N83.209, T38.3× 6A

Of the 4973 encounters with a single code, 62.26% (n=3096) were concordant and 37.74% (n=1877) were discordant. Of the 1877 discordant encounters, there were 68.67% (n=1289) of instances in which 1 coder was concordant with the arbitrator, and 31.33% (n=588) of instances that had a unique diagnosis assigned by the arbitrator which was not assigned by either coder. Therefore, only 11.82% (588/4973) single diagnosis encounters had a diagnosis that was not assigned by either of the initial 2 coders.

XSL•FO
RenderX

Of the 1570 encounters with multiple diagnosis codes, 13.69% (n=215) had complete concordance between the 2 coders, 64.65% (n=1015) were partially concordant, and 21.66% (n=340) were completely discordant. Of the 340 completely discordant encounters, there were 22.94% (n=78) of instances in which 1 coder was concordant with the arbitrator, 61.47% (n=209) of instances in which 1 coder was partially concordant with the arbitrator, and 15.59% (n=53) of instances that had unique diagnosis codes assigned by the arbitrator which were not assigned by either coder. Therefore, only 3.38% (53/1570) of multidiagnosis encounters had a diagnosis that was not assigned by either of the initial 2 coders.

The most frequent diagnoses in concordant clinical encounters were hypertension, acute upper respiratory tract infection, acute nasopharyngitis, viral infection, urinary tract infection, cough, and diabetes mellitus. The most frequent diagnoses in discordant clinical encounters were hypertension, headache, repeat prescription, diabetes mellitus, cough, abdominal pain, and history of diseases of the circulatory system. The frequency of concordance was not significantly different across sex categories: concordance was observed between 38.15% (1985/5203) of encounters with female patients and 39.73% (1294/3257) of encounters with male patients (P=.34). Concordance in diagnosis codes in encounters across age strata ranged from 30.66% to 42.91%. Clinical encounters with older patients (those older than 40 years) had lower concordance between coders than those with other age groups (P<.001). Concordance ranged from 30.43% to 46.05% in encounters across different countries of origin (Table 1).

Encounters with fewer words were more frequently coded in a concordant manner than encounters with more words (Table 1). Specifically, encounters with fewer than 2 words were coded concordantly 75.04% (1572/2095) of the time whereas encounters with greater than 28 words were coded concordantly 13.72% (300/2186) of the time. We found that *ICD-10* codes with less specificity (eg, Z00: Encounter for a General Examination Without Abnormal Findings) were more frequently assigned to encounters with 0 or 1 words.

Discussion

In this analysis of clinical records from ad hoc humanitarian clinics serving displaced persons migrating in Mexico, we developed a system to assign medical diagnosis codes to clinical encounters. This system relied on entry-level medical coders to independently review encounters and then more senior medical coders to arbitrate differences between their assigned *ICD-10* codes. Our dataset included 8460 clinical encounters over a 16-month study period, representing 5623 unique patients. We found that the first 2 medical coders demonstrated concordance in more than 60% of their assignments of single- and multidiagnosis encounters. In cases where they differed, additional review by a third, more experienced coder allowed for resolution of most of the discordance. This novel method can be applied to other circumstances where it is necessary to review medical information collected through the course of medical relief operations.

Our analysis suggests that this approach is reliable across most patient demographic categories. As could be expected, encounters with multiple diagnoses were less frequently coded in a completely concordant manner than encounters with single diagnoses. Encounters with older patients in our sample had a lower proportion of their diagnosis codes completely concordant between assignments. This could be indicative of more comorbidities or more complex medical diagnoses in patients who are older. It is also possible that older adults had more frequent multidiagnosis encounters than younger patients, which could produce discrepancies in the diagnosis assigned based on the free-text medical encounter. While many of the same diagnoses were frequently assigned in both concordantly and discordantly coded encounters, some nonspecific diagnoses (eg, abdominal pain and history of disease of circulatory system) were more commonly assigned in discordantly coded encounters. There was also variation observed between the proportion of encounters with concordant diagnosis assignments across patients of different countries of origin; however, these differences were relatively small. It is possible that there are differences in complexity of the clinical documentation between people with different medical conditions and migration experiences. It is also possible that linguistic or communication barriers were present for some patients based on their country of origin, which may have impacted the clarity with which clinicians documented their evaluation.

We also noted a difference in how medical encounters were coded based on the length of free-text documentation in the medical record. Interestingly, clinical encounters with more text were less frequently coded in a concordant manner than encounters with fewer words. This may be because in encounters with few words, the clinicians frequently just stated the diagnosis rather than any of the clinical findings (eg, “pneumonia” or “hypertension”) whereas lengthy documentation in other encounters may describe several findings that could be coded in different ways. It is also likely that clinical encounters with lengthy documentation may systematically differ from less thoroughly documented encounters as the former may include greater complexity in their presentation, disease process, or management considerations.

To address these challenges, future adaptations of this approach should prioritize enhanced training for coders focused on complex cases, particularly those involving multidiagnosis encounters or nonspecific presentations common in low-resource settings. Future adaptations could also incorporate training on culturally specific presentations of diseases and variations in medical terminology across demographic groups [16]. This could help coders better understand and interpret free-text medical records originating from diverse populations. Collaborating with clinicians to improve the clarity and consistency of free-text documentation would further reduce ambiguities and support more accurate assignments, although this may not be feasible in many austere environments. Finally, periodic audits of coding concordance stratified by demographic characteristics could provide valuable feedback to ensure equity in coding across diverse patient populations.

There is growing use of electronic health records among relief organizations serving displaced persons worldwide [11,12,14].

XSL•FO
RenderX

Past reports from humanitarian settings have identified challenges in the implementation of *ICD-10* coding into existing health records, including the time required for data entry, staff turnover, and the operational capacity for data analysis [13,17,18]. The approach used in this study can be used to characterize medical diagnoses from electronic health record systems in disaster response and other austere settings with a high level of consistency [15]. The strengths of this approach include the reliability in coding and the ability to have records reviewed and coded remotely while relief operations are ongoing. It also has applicability to diverse geographic and sociopolitical contexts where clinicians work in low-resource environments. It should be noted that we have no way to ascertain diagnosis accuracy (ie, the "true" illnesses and conditions present in the clinical encounters studied). Our method of completing multiple reviews of each encounter presents challenges for efficiency with high-volume clinical operations. Future work may leverage large language models to more efficiently code clinical encounters, but this would require validation before implementation [12]. As with other operations involving electronic health records, patient privacy and data security are also paramount concerns [16].

There are limitations in this analysis and approach. First, given that this analysis was conducted retrospectively, we cannot compare the accuracy of diagnostic codes with the reference standard of clinician designation, nor is this information readily available from clinics in austere environments. In addition, because of the limited diagnostic capabilities in the clinical sites studied, most of the diagnoses were based on the bedside examination (ie, history and examination), which resulted in nonspecific diagnoses being assigned.

In summary, we developed a system to assign *ICD-10* codes to thousands of clinical encounters for displaced people in transit at the Mexico-US border, with a variety of clinical presentations for a diverse patient population. The simple methodological approach described in this report holds potential to be adapted to other disaster response and resource-limited settings to advance the provision of clinical care and population health research. Scale-up of the electronic health record technology described in this study can improve patient safety by allowing program managers to monitor quality of care of diagnoses across patient populations. It can also provide critical information to public health officials regarding risk and clusters of transmissible infections, trauma and injuries, and outbreak preparedness.

Acknowledgments

The authors wish to thank the clinical and project staff who worked in the relief clinics and the coding staff at fEMR (Fast Electronic Medical Record).

Abstract

Background: The digital transformation of health services accelerated during the pandemic. While "digital health" strategies were created, they paid minimal attention to public health services like health promotion, disease surveillance, emergency preparedness, and health protection.

Objective: This study aimed to inform a digital public health (DPH) strategy at the British Columbia Centre for Disease Control (BCCDC) and explored public health practitioners' perspectives on challenges and opportunities of integrating digital technologies into public health functions within the organization.

Methods: In this qualitative description, we conducted 18 focus groups (FGs) between January and June 2023, drawing practitioners from 9 organizational subunits of the BCCDC including population and public health, environmental health, clinical services, vaccine-preventable diseases, communications, knowledge translation, data analytics, and Indigenous health (2 FGs per subunit). Discussions explored practitioners' application of digital technologies in their public health work, focusing on challenges encountered during implementation (current state FGs) and perceived opportunities (future state FGs). Sessions were audio-recorded, and detailed field notes were taken. Thematic analysis was conducted, comparing perspectives across groups using constant comparative techniques.

Results: We identified 3 themes. First, "bridging existing inequities—an opportunity and a challenge contingent on public trust" described participants' excitement about opportunities for DPH to disrupt historical inequities if centered on trust and reconciliation, while recognizing current digital transformation efforts risk exacerbating existing inequities with the digital divide. Second, "a sense of disconnect between "digital" and "public health" functions" described perceptions of DPH as being out of scope of core public health duties, requiring new competencies and navigation of complex organizational policies for which support is suboptimal. Third, "balancing the need for responsive DPH with necessary reactivity" highlighted practitioners' yearnings for a proactive DPH strategy rather than current issue-based reactive approaches. Participants suggest that a centralized systematic program can help achieve this goal.

Conclusions: A cohesive, systematic, and proactive organizational strategy for DPH is critical to enable equity-focused digital transformation. Such a strategy can bridge perceived disconnects between digital and public health functions through organizational supports like competency development and streamlined policies that can better support public health practitioners to integrate digital technologies into their work.

Introduction

Uptake of digital technologies for public health functions accelerated in the past decade, especially during the COVID-19 pandemic [1-3]. These technologies have been used to streamline real-time data processing, analysis, and reporting for health surveillance and emergency response [1,2,4]. They have also been used to expand the reach of contextually relevant and personalized health promotion and protection services through social media, mobile apps, and other similar technologies [1,5-7]. In 2022, Canada's Chief Public Health Officer identified medical and digital health technology as a key part of strengthening Canada's public health systems, recognizing its potential to improve the speed, efficiency, and impact of public health programs [8]. The strategy includes using digital technologies to strengthen early warning systems, improve supply chains and laboratory services through real-time tracking, support evidence-based decision making, and promote adherence to public health interventions via social media [8,9]. At the same time, it highlights the importance of carefully evaluating these technologies in light of legal and ethical concerns [8].

Current digital health strategies primarily focus on clinical applications, often overlooking the broader public health implications of digital transformation [10]. For instance, British Columbia's digital health strategy emphasizes a trusted, digitally enabled health system aimed at patient empowerment, provider experience, system connectivity, and operational efficiency—largely within clinical settings [10,11]. However, the rapid adoption of digital technologies across sectors like commerce, education, and social services has significant public health implications [10,12]. Social media and the digital information environment also contribute to health inequities, particularly through misinformation and disinformation, which disproportionately affect the youngest, oldest, and least digitally literate populations [10,12-14]. Digital access and literacy influence key health determinants, shaping employment, education, and income, which in turn affect health behaviors, access, and outcomes [10,12,15,16]. A recent expert consensus highlights how digital transformation intersects with social, commercial, and political determinants of health [17]. Recognizing this, BC's 2024 Population and Public Health Framework formally identifies the digital environment as a key determinant of health requiring public health action [18].

Yet, few public health agencies have developed digital public health (DPH) strategies that not only consider the role digital technologies play in strengthening public health functions, but also better position them to respond to the public health implications of society's digital transformation as described [10]. This project was conducted as part of efforts to inform a DPH strategy within a provincial public health organization in Canada. This provincial organization is responsible for providing health surveillance, disease and injury prevention, diagnosis and treatment of diseases of public health importance, health promotion (including healthy public policy), and emergency response functions. This project was conducted in part to align organizational public health action with the broader British Columbia digital health strategy and the 2024 British Columbia population and public health framework, seeking to better position the organization and its workforce to address this evolving public health need. Therefore, we explored public health practitioners' perspectives on the challenges and opportunities of applying digital technologies to public health functions within our organizational context.

Methods

Study Design

This was a qualitative description of public health practitioners' perspectives on the opportunities and challenges of leveraging digital technologies to operationalize public health functions [19]. Our aim was to generate meaningful insights to inform the deliberations regarding the development of a DPH strategy within our organization. Similar qualitative approaches have been used to guide health services planning and policy formulation [20]. Our inquiry was grounded in a pragmatic and constructivist orientation, enabling us to draw from relevant theory while remaining participant-driven [21]. We built on the British Columbia Centre for Disease Control's (BCCDC) strategic plan, which identifies "promoting digital health and clinical services" as a transformational priority, situating our study within the context of organizational change [10,22]. To inform our exploration of contextual factors shaping digital transformation, we drew on Weiner's theory of organizational readiness for change, with attention to organizational policies, strategic priorities, perceived value of the change (change valence), and available resources [23]. Our working definitions of DPH were derived from a scoping review by our research team, alongside an internal review and national consultation process -Textbox 1 [22].

The project was led by public health practitioners (DH, GM, IR, II, and MG) with experience designing, implementing, and evaluating DPH interventions within the organization in collaboration with relevant health systems partners [24]. The research team also included private sector consultants with expertise in digital transformation across various health contexts (IW and CK) and public health researchers with qualitative research experience in applied health systems settings (II and AC). All authors were part of a DPH working group established with representation across the organization to guide the implementation of the project.

We acknowledge that our diverse professional roles and previous engagement with digital transformation influenced our philosophical stance and study design. Our constructivist approach was informed by an understanding that participants' perspectives are shaped by their specific roles, work environments, and organizational objectives [19]. To mitigate potential bias and enhance reflexivity, data collection was conducted by consultants external to the organization, and analysis was led by an independent qualitative researcher who maintained a hands-off approach to support analytic independence. The full team engaged in regular reflective discussions on the emerging findings, using these sessions to critically examine how our positionality as insiders and researchers may have influenced interpretation. These ongoing reflective practices were integral to maintaining transparency and rigor in our approach.

Textbox 1. Operational definition of digital public health.

Definition of digital public health

- Digital public health is the use of digital technology to transform the delivery of public health functions in people-centered ways that optimize health outcomes for all. It brings together expertise in health, technology, and other disciplines to improve the health of populations, while addressing modern public health challenges that are amplified through the rapid and widespread uptake of digital technologies.
- Digital public health uses digital technologies to design, implement, evaluate, and scale up interventions to address public health challenges and promote health equity. It includes a wide range of digital technologies and applications, including data analytics, mobile health, social media, virtual health, and others.

Study Setting, Sampling, and Recruitment

This project was conducted at the BCCDC, a program of the Provincial Health Services Authority responsible for provincial and national leadership in disease surveillance, detection, treatment, prevention, and health promotion. The program is organized into subunits called service areas including clinical prevention services and its 2 clinical programs (sexually transmitted infections and tuberculosis clinics); data and analytics services (DAS); environmental health services (EHS); immunization program and vaccine-preventable diseases; public health response (PHR); Population and Public Health and cross-cutting programs including the Chee Mamuk Indigenous Health Program and the communications and knowledge translation (KT) Program. This project was informed by broader organizational strategic planning goals of promoting digital health and clinical services.

Participants were recruited from across key organizational subunits (service areas and programs) to ensure a range of operational perspectives on DPH. Recruitment followed a purposive sampling approach, with invitations shared through team leads and internal email lists. All staff within the selected units were eligible to participate, and participation was voluntary. Due to privacy and organizational sensitivities, particularly given the small size and specialized nature of many teams, we do not report detailed participant characteristics such as roles or years of experience.

Data Collection

Between February and April 2023, we conducted 2 rounds of focus groups (FGs-18 in all) with each of the service areas as described. FGs lasted an average of 52 minutes (range: 39 - 64 min). In the first round, we explored challenges with applying digital technologies to public health functions in the current organizational context. In the second round, we explored potential opportunities and priorities for a desired future state of DPH within the organization. FG guides were adapted to each service area, with initial sessions informing slight adaptations to ensure that discussions elicited context-specific insights while maintaining comparability across groups Multimedia Appendix 1. FGs were facilitated by (DH, IW, and CK) who have experience leading group discussions. FGs were conducted on Microsoft Teams and all sessions were auto-transcribed, with transcripts reviewed for accuracy to mitigate potential technology-related issues. Detailed field notes were also recorded during and after each FG.

Ethical Considerations

This project did not require formal ethics approval as it was classified as quality improvement given that it was under the jurisdiction of a public health authority and did not have research as a primary goal [25]. However, we followed basic ethical principles [26]. We obtained client consent, including verbal assent for recordings. To protect privacy, no identifiable information was collected. Participants could skip questions or withdraw at any time. No honorarium was provided, as FGs occurred during paid work hours.

Data Analyses

We conducted a reflexive thematic analysis on the combined dataset from both rounds of FGs, following Braun and Clarke's recommendations [27,28]. First, verbatim transcripts and field notes from both rounds of FGs were reviewed for accuracy and edited as necessary. All transcripts were imported into QSR NVivo (version 12) for data management and analysis [29]. The initial coding was performed by a primary analyst (AC), who closely read and reread transcripts to identify salient ideas and patterns in the data. A codebook was developed inductively and iteratively refined through regular consultations with the DPH working group Multimedia Appendix 2. A second analyst (II) reviewed the coding tree and assigned codes to ensure accuracy.

Throughout the coding and analysis process, we held weekly meetings with the DPH working group to discuss emerging codes, reflect on interpretive questions, and consider how organizational context influenced participants' perspectives. We used triangulation across field notes, participant quotes, and group discussions to ensure credibility and conducted crosstabulations to explore patterns across different roles and areas of practice. Themes were developed, refined, named, and described through a process that balanced theoretical sensitivity with fidelity to participants' voices. The final themes reflect the contextual realities, expectations, and concerns of practitioners engaged in DPH-related initiatives. In line with the qualitative descriptive approach, our analysis focused on capturing rich, context-specific insights without aiming for data saturation [19]. Our reporting adheres to the consolidated criteria for reporting qualitative research (COREQ) Checklist 1 [30].

Results

Description of FG Participants

Table 1 describes participants recruited from various service areas and programs in 2 rounds of FGs. Overall, there were 60 unique participants across 18 FGs, representing 6 service areas and 5 programs within BCCDC. Participants worked at varying

XSL•FO
RenderX

levels including frontline clinical services, middle level, and executive-level management.

We identified 3 themes which are described in detail below, including representative quotes as appropriate.

Table . Description of focus group participation by Sub-Unit and round–British Columbia Centre for Disease Control (2023).

Focus group	Number of participants	
	Round 1	Round 2
Clinical prevention services line–sexually transmitted infections program	8	7
Clinical prevention services line-tuberculosis program	3	5
Data and analytics services line	6	5
Environmental health services	5	6
Immunization program and vaccine-preventable diseases	3	4
Public health response	6	4
Population and public health	4	10
Chee mamuk indigenous health program	9	4
Communications and knowledge translation programs	3	4

Bridging Existing Inequities: An Opportunity and a Challenge Contingent on Public Trust

Practitioners described digital transformation as an opportunity to improve equity of public health services among historically marginalized populations. This was especially recognized for Indigenous peoples in Canada for whom additional opportunities for reconciliation exist. Practitioners emphasized that realizing the potential of digital transformation is contingent on establishing public trust which is influenced by the reach and effectiveness of current DPH efforts, the accessibility of digital services and resources, the timeliness of current efforts to bridge existing digital divides, and perceived benefits of digital transformation to various populations. Priorities for equity and reconciliation were especially emphasized for Indigenous communities who may be marginalized by current digital strategies. One participant said

> *The truth of the matter is, there's a lot of communities who are still existing on those older systems and like to me, it's I guess for where I would like to currently sit on this conversation, is sitting in that tension of those who have and those who do not have, because at the end of the day, the people who are most going to pay for not being digitally connected are Indigenous people and that's already knowing like we literally already know that and none are. But in the health systems, we're actually going more to virtual and digital and we're ensuring that we leave Indigenous people out.* [Indigenous health program, Session 2]

While recognizing the potential for increased accessibility, reach, equity, effectiveness, and efficiency of public health services through digital transformation, service areas emphasized concerns about further marginalizing populations without dependable digital access and literacy. Practitioners described scenarios where Indigenous, rural, and remote communities, people with lower socioeconomic status, and people experiencing language barriers or visual impairments are already being marginalized by our current digital transformation efforts. For example, one participant described a situation where Indigenous Elders seeking vaccines were caught in a technological dilemma

> *We had elders that were reaching out to the 1 - 800 number looking for vaccination. Only to call the number, sit on the line for 45 minutes, and then for them to get on to the line of like saying, "Hey, you have to go to this website" and you're like, "Well, we don't have a laptop, nor do we have Internet. We were told to call this number." And they're like, "Yeah, you have to go to this website." And so they were basically just pointing at each other.* [Indigenous health program, Session 1]

Carefully considering the benefits of digital transformation of public health alongside limitations of the digital divide was described as an important way to avoid creating an inherently inequitable 2-tiered system. Practitioners also suggested that fostering trust in DPH is dependent on broader sociocultural contexts. They described various negative community perceptions of public activities including data collection through intervention, to planning implementation and KT. The need to address these perceptions in meaningful ways was described as fundamental to the organization's ability to make progress within the fast-paced technological landscape

> *Privacy is a constant struggle and it feels like there's often the implicit assumption that we are trying to use the data to do terrible things and you know changing the conversation and it's starting to change for sure, but changing the conversation to reframe it as the things we can do to benefit the population when*

XSL•FO
RenderX

> *the data exist and are accessible to us as opposed to the, you know, the various purposes that that we might put the data to you and you know if I had a blue sky world, you know that would be the first thing that everybody thought of when we asked for data or made a request for data was "wow, think of what good these people could do if they had access to those data.* [EHS, Session 2]

Practitioners highlighted the importance of recognizing how socioeconomic status, geographical location, and access to health care services can both facilitate and hinder public trust in DPH, encouraging careful consideration of DPH's role to address the potential harms of the broader digital transformation of society and new inequities resulting from the process (ie, the digital determinants of health)

> *It would be a miss if we didn't consider our mandate to address some of the harms and facilitators that there are from digital technology adoption and the broader community in the work that we do. I mean just looking at how certain technologies-through inequitable uptake- can exacerbate underlying inequities within society and how that addresses or how that can exacerbate the social determinants of health.* [Population and public health, Session 2]

Practitioners also emphasized the need to provide concurrent non-digital options for public health interventions to promote equity. The following quote provides important context on addressing the digital divide as a 2-fold process

> *The digital divide, I would characterize as two separate issues. The first one is people who just simply do not have digital access at all and that could be anything from having their own personal contact number, but it could also be like not having financial resources to have Internet connectivity. Because even people who have devices actually often do not have access because of the cost of data in Canada, or they don't actually have consistent access to the Internet… And so, I think that this is actually something that's a very kind of important gap and challenge for us to be thinking about, but also acknowledging. And then the second part of the digital divide is people who actually have access to these things, but do not have the digital literacy to be able to actually fully utilize them, and I would put a bunch of people into that kind of category. You know, myself included.* [Sexually transmitted infections, Session 2]

Practitioners suggested that implementing strategies to address these issues can foster trust building among diverse populations, potentially enhancing the acceptability, efficacy, and efficiency of DPH.

A Sense of Disconnect Between "Digital" and Public Health Functions

The second theme highlighted a perceived disconnect between the staff's daily work and the envisioned or idealized practice of "doing DPH work." Practitioners described how engaging with digital health and technologies was often viewed as "being in excess of assigned roles." While often described with some frustration, practitioners also expressed excitement about the potential of DPH skill sets and practices to improve the reach, efficiency, and effectiveness of internal and external services of the organization. For example, this participant said

> *I'm kind of thinking, wow, if we had a tool to do this, that would be great. I have all these potential future uses in mind now but I have no idea if there is such a thing. But you know, if there's something that could help us do the work better or, you know, in new ways and reach more people, then that's really exciting.* [PHR, Session 1]

Practitioners described being unable to effectively formulate digital solutions to health systems problems they encounter. They emphasized needing in-service training and centralized supports to address competency gaps. These competency gaps were described as contributory to feelings of frustration with systems inefficiencies which exacerbate current workloads:

> *My experience trying to submit my [cloud-based data platform] application was excruciating. Like I'm a pretty smart person, but not having expertise made that a horrible, very, very long process. Whereas if I had someone that was used to doing that, skilled in doing that, they could have sat down with me and spent an hour. So, trying to make each individual group become an expert, or at least skilled in doing this as opposed to having central resources that already have those skills and do it all the time, I think is really inefficient and it leaves opportunities on the table.* [EHS, Session 1]

As described, practitioners acknowledged competency gaps but also emphasized the role of centralized support in filling capacity gaps for DPH services given current workloads and a sense that DPH services are not a core responsibility. For example, this participant said:

> *We can give information, but it's not on us because we literally don't have the capacity, like we just don't. And it would make sense […] like, where's that digital team?* [Indigenous health program, Session 2]

Practitioners also suggested creating novel positions with technology-specific job descriptions, with comparable remuneration rates to similar roles in the private sector. This was described as a prerequisite for effective DPH transformation, involving a re-evaluation of current human resource classification systems and securing additional funding

> *I think that is one thing that basically requires creating a new stream of jobs within BCCDC […]. Just say like we don't have these jobs and have been working on even bringing one person on board and we have been just kind of like trying to pigeonhole these people into our existing positions and that also kind of like goes back to our comp and class system, which is a little bit archaic. It takes quite a bit of time to get a new position classified and so on, so it's at multiple levels. First is just kind of like the realization to think through, these are skills that are needed for*

XSL•FO
RenderX

> *the future of work that we do at [BCCDC]… and then the second is creating these job descriptions, having funding allocated to hire these people and then create an ecosystem–whether it's through partnerships with academics and the scientists here to provide that environment where people are successful in implementing their skills and providing solutions to our problems.* [DAS, Session 2]

Practitioners suggested internal capacity-building to effectively use existing digital technologies (eg, limited knowledge of Microsoft Office suite tools, graphic design, and tools to support building and maintaining internet-based courses and manuals) while prioritizing the need to hire in-house resources to support more advanced digital and analytics projects.

Balancing the Need for Responsive DPH With Necessary Reactivity

This theme emphasizes the need to balance systems' reactivity with responsivity through an approach that fosters a proactive DPH strategy across service areas and programs. Here, reactivity was used to describe issue-based and unplanned implementation of digital technology in response to emergent public health issues as compared with responsivity, which describes proactive and planned strategies for considering DPH within broader public health responses. Practitioners described creative, adaptive, and individual approaches to implementing digital tools and programs, both internally and externally, and described needing a centralized approach at the BCCDC to guide DPH transformation. Practitioners critiqued overly reactive systems built on assumptions of public health's inherent function of reacting to emerging threats. This was said to result in multiple and inconsistent communication channels with public and providers, potentially limiting the organization's public health impact. For example, one practitioner said

> *So, in terms of messaging information and from a communicable disease, rapid response perspective, being able to push out consistent messaging on a new emerging [threat], whether it's a measles outbreak or an upcoming heat [wave] because we don't have that one-stop shop […] It's just–there's too many ways to get slightly different information and then we end up potentially not having the most impactful inputs or support to that group of providers.* [PHR, Session 2]

This reactive approach often leads to rapidly developed DPH interventions described as frequently untested, duplicative of previous efforts, and contributing to fragmented DPH systems. These fragmented systems were described as potentially wasteful and challenging to integrate into existing systems, ultimately undermining confidence in DPH initiatives. To reduce this reactivity, one participant suggested promoting broader access to and understanding of emerging digital tools across the organization

> *It's not just someone to help create that vision with using all these tools, but also the access to the right resources in a timely manner to learn what else is coming. I could dream up a lot of things, but I can only go so far because I don't know what else is in the [IT subunit] world. The funny thing is, like the texting solution that worked on the COVID side, I was the technology expert, way back in the day, we had created the concept before, and it just sat on the shelf.* [EHS, Session 2]

While the organization may not anticipate all potential technological shifts, setting the groundwork for information management (eg, privacy guidelines and standards for novel datasets), communication, and centralized support will provide needed foundations for service areas to work from. Perspectives of unclear DPH foundations are compounded by the current ad-hoc approach to DPH relying on staff motivation, as illustrated in the following quote about the lack of institutional knowledge in creating online courses for health care providers

> *I mean, going back to the conversation we're having about the courses that are built on [software name]. Like we don't necessarily have any training. People just have taken it upon themselves to figure it out.* [STI, Session 1]

Practitioners' narratives emphasized the need for a systematic and centralized program to lead the organization's effort in a more responsive and proactive approach to DPH. This also involves enhancing data, clinical, and operational interoperability among health authorities, governmental levels, and other health systems partners. Participants highlighted the challenges they experienced with provincial interoperability

> *These...solutions within [health authority (HA1)] and then later on within [HA2] and then for the regular communicable disease and other diseases. We have [software 1] which is being used by one or two health authorities. Then we have [software 2] within [HA3] and then we have [software 3] within [HA1] and then a different system in [HA4]. Like we don't have a good mechanism to capture information and then a mechanism to develop some of these solutions on the fly, because in public health you need to have some nimbleness, like when COVID emerged.* [DAS, Session 2]

Interoperability challenges were also said to result from complex and inconsistent data access protocols, agreements, and platforms that are cumbersome to navigate at an interinstitutional level, while acknowledging ongoing work to address these barriers.

> *There just isn't provincially consistent and reliable structures for sharing data across groups, and we get hung up in, you know, information–like establishing information sharing agreements can take years in some cases, and it really impedes our ability to do the work that we need to do. So that's kind of a constant frustration.* [EHS, Session 1]

Practitioners highlighted opportunities to leverage and repurpose existing technologies and platforms across service areas, automate tasks (eg, data entry and cleaning, communication with patients and providers), and improve communication, policies, and training opportunities as potential solutions aligned with public health needs. As noted by this participant, lengthy

XSL•FO
RenderX

approval processes do not align with priorities for nimble responsiveness or necessary reactivity.

> *The thought is that there needs to be a generally rapid response if something is out there, and currently, because of the communication approval process, there's very little that's rapid. So, I think there's a lot of like bits feeding into, you know, even if we do decide that we need to change how we manage mis- or disinformation, we're not set up for success in that at the moment.* [KT, Session 2]

Clinical staff also noted technological gaps that could alleviate frustrations in patient-facing services if addressed. Comprehensively integrating more flexible and automated services was highlighted as a change that could improve system responsivity. For instance, while acknowledging external constraints (ie, interinstitutional interoperability), the clinical tuberculosis program offered suggestions to improve internal responsivity through specific channels

> *There's the appointment reminders piece, like the automated appointment reminders piece. There's the fact that we still mail things out. So, there's no direct fax capability like there is with basically any EMR that you buy off the shelf. We don't have a texting platform. We don't have a scheduler that actually allows us to provide and schedule the patients in the way in which we would like to schedule them–like we have an incredibly rigid scheduler.* [Tuberculosis, Session 1]

Practitioners emphasized needing robust mechanisms for information, data exchange, and collaboration among partners within the DPH landscape. This includes advocacy for standardized protocols and frameworks that facilitate seamless data sharing and communication among health authorities and government entities at various levels. However, prioritizing efforts to enhance the accessibility, timeliness, and utility of DPH tools (including digital clinical tools) is easier to achieve internally and will build in the desired system responsivity.

Participants also highlighted concerns about the sustainability of DPH transformation processes, including the infrequency of comprehensive and full-cycle planning that considers evaluation and knowledge translation for DPH interventions. Insufficient evaluation was said to limit the organization's ability to demonstrate impact and secure ongoing funding for DPH interventions. For example, participants emphasized the importance of rigorous evaluation of DPH interventions

> *That evaluation component I think is really, really important and something our team really wants to try and get sorted. But again, capacity is a huge component of that for us, so.* [KT, Session 2]

> *Whatever we decide to move forward with, we want to have a fairly robust evaluation strategy built into that to make sure it's gonna be effective and be of use for the target population.* [Immunization program and vaccine-preventable diseases, Session 2]

Addressing these issues requires a shift toward a more structured and comprehensive DPH transformation approach within the organization, integrating systematic DPH planning, program design with clear goals, effective implementation, evaluation, and knowledge translation. Moreover, establishing rigorous evaluation frameworks is essential to generating evidence on the efficacy and effectiveness (including cost-effectiveness) of DPH interventions, potentially enhancing their long-term success and sustainability. Participants considered the importance of interdisciplinary academic and industry partnerships in addressing these 'full cycle' approaches to DPH interventions

> *There were folks at the University of Waterloo, and their computer sciences and health management system. And they wanted to work with us. But we got busy in the pandemic. Similarly, here at UBC and SFU. So, there are so many things–like they could develop apps, they could come up with completely new ideas because we don't usually work in that environment. And our sphere of thought processes revolves mainly around epidemiology and statistics. And we are not engaging in computer science. And some of the digital people who work on some of these solutions from their point of view and if you bring it that kind of like cross-disciplinary approach, we may be able to come up with the solutions which are a little bit better suited than what we have right now.* [DAS, Session 2]

Discussion

Principal Findings

In this qualitative descriptive study of practitioners' perspectives on the challenges and opportunities of DPH, we identified 3 interconnected themes. These align with broader digital health strategies and reflect constructs from organizational change theory, including change valence, change efficacy, organizational norms and procedures, and perceptions of contextual resources [23,31].

First, practitioners' expressed narratives about bridging existing inequities - an opportunity and a challenge contingent on public trust. This reflected practitioners' optimism about the potential for DPH to advance equity, effectiveness, and reconciliation while being concerned about its capacity to widen the digital divide. This emphasized building and maintaining public trust as a foundational element of DPH. Second, practitioners reported a sense of disconnect between "digital" and public health functions. DPH was often viewed as outside the traditional scope of public health work, reflecting concerns about limited digital competencies and fragmented systems. Practitioners described needing centralized supports, targeted in-service training, and restructured human resource systems aligned with emerging DPH needs. Third, practitioners' discourse regarding balancing the need for responsive DPH with necessary reactivity described challenges with overly reactive and somewhat ad-hoc approaches to digital transformation across the organization. Digital initiatives were often issue-specific and fragmented. These accounts reflect a reactive organizational culture, underscoring needed shifts toward more proactive, integrated approaches. Practitioners emphasized needing improved internal and external coordination within the DPH ecosystems. Effective

XSL•FO
RenderX

communication, interoperability, and rigorous evaluation were identified as essential components of a sustainable DPH system.

Our findings contribute to the limited but growing body of literature on organizational transformation in public health settings [22,32]. While digital health implementation is often studied in clinical contexts, few studies have examined how public health organizations navigate structural, cultural, and operational shifts in the context of digital transformation [10]. Echoing findings from clinical settings, practitioners in this study expressed optimism about the potential of digital tools to improve access, coordination, and outcomes [32]. However, they also raised concerns about the absence of coherent organizational strategies, limited digital infrastructure, and persistent gaps in workforce capacity [33-37]. Our findings reinforce the need for digital transformation efforts to be accompanied by robust organizational capacity-building strategies. Gaps in digital competencies, which range from basic digital literacy to specialized technical skills, undermine practitioners' ability to engage with and sustain digital initiatives [33,37,38]. Our findings also align with studies demonstrating public trust and engagement as a core part of digital transformation strategies and can be facilitated through proactive communication and transparent partnerships [33,35,37,38].

This study also illustrates tensions public health practitioners must navigate while facilitating the digital transformation of public health within broader societal digital transformation. Practitioner perspectives reflect a pre-existing institutional focus on equity and reconciliation [18]. However, perceived tensions emphasize calls for a techno-realistic equity-focused approach to digital transformation [9,39]. Further, practitioners' sense of disconnect between DPH and core public health functions is explained by expressed concerns about change efficacy for transformation [23]. These concerns exist at both individual and system levels, echoing similar concerns identified in our prior research [23,38,40]. Change efficacy concerns also demonstrate potential misalignments between the prevailing organizational culture and a view of DPH as integral to core public health functions [23,31,37].

This misalignment may be reinforced by current issue-focused and ad-hoc approaches to deploying digital tools to address specific short-term public health concerns [37,38]. Other studies suggest this approach, combined with organizational bureaucracies, reinforces the apparent fragmentation of digital systems and limits the potential for digital transformation of public health [31,37,41]. Within this context, incentives for privacy and infrastructure workarounds that are dependent on an enthusiastic few continue to complicate perceived fragmentation [22,37,41]. These findings demonstrate the role of proactive leadership capable of shaping organizational norms, culture, and processes to support long-term digital transformation, while also navigating short-term operational demands [23,31]. Such efforts must support practitioners to see DPH as integral to long-term visions, rather than peripheral to their mandate.

Implications for Public Health Practice and Research

Our study has implications for organizational DPH strategies. Given existing recommendations for people-centered digital health strategies guided by integrated leadership, financial, organizational, human, and technological resources, it is reassuring that our findings are well aligned with British Columbia's broader digital health strategy which centers trust and equity [11,42,43]. Building on this will require better governance and collaboration among partners and teams across the organization and served communities to not only build trusted integrated systems but also prevent duplication of efforts. These efforts must occur alongside ongoing advocacy for equitable digital access and literacy [44,45]. Moreover, our findings of a disconnect emphasize the need for an integrated review of public health training programs and their curricula to more appropriately reflect the role of digital transformation in contemporary public health, starting with basic general digital competencies with opportunities for specialization [46]. Our findings emphasize the need for a cohesive strategy to train public health practitioners across the organization on an ongoing basis to ensure they are up to date with modern digital technologies. Our findings also highlight the need for a revamp of current hiring practices with updated job descriptions (especially in a transdisciplinary context) and new public health roles for digital specialists (eg, highly skilled data scientists, computer scientists, and artificial intelligence and machine learning experts) with clearer career progression plans and competitive compensation packages [37,42].

Finding the need to balance responsivity with necessary reactivity highlights longstanding tensions in public health that significantly affected the public health response during the COVID-19 pandemic [8,41]. While the pan-Canadian and the British Columbia digital health strategies seek to implement people-centered interoperable systems, our study suggests adapting and extending this same vision across the organization to include all digital systems and supports [41,42]. Such an approach will require a centralized DPH program with digital specialists to support effective communication across the organization, maintain a repository of digital interventions and identify opportunities for shared costs, support ongoing practitioner training, support surveillance and attention to the growing risk of digital determinants of health, support rigorous evaluation of DPH interventions and ensure governance of these systems [37]. However, we must be careful not to allow these resources to constitute barriers to innovation while helping to transition the organization from reactive to more proactive and people-centered DPH systems [42]. Effective implementation will require not only technical resources but also strong organizational readiness, including alignment between leadership, workforce capacity, and operational structures that can sustain digital transformation over time [23].

Findings from this study should be considered based on its strengths and limitations. First, this study uniquely focuses on practitioner perspectives in real-world DPH contexts. Much of the literature has focused on mainly clinical and health systems. Our study explores the realities of public agencies that are reliant on internal and external process and data flows necessary for public health action across varied jurisdictions. It also accounts for the growing role of digital determinants of health. Our study comprehensively explores experiences of practitioners within a provincial public health organization, reflecting perspectives

XSL•FO
RenderX

from similarly sized organizations which support comparable mandates. However, care must be taken to transfer findings from this study to other jurisdictions, given the uniqueness of the organization (ie, a provincial role) and the health systems within which the organization is located. We have also not accounted for community and partner perspectives in this study and our recommendations. Further research is needed to appropriately capture these perspectives to inform a comprehensive DPH strategy. Research is also required to understand the models through which recommendations for centralized supports, ongoing training, and systems revisions will become operable.

Conclusions

While practitioners share excitement about the opportunities for DPH to facilitate equitable, efficient, and reconciliatory public health action, there are shared concerns about DPH being out of scope of core public health work, digital competency gaps, and a reactive approach to digital transformation within the organization that results in fragmented systems that limit DPH's potential impacts. Organizational DPH strategies are needed to support practitioners to achieve equity through DPH by providing a cohesive, systematic, and proactive approach to digital transformation through clear and careful communication with partners and communities, updated human resource and in-service training policies that support the organization with engaging and retaining the right digital talent, and creating centralized supports to ensure a more responsive approach to DPH.

Acknowledgments

The authors would like to thank public health practitioners of the British Columbia Centre for Disease Control who contributed their time and experiences towards this project. ChatGPT was used in copyediting the manuscript. All original content was generated by the authors and outputs were reviewed by the authors. ChatGPT had no role in study design, data collection, and analysis. The authors received no specific funding for this project. II is supported by the Canadian Institutes for Health Research (CIHR) Health Systems Impact Fellowship (Award number 521442), Michael Smith Health Research BC Trainee Award (Award number – HSIF-2024- - 04465) and the CIHR Canadian HIV Trials Network (CTN+) post-doctoral fellowship. MG is supported by the CIHR Applied Public Health Chair Award [47].

Data Availability

The datasets generated or analyzed during this study are not publicly available due because they were generated as part of organizational improvement efforts, but are available from the corresponding author on reasonable request.

Abstract

Background: The digital transformation of society and public health has created an urgent need for new competencies to address evolving and contemporary public health challenges. While some public health institutions and schools worldwide have begun responding through various training programs and approaches, many have yet to do so. A clearer understanding of the current training landscape can inform more coordinated efforts to update curricula and strengthen digital competency within the public health workforce.

Objective: This study aimed to map and describe existing digital public health (DPH) training programs, identifying common curricula content, disciplinary involvement, and training approaches. It also aimed to identify gaps and opportunities for curricular adaptation.

Methods: This environmental scan was conducted in 2 stages, drawing on guidance from studies by Rowel et al and Wilburn et al. First, we performed a systematic search of DPH training programs, followed by interviews with selected program directors to explore their program design and implementation. The scan emphasized a transdisciplinary lens, consistent with the evolving nature of DPH. Between March and May 2023, we searched Google and public health association directories to identify degree programs and courses (as part of degree awarding programs) focused on building capacity for using digital technologies in public health. We then conducted semi-structured interviews with 4 directors of identified programs exploring program characteristics and the inter- or transdisciplinary partnerships essential to their design. Search data were summarized using narrative synthesis, while content analysis was applied to the interview data.

Results: Overall, 58 DPH training programs were identified, categorized into 3 groups: public health data science (29/58, 50%), public health informatics (16/58, 28%), and a mix of programs exploring digital competencies (13/58, 22%) related to project management and addressing the digital determinants of health. Interviews revealed that motivation for developing interdisciplinary DPH programs stemmed from the need to meet evolving job market demands and respond to calls for curricular renewal among professional bodies. Effective design and delivery were supported by academic–industry partnerships, which aimed to cultivate professionals with depth in public health and breadth in digital competencies. These programs drew on diverse disciplinary perspectives from academia, the public sector, and private industry. However, sustaining such partnerships was challenged by the need to negotiate shared priorities, reconcile differing viewpoints, and secure ongoing funding.

Conclusions: This global scan of DPH training programs found a strong focus on data-centric competencies, with less emphasis on digital skills for health promotion, leadership, and addressing digital determinants of health. Bridging these gaps requires a stepwise approach: integrating digital competencies into existing curricula, offering stand-alone programs for specialized skills, and strengthening partnerships to navigate funding and administrative barriers while promoting equity-driven, interdisciplinary collaboration.

digital health technology; public health schools; professional competence; public health education for professionals; digital health; competency-based education; health workforce

Introduction

The digital transformation of society, including public health, was significantly accelerated during the COVID-19 pandemic [1-3]. Digital technologies have been adopted to enhance the efficiency, effectiveness, and reach of essential public health functions, such as real-time precision disease surveillance using big data and artificial intelligence, targeted health promotion via social media, apps, and wearables, and environmental health protection informed by sensor data [2-5]. Digital access and literacy have recently emerged as important determinants of health, directly and indirectly shaping public health outcomes [6-8]. For example, limited digital access and literacy may restrict social and economic opportunities, which in turn limit access to digitally mediated health and social services [8,9]. Conversely, for those with digital access, exposure to misinformation, disinformation, and exploitative practices by big tech platforms can adversely impact health and health behaviors [8,10,11].

To harness these opportunities and address the evolving challenges, the contemporary public health workforce must develop new digital competencies [12,13]. In our previous research, we conducted a rapid literature review and identified 45 unique digital competency statements that cut across all 7 categories of the 2008 Core Competencies for Public Health in Canada framework [12]. We also identified a potentially new competency category related to digital data, data systems management, and governance [12]. While these competencies are not exhaustive, especially with rapidly developing digital technologies, they represent aspirations of public health practitioners and educators to address existing competency and curricular gaps [14,15]. For instance, the Association of Schools for Public Health in the European Region (ASPHER) task force for digital transformation has recommended updates to the public health curriculum across themes such as digital literacy, health data collection and analysis, health data management and governance, ethics and regulation of digital transformations in society, and understanding the infosphere and spread of information over digital networks [16]. They emphasize the need for interdisciplinary and transdisciplinary academic communities that understand public health, as well as computer science, data science, and other sciences relevant for digital public health (DPH) [16,17]. Ongoing efforts by the Public Health Agency of Canada, including commissioning the National Collaborating Centers for Public Health to update the Core Competencies for Public Health in Canada, are also examples of work to address these competency needs [18].

It remains unclear how these competency aspirations and curricular recommendations have been implemented in public health training programs and courses. Gaining insight into how these competencies have shaped curricular updates can guide targeted recommendations for digital competency development and curriculum design in Canada. This would support the broader vision of transforming public health and enable schools of public health to make necessary adaptations [13]. In addition, with well-documented challenges in inter- and transdisciplinary practice, there is limited understanding of the disciplinary perspectives incorporated into these programs and how educators navigate diverse viewpoints in practice [17,19].

Therefore, our main objective was to map, explore, and describe training programs designed to integrate and enhance the use of digital technologies specifically for public health and its subspecialties around the world. Specifically, we examined common curricular content, the academic disciplines involved in program design and delivery, and the training approaches used to implement these curricula. We also identified opportunities for curriculum adaptation and strategic pivots in response to emerging needs and gaps in current DPH curricula and training programs. This work is part of a broader study supporting the digital transformation of public health by informing competency development, encouraging interdisciplinary collaboration, and guiding future curriculum planning [12,20]. Ultimately, this work seeks to better prepare public health practitioners to engage with and lead within an increasingly digital health landscape.

Methods

Study Design

The study was an environmental scan conducted following a 2-stage approach: a systematic search for DPH programs aligned with the study objectives and semistructured interviews, with program directors or faculty members from programs emphasizing inter- or transdisciplinary perspectives in their curriculum planning and delivery [21,22].

Systematic Search for DPH Program Websites

Two members of the research team (II and SR) conducted independent searches using Google's advanced search (google.com/advanced_search) without country restrictions. Search terms included ("digital public health" OR "digital health" OR "digitalization" OR "digital transformation" OR "data science" OR "social media" OR "artificial intelligence" OR "machine learning") AND ("school of public health" OR "college of public health" OR "department of public health" OR "division of public health" OR "institute of public health") AND (degree OR program OR course). Thereafter, the search was repeated, restricting returns to countries identified as prominent contributors to DPH literature, including Australia, Canada, China, France, Germany, Italy, Sweden, the United Kingdom, and the United States of America (Multimedia Appendix 1) [1,17]. We reviewed the first 100 returns for each search. Thereafter, we searched popular global online directories of schools of public health, including the Council on Education for Public Health, ASPHER, and the Public Health Agency of Canada, to identify potential programs or courses for review. All relevant returns were reviewed against the inclusion and

XSL•FO

exclusion criteria (Table 1). All searches were conducted between March 24, 2023, and May 16, 2023.

Table . Program inclusion and exclusion —environmental scan of digital public health training programs (2023).

Domain	Inclusion criteria	Exclusion criteria
Population	Focus on public health students, public health informaticians and analysts, practitioners (including public health physicians), public health researchers, and decision- and policy-makers.	Exclusive focus on clinicians, programmers, or other related technologists, informaticians, or other allied health system practitioners.
Concept	Programs focused on building capacity for designing, implementing, and evaluating digital technologies in any of the domains of public health or across public health.	Programs focused on the broader field of digital health or a mostly clinical perspective (eg, telemedicine or virtual health in a clinical context).
Context of training program (ie, context of application)	Population and public health	Clinical or solely clinical contexts
Program type	Established degree awarding training programs at undergraduate and graduate levels or courses undertaken as a requirement for a degree awarding public health program.	Short courses, workshops, webinars, and courses not related to a public health program.
Timeline	Must be currently available for enrollment	Previously available programs that have been discontinued or truncated.

Program Selection

We adopted a definition of an eligible DPH training program as any undergraduate or graduate-level degree-awarding public health training programs that were currently available for enrollment and entirely focused on applying digital technologies to all or to specific public health domains as defined in the Canadian Public Health Association's conceptual framework for public health (Table 1) [23]. We also included course modules that are part of degree-granting public health programs. In addition, programs with a broader medical focus were included if they explicitly addressed public health, such as through modules relevant to public health as described within their overall objectives. We excluded programs and courses that are exclusively focused on clinical and clinical informatics perspectives and those offered as short courses (ie, stand-alone course modules not offered as part of a degree-awarding program). One member of the research team (SR) reviewed search returns based on our inclusion and exclusion criteria (Table 1), with another researcher (II) reviewing the list of included programs and courses for accuracy based on the inclusion and exclusion criteria.

Data Collection

We reviewed the websites for each included training program and course, identifying program documents and training curricula available on their websites. Data from these documents were extracted using pretested data extraction forms (Multimedia Appendix 2) adapted from the guidelines for reporting evidence-based practice educational interventions and teaching [24]. Extracted data included basic program information (eg, program name, country, city, and year of commencement) and program descriptors (eg, target audience, level of training, educational materials used, characteristics of the instructor(s), and underpinning theories ([ie, educational or field-specific theory(ies) guiding the program]). For program websites not originally in English, Google Translate was used to access the documents before extraction.

Semi-Structured Interviews

We reviewed online documents for each included program to identify evidence of a clear mandate for inter- and transdisciplinary training. This included mission statements, faculty from diverse disciplines, and explicitly stated inter- or transdisciplinary partnerships. For each qualifying program, we invited program directors or staff involved in program design, delivery, and evaluation to participate in semi-structured interviews. Additional eligibility criteria included being an established graduate- or undergraduate-level degree-awarding program with English-speaking staff. Recruitment emails were sent using contact details from program websites, and a convenience sample of staff who responded to invitations was recruited. Each eligible program received up to 3 reminders. Using a snowball sampling approach, we identified an additional program that was not on the original list, as it did not have a listed degree-awarding program on its website. However, their strong emphasis on transdisciplinary DPH training and traditional public health training focused on DPH research justified their inclusion in the interviews. Interviews were conducted with consenting participants over Zoom Online (Zoom Communications Inc.). We used a topic guide that explored characteristics of the DPH training programs, academic and practice disciplines involved in designing and delivering the program curricula, characteristics of these inter-/transdisciplinary collaborations, and lessons learned (Multimedia Appendix 3). The topic guide was developed based on initial findings from our rapid review of DPH competency recommendations, insights from previous DPH-related literature reviews, and consultations with education leads from schools of public health who served as co-investigators on the project [12,17]. All interviews were conducted by II, who is trained in qualitative health research methods, supported by SR who received training on the data collection protocol and made detailed field notes. All interviews were audio recorded and automatically transcribed using Zoom's auto-transcribe function. Transcripts were reviewed for accuracy and corrected as

XSL•FO
RenderX

appropriate. Data analyses were concurrently conducted alongside interviews. Each interview lasted on average 47 minutes (range 39 - 53 min).

Ethical Considerations

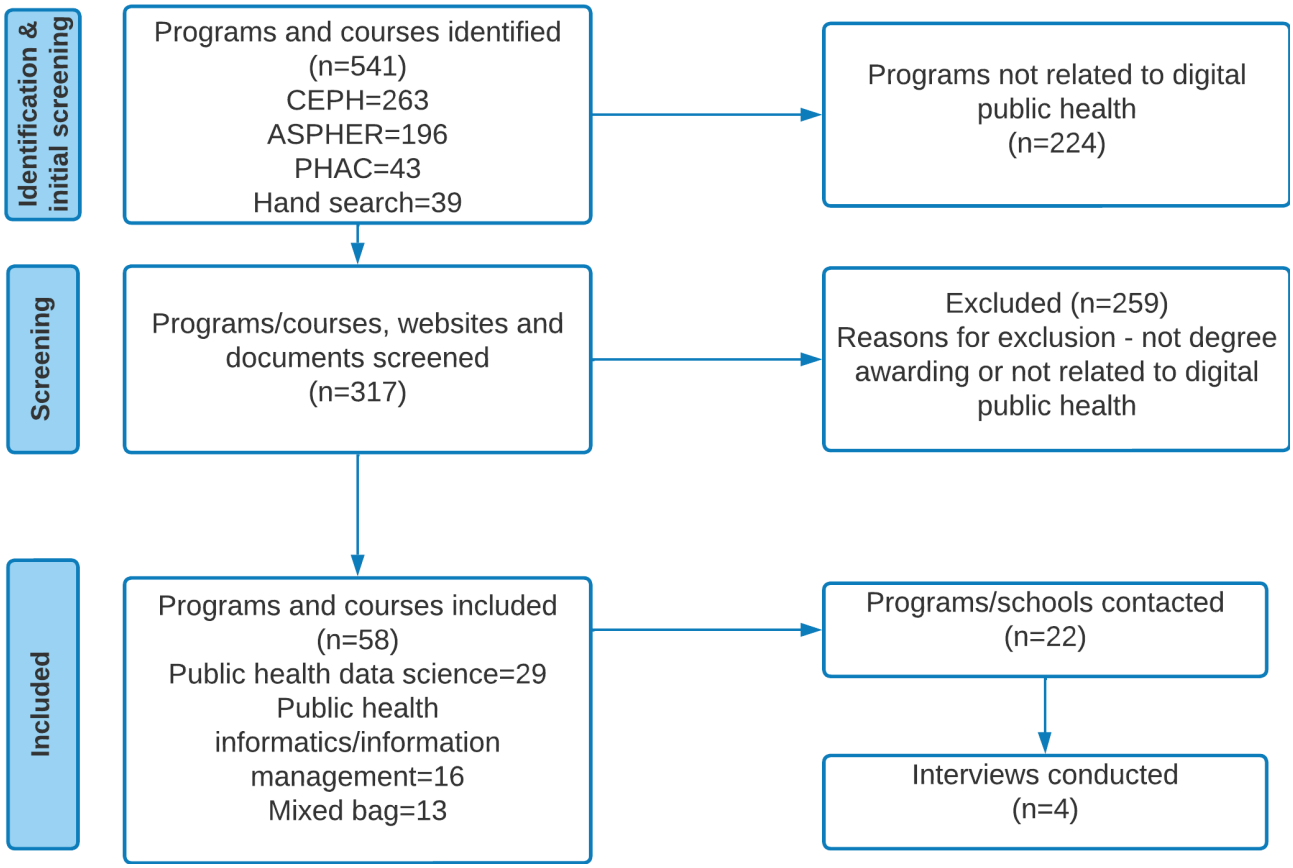
This study was reviewed by the University of British Columbia's Behavioral Research Ethics Board (ethics #H22-03153). We obtained written informed consent from each participant at least 24 hours before the interviews via email and assigned each participant an identification number, which was included in all interview transcripts and field notes (Multimedia Appendix 4). All study materials were stripped of personal identifiers before analyses. Participants did not receive an honorarium.

Data Analyses

We summarized data from the systematic search using descriptive statistics (frequencies and proportions) in Microsoft Excel and conducted a narrative synthesis. For the semistructured interviews, transcripts and field notes were imported into QSR NVivo version 1.3 for data management and analysis [25]. We conducted a content analysis exploring key descriptions of programs, inter/transdisciplinary collaborations, and lessons learned from implementing such collaborations within the program context. Our analyses followed an inductive process beginning with initial coding, categorization, and interpretation of findings [26,27]. Emergent codes and categories were reviewed with the research team consisting of public health educators and DPH experts whose views informed ongoing refinement and interpretation of codes and categories generated during analysis [27]. Throughout the analyses, II and SR made reflexive memos about our perspectives of the data [28]. These memos also informed the analysis and the final report draft.

Results

DPH Programs and Courses Identified From Systematic Search



Overview of Included Programs

Overall, we identified 58 DPH training programs and courses offered as requirements for a degree awarding program applying digital technologies for public health functions (Figure 1. Of 58 programs, 35 (60.3%) were from universities and colleges in the United States (Table 2), 46 (79.3%) were at the master's degree level, 25 (43.1%) were delivered in-person (including options for applied components such as practicums and internships), and 47 (81%) did not explicitly describe theoretical foundations of their programs and courses (Multimedia Appendix 5). Regarding foundational theories underpinning programs, only 11 (18.9%) of 58 explicitly described being built on modern statistical theories, including probability and Bayesian frameworks.

Identified programs focused on 3 main DPH categories: public health data science (29/58, 50%) programs focused on using modern statistical and analytic approaches to harness digital data streams to provide evidence for public health decision making; public health informatics (16/58, 28%) programs focused on using information, computer science, and technology to create and manage the infrastructure and systems needed for digital data streams and analytic techniques; and a mix of programs and courses (13/58, 22%) focused on various digital competencies, including digital leadership, project management, digital health communication, digital transformation leadership, digital design and implementation, digital monitoring and evaluation, and tackling the digital determinants of health. There was significant overlap between programs across all 3 categories. However, the first 2 focused on a previously identified competency category related to digital data, data systems management, and governance.

Table . Characteristics of included DPH training programs and mandatory courses—environmental scan (2023).

Program characteristics	Frequency (N=58), n (%)
Country of program	
USA	35 (60.3)
Canada	6 (0.3)
UK	4 (6.9)
Australia	2 (3.4)
Germany	2 (3.4)
India	2 (3.4)
Others	7 (2.1)
Level of training	
Undergraduate	4 (6.9)
Master's	46 (79.3)
PhD (Doctoral level)	1 (1.7)
Combined Master's and Doctoral training	4 (6.9)
Others	3 (5.2)
Foundational theories	
Not stated	47 (81.0)
Biostatistics/statistics, probability, or related theories	10 (17.2)
People centeredness[a]	1 (1.7)
Partnerships reported (ie, public and private sector partners)	
Not stated	51 (87.9)
Industry partners (eg, health departments and health analytics consulting groups)	4 (6.9)
Health industry and university partnerships	3 (5.2)
Delivery	
Not stated	12 (20.7)
Online[b]	9 (15.5)
Blended	12 (20.7)
In person	25 (43.1)

[a]Emphasizes person-centredness as an organizing framework, in contrast to traditional informatics approaches.

[b]Includes online-delivered programs that incorporate in-person practicums or internships.

Curricula Content and Training Approaches

Identified programs had diverse learning objectives, foundational components, and emphasized various public health domains and functions. The majority of the public health data science programs and courses explored subjects related to public health sciences, biostatistics, computer science, and variants of these core content areas as presented as data science training. Most of these programs focused on public health and health services research, epidemiology, disease surveillance, and prevention. Public health informatics programs leveraged information science, computer science, data management, and health management information systems as applied to public health generally. The mixed bag of programs and courses leveraged varied digital content applied in health promotion, program development and evaluation, epidemiology, disease surveillance, and public health more generally. The majority of the programs (33/58) were delivered online, while others used blended learning (12/58) or in-person training (12/58). Most of the in-person training involved a blend of coursework and internships or practicums in real-world settings. The majority of these were focused on public health data science and public health informatics. Importantly, courses within the mixed-bag category leveraged industry–academic partnerships to facilitate content delivery as appropriate.

Disciplines Involved in Training Programs

While most programs highlighted their multi-, inter-, or transdisciplinary perspectives using broad statements, 17/58 programs (29.3%) did not clearly describe the disciplinary perspectives involved in the design and delivery of the training programs and courses. Where specified, programs predominantly

XSL•FO
RenderX

indicated specific disciplines, including public health sciences (including specific fields such as epidemiology and biostatistics). Beyond public health sciences, programs highlighted the involvement of statistics, computer science, information technology and informatics, health care administration, mathematics, life and health sciences, media and communication, health economics, law bioethics, psychology, anthropology, management, and so on (Multimedia Appendix 5).

Qualitative Interview Results—Considerations for Interdisciplinarity

Overview

A total of 4 program directors or faculty representing 4 of the included programs participated in interviews. Interviews were with program directors of programs in Canada, Australia, Germany, and the Netherlands. From the interviews, we identified 4 main qualitative categories that characterize interdisciplinary partnerships and offer insights into implementing transdisciplinary DPH programs in real-world settings. Each category is supported by exemplar quotes.

Motivation For Interdisciplinary DPH Programs

This reflected program directors' impetus for developing programs focused on interdisciplinarity. First, programs recognize the need to align their curricula and training with evolving digital trends in public health, responding to job market competency requirements and current course offering gaps based on previous research and professional experiences that emphasize the need for applied skills in inter- and transdisciplinary settings. Moreover, program directors' interdisciplinary training was also a key motivation for developing and implementing interdisciplinary programs that reflect their understanding of the current job market. For example, one participant said:

> *I am pure technologist by training, and being a digital health researcher, my research findings suggested that there is a need to have consumer education in public health... So, I wouldn't say that I'm an expert in public health that's not my area of expertise, but I've learned a lot in the past few years since I've been here...* [Participant 2]

Program directors emphasized the need to align their programs with curricular updates from professional bodies (such as ASPHER and the Australian Digital Health Agency) that have issued recommendations for digital competencies. They also noted that interdisciplinary programs were designed to address students' expressed learning needs, emphasizing the importance of experiences that closely reflect real-world working conditions.

Design and Delivery of Interdisciplinary Programs

Program directors primarily designed their programs with a focus on desired student outcomes. A common aspiration was to develop *T-shaped professionals*—individuals with broad knowledge across digital technology fields and deep expertise in at least one public health discipline. For most programs, their design was informed by active partnerships with industry practitioners, including private sector partners. For example, some program directors described program design supervised by an advisory board consisting of public and private industry partners that highlighted competencies needed in the workplace. Programs were structured around competencies aimed at fostering interdisciplinary collaboration, as well as practical understanding of digital regulatory frameworks, leadership in digital technology, design thinking, and advanced analytics.

While directors acknowledged the limited availability of competency frameworks in this area, they often described building curricula based on their vision for student outcomes. This involved inviting key partners to contribute and leveraging their various disciplinary expertise areas to align with the program's goals:

> *I think what really helped us work together was having this clear vision of you know this is who the ideal graduate is. This is what we want them to be able to do in the workplace, and then taking that vision and really breaking it apart, right? And then the data scientists could really say, okay, if I put myself in a position of having to work with this person, what would I want them to know? And I could put myself in the position of okay. If this is a person that's going to advise me on governance issues, you know, hospital policy, these kinds of things. What would I want them to tell me about technology, right? ... So, that allowed us to again retreat in our, you know, disciplinary silos. But at least work on the curriculum as a team, right? But again, it was from our perspectives...* [Participant 1]

Regarding training approaches, all interviewed programs described prioritizing experiential learning using a combination of foundational class-based courses and practicums or internships within public health organizations demonstrating interdisciplinary work. For instance, one of the public health data science programs is implemented with triads within the program, combining students of varied backgrounds (eg, public health sciences, computer science, and biostatistics) to solve real-world problems within health systems.

Characteristics of Interdisciplinary and Transdisciplinary Partnerships Supporting Identified Programs

Program directors suggested that interdisciplinary partnerships are built off a core group of leaders who can engage other disciplines based on the goals for the "T-shaped professional." Partnerships span multiple disciplines, including public health and medicine (eg, biostatistics, epidemiology, public health sciences, clinical medicine, psychology); applied sciences and technology (eg, computer science, data science, human–computer interaction, informatics, and cybersecurity); and the arts and humanities (eg, law, bioethics, media and communications, and anthropology). These partnerships essentially were prioritized based on the competencies for the envisioned T-shaped professional, starting within the internal academic environment first, extending to public and private sector partners as needed, including the formation of advisory boards as described. In addition, these partnerships are leveraged

XSL•FO
RenderX

for curricular content delivery to align student experiences with real-world experiences and expectations:

> *We have a what we called a stakeholder advisory board as well where we have some people from industry and we had different workshops where we invited people to present you know what they had been doing what they're forward or line of thinking is ...* [Participant 4]

Challenges With Implementing Interdisciplinary and Transdisciplinary Partnerships

Program directors highlighted a range of challenges associated with establishing transdisciplinary partnerships, as well as those stemming from administrative processes or the implementation of innovative programs within established schools. In terms of partnerships, challenges included negotiating shared commitment and perspectives among diverse experts with differing methodologies, views on knowledge, and levels of commitment to public health principles. These issues were particularly pronounced in academic–industry collaborations, especially with private entities. Concerns centered on the potential for noncritical, techno-optimistic implementation of technologies and the risk of exploitation within such partnerships. Participants emphasized the importance of having a clear understanding of the principles driving the operations of private entities. For example, one participant stated:

> *I mean, they're [private entities] obviously a big player in this because they are substantially driving the field if we think about all these health apps. So far, they are actually shaping some of the stuff that perhaps others should shape but it's just because they're doing it and they're not asking too much too many questions... They just want to produce products... Nevertheless, we would certainly continue also to, you know, aim to work with them. You find some yeah enlightened groups there to work with [and] not get this feeling of you know exploitation in some ways or going on their own in the wrong direction this is really important ...* [Participant 4]

Program directors also described difficulties in establishing a shared vocabulary and a common definition of "digital public health" among partners. Funding and resource challenges were frequently mentioned, with some programs relying heavily on grant funding to support their programs. These resource constraints influenced decisions regarding the depth versus breadth trade-offs in curriculum design and the need to compensate instructors for their time. In addition, resourcing challenges impacted decisions to limit the number of partnerships pursued for curriculum implementation.

Additional challenges included difficulties in gaining accreditation, particularly within traditional public health education systems that may undervalue the goal of developing T-shaped professionals. These challenges were addressed by securing leadership buy-in and institutional support. Program directors also emphasized the difficulty of creating curricula responsive to the rapid evolution of digital technology. To address this, they focused on fundamental principles such as systems thinking, privacy, and data governance, while incorporating applied training. This approach ensures students interact with current tools to better understand and apply these foundational principles.

Discussion

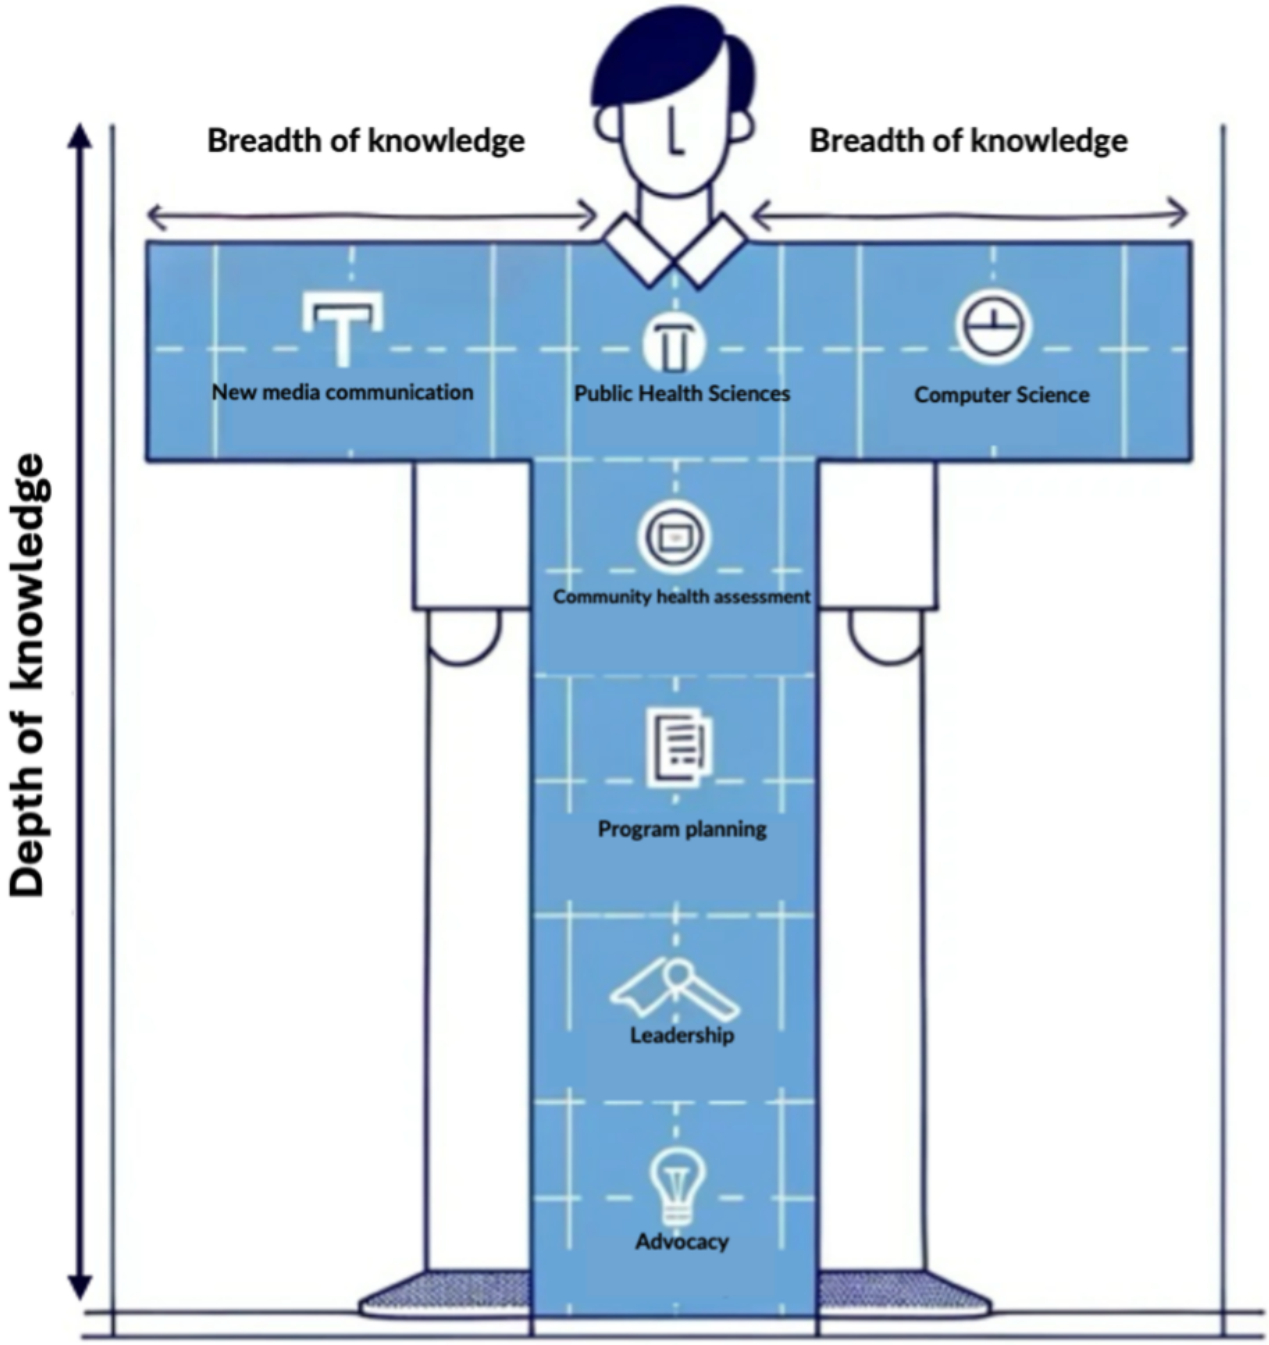
Principal Findings

In this environmental scan of DPH programs, we identified 58 programs and courses on digital competencies worldwide, the majority of which were in high-income countries. These initiatives addressed digital competencies across 3 main areas. The first 2 were related to public health data science and public health informatics, which build competencies for digital data, data systems management, and governance, consistent with our previous research showing this as a focus for digital competencies in public health [12]. Furthermore, we identified a third category of DPH programs and courses leveraging varied digital content applied in health promotion, program development and evaluation, epidemiology, disease surveillance, and public health. This category also included programs and courses aimed at understanding and addressing the digital determinants of health. For the interdisciplinary programs, most have aligned with external pressures from job market trends, student demands, and curricular recommendations for interdisciplinary practice [15,16]. While most programs emphasize applied learning within interdisciplinary frameworks to develop T-shaped professionals, challenges such as funding constraints and difficulties in achieving shared public health commitments and vocabulary remain significant barriers.

To the best of our knowledge, this is one of the first global scans of DPH programs and courses. Previous jurisdiction-specific scans, such as one in Germany, indicated that only about 20% of public health programs integrate digital competencies across their curricula [29]. While the German scan highlighted a strong focus on digital data analytics and informatics, it noted limited attention to social and equity perspectives in DPH—findings consistent with our scan. However, our global scan identified a few programs beginning to address these social perspectives, including understanding and tackling the digital determinants of health [29,30]. In Canada, while no specific environmental scans have been conducted, literature reviews emphasize the need for competency updates to support the deployment of artificial intelligence and other DPH interventions in public health [12,31]. Our study extends the literature by characterizing the nature of inter- and transdisciplinary partnerships, which are critical for designing and delivering such training programs [17,29,32]. The geographic distribution of programs and courses we identified shows a concentration in high-income countries, highlighting significant digital competency gaps in low- and middle-income countries. In many low- and middle-income country contexts, limited digital competency within the public health workforce, often coupled with low self-efficacy, is a key barrier to the uptake of digital technologies [33,34]. This is a gap requiring adaptive models that can leverage open-access curricula and a blend of learning approaches that are adapted to resource-constrained settings.

XSL•FO
RenderX

Given global recognition of the public health implications of societal digital transformation, our study offers valuable guidance to update public health workforce training programs [8]. In Canada, the Chief Public Health Officer's vision for transforming public health prioritizes the use of digital technology [13]. Our findings show that schools of public health are adapting to this global vision in nonstandardized ways. They have focused primarily on data-centric fields such as data science and public health informatics for surveillance, epidemiology, and research through biostatistics and computer sciences [12,29,31]. Furthermore, few programs have comprehensively addressed broader DPH issues, such as digital health promotion, program evaluation, leadership, new media communications, and the digital determinants of health [12,29,35]. Contemporary challenges, such as mis- and disinformation exacerbated by digital transformation, underscore the need to expand efforts in these areas [32,35-37].



While the ASPHER task force on digital transformation has recommended integrating digital determinants of health into curricula, their suggestion to avoid stand-alone courses does not fully support the development of inter- and transdisciplinary skills required for specialized DPH roles [16,38]. Public health professionals require both foundational knowledge through curricular integration and deeper expertise through stand-alone programs or courses [38]. A stepwise approach is needed to review and integrate digital competencies into existing public health curricula as core competencies for all professionals, while also offering specialized training opportunities [38]. This approach must prioritize inter- and transdisciplinary frameworks to develop "T-shaped professionals" equipped to navigate complex challenges while ensuring opportunities for applied training in real-world contexts (Figure 2) [38-40].

However, adopting this inter- and transdisciplinary paradigm requires addressing challenges such as partnerships, administrative barriers, and funding constraints within schools of public health [40,41]. Funding is essential for baseline integration and the design of specialized DPH programs. Advocacy and collaboration with organizations aligned with transdisciplinary public health goals can catalyze this process, as has been demonstrated by programs such as the Canadian Health Systems Impact Fellowship [42]. Establishing transdisciplinary programs requires engaging motivated partners first, gradually expanding to include other collaborators with clearly defined roles and expectations based on desired graduate competencies [39-41]. Engagement with public and private health sectors and digital actors must follow a principles-driven approach that prioritizes equity and health over commercialization and techno-optimism [9,43].

Reflexivity, ongoing dialog, and program co-creation with partners are essential for the effective development and implementation of these programs. Public sector collaboration is crucial to ensuring programs align with health system needs. Educators must clearly define the value and roles of program graduates to enhance their real-world impact. In addition, curricula should prioritize evaluation using clear indicators to measure effects on partner organizations, workforce competencies, and public health outcomes. As many of the identified programs are relatively new, formal evaluations were considered beyond the scope of this study. We recognize that assessing outcomes will be essential for understanding their effectiveness and for securing long-term funding and institutional support [41].

XSL•FO
RenderX

Figure 2. Depiction of a T-shaped professional.

Strengths and Limitations

The findings from this study should be interpreted considering its strengths and limitations. To our knowledge, this is the first systematic documentation of DPH training programs globally. Our approach combined a review of available programs with interviews with training program staff, ensuring both rigor and a deeper understanding of program contexts. We also aimed for an expansive review by including all eligible programs worldwide. However, our reliance on Google Search and the use of English-only terms in the search strategy may have introduced bias, as search algorithms are location specific and prioritize popular programs. To mitigate this, we used Google Translate where appropriate to ensure returns in languages other than English were not excluded. In addition, this study did not comprehensively review all nondigital courses in public health training programs to assess whether current coursework incorporates DPH perspectives. Other similar environmental scans adopted this approach and showed approximately 20% of programs have considered DPH mainly using similar approaches as identified in our review [29]. Our assumptions of digital programs and courses being hosted within the schools of public health, as demonstrated in our search, may have inadvertently missed important DPH programs hosted in other allied schools or programs leveraging cross-listed courses. We also acknowledge limitations in the sample size for the interview with only 4 participants responding out of 22 invitations sent. This limited us from making any interjurisdictional comparisons. While our coding was inductive and did not follow a predetermined framework, the limited sample size led to

XSL•FO
RenderX

categories that closely mirrored the main areas outlined in the topic guide. Nevertheless, the breadth and depth of conversations in the interviews ensure that we can gain useful insights from other programs while encouraging careful appraisal of readers' own context when considering transferability of findings. Further research could include more broad qualitative inquiry of international perspectives, but our work represents an important first step.

Conclusions

This environmental scan of DPH training programs highlights the predominance of data-centric competencies, such as public health data science and informatics, while identifying critical gaps in addressing competencies for digital health promotion, program evaluation, leadership, and digital determinants of health. Despite efforts by schools of public health to align with global and national priorities, progress remains fragmented and geographically limited. To address these gaps, we recommend a stepwise approach that integrates digital competencies as core elements in public health curricula while developing stand-alone programs to cultivate specialized skills. Emphasizing inter- and transdisciplinary frameworks is essential for building "T-shaped professionals" capable of navigating complex public health challenges, but overcoming barriers related to funding, administrative constraints, and partnerships will require sustained advocacy, principles-driven collaboration, and robust evaluation frameworks. These efforts must prioritize equity and health outcomes over commercial imperatives, ensuring that DPH training equips the workforce to respond effectively to the challenges and opportunities of societal digital transformation.

Acknowledgments

The authors would like to express their gratitude to the program directors who freely contributed their time for interviews. This research was supported by the Canadian Institutes for Health Research (CIHR) through the Chief Public Health Officer Catalyst Grant for Transforming Public Health (grant AWD-022946). II is supported by the CIHR Health Systems Impact Fellowship (Award number 521442), Michael Smith Health Research BC Trainee Award (Award number HSIF-2024-04465), and the CIHR Canadian HIV Trials Network (CTN+) postdoctoral fellowship.

Data Availability

The datasets used and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

II and MG conceptualized the study and drafted the study protocol, which was reviewed by HJC, AK, AB, FIC, HD, and GM; II and SR conducted data collection; II and SR analyzed the data and reviewed outputs with all authors; SR and II drafted the manuscript; MG secured funding for the study, and all authors critically reviewed and approved the final version of this manuscript.

Conflicts of Interest

II serves on the board of the Public Health Association of British Columbia. All other authors declare no conflicts of interest.

Abstract

Background: Chronic hepatitis B (CHB) remains a significant health burden for at least a hundred thousand Canadians. The government of Canada has endorsed the global strategy to eliminate hepatitis as a public health threat by 2030, but effectively targeting public health interventions is complicated by the silent nature of the disease, which can remain asymptomatic for decades.

Objective: This study develops a framework to estimate the prevalence of CHB and the proportion of the infected population that remains undiagnosed. We apply the proposed method to national data from Canada, from 2007 to 2021.

Methods: We infer the prevalence and undiagnosed proportion of CHB by fitting a mathematical state-transition model, based on the natural history of CHB, to observed CHB-related events. Data for the calibration were obtained from the Public Health Agency of Canada and Statistics Canada.

Results: We estimate the national prevalence of CHB in Canada in 2021 to be 0.483% (95% CI 0.443%-0.535%). The corresponding percentage of undiagnosed cases was estimated to be 54.3% (95% CI 50.9%-58.9%).

Conclusions: The estimates of CHB prevalence obtained via our method are in line with previous estimates obtained from national seroprevalence studies. More specialized estimates, stratified by province or age cohort, may be achievable with detailed health administrative data.

Introduction

Chronic hepatitis B (CHB) is a silent disease. In its early stages, which can last decades, it is largely asymptomatic. Because of this, those with the disease can remain undiagnosed for years until they are alerted to their condition by late-stage complications: decompensated cirrhosis (DC), hepatocellular carcinoma (HCC), and liver failure. It was estimated that hepatitis B caused 1.1 million deaths worldwide in 2022 [1].

In 2016, Canada endorsed the Global Strategy to eliminate hepatitis as a public health threat by 2030 [2]. It has already made progress toward this goal; a seroprevalence study published in 2013 estimated the national prevalence of CHB to be 0.4%, well below the global average [3]. This is in large part thanks to Canada's robust vaccination program. In 2021, vaccine coverage was 89% for those aged 14 years or older [4]. However, many challenges remain: hepatitis B was one of the most frequently refused vaccines in 2021, third behind only varicella and rotavirus, and the lack of a nationally standardized vaccine schedule means that children who move across provincial lines may miss vaccination due to conflicting schedules [4,5]. Moreover, this vaccination program leaves several key populations underprotected, notably immigrants from countries with high hepatitis B prevalence and children exposed prior to vaccination, a risk that is elevated in provinces that do not have an infant vaccination program. The same 2013 seroprevalence study found that the CHB prevalence among the foreign-born population was 1.6%, 4 times the national

XSL•FO
RenderX

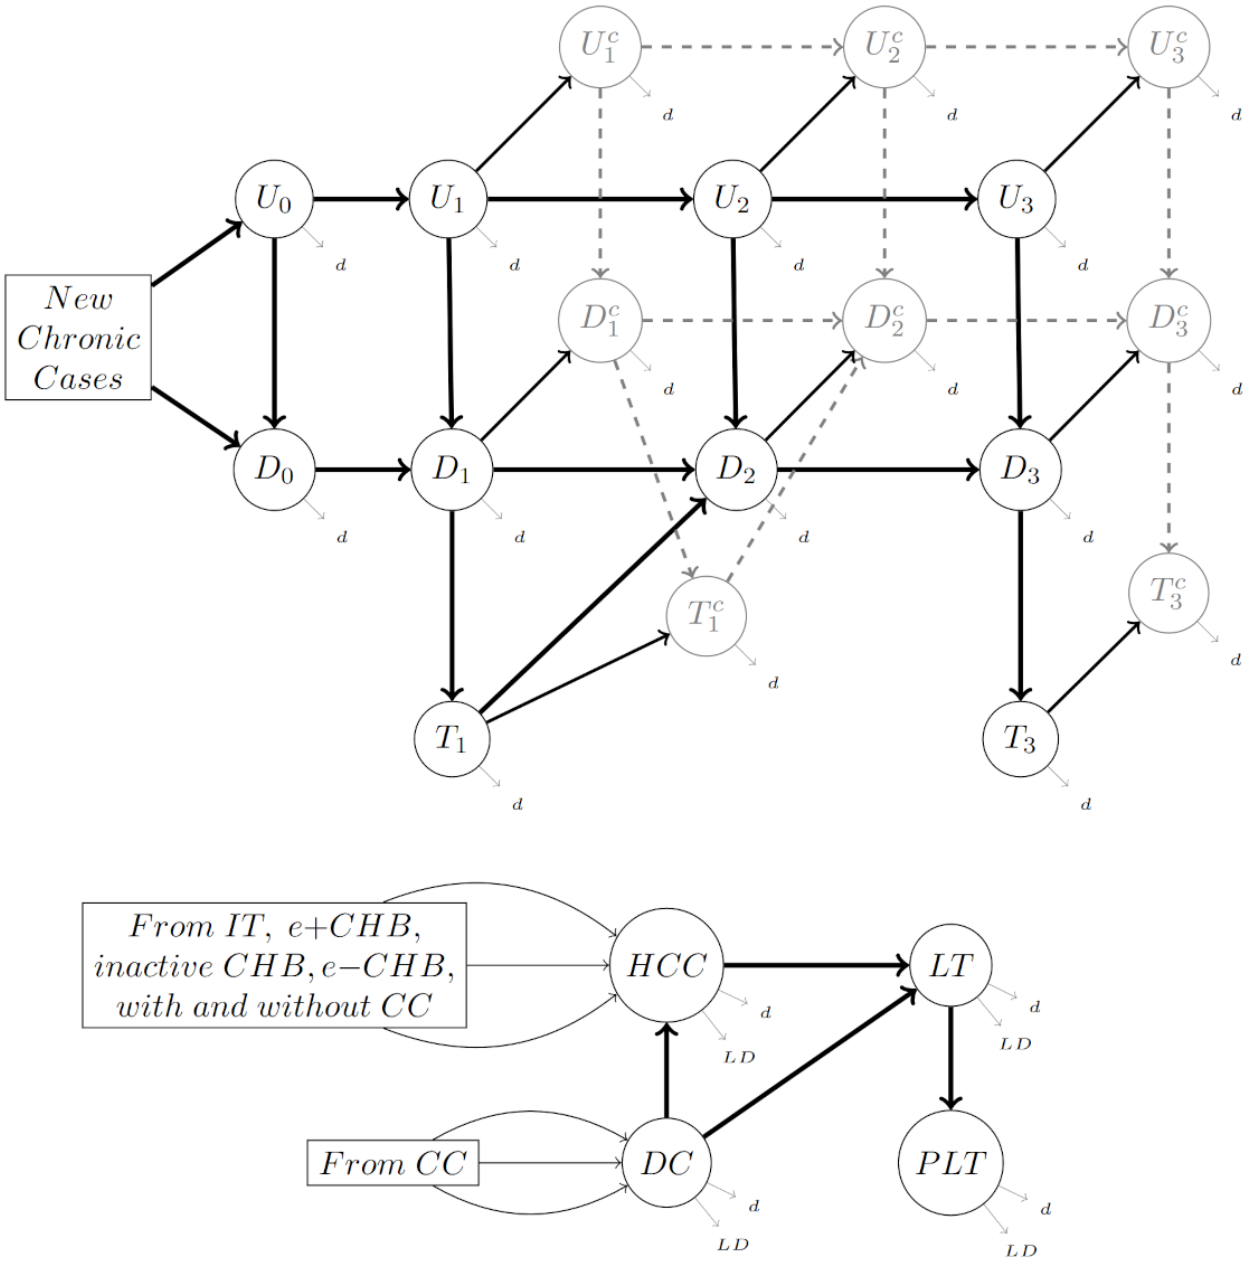
average [3], and 90% of unvaccinated infants born to hepatitis B virus (HBV)–infected mothers will develop CHB within 6 months [6]. The risk of contracting CHB also increases with exposure to infected blood and other body fluids, such as through needle sharing or unprotected sex [1].

These at-risk groups comprise a significant portion of Canada's population. According to the most recent Canadian census published in 2021 [7], immigrants represent 23% of the country's total population. Many of these originate from regions where HBV is either highly or moderately endemic, notably China and the Philippines, which, along with India, have been the top 3 sources of immigrants to Canada since 1991. As a result, a significant proportion of the CHB population in Canada is comprised of immigrants. Furthermore, Canada's vaccination program leaves a significant portion of the population underprotected. Many of the provinces still perform adolescent vaccination instead of birth dose vaccination [8]. Other gaps exist in the country's prevention strategy. For example, in Ontario, prenatal screening for HBV was not universal, with a coverage of 92.7% between 2012 and 2016. These gaps resulted in at least 139 children born between 2003 and 2013 being infected with HBV before being eligible for adolescent vaccination [9].

Meeting Canada's elimination goals will require further evidence-based interventions, such as screening and community outreach, rooted in robust estimates of CHB prevalence to track the impact and the efficacy of these investments in public health. In this paper, we present a model-based framework for estimating the prevalence and undiagnosed proportion of CHB. Our approach follows in the line of similar back-calculation methods used for other diseases with long incubation periods, such as hepatitis C [10,11] and HIV [12]. Similar methods have also been used to estimate the prevalence and undiagnosed fraction of COVID-19 [13]. To our knowledge, the present study represents the first attempt to apply such back-calculation techniques to CHB.

Methods

Overview



In this section, we describe the mathematical framework we use to estimate the prevalence of CHB in populations of interest. We developed a state-transition model of CHB progression based on the natural history of the disease, building on earlier work in [14]. The model includes several late-stage clinical health states, such as DC and HCC, which are more readily diagnosed than the asymptomatic stages of CHB. Indeed, we assume that the symptoms of these late-stage clinical health states are severe enough that they will be diagnosed within 1 year. Using a Bayesian calibration method based on the Metropolis-Hastings algorithm, we used publicly available diagnosis data for these late-stage complications, in combination with diagnosis data for CHB itself, to back-calculate the prevalence and undiagnosed fraction of CHB.

Natural History Model

We developed a state transition model to describe the infection, progression, and treatment process, following the natural history of CHB. A schematic of this model is presented in Figure 1. We assume that people infected with CHB will remain in exactly one state for the duration of a given calendar year. Once per year, individuals may transition to a different state based on probabilities derived from the parameters in Table 1 and Multimedia Appendix 1. Some of these state transitions, such as the transition from an undiagnosed state to a diagnosed state, correspond to observable events recorded by public health officials. Our goal is to infer the number of individuals in each state by calibrating the model to reproduce the time evolution of these observables.

XSL•FO

Table . Unknown model parameters. The minimum and maximum constrain the range explored during the calibration process.

Parameter	Description	Min	Max
dl/r	Annual probability of CHB[a] diagnosis	0.005	0.5
dcc	Annual probability of CC[b]-specific diagnosis	0	0.1
daa	Probability of newly infected individuals being diagnosed with CHB within the first year	0	0.3
µl/r	Annual CHB incidence	0	0.1
rhcc0	Adjustment to CHB-related HCC[c] risk	0	1

[a]CHB: chronic hepatitis B.

[b]CC: compensated cirrhosis

[c]HCC: hepatocellular carcinoma.

The structure of our state-transition model is depicted in Figure 1. For clarity, the early stages in the top portion of the diagram are organized along x-, y-, and z-axes based on their nature. The states are organized in rows and denoted by U, D, and T, corresponding to the cascade of care, specifically, the undiagnosed and untreated states, for those who have CHB but are unaware of their infection; the diagnosed and untreated states, for those with a positive CHB diagnosis who have not initiated treatment; and diagnosed and treated states, for those receiving treatment for their CHB infection. Each of these basic states is further subdivided into sub-stages, organized into columns, that represent the natural history of CHB. These sub-stages are denoted using a subscript. The subscript 1 denotes chronic hepatitis B e-antigen (HBeAg) + hepatitis B (hepatitis B surface antigen [HBsAg]: positive, HBeAg: positive, viral load: high, ALT level: high). The subscript 2 denotes Inactive Hepatitis B (HBsAg: positive, HBeAg: negative, viral load: low, ALT level: normal). The subscript 3 denotes Chronic HBeAg-Hepatitis B (HBsAg: positive, HBeAg: negative, viral load: high, ALT level: high).

Finally, each of these states can exist with or without compensated cirrhosis (CC), which, when present, is represented with a superscript C. In order to cover the whole natural history of CHB, we also include 2 states, U0 and D0, corresponding to the immune tolerant state (HBsAg: positive, HBeAg: positive, viral load: high, ALT level: normal).

People infected with CHB may progress into advanced stages of liver disease, which are depicted in the bottom half of Figure 1. These advanced stages are categorized into the following states: HCC, DC, liver transplant (LT), and post–liver transplant (PLT).

We define the LT state to last at most 1 year. Transplant recipients who have survived more than 1 year after their liver transplantation enter the PLT state. Additionally, we assume that individuals in these later states have a probability of mortality greater than the background all-cause mortality. This is represented by arrows to a liver death state, LD. Background mortality is represented by an arrow to a death state, d. A full list of model states is included in Multimedia Appendix 2.

Finally, we assume that in the year *t*, there are u(t) new CHB infections. These new infections include observed infections that are diagnosed within the first year, in which case they will be directed to the state D0, as well as unobserved cases that remain undiagnosed and go to U0.

Model Transition Probabilities

The transition probabilities of the model depend on a mix of known and unknown parameters. The known parameters are obtained from the literature and are presented in Multimedia Appendix 1. The unknown parameters are presented in (Table 1). We will estimate these unknown parameters using our calibration procedure, which is described in later sections of this paper.

Because CHB is initially asymptomatic, we assume that the probability of receiving a diagnosis is constant across all the undiagnosed states U_i. In principle, these diagnosis probabilities can vary significantly from year to year. As a simplifying approximation, we assume that this trend is linear over the period being modeled, with a diagnosis probability of dl in the first year being modeled, tinit, and a final diagnosis probability of dr in the last year modeled, tfin. For notational convenience, we denote this time-dependent quantity dl/r(t). For undiagnosed states with compensated cirrhosis, we add an annual probability of CC-specific diagnosis, dcc, to allow for the fact that compensated cirrhosis may likely produce symptoms, which increases the probability of diagnosis. Thus, the diagnosis probability for an individual in one of the UiC states would be dl/r(t)+dcc. Finally, we apply a different diagnosis probability for the first year of infection, daa. In any given year, daau(t) new cases will be added to the D0 state, with the remaining (1−daa)u(t) cases being added to the U0 state. This first-year diagnosis probability allows us to account for CHB-infected individuals who seek screening following high-risk behavior or immigrants who disclose their health status on entering the country.

Much like the diagnosis probability, we also assume that CHB incidence, µ, is a linear function of time. Following the same notational convention as earlier, the number of new cases in a given year is given by u(t)=µl/r(t)·Pop(t), where Pop(t) is the

XSL•FO
RenderX

population of the cohort being studied. We note that several of the parameter extrema, such as a CHB incidence of 0.1, are set implausibly high to grant the model the flexibility to explore all plausible parameter values.

The final calibration parameter, rhcc0, is an adjustment parameter that aims to account for uncertainty in the probability of developing HCC. The annual probabilities of developing HCC, as reported in the literature, are compiled in Multimedia Appendix 1.

Finally, we note that these model parameters, both known and unknown, represent the underlying probabilities associated with any basic state transition. In principle, simulating the full state transition model represented by Figure 1 would also require knowledge of joint probabilities. In order to obtain a tractable model, we make the simplifying assumption that each of these basic events is independent.

Model Assumptions

We highlight some key simplifying assumptions made during the development of the model (Textbox 1).

Textbox 1. Model assumptions.

- Incidence rate is a linear function of time and does not explicitly depend on other factors, such as vaccine uptake.
- The age distribution of the population with chronic hepatitis B (CHB) matches that of the general population. In particular, age-related quantities, such as the background mortality rate, are the same in both populations.
- There is no net migration of infected individuals after arrival. Moreover, because CHB has no readily available cure (spontaneous loss of hepatitis B surface antigen [HBsAg] is possible, but rare), we assume that the number of cases can only decrease by death.
- Treatment uptake and efficacy remained constant over the observed period, as did survival rates of late-stage complications.

Model Dynamics

For each of the model states (U0, D0, U1, ..., HCC, DC, LT, and PLT), the state-transition model generates a time series for the expected number of individuals in each state. We denote these by U0(t), D0(t), ..., and PLT(t), for t=tinit,...,tfin. Additionally, we record the number of individuals transitioning between states. These simulated time series—the number of individuals in each state and the number of individuals transitioning between states—are used to calculate 4 *observables*, which are used to calibrate the model. The first of these is the number of people receiving treatment, T1(t)+T3(t)+T1C(t)+T3C(t). Based on clinical guidelines [15], treatment is mainly offered to infected individuals in HBeAg+ and HBeAg- states, and thus our model does not include an inactive treatment state, T2. The remaining observables are the number of CHB diagnoses, the number of HCC diagnoses, and the number of late HCC diagnoses, which we define as any transition from an undiagnosed state, Ui-/C, to the HCC state. These diagnosis events correspond to transitions between undiagnosed states to diagnosed states. The details of these computations can be found in (Multimedia Appendix 2).

Data Sources

The observables described earlier are compared to 3 data sources: the annual number of HCC diagnoses, obtained from Statistics Canada [16], which we will denote YHCCTotal(t); the annual number of CHB diagnoses, obtained from the Public Health Agency of Canada's (PHAC) Notifiable Diseases Online [17], denoted YCHB(t); and CHB treatment data, which is based on prescription data obtained from IQVIA via collaboration with PHAC, denoted YTreat(t). The CHB and treatment data can be directly compared to their corresponding observables, but the other 2 observables require additional assumptions on the data before they can be used.

The HCC figures from Statistics Canada include all instances of HCC, regardless of cause. Following [14], the estimated number of CHB-related HCC cases is 9% of total HCC cases, $YHCC(t) = 0.09 \cdot YHCCTotal(t)$.

In [18], an estimated 1.07% of CHB diagnoses (198 of 18,434) occur within ±6 months of an HCC diagnosis. Thus, we assume the number of late HCC diagnoses per year is given by

$$.YLateHCC(t)=0.0107 \cdot YCHB(t)$$

Reporting HBV cases is mandatory. Therefore, we can be confident that the Notifiable Diseases Online database accurately reflects the number of HBV diagnoses. However, although HBV diagnoses must be reported, the chronic versus acute distinction is not reportable in all provinces and territories. Unspecified cases were apportioned based on the chronic-to-acute ratio observed in the specified cases. We note that although the rate of HBV diagnosis per se may be biased (not all people who are infected will seek medical attention, and therefore the Notifiable Diseases database might systematically underrepresent populations less likely to interact with the health care system), the structure of our mathematical model accounts for this possibility. Bias or underreporting in the diagnoses of late-stage complications represents a greater source of uncertainty in the model. As such, the HCC data from Statistics Canada represents the most significant source of data-related uncertainty in our analysis. The data for model calibration are available in Multimedia Appendix 3.

Model Calibration

The model contains several unknown quantities that need to be inferred via model calibration. These come in 2 broad categories: the unknown parameters from Table 1, and the initial population sizes for each of the model states.

If the initial population distributions in the year tinit deviate too much from the true values, the calibration converges to a spurious local optimum. In order to avoid this, we use a 2-stage calibration process. We begin by assuming a prevalence of 0.4%, in line with earlier seroprevalence results [3], and distribute these among the states in the model based on

XSL•FO
RenderX

percentages used in previous modeling studies [19]. We then calibrated the model against data from a subset of provinces—Alberta, British Columbia, Ontario, and Saskatchewan—whose diagnosis, treatment, and HCC data were the most complete and selected the population distribution that yielded the closest match to their data. These population distributions then served as our initial distribution in all subsequent calibrations.

In order to obtain an initial estimate of incidence, μl/r, we assume the system is in approximate equilibrium and apply the same 0.4% seroprevalence estimate. This yields a preliminary estimate of μl/r≈0.00004.

In principle, the early diagnosis parameter, daa, can take any value between 0 and 1, though in practice we know that values close to 1 are unrealistic. We restrict our search range to 0≤daa≤0.3 [18].

Calibration Algorithm

Following [10], we use a 2-stage calibration algorithm, which is designed to account for the uncertainty in the literature-derived parameters. Let vlit=[q01,...,dld4] be a set of the literature-derived model parameters, ie, a set of parameters sampled from the ranges in Multimedia Appendix 1. Similarly, let vcal= [dl,...,rhcc0,U0(tinit),...,PLT(tinit)] denote a set of the calibration parameters, ie, a set of the unknown model parameters from Table 1 and a set of initial population estimates. Taken together, a single pair (vlit,vcal) determines the initial conditions and transition probabilities, and thus fully specifies the behavior of the state transition model. The goal of our calibration is to generate pairs that yield a good fit with the available data.

Our 2-stage calibration algorithm is described as follows:

Stage 1: We begin by generating k sets of the literature-derived parameters,

[v1lit,…,vklit], by sampling uniformly from the ranges in Multimedia Appendix 1. For each sample vilit, we calibrate the model using the Metropolis-Hastings MCMC algorithm [20], using the likelihood function described in Multimedia Appendix 2, until the Markov chain converges to a stationary distribution, P(vcal|Y,vilit). Discarding the burn-in, we obtain a set of n samples for the unknown parameters, [v1cal,…,vncal], sampled from this distribution.

Stage 2: The samples generated in the first stage are conditioned on a choice of vilit. Thus, in order to obtain a full set of model parameters, we perform a second sampling step. We first sample uniformly from the literature-derived parameters obtained in step 1, [v1lit,…,vklit], and then sample uniformly from the associated distribution obtained via the MCMC algorithm. The result is a single combined set of parameters, (vlit,vcal), sampled from the distribution P(vlit,vcal|Y).

For each pair (vlit,vcal) derived in this way, the model produces a time series for each of the model states, U0(t), D0(t), ..., PLT(t). In order to describe the typical behavior of our model, we sample multiple pairs (vlit,vcal) and compute the means of the associated time series, $\bar{U0}(t)$, $\bar{D0}(t)$, ..., $\bar{PLT}(t)$, as well as the corresponding standard deviations.

We obtain a prevalence estimate by summing over all model states and dividing by the total population size.

$$\text{CHB prevalence}(t)=[\bar{U0}(t)+\bar{D0}(t)+...+\bar{PLT}(t)]/\text{Pop}(t)$$

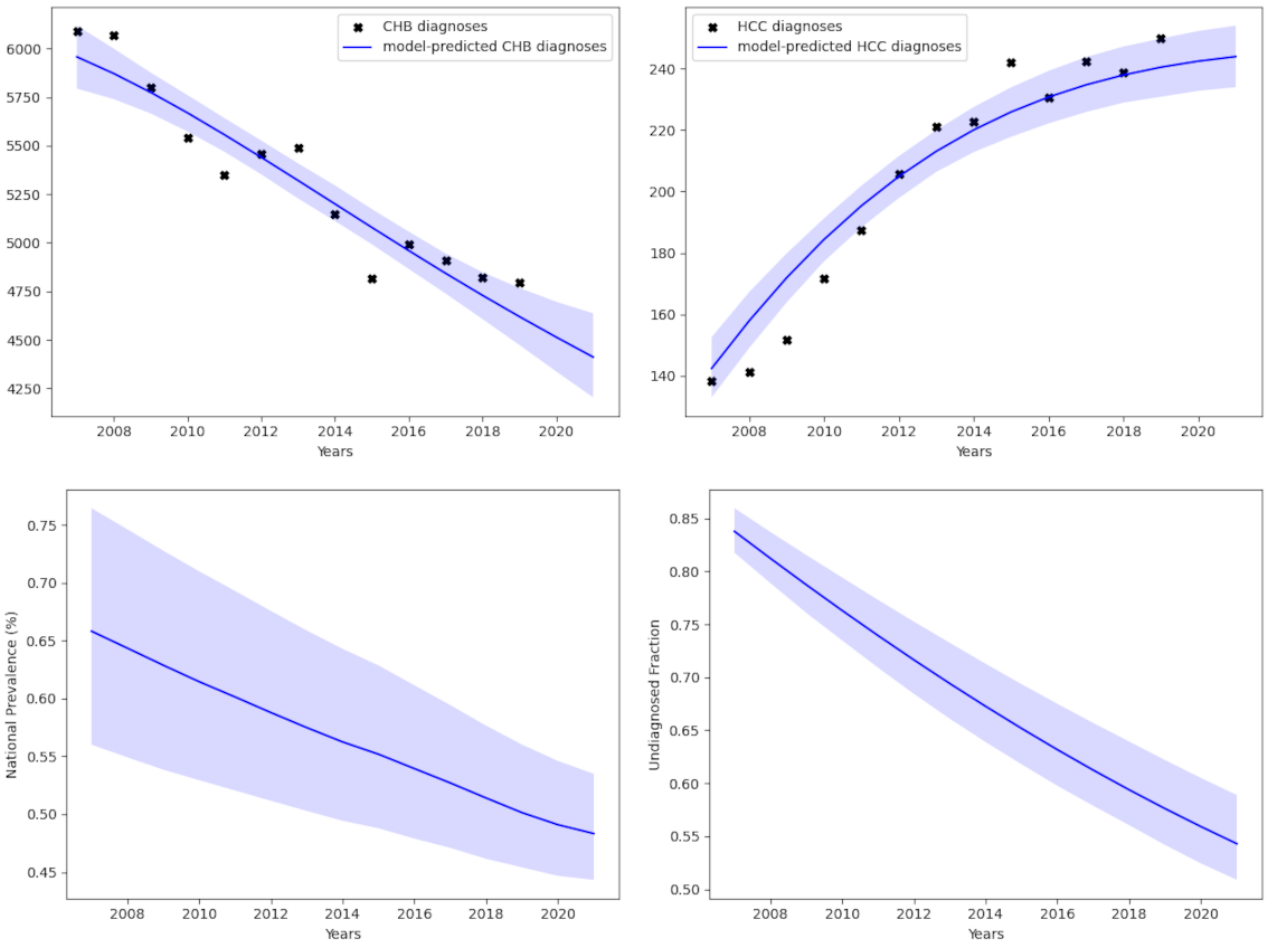
The undiagnosed fraction is computed as the ratio of all undiagnosed states and the total CHB.

U

$$\text{Undiagnosed fraction}(t)=\bar{U0}(t)+\bar{U1}(t)+...+\bar{U3C}(t)\bar{U0}(t)+\bar{D0}(t)+...+\bar{PLT}(t)$$

Using this 2-stage calibration algorithm, we first estimate the national prevalence. We then conduct a stratified analysis for male and female populations. Finally, we conduct a one-way sensitivity analysis to explore the uncertainty associated with these estimates.

Ethical Considerations



This study uses publicly deidentified data collected by Public Health Agency of Canada and Statistics Canada. The analysis procedure has been approved by the Research Board at the University of Waterloo (#43995).

Results

After completing the calibration process outlined earlier, the algorithm identified a set of model parameters and initial conditions that can closely match with the observed statistics on CHB diagnosis and HCC diagnosis (Figure 2). In order to produce such a fit, the national prevalence of CHB in 2021 was estimated to be 0.483% (95% CI 0.443% - 0.535%), while the proportion undiagnosed in 2021 was estimated to be 54.3% (95% CI 50.9% - 58.9%; Figure 2). The model had a deviance information criterion of 53.9.

XSL•FO

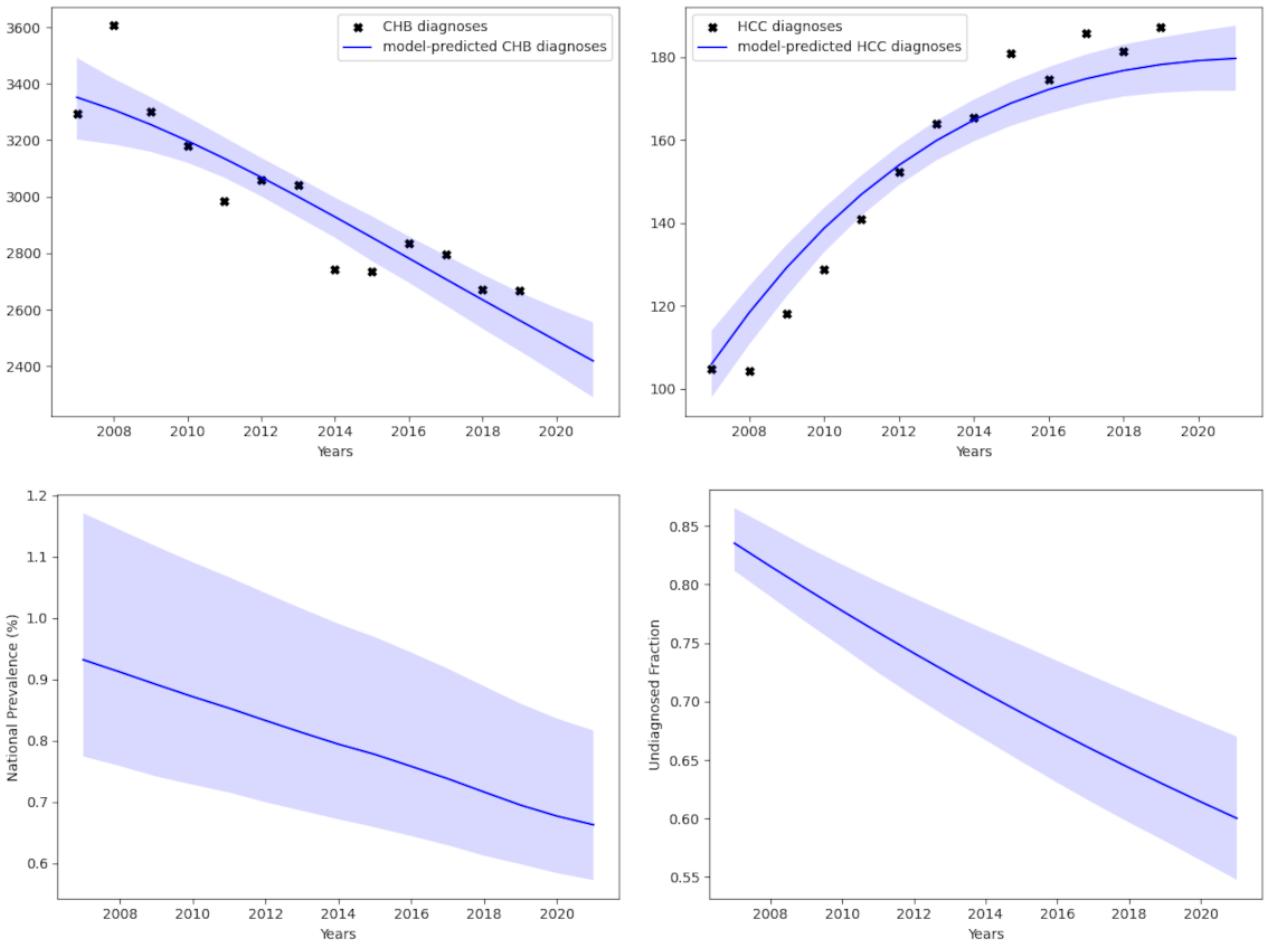
Figure 2. Estimates of the national chronic hepatitis B (CHB) prevalence across all cohorts. The top 2 plots show the model fit compared to data for CHB diagnoses (top left) and CHB-attributed hepatocellular carcinoma (HCC) diagnoses (top right). The bottom 2 plots accordingly display the estimates of prevalence (bottom left) and of the undiagnosed proportion (bottom right).



Stratified Analyses

We conducted a second calibration stratified by sex. Again, the algorithm identified a set of model parameters and initial conditions that closely match the observed statistics on CHB diagnosis and HCC diagnosis for the male population (Figure 3) and the female population (Figure 4). In order to produce these fits, the stratified analyses suggest a slightly higher prevalence of 0.663% (95% CI 0.572% - 0.816%) in the male population, while the proportion undiagnosed in 2021 was estimated to be 60.0% (95% CI 54.8% - 67.0%; Figure 3). In the female population, we obtain a slightly lower prevalence of 0.382% (95% CI 0.347% - 0.424%), while the proportion undiagnosed in 2021 was estimated to be 48.8% (95% CI 44.2% - 54.0%; Figure 4). The male and female fits had deviance information criteria of 9.0 and 73.2, respectively. The differences in prevalence obtained from this calibration process are consistent with the known sexual dimorphism in CHB [21].

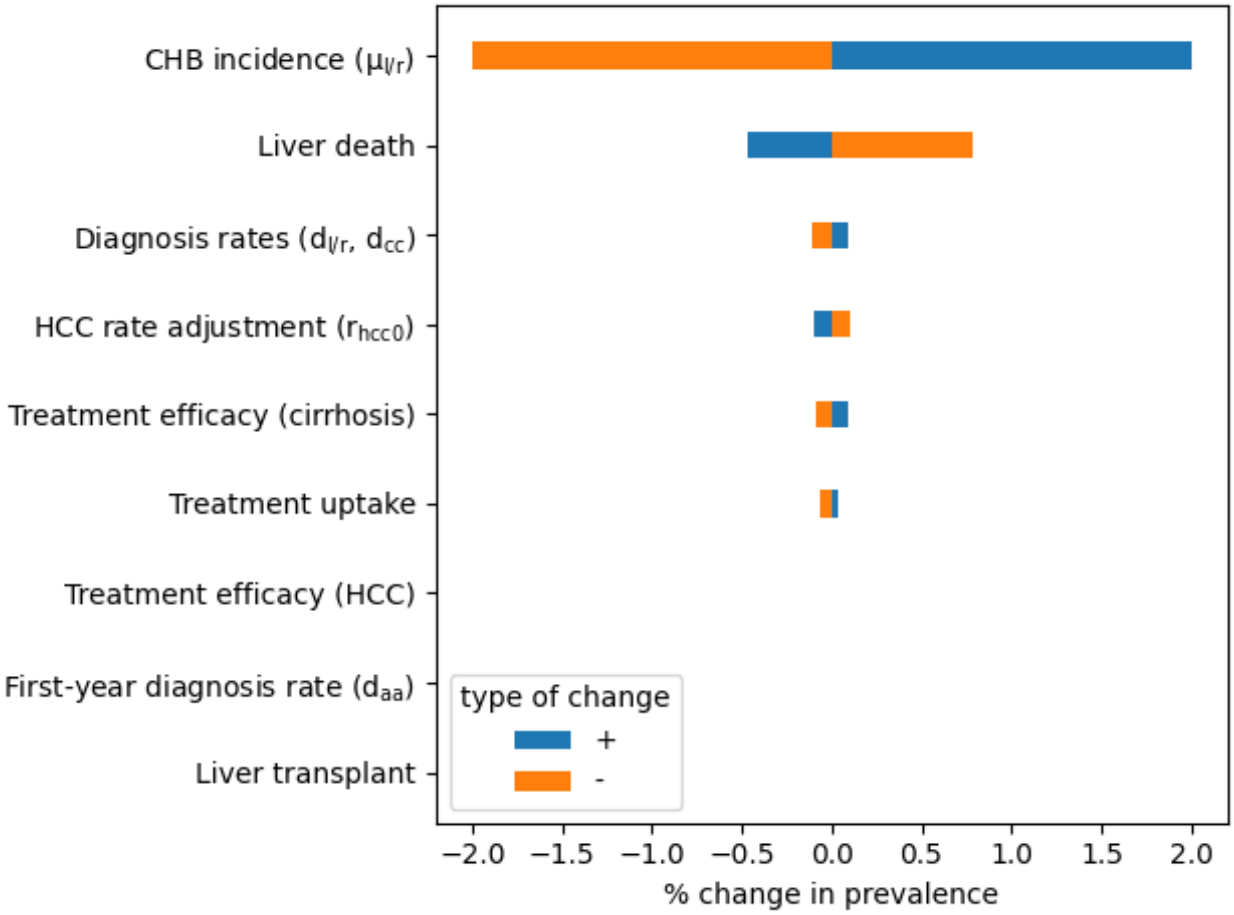
Figure 3. Estimates of the chronic hepatitis B (CHB) prevalence in males. The top two plots show the model fit compared to data for CHB diagnoses (top left) and CHB-attributed hepatocellular carcinoma (HCC) diagnoses (top right). The bottom 2 plots accordingly display the estimates of prevalence (bottom left) and of the undiagnosed proportion (bottom right).

XSL•FO
RenderX

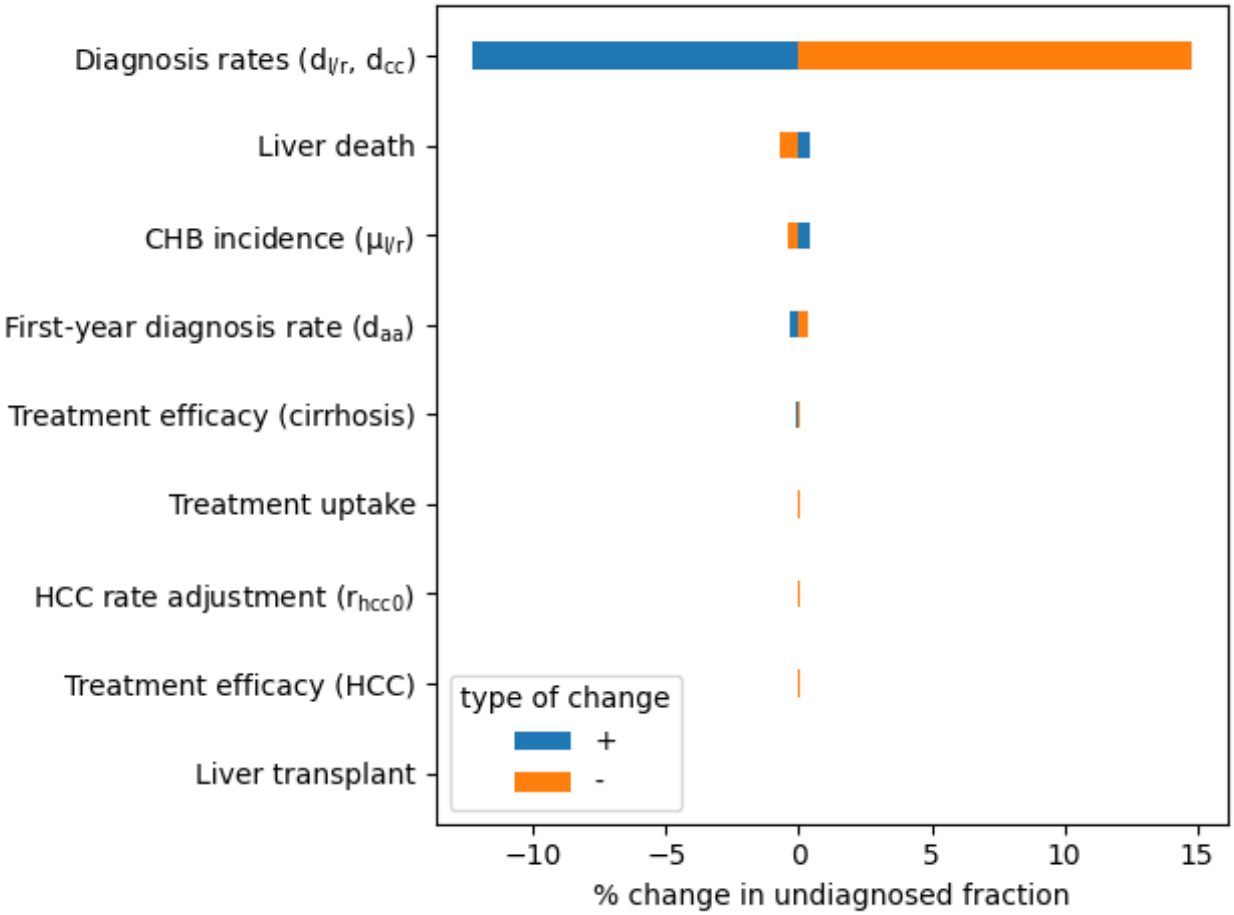
Figure 4. Estimates of the chronic hepatitis B (CHB) prevalence in females. The top two plots show the model fit compared to data for CHB diagnoses (top left) and CHB-attributed hepatocellular carcinoma (HCC) diagnoses (top right). The bottom 2 plots accordingly display the estimates of prevalence (bottom left) and of the undiagnosed proportion (bottom right).



In addition to stratifying by sex, we also attempted an analysis based on age cohort. However, because late-stage complications are highly skewed toward older individuals, the dataset for the younger cohort was too small and noisy to make reliable inferences. We intend to address this in future work with better health administrative data.

Sensitivity Analysis

We performed a 1-way sensitivity analysis of the calibrated model, varying the parameters in Table 1 to determine which components of the model caused the greatest variation in the estimates of the prevalence and undiagnosed fraction. Parameters were varied by ±50%, and we measured the resulting change in the prevalence and diagnosed fraction, averaged over the time period studied (2007 - 2021). The results are presented in Figures 5 and 6.



XSL•FO
RenderX

Figure 5. One-way sensitivity analysis for the estimated prevalence of chronic hepatitis B (CHB). HCC: hepatocellular carcinoma.

XSL•FO
RenderX

Figure 6. One-way sensitivity analysis for the estimated undiagnosed proportion of CHB infections. CHB: chronic hepatitis B; HCC: hepatocellular carcinoma.

As expected, the yearly CHB incidence has the largest impact on prevalence. Other parameter changes impact prevalence indirectly by changing the mortality rate. This effect was seen most strongly in the probability of liver death associated with late-stage complications. Changing the diagnosis probabilities or HCC incidence also increased prevalence, presumably because of their downstream effects on CHB-related mortality. Similarly, increasing the treatment uptake and treatment effectiveness increased prevalence due to the associated drop in mortality. The effects of daa on prevalence were negligible.

Changes in the diagnosis probabilities had the largest effect on the undiagnosed fraction, followed by the probability of liver death, CHB incidence, and daa, which had comparable effects. Changes in events downstream of diagnosis, such as HCC incidence or treatment effectiveness, did not change the overall prevalence enough to have a significant impact on the undiagnosed proportion.

Discussion

Principal Results

CHB has a long incubation period, often progressing undetected until the onset of late-stage complications. This creates significant uncertainties in the prevalence and undiagnosed proportion and poses challenges to policymakers who wish to measure the efficacy of public health interventions or track progress toward elimination targets. We have proposed a model-based method to estimate these quantities. Using limited CHB and HCC diagnosis data, we estimate prevalence in 2021 to be 0.483% (95% CI 0.443% - 0.535%). These results are in line with previous 0.4% seroprevalence estimates [3]. Additionally, the proposed method provides estimates of the fraction of CHB cases that remain undiagnosed, in this case 54.3% (95% CI 50.9% - 58.9%). Again, this is in line with previous estimates. The same Canadian seroprevalence study indicated that 46% of respondents who tested positive for a present HBV infection knew of their infected status.

These numbers are comparable to estimates obtained in other countries. In 2022, approximately 205,549 individuals in Australia were living with CHB, representing 0.78% of the population. It is estimated that 27.9% of these remain undiagnosed [22]. The prevalence of hepatitis B varies across European Union/European Economic Area countries, with estimates ranging from 0.1% in Ireland to 4.4% in Romania [23]. The proportion of undiagnosed infections also varies widely, ranging between 45% and 85%, highlighting gaps in national testing programs [24]. Although our results are focused on Canada, other high-income, immigrant-receiving countries like the United Kingdom and Australia may also benefit from applying the methods developed in this paper.

XSL•FO
RenderX

A 1-way sensitivity analysis identifies CHB incidence as the greatest factor influencing overall prevalence, followed by the probability of liver death in late-stage clinical health states, followed by treatment efficacy against cirrhosis. The undiagnosed fraction was sensitive to changes in diagnosis probabilities and CHB incidence, but treatment efficacy did not impact prevalence enough to have a significant effect on the undiagnosed proportion.

Limitations

The estimation method we have presented has several advantages. For one, it is systematic: the analysis we have performed can, in principle, be extended to any cohort for which data are available. Additionally, the 2-step calibration method accounts for uncertainty in the model parameters that are derived from the literature, yielding statistically robust estimates. However, a few important limitations constrain its use. We made the simplifying assumption that the CHB incidence is a linear function of time, but the 1-way sensitivity analysis identified CHB incidence as the parameter with the largest impact on prevalence. Therefore, the assumption of linearity greatly limits the time resolution of the model. As such, the time series presented in this paper should be taken as indicators of overall prevalence trends, rather than a detailed year-by-year accounting. In particular, the model incidence as currently formulated cannot accommodate sudden changes in vaccine uptake or immigration rates. This latter limitation may be addressed by immigrant sub-cohort modeling, though we currently lack the data required to perform this analysis. There is also considerable uncertainty surrounding HCC incidence. For one, the HCC data we use for calibration include HCC from all causes. Following [14], we estimate that hepatitis B accounts for 9% of HCC cases, but this estimate does not account for annual variation. Moreover, as with all cancers, HCC incidence is known to be highly age-dependent, but the available HCC data were not detailed enough to calibrate a state transition model that accounts for age. This latter limitation makes it impossible to reliably stratify our analysis by age cohort. Fortunately, both of these HCC-related limitations can be addressed with more accurate health administration data.

Conclusions

With these limitations in mind, our results point to some notable public health concerns. Despite Canada's 2016 endorsement of ambitious elimination targets, our 2021 CHB prevalence estimate does not indicate a significant decrease over previous estimates from 2013. Hepatitis B continues to be a substantial health burden for at least a hundred thousand Canadians. Of these, a significant proportion remains undiagnosed and untreated, putting them at increased risk of serious complications. Our analysis suggests that measures to decrease CHB incidence, such as vaccination and screening, have the greatest potential to decrease the overall disease burden. Based on our current data limitations, further stratified analysis is not possible. Our next step will be accessing health administrative data to overcome this barrier, with the aim of producing more reliable and detailed estimates.

We have presented a method to estimate the prevalence of CHB, using a state transition model based on the natural history of the disease. The estimates are obtained via a 2-stage calibration process that incorporates multiple sources of uncertainty, yielding results that are robust to perturbations of the model. This calibration process relies only on diagnosis data, which are already collected by the health care system, making it an attractive alternative to seroprevalence studies and other methods that require the collection of novel data. Conversely, a lack of high-quality health administrative data significantly limits the accuracy of the model. This is especially true among small populations and younger age cohorts, as younger individuals will typically not have developed a large and statistically robust pattern of late-stage complications. With more data, these estimates can further be stratified by region or by age cohort, allowing them to inform the targeting of public health interventions.

Acknowledgments

Abstract

Background: Viral infections, including those leading to sepsis, are common but often overlooked in clinical practice, yet the treatment strategies for viral sepsis remain inadequately defined.

Objective: This study aims to investigate the effectiveness of antivirals nirmatrelvir-ritonavir and molnupiravir in the treatment of culture-negative sepsis.

Methods: This retrospective cohort study was conducted across public hospitals in Hong Kong. We included patients diagnosed with COVID-19 between February 22, 2022, and June 30, 2023, who had no secondary bacterial or fungal infections. Propensity score matching was used to assess the efficacy of the antivirals nirmatrelvir-ritonavir and molnupiravir in patient subgroups with or without organ dysfunction at hospital admission, including circulatory shock, respiratory failure, acute kidney injury, coagulopathy, acute liver impairment, a composite of all organ dysfunctions, or no organ dysfunction. Key outcomes were in-hospital mortality and length of stay, reported as hazard ratios (HR) and mean differences, respectively.

Results: The study included 15,599 COVID-19 patients with a mean age of 75.1 (SD 15.9) years. Molnupiravir treatment was associated with a significantly lower risk of mortality in patients in both the presence of any organ dysfunction (HR 0.75, 95% CI 0.58 to 0.96) and without organ dysfunction (HR 0.29, 95% CI 0.15-0.56). Nirmatrelvir-ritonavir was associated with decreased mortality with respiratory failure (absolute risk difference: 9.5%, 95% CI 6.26-12.72) and without organ dysfunction (HR 0.17, 95% CI 0.05-0.56). Antivirals also reduced the length of hospital stay; nirmatrelvir-ritonavir reduced length of stay in respiratory failure by an average of 3.37 (95% CI 2.32-4.42) days, acute kidney injury by 7.25 (95% CI 2.97-11.52) days, and coagulopathy by 7.04 (95% CI 2.99-4.05) days. Molnupiravir reduced the length of stay in acute kidney injury by an average of 6.7 (95% CI 2.39-11.08) days and coagulopathy by 5.68 (95% CI 1.20-10.16) days.

Conclusions: Antivirals reduced mortality among hospitalized COVID patients, with the greatest reduction observed in patients without organ dysfunction. Antivirals were also effective in reducing the length of hospital stay.

RenderX

Introduction

Sepsis, a syndrome characterized by organ dysfunction resulting from a dysregulated response to infection, poses a significant mortality risk [1]. While bacterial and fungal infections are well-recognized causes of sepsis, viral infections—especially in older people and immunocompromised individuals—are often overlooked despite their potential to cause severe illness [2].

Extensive literature has primarily focused on bacterial sepsis, with early antibiotic administration being the cornerstone of its treatment [3,4]. However, the emergence of COVID-19, caused by the SARS-CoV-2, has sparked renewed interest in the role of viral infections in sepsis. Despite ongoing vaccination efforts that have reduced the severity and mortality associated with COVID-19 [5], the disease continues to significantly impact vulnerable populations, particularly older people.

A meta-analysis revealed that the majority of COVID-19 patients admitted to the ICU met the Sepsis-3 criteria [6]. During the early phases of the pandemic, COVID-19 accounted for 1 in 6 sepsis cases [7]. COVID-19 is associated with a range of organ dysfunctions, including circulatory shock, respiratory failure, acute kidney injury, liver impairment, and coagulopathy [8]. Yet, the use of antivirals in patients across varying organ dysfunction presentations remains inadequately understood. On a related note, recent studies support nirmatrelvir-ritonavir use in other critical conditions, such as in patients with advanced kidney disease [9], in hematologic malignancies [10], and in immunosuppressed patients [11], where antivirals reduced length of stay, shortened time to symptom resolution, and reduced viral load.

Viral sepsis remains underdiagnosed due to its lack of specific clinical manifestations [12]. Early research indicates that viral sepsis often occurs without secondary bacterial and fungal infections; for instance, 76% of blood and sputum cultures from COVID-19 patients were negative for bacteria and fungi [13].

Currently, guidelines offer limited recommendations for the use of antivirals in patients with viral sepsis [14,15], highlighting the need for further research to establish effective treatment protocols. This study aims to evaluate the effectiveness of antiviral treatment in a cohort of COVID-19 patients who had negative blood culture results during their hospital stay, thereby contributing to the evidence base for managing viral sepsis.

Methods

Cohort Identification

All patients included in this study were identified using the Clinical Data Analysis and Reporting System (CDARS), a comprehensive territory-wide electronic health care database encompassing all public hospitals managed by the Hospital Authority, which serves a population of 7.1 million. CDARS has been reliably used for numerous large-scale population-based studies [16], including research on antiviral use for COVID-19 [17,18], where diagnoses are stored using *International Classification of Diseases, Ninth Revision, Clinical Modification* (*ICD-9-CM*) codes. Each patient's data, including prescription, admission, and diagnosis, were linked using a unique anonymous identifier. Patients were potentially included in this study if they had related service records, such as admission and medication use within CDARS.

Study Design

This retrospective cohort study used CDARS to investigate culture-negative viral infection among COVID-19 inpatients. The study compared the effect of antiviral treatments (nirmatrelvir-ritonavir or molnupiravir) versus no antiviral treatment (control) on 30-day in-hospital mortality and length of stay, across various conditions of organ dysfunction.

Eligibility Criteria

The cohort selection is detailed in Figure S1 in Multimedia Appendix 1. Eligible patients were those aged 18 years and older with a diagnosis of COVID-19, identified using *ICD-9-CM* code 519.8(8). Patients admitted between February 22, 2022, and June 30, 2023, were included in the study. The baseline time was defined as the date of hospital admission. To meet the culture-negative criteria, patients had to have at least one blood culture record during admission. Within the first 21 days of admission, no organism should have been identified from the culture, or only "negative organisms" should have been considered irrelevant to the viral infection course, as defined in Table S1 in Multimedia Appendix 1. Only patients who were culture-negative were included. As the study focus is on sepsis, other cultures, such as sputum culture, were not used to fulfill the culture-negative criteria; moreover, viral co-infections were not excluded, as they are within the scope of the study.

Organ Dysfunction

Patients were categorized into one of 6 organ dysfunction groups (circulatory shock, respiratory failure, acute kidney injury, acute liver impairment, coagulopathy, composite organ dysfunction) based on the presence of organ dysfunction within the first 3 days of admission, as defined in Table S2 in Multimedia Appendix 1. These groups use the same method used to identify organ dysfunction according to the Hospital Toolkit for Adult Sepsis Surveillance released by the US Center for Disease Control and Prevention [19]. Patients without any organ dysfunction during the entire follow-up period and without death in the first 3 days of hospitalization were categorized into the no organ dysfunction group, which represents COVID-19 patients with mild to moderate illness severity.

Exposure

The study examined the treatment strategy of using antivirals versus not using antivirals. Specifically, there were two primary anti-exposure interests: (1) nirmatrelvir-ritonavir and (2) molnupiravir. Each antiviral group was compared with a control group consisting of patients who did not receive any antiviral treatment during their hospital stay. We used a new-user design, including only patients who had received antiviral treatment within the 3 days of admission [20], and excluded those who began antiviral treatment before admission. Controls were defined as patients who did not use antivirals at any point during the study period. To ensure the selection of new users, we included only patients who had not received antivirals within

XSL•FO
RenderX

7 days prior to admission and excluded those concurrently using both antivirals.

Follow-Up Period and Outcomes

Patients were followed until one of the following events occurred: death, discharge, or 28 days after admission. The primary outcome of interest was in-hospital mortality and length of stay, defined by the time difference between the date of admission and the end of follow-up.

Covariates

Baseline covariates included: age, sex, residency in care homes for older people, health status over the past 2 years as indicated by the Charlson Comorbidity Index, prior antibiotic use, the calendar year and month of COVID-19 diagnosis, and socioeconomic status as indicated by the Social Deprivation Index (SDI) of their residential address [21,22]. An SDI quartile of Q4 indicated the most deprived, while Q1 indicated the least deprived. To account for evolving COVID-19 characteristics due to emerging variants, the month of admission was included in the propensity score model. Patients with missing data were excluded from analyses.

Statistical Analysis

We hypothesized that antiviral use (nirmatrelvir-ritonavir or molnupiravir) would be associated with a decreased risk of mortality and a shorter length of stay compared with no antiviral use. Propensity score matching was used to balance baseline characteristics among the groups, using a 1:2 ratio with the nearest neighbor algorithm. A caliper width of 0.2 was chosen to optimize matching [23]. Covariate balance postmatching was evaluated using standardized mean differences (SMD), with a SMD value <0.2 considered indicative of balance. Descriptive statistics were reported as mean (SD) and count (percentage [%]) wherever appropriate. Estimates for in-hospital mortality were presented as hazard ratios (HR) with 95% CIs, derived from a univariate Cox proportional hazards model. The proportional hazards assumption was tested using the Schoenfeld Residual test, which confirmed that the assumption was met. Length of stay estimates were expressed as mean difference with 95% CI. Absolute risk difference, reported as percentages (%) with 95% CI, is calculated as the difference between absolute risks of antiviral and control groups, which are individually calculated as (number of events / number of patients × 100%).

Additionally, 2 sensitivity analyses were conducted: excluding patients who received adjuvant therapies such as remdesivir, interferon-beta 1b, tocilizumab, baricitinib, and plasma infusions during hospitalization; and a landmark analysis of in-hospital mortality on the 3rd day of admission.

All analyses were performed using R (version 4.4.1; R Foundation for Statistical Computing). All tests were 2-tailed, and a *P* value <.05 was considered statistically significant. Generative artificial intelligence was not used in any portion of the composition of the manuscript.

Ethical Considerations

This study received approval from the Hospital Authority Hong Kong West Cluster/The University of Hong Kong Institutional Review Board (UW 20 - 112) and was carried out in accordance with the Helsinki Declaration. The requirement for obtaining informed consent from patients was waived by the institutional review board, as all patient data collection and extraction was anonymized. No compensation was received for human participants' research, and no identification of individual participants is possible in the study materials.

Results

Study Population

Following the exclusion of patients who did not meet the culture-negative criteria or fit within defined organ dysfunction groups, our analysis encompassed 15,599 patients (Table 1). The mean age of the cohort was 75.10 (SD 15.86) years. Among those identified with organ dysfunction, 511 patients experienced circulatory shock, 5236 had respiratory failure, 1053 had acute kidney injury, 880 had coagulopathy, and 162 exhibited acute liver impairment. Notably, respiratory failure frequently co-occurred with other organ dysfunctions, manifesting in 386 patients (76.1%) with circulatory shock, 632 (60.5%) patients with acute kidney injury, 521 (59.5%) patients with coagulopathy, and 76 (46.9%) patients with acute liver impairment. A total of 5695 patients had at least one type of organ dysfunction upon admission, classifying them under the composite organ dysfunction group.

[a]COVID-19 patients were retrospectively identified from electronic health care records in Hong Kong. The most common organ dysfunction presenting in patients was respiratory failure (n=5236), followed by acute kidney injury (n=1053) and coagulopathy (n=880). Most patients had used antibiotics before receiving antiviral treatment.

[b]Q: Quartile.

[c]Not applicable.

Propensity Score Matching

To ensure comparability between treatment groups, propensity score matching was conducted, resulting in 14 well-balanced cohorts, with all matched variables achieving an SMD of less than 0.2. The distribution of propensity score postmatching is depicted in Figure S2 in Multimedia Appendix 1.

In-Hospital Mortality

In-hospital mortality data, along with cohort sizes and death counts across comparator groups, are detailed in Table 2. Antiviral use was associated with significantly decreased mortality in patients without organ dysfunction, for both nirmatrelvir-ritonavir (HR 0.17, 95% CI 0.05-0.56) and molnupiravir (HR 0.29, 95% CI 0.15-0.56). Molnupiravir was

XSL•FO
RenderX

associated with a significantly reduced mortality hazard (HR 0.75, 95% CI 0.58-0.96) among patients with composite organ dysfunction, and a marginally significant reduction (HR 0.69, 95% CI 0.46-1.02) among patients with respiratory failures. Nirmatrelvir-ritonavir was also associated with reduced absolute mortality risk among patients with respiratory failure (absolute risk difference: 9.5%, 95% CI 6.26%-12.72%) and composite organ dysfunction (absolute risk difference: 6.0%, 95% CI 3.18%-8.91%). In other subgroups of patients with individual organ dysfunction, the reductions in mortality were not statistically significant and had wide CIs.

Table . In-hospital mortality grouped by organ dysfunction and use of antiviral medication after propensity score matching.

Treatment	Antiviral				Control					
	Patients, n	Events, n	Patient-days, n	Absolute risk, %	Patients, n	Events, n	Patient-days, n	Absolute risk, %	Absolute risk difference, % (95% CI)	Hazard ratio (95% CI)

Molnupiravir										
Circulatory shock	34	7	619	20.6	65	11	958	16.9	−3.69 (−20.03 to 12.70)	1.21 (0.47 to 3.13)
Respiratory failure	327	33	3657	10.1	653	97	7226	14.9	4.8 (0.51 to 9.02)	0.69 (0.46 to 1.02)
Acute kidney injury	123	20	2360	16.3	242	73	6273	30.2	13.9 (5.19 to 22.62)[a]	0.77 (0.44 to 1.34)
Coagulopathy	109	18	2110	16.5	213	50	5333	23.5	7.0 (−2.04 to 15.96)	0.90 (0.53 to 1.55)
Acute liver impairment	23	4	254	17.4	43	7	698	16.3	−1.09 (−20.13 to 17.91)	0.70 (0.43 to 1.15)
No organ dysfunction	1533	10	8927	0.7	1801	64	14,568	3.59	2.9 (1.96 to 3.85)[a]	0.29 (0.15 to 0.56)[a]
Composite organ dysfunction	619	83	9036	13.4	1237	225	18,641	18.2	4.8 (1.34 to 8.22)[a]	0.75 (0.58 to 0.96)[a]

[a]Denotes statistically significant. Absolute risk difference is calculated as the difference between absolute risks of antiviral and control groups, which are individually calculated as (number of events / number of patients×100%). Reduced in-hospital mortality was seen for nirmatrelvir-ritonavir users in respiratory failure, composite organ dysfunction, and no organ dysfunction; and for molnupiravir users in acute kidney injury, composite organ dysfunction and no organ dysfunction. Due to small sample size in the acute liver impairment group using nirmatrelvir-ritonavir, hazard ratio was not calculated for that group.

[b]Not available.

Length of Stay

Our analysis demonstrated that the use of both nirmatrelvir-ritonavir and molnupiravir was associated with a reduced length of hospital stay for patients with various types of organ dysfunction at admission, detailed in Table 3. Specifically, nirmatrelvir-ritonavir significantly reduced the length of stay in patients with respiratory failure by an average (mean) of 3.37 (95% CI 2.32-4.42) days; acute kidney injury by 7.25 (95% CI 2.97-11.52) days; coagulopathy by 7.04 (95% CI 2.44-11.64) days, and in those without organ dysfunction by 3.52 (95% CI 2.99-4.05) days. Additionally, it reduced the length of stay by 3.97 days in patients with composite organ dysfunction (95% CI 2.77-5.17). However, no significant reduction was observed in patients with circulatory shock (2.23, 95% CI −4.54 to 9.00 days) and acute liver impairment (5.16, 95% CI −0.96 to 11.28 days).

Table . Length of stay (days) grouped by organ dysfunction and use of antiviral medication.

Treatment	Antiviral, mean (SD)	Control, mean (SD)	Mean difference (95% CI)
Nirmatrelvir-ritonavir			
Circulatory shock	14.74 (16.26)	16.97 (15.66)	2.23 (−4.54 to 9.00)
Respiratory failure	7.73 (8.62)	11.1 (11.46)	3.37 (2.32 to 4.42)[a]
Acute kidney injury	16.87 (12.58)	24.12 (22.3)	7.25 (2.97 to 11.52)[a]
Coagulopathy	17.84 (13.7)	24.88 (23.96)	7.04 (2.44 to 11.64)[a]
Acute liver impairment	10.57 (8.36)	15.73 (10.22)	5.16 (−0.96 to 11.28)
No organ dysfunction	4.40 (4.17)	7.92 (10.18)	3.52 (2.99 to 4.05)[a]
Composite organ dysfunction	10.5 (11.2)	14.5 (17.0)	3.97 (2.77 to 5.17)[a]
Molnupiravir			
Circulatory shock	18.21 (22.53)	14.74 (14.86)	−3.47 (−12.07 to 5.14)
Respiratory failure	11.18 (11.26)	11.07 (10.8)	−0.12 (−1.60 to 1.36)
Acute kidney injury	19.19 (17.53)	25.92 (24.03)	6.73 (2.39 to 11.08)[a]
Coagulopathy	19.36 (16.94)	25.04 (23.34)	5.68 (1.20 to 10.16)[a]
Acute liver impairment	11.04 (7.85)	16.23 (13.82)	5.19 (−0.14 to 10.52)
No organ dysfunction	5.82 (5.93)	8.09 (9.99)	2.27 (1.72 to 2.81)[a]
Composite organ dysfunction	14.6 (14.9)	15.1 (17.9)	0.47 (−1.06 to 2.01)

[a]Denotes statistically significant. Nirmatrelvir-ritonavir reduced length of stay in respiratory failure, acute kidney injury; while molnupiravir reduced length of stay in acute kidney injury and coagulopathy.

Molnupiravir also showed a significant reduction in the length of stay for patients with acute kidney injury by an average (mean) of 6.7 (95% CI 2.39-11.08) days, coagulopathy by 5.68 (95% CI 1.20-10.16) days, and in those without organ dysfunction by 2.27 (95% CI 1.72-2.81) days. However, no significant reduction was observed for circulatory shock (−3.47, 95% CI −12.07 to 5.14 days), respiratory failure (−0.12, 95% CI −1.60 to 1.36 days), acute liver impairment (5.19, 95% CI −0.14 to 10.52 days), or composite organ dysfunction (0.47, 95% CI −1.06 to 2.01 days).

Sensitivity Analysis

Results excluding patients who received adjuvant therapy are described in Tables S3 and S4 in Multimedia Appendix 1.

The sensitivity analysis revealed reduced mortality associated with nirmatrelvir-ritonavir in respiratory failure (absolute risk difference: 8.3%, 95% CI 2.4%-14.2%) and molnupiravir use in patients with coagulopathy (absolute risk difference: 13.0%, 95% CI 2.2%-23.8%). Consistent with the main analysis, both antivirals were associated with decreased mortality in patients without organ dysfunction and composite organ dysfunction.

Nirmatrelvir-ritonavir use was associated with a decreased length of stay in patients with respiratory failure by an average of 8.4 (95% CI 5.1-11.7) days, acute kidney injury by 11.6 (95% CI 4.1-19.1) days, coagulopathy by 12.8 (95% CI 4.7-20.9) days, and those without organ dysfunction by 3.7 (95% CI 3.1-4.3) days. Molnupiravir was associated with a decreased length of stay in patients with acute kidney injury by an average of 8.1 (95% CI 1.5-14.7) days, coagulopathy by 7.8 (95% CI 0.2-15.4) days, and those without organ dysfunction by 2.2 (95% CI 0.5-6.2) days. Nirmatrelvir-ritonavir was associated with decreased length of stay in patients with composite organ dysfunction by an average of 9.8 (95% CI 7.3-12.2) days, while molnupiravir was associated with an average reduction of 3.4 (95% CI, 0.5-6.2) days in the length of stay among patients with composite organ dysfunction.

Results of the landmark analysis 3 days after hospitalization are available in Table S5 in Multimedia Appendix 1. Consistent with the main analysis, nirmatrelvir-ritonavir was associated with decreased mortality in respiratory failure (HR 0.43, 95% CI 0.22-0.82) and composite organ dysfunction (HR 0.42, 95% CI 0.22-0.80), as well as lower risk of circulatory shock

XSL•FO
RenderX

(absolute risk difference: 13.7%, 95% CI 3.1-24.4). Molnupiravir was similarly associated with decreased mortality in respiratory failure (HR 0.19, 95% CI 0.08-0.47) and composite organ dysfunction (HR 0.19, 95% CI 0.08-0.48).

Discussion

Principal Findings

In our study of patients diagnosed with culture-negative viral sepsis, antiviral use was associated with reduced mortality among those without any organ dysfunction, with respiratory failure, or with composite organ dysfunction. The strongest reduction in mortality was observed among patients without any organ dysfunction. The use of these antivirals was associated with reduced length of stay across most types of organ dysfunction, except for circulatory shock and acute liver impairment. Importantly, the decreased length of stay was consistent regardless of whether patients received adjuvant therapies including remdesivir, interferon-beta 1b, tocilizumab, baricitinib, or plasma infusions. These findings build on our recent research using an inverse probability weighting approach to evaluate the impact of antivirals in preventing the onset of new organ dysfunction [24].

Our results are in line with previous studies that have investigated the utility of treating COVID-19-associated organ dysfunction. For patients hospitalized with COVID-19, both nirmatrelvir-ritonavir and molnupiravir have been associated with a decreased risk of developing new organ dysfunctions, such as circulatory shock and respiratory failure [24]. Additionally, earlier research has shown that antivirals can reduce the length of hospital stay and accelerate viral clearance times [17,25,26].

The 2021 Surviving Sepsis Campaign COVID-19 guideline did not provide specific recommendations for the newly introduced nirmatrelvir-ritonavir and molnupiravir [14]. They did recommend intravenous remdesivir due to its ability to reduce hospital stay and shorten time to clinical recovery, although it did not reduce mortality benefit across different disease severity strata [27]. In our study, the antivirals nirmatrelvir-ritonavir and molnupiravir showed a mortality benefit for those with mild to moderate disease, with stronger effects in patients without presenting organ dysfunction.

The Infectious Diseases Society of America Guidelines on the Treatment and Management of Patients with COVID-19 advocate for the timely administration of antivirals, including nirmatrelvir-ritonavir and molnupiravir, within 5 to 7 days of symptom onset [15]. This period is deemed most effective due to high viral load and immature immune response characteristic of early infection. These antivirals are specifically recommended for patients with mild to moderate COVID-19 [28,29]. However, many patients are admitted with pre-existing organ dysfunction, indicative of an excessive inflammatory response typical of moderate to severe disease, where the efficacy of antivirals diminishes. Our findings highlight that organ dysfunction constitutes a significant proportion of COVID-19 inpatient deaths. While anti-inflammatory treatments, such as corticosteroids or tocilizumab, are recommended for critically ill COVID-19 patients [14], our data suggest that antivirals still have clinical utility by reducing the length of hospital stay and hastening recovery.

For patients with suspected sepsis but unconfirmed infection, it is recommended to consider alternative diagnoses and the discontinuation of antibiotics [14]. Given the high prevalence of COVID-19, particularly among older adults, it is crucial to consider COVID-19 as a potential source of sepsis when bacterial, parasitic, or fungal causes of infection are not established.

This study has several limitations. First, the study did not account for the varying severity of organ dysfunction due to the heterogeneous clinical presentation of sepsis in undifferentiated COVID-19 patients. It is plausible that antivirals could demonstrate a mortality benefit in patients with mild organ dysfunction. Second, the study assumed that all patients initiated on antivirals completed the full course of treatment. Thirdly, this study excluded patients who did not have blood culture records and those with positive blood culture records; thus, the results may not be generalizable to all COVID-19 inpatients. Last, COVID-19 diagnoses were identified from *ICD-9* codes. Nevertheless, CDARS has previously demonstrated high coding accuracy and data completeness in prior studies [30,31].

Conclusion

Using electronic health data representative of Hong Kong residents, we investigated the effect of nirmatrelvir-ritonavir and molnupiravir on reducing mortality and hospital stay among patients with or without early-onset organ failures. Their association with reduced mortality and hospital stay underscores their potential role in expediting clinical recovery.

Abstract

Background: Nonpharmaceutical interventions (NPIs) such as mask-wearing and social distancing during the COVID-19 pandemic significantly reduced the transmission of common respiratory viruses, including influenza virus and respiratory syncytial virus (RSV). As NPIs were stopped, concerns emerged about “immunity debt,” which suggests that limited natural exposure to pathogens may have increased susceptibility and severity, particularly among young children. However, despite growing attention, the postpandemic impact of NPIs on epidemiologic patterns and shifts in age-specific disease burden remains underexplored.

Objective: This study aims to investigate, using national surveillance data, the repercussions of the COVID-19 pandemic on the epidemiology and clinical burden of influenza virus and RSV infections in Korea, with an emphasis on the influence of NPIs on the incidence and clinical severity of these infections, particularly among young children.

Methods: We analyzed weekly virologic, outpatient, and inpatient surveillance data on influenza virus and RSV infections from the Korea Disease Control and Prevention Agency from 2017 to 2024, covering the prepandemic, pandemic, and postpandemic periods. Time-series analyses were conducted to examine changes in seasonality and to estimate age-specific incidence and clinical severity of influenza virus and RSV infections before and after the COVID-19 pandemic.

Results: In the postpandemic seasons, both RSV and influenza virus infections showed disrupted seasonality with delayed and prolonged epidemics. While the overall burden of both viruses was comparable to that for prepandemic periods, there was a notable shift in the age distribution of severe cases. Among influenza–associated hospital admissions, the proportion of school-aged children (7 - 18 years) doubled, rising from 14% (1,814/12,660) in 2019/20 to 28% (2,176/7,755) in 2022/23. Hospitalization rates in this age group also increased significantly, from 46.8 to 64.4 per 100,000 among children aged 7 - 12 years, and from 16.4 to 30.0 per 100,000 among those aged 13 - 18 years. For RSV infections, the burden shifted most prominently to young children aged 1 - 6 years, whose share of hospital admissions rose from 48% (5,789/11,969) to 61% (7,316/12,011) over the same period. This age group also experienced the largest rise in RSV-associated hospitalization rates, increasing from 230.8 to 357.5 per 100,000 between the 2019/20 and 2022/23 seasons.

Conclusions: The patterns of influenza virus and RSV infections in Korea following the COVID-19 pandemic reveal distinct shifts in timing, severity, and the age groups that were most affected. Postpandemic influenza and RSV activity in Korea showed delayed and prolonged epidemics, with shifts in age-specific disease burden rather than an overall increase. Substantial increases in susceptibility and severity among young children for RSV infections and older children for influenza virus infections suggest lingering immunity gaps from reduced exposures during the pandemic. These effects may be further compounded by declining influenza vaccine uptake among children following the pandemic. Our findings underscore the importance of ongoing surveillance and targeted public health measures to manage respiratory viruses in the postpandemic era.

Introduction

Nonpharmaceutical interventions (NPIs), including mask-wearing and social distancing, were widely implemented during the COVID-19 pandemic to mitigate the spread of SARS-CoV-2. While effective in controlling COVID-19, these measures also led to an unprecedented decline in the circulation of other respiratory viruses, including influenza and respiratory syncytial virus (RSV) [1-3].

The concept of "immunity debt," which suggests that reduced exposure to common pathogens during the pandemic may have increased susceptibility and the risk of more severe outcomes upon re-exposure, has gained growing attention as an important factor affecting the postpandemic resurgence and altered epidemiology of respiratory viruses. This theory is particularly relevant to influenza virus and RSV infections [1,4-7], as early-life exposures are critical for developing immune defenses. For example, a recent modeling study demonstrated that prolonged NPIs delayed natural RSV exposure, resulting in a higher burden of infection among young children, most of whom are typically exposed to RSV by the age of 2 [8].

Numerous studies from Europe and North America have reported increased hospitalizations and shifts in age-specific severity for influenza virus and RSV infections following the COVID-19 pandemic [9-12]. A cohort study of 2809 children hospitalized with RSV in the United States found a significant increase in the proportion of children aged 2 to younger than 5 years (34.2% in 2022‐23 vs 23.4% in prepandemic seasons) [9], suggesting increased susceptibility and severity in this age group that may be linked to immunity debt. Another study of patients with RSV infections 5 years or younger in the United States reported an increase in the median age of children with RSV (11.3 mo in 2022‐23 vs 6.8 mo in prepandemic seasons) and children with severe RSV infections requiring advanced respiratory support (6.9 mo in 2022‐23 vs 4.6 mo in prepandemic seasons for high-flow nasal cannula) [10]. A cohort study in Italy also showed that RSV-associated hospitalizations significantly increased in postpandemic seasons, particularly among older age groups, whose risk of severe RSV increased by 4.7 times in 2021‐22 [11]. However, limited data are available from Asian countries that implemented more stringent and prolonged NPIs compared to many Western countries. Recent research [6] has shown that the intensity of NPIs is positively associated with the magnitude of subsequent immunity debt, with countries enforcing stricter measures experiencing larger surges in respiratory infections following the relaxation of NPIs.

As such, this study aims to fill this gap by analyzing shifts in influenza and RSV epidemiology and clinical burden before and after the COVID-19 pandemic using nationwide surveillance data in Korea, where strict NPIs, including prolonged mask mandates and rigorous social distancing policies, remained in place until as late as March 2023, and investigating how immunity debt may have manifested in this unique context.

By directly comparing influenza virus and RSV infections (often jointly discussed in the context of the "tripledemic" alongside COVID-19) across pre- and postpandemic periods, this study aims to provide a more comprehensive understanding of pandemic-driven shifts in respiratory virus patterns. Furthermore, it aims to offer novel insights into the concept of immunity debt, with a particular focus on differences in age-specific impact of influenza virus and RSV infections in the postpandemic period.

Methods

Study Design

We conducted a retrospective observational study to examine shifts in seasonality and age-specific incidence and severity of influenza virus and RSV infections using national surveillance data. Time-series approach was used to characterize patterns of influenza virus and RSV activities and associated hospitalization rates over the study period. Age-specific proportions of hospitalizations were compared between pre- and postpandemic, and influenza virus and RSV infections.

Data Sources

We analyzed weekly virologic, outpatient, and inpatient surveillance data collected from September 3, 2017 (wk 36) to August 31, 2024 (wk 35) through the Influenza and Respiratory Viruses Surveillance System (KINRESS) by the Korea Disease Control and Prevention Agency (KDCA). KINRESS is a nationwide sentinel surveillance system designed to monitor influenza and other respiratory viruses, including RSV. As of February 2025, KINRESS integrates data from 300 sentinel clinics (outpatient surveillance), 18 public health laboratories in each city or province testing respiratory specimens from 106 clinics (virologic surveillance), and 221 hospitals (hospitalization surveillance) across Korea. The KDCA publishes Weekly Sentinel Surveillance Reports on its website, which are available to the public. These reports provide weekly updates on 23 Category IV infectious diseases that are considered less severe but highly prevalent, such as influenza, RSV, and other acute respiratory infections. For this study, we extracted data from these reports, including the proportion of influenza-like illness (ILI) consultations from outpatient surveillance and the proportion of respiratory specimens testing positive for influenza virus (by subtype) and RSV from virologic surveillance coordinated through the Korea Respiratory Virus Integrated Surveillance System (K-RISS), to estimate weekly influenza and RSV activity. K-RISS conducts real-time RT-PCR on respiratory specimens collected from participating clinics to test for 8 common respiratory pathogens, including influenza virus and RSV, and publishes weekly updates on the KDCA's Weekly Sentinel Surveillance Reports. We also used the age-specific number of hospital admissions with confirmed influenza virus or RSV infections from inpatient surveillance, which is publicly available from the KDCA online portal, to estimate age-specific proportions and incidence rates of hospital admissions associated with influenza or RSV.

Statistical Analysis

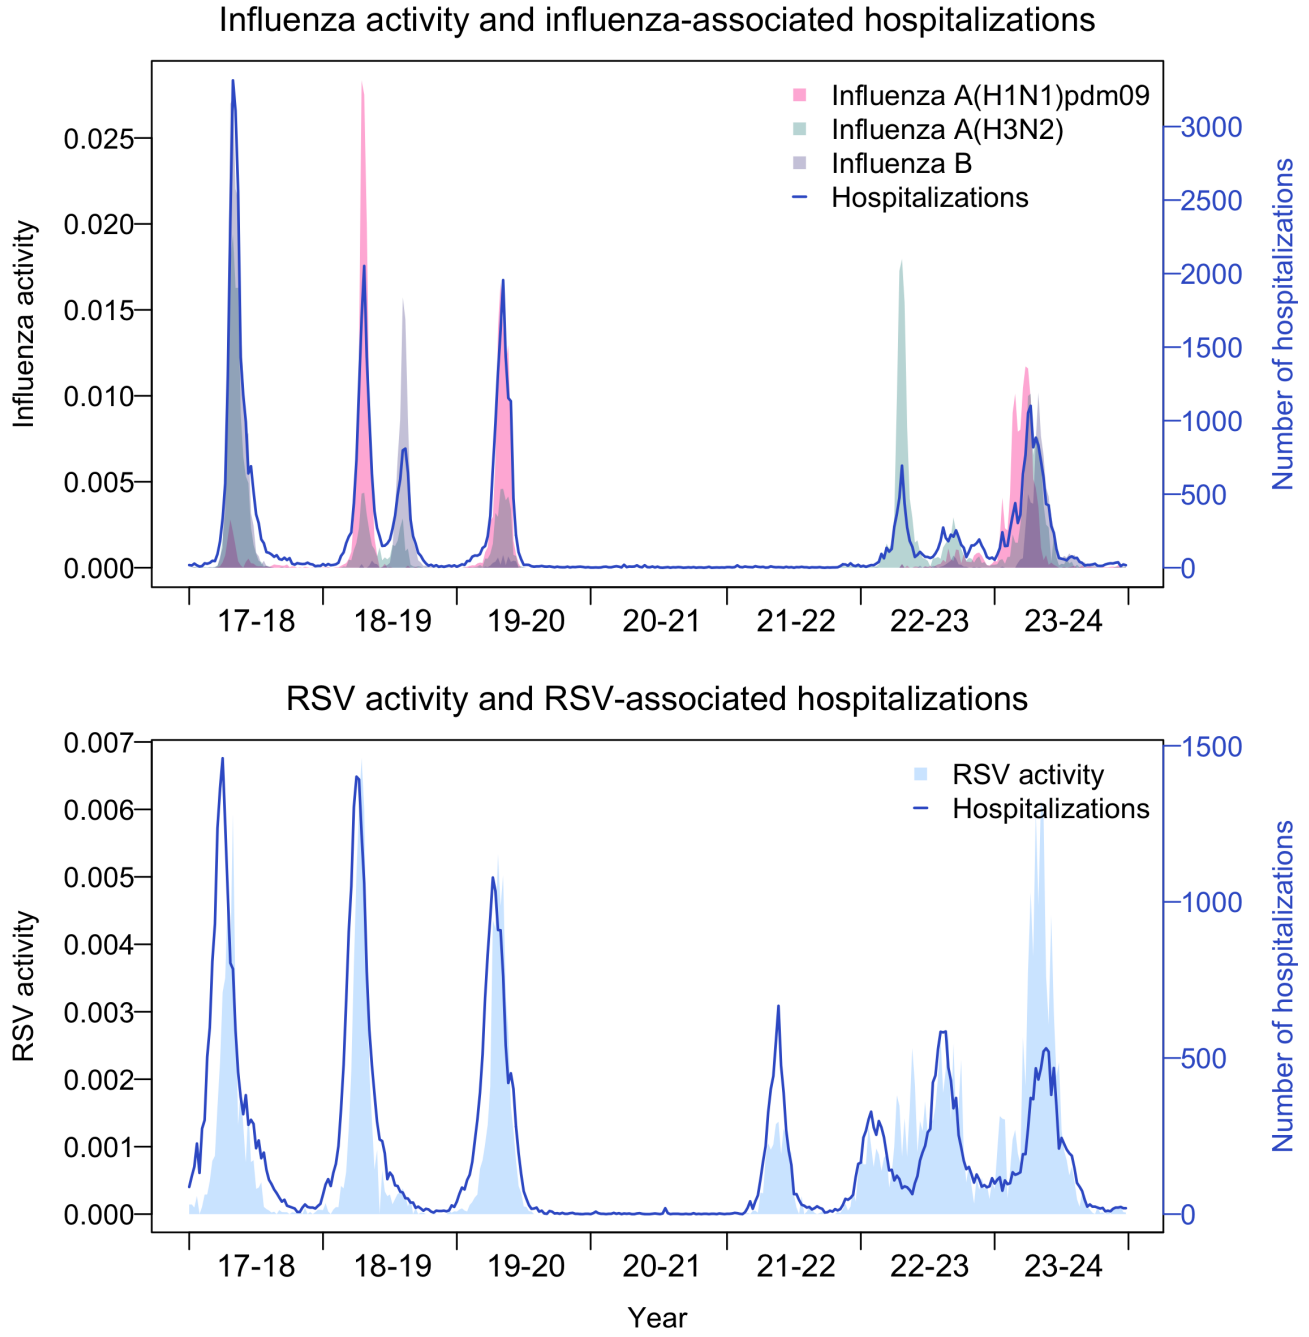
Each season was defined from week 36 of one year to week 35 of the following year, as per KINRESS. We then categorized these 7 seasons into three distinct periods as follows: prepandemic (2017/18 to 2019/20; 3 seasons), pandemic

XSL•FO
RenderX

(2020/21; 1 season), and postpandemic (2021/22 to 2023/24; 3 seasons). For this study, we consider the 2021/22 season as postpandemic since it followed the government's "Living with COVID-19" plan, a phased approach aimed at progressively lifting NPIs and returning to normal life, which began on November 1, 2021, although some control measures did continue through to mid-2022, and there was a period in early 2022 where some measures were temporarily re-introduced to manage a large surge in Omicron cases [13].

As with our previous study on influenza [14], we multiplied the proportion of patients with ILI by the proportion of respiratory specimens testing positive for each influenza type and subtype or RSV to derive a weekly indicator of influenza or RSV incidence. The proportion of patients with ILI was calculated as the percentage of total outpatient visits that meet the KDCA's ILI case definition (ie, fever ≥38°C with cough or sore throat). The proportion of respiratory specimens testing positive for influenza or RSV was calculated based on the total number of real-time RT-PCR tests done in each week. We conducted a time-series analysis using the proxies to describe trends and seasonal patterns of influenza and RSV during the past 7 years, from 2017/18 to 2023/24. The weekly count of hospitalizations associated with influenza virus and RSV was collated by age group for each season to compare the clinical severity across pre- and postpandemic periods. We then determined influenza- and RSV-associated hospitalization rates per 100,000 persons using age-specific mid-year population estimates for 2017‐2024 retrieved from Statistics Korea [15] to adjust for demographic shifts and enable comparisons across age groups. All analyses were conducted using R version 4.1.1 (R Foundation for Statistical Computing).

Ethical Considerations



This study used aggregated, routinely collected surveillance data that contained no personally identifiable information and was therefore granted an exemption from ethics review by the Institutional Review Board of Ewha Womans University (ref no. 2025‐0096). Individual informed consent from participants was not required.

Results

In prepandemic seasons, influenza virus and RSV infections followed a similar seasonal pattern, both peaking in winter, with RSV epidemics typically occurring 3‐4 weeks earlier than influenza (wk 49‐50 for RSV and 52‐2 for influenza, respectively), as illustrated in Figure 1.

XSL•FO
RenderX

Figure 1. Virus activity and the number of hospitalizations: influenza and RSV in South Korea, 2017/18 to 2023/24. RSV: respiratory syncytial virus.

Following the pandemic, RSV infections reappeared in the 2021/22 season with a delayed epidemic peak in week 5, which occurred 7 - 8 weeks later than usual. In the 2022/23 season, RSV had 2 distinct peaks: an early peak in week 41, 8 - 9 weeks ahead of the typical timing, and a second peak in week 17 amid a prolonged epidemic. Influenza took one more season than RSV to reappear in the 2022/23 season with a typical winter peak in week 1.

The number of influenza- and RSV-associated hospitalizations from 2017/18 to 2023/24 is shown in Multimedia Appendix 1. The overall burden was substantially reduced in postpandemic seasons. Between the 2019/20 and 2020/21 seasons, there was a significant reduction in the number of hospital admissions associated with influenza virus (n=12,660 to n=211; 98.3%) and RSV (n=11,969 to n=80; 99.3%) across all age groups (Multimedia Appendix 1). In prepandemic seasons (2017/18 to 2019/20), influenza virus and RSV infections caused a mean of 17,000 (SD 4483) and 14,583 (SD 2441) hospital admissions, respectively. In postpandemic seasons (2021/22 to 2023/24), RSV infections caused a mean of 8728 (SD 3319) hospital admissions, which is only about 60% of the admissions from prepandemic seasons.

A similar pattern was observed in influenza- and RSV-associated hospitalization rates (Table 1). The overall influenza-associated hospitalization rate significantly declined from 24.7 per 100,000 in the 2019/20 season to nearly zero in the pandemic and early postpandemic years, but bounced back to 23.9 per 100,000 by the 2023/24 season, indicating a near full recovery to prepandemic levels. As for RSV, hospitalization rates dropped significantly across all age groups during the pandemic before rebounding to near pre-pandemic levels in the 2022/23 season. The overall RSV hospitalization rate substantially declined from

XSL•FO
RenderX

23.3 per 100,000 persons to just 0.2, then to 10.5 in the 2020/21 and 2021/22 seasons, respectively. By the 2022/23 season, the rate had recovered to 23.4 per 100,000, closely mirroring prepandemic levels.

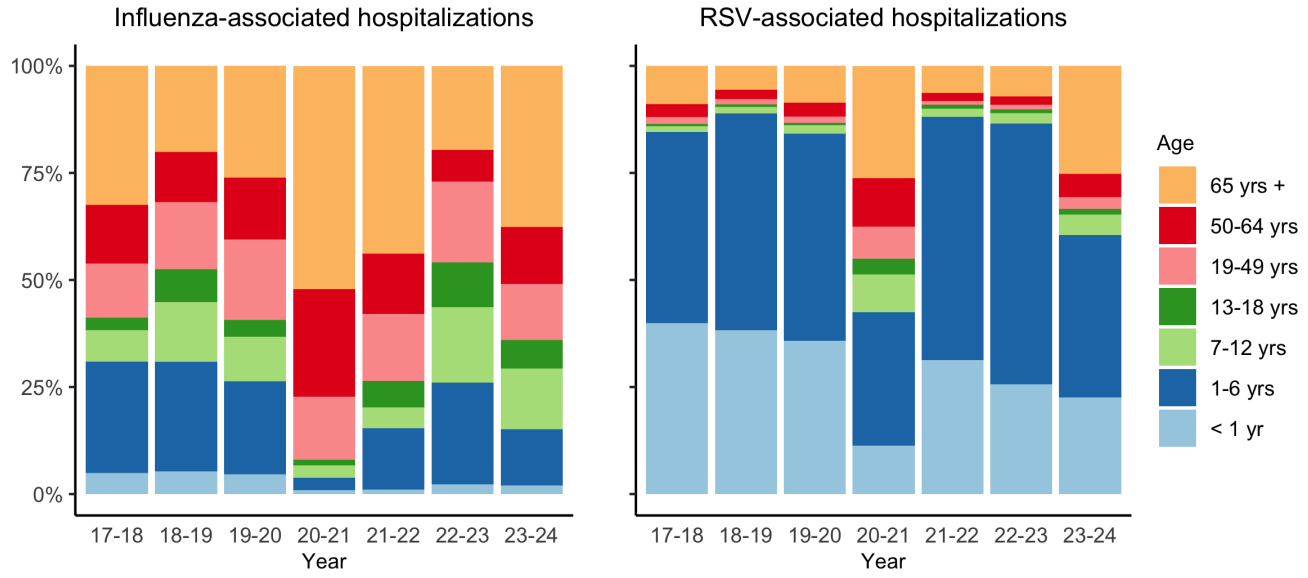


Table . Influenza- and respiratory syncytial virus–associated hospitalization rates (per 100,000 persons).

Season	Peak (wk)	Seasonal hospitalization rates (per 100,000 persons)

[a]RSV: respiratory syncytial virus.

For influenza virus infections, more older children aged 7 - 12 years and 13 - 18 years experienced severe outcomes requiring hospitalization postpandemic (Figure 2 and Multimedia Appendix 1). In the 2022/23 season, the proportion of children aged 7 - 12 years was 18% (1,372/7,755), a significant increase from 10% (1,323/12,66) in the 2019/20 season. Similarly, the proportion for children aged 13 - 18 years increased from 4% (491/12,660) in the 2019/20 to 10% (804/7,755) in the 2022/23 season. Similarly, children aged 7 - 12 years and 13 - 18 years experienced the greatest increase in influenza-associated hospitalization rates postpandemic. For children aged 7 - 12 years, the rate rose from 46.8 per 100,000 in the 2019/20 season to 64.4 per 100,000 in the 2023/24 season, while for those aged 13 - 18 years, it increased from 16.4 to 30.0 per 100,000. On the other hand, the hospitalization rates for infants (<1 y) and children aged 1 - 6 years declined (Table 1).

Figure 2. Influenza- and respiratory syncytial virus–associated hospitalizations by age group (%). RSV: respiratory syncytial virus.

XSL•FO
RenderX

For RSV infections, the proportion of young children aged 1 - 6 years among RSV-associated hospitalizations increased post pandemic (Figure 2 and Multimedia Appendix 1). In the 2021/22 season, this age group accounted for 57% (3,057/5,375) of RSV hospitalizations, up from 48% (5,789/11,969) in the 2019/20 season. By the 2022/23 season, this figure rose further to 61% (7,316/12,011). This contrasts with all other age groups, whose proportions either remained the same or decreased in postpandemic seasons. Similarly, age-specific hospitalization rates show that the most significant increase in RSV-associated hospitalizations postpandemic occurred in children aged 1 - 6 years (Table 1). This group saw their hospitalization rate rise from 231 per 100,000 in the 2019/20 season to 358 per 100,000 in the 2022/23 season, marking the greatest increase among all age groups. Meanwhile, infants younger than 1 year of age, who had the highest RSV burden prepandemic, experienced a considerable decline, with the rate dropping from 1400 per 100,000 in the 2019/20 season to 1,240 per 100,000 in 2022/23.

Discussion

Principal Findings

The widespread implementation of NPIs during the COVID-19 pandemic led to substantial reductions in the transmission of influenza virus and RSV in Korea, as it did elsewhere [1-3]. As the NPIs were progressively relaxed in late 2021, RSV returned almost immediately, followed by influenza a year later. We identified substantial changes in RSV and influenza activity, with both viruses having delayed and prolonged epidemics in postpandemic seasons. However, this prolonged activity was not linked to an increased burden. In fact, our analysis revealed a lower overall epidemiological burden compared to previous years. This was contrary to the feared “triple-demic” [16]. The lessened impact could be due to a step change in awareness of infectious disease prevention, such as more frequent hand-washing and mask-wearing after the pandemic.

An important observation in our study is the significantly increased proportion of young children aged 1 - 6 years among RSV-associated hospital admissions in the postpandemic years. This may indicate that the susceptibility to severe infections, especially in young children, may be higher than in prepandemic seasons. This could be partly due to the accumulated “immunity debt,” where more young children are susceptible to severe outcomes because they have not developed immunity through prior exposures during the pandemic [4,5]. In particular, our findings suggest that immunity debt was more significant for RSV infections, particularly in children aged 1 - 6 years. They were the only age group that experienced an increased severity, with an increased proportion among all RSV-related hospital admissions in the first 2 postpandemic seasons. This is consistent with a recent US study [17], which found a significantly higher RSV burden in children aged 2 - 5 years, having almost 4.86 times as likely to be hospitalized in 2022 compared to prepandemic years, whereas younger children, such as infants aged 0 - 5 months, were only 1.77 times as likely. Primary RSV infections tend to be more severe than re-infections [18], and by delaying primary infections for one or two years, clinical severity may have become elevated in slightly older children who had avoided RSV infection during the COVID-19 pandemic.

Our analysis revealed that the proportion of older children aged 7 - 18 years increased among influenza-associated hospital admissions in the postpandemic years. It may be partly due to the delayed exposure to influenza virus infections during the pandemic, which may have resulted in reduced immunity in these school-age children. School closures, remote learning, and reduced social interactions during the pandemic likely disrupted the usual circulation of influenza, leading to fewer infections in younger populations. As restrictions eased and normal social interactions resumed, these children who had lower pre-existing immunity became more susceptible to the virus, contributing to higher hospitalization rates in this age group.

In addition, changes in vaccination coverage or the effectiveness of influenza vaccination in these years may also have played a role in the observed increase in hospitalizations. In Korea, all children aged 6 months to 13 years are currently eligible to receive free annual influenza vaccination under the National Immunization Program. While vaccination uptake among children remains relatively high compared to other countries, it has been declining in recent years, dropping from 78.5% in the 2019/20 season (prepandemic) to 72.7% in 2020/21 (pandemic), and further to 69.5% in 2023/24 (postpandemic). This slight decline in influenza vaccination coverage, combined with increased susceptibility due to immunity debt, may have contributed to the rise in influenza-associated hospitalization rates, particularly among school-aged children, who consistently have the lowest vaccination rates (82.5% for children aged 6 to 59 months of age vs 49.2% for children aged 13 years). The new RSV monoclonal antibody nirsevimab is not yet available in Korea for the prevention of RSV infections in infants.

Furthermore, while both influenza virus and RSV have returned as NPIs eased, the timing and clinical burden of these rebounds varied. RSV returning a year earlier than influenza might suggest that NPIs had less effect on RSV. RSV is thought to spread more through direct contact with contaminated surfaces and is more stable on these surfaces than influenza virus, allowing it to survive longer outside the human body [19]. This stability, combined with the virus’s prolonged shedding in infected individuals, especially children, could make RSV transmission more resilient to NPIs focused on airborne spread, such as masking and social distancing. In contrast, influenza’s shorter infectious period and reliance on airborne transmission make it more susceptible to these interventions, leading to a more effective reduction in its spread than RSV.

Our study contributes to the growing body of evidence on the postpandemic epidemiology of respiratory viruses and highlights the need for age-specific surveillance and vaccination approaches in the evolving landscape of respiratory infectious diseases. While similar trends of early and intensified RSV and influenza activity have been reported in other regions, the Korean experience offers important comparative insights due to the country’s prolonged and comprehensive implementation of NPIs. The distinct timing and magnitude of respiratory virus resurgence observed in Korea highlight how variations in public

XSL•FO
RenderX

health interventions and population behaviors can differentially influence viral epidemiology. By providing data from an East Asian setting, our study expands the geographic scope of evidence on immunity debt and informs future policy planning for vaccination strategies, hospital resource allocation, and public health preparedness at the global level.

Limitations

Our study has several limitations. First, our analyses are based on weekly virologic, outpatient, and weekly surveillance data. We did not have additional information, such as serologic data, which would allow a more comprehensive picture of the incidence and severity of infections in the community, as well as estimate population immunity. Second, changes in the burden of severe influenza virus or RSV infections in postpandemic seasons could be partially associated with increases in testing after the pandemic linked to increased laboratory capacity and attention to viral infections [20]. However, it is unlikely that increased testing fully explains our observations, particularly for RSV. In Korea, RSV diagnostic testing is generally less actively conducted than for influenza or COVID-19 due to the absence of a standard antiviral treatment, although testing is more common in infants who are at higher risk of severe illness. While increased testing postpandemic could contribute to higher reported cases, our focus on hospitalization rates rather than raw incidence mitigates this effect, as severe outcomes are less influenced by testing frequency. Furthermore, the diagnostic methods for RSV, such as rapid antigen tests, PCR, and viral culture, have not significantly changed before or after the COVID-19 pandemic. Thus, despite the pandemic's impact on health care, the frequency and methods of RSV testing in Korea likely remained consistent, suggesting that this factor is unlikely to fully explain the observed severity shifts. This is a challenge shared by similar studies adapting to heightened postpandemic surveillance. Third, changes in health-seeking behaviors after the pandemic must also be accounted for when interpreting results from the study. The COVID-19 pandemic significantly altered how individuals accessed health care services, often delaying or avoiding visits to hospitals or clinics due to fear of exposure, public health restrictions, or overwhelmed health care systems. This shift may have resulted in the underreporting of cases in the surveillance data, affecting the comparability of pre- and postpandemic disease burden. Although altered health-seeking behaviors during the pandemic may have led to underreporting, our reliance on inpatient surveillance data, which reflects severe cases necessitating care, likely minimizes this bias. As restrictions eased post-2021, health care access likely stabilized, suggesting this limitation is more relevant to the pandemic peak than the postpandemic trends we emphasize. Future studies could refine these findings by integrating health care use data. Finally, increased awareness of respiratory infections may have heightened case detection postpandemic, but our emphasis on hospitalization trends, which should be less influenced by awareness than outpatient visits, anchors our conclusions regarding clinical severity. This awareness, potentially reducing transmission through sustained preventive behaviors, may even offset inflated detection, aligning with the lower overall burden we observed. This reflects a broader postpandemic shift in public health consciousness. Our study's limitations, including potential biases from increased testing, shifting health-seeking behaviors, and heightened awareness, are tempered by our focus on hospitalization data and the consistency of diagnostic practices in Korea. These factors, common to postpandemic research, introduce uncertainty but do not negate the distinct shifts in influenza and RSV patterns we identified. Future analyses adjusting for these variables could further enhance our understanding of the role of immunity debt.

Conclusions

The patterns of influenza virus and RSV infections in Korea following the COVID-19 pandemic reveal distinct shifts in timing, severity, and affected age groups. While the resurgence of RSV and influenza was anticipated with the relaxation of NPIs, the delayed and prolonged epidemic patterns observed in the postpandemic seasons did not correspond with an increased overall disease burden. Instead, we found specific increases in susceptibility among younger children for RSV infections and older children for influenza virus infections, potentially due to immunity gaps arising from limited exposure during the pandemic. These findings highlight the lasting impacts of pandemic-related disruptions on population immunity and respiratory disease transmission patterns. Ongoing surveillance and targeted public health measures remain critical to understanding and managing seasonal respiratory viruses in a postpandemic context.

Acknowledgments

We are grateful to the Korea Disease Control and Prevention Agency (KDCA) for providing the weekly respiratory virus surveillance data.

Authors' Contributions

MP, WSC, and BJC designed the study. MP collected and conducted all statistical analyses. MP and BJC wrote the first draft. WSC reviewed and commented on the manuscript.

Conflicts of Interest

WSC has consulted for Moderna, Sanofi Pasteur, and CSL, and has been an investigator in clinical trials sponsored by SK Bioscience, GlaxoSmithKline, Pfizer, Moderna, Sanofi Pasteur, and Janssen. BJC has consulted for AstraZeneca, Fosun Pharma, GlaxoSmithKline, Haleon, Moderna, Novavax, Pfizer, Roche, and Sanofi Pasteur.

Abstract

Background: Negative attitudes toward vaccines and suboptimal vaccination rates among African American and Black (Black) Americans have been well documented, due to a history of medical racism and human rights violations in the United States. However, digital health interventions (DHI) have been shown to address racial disparities in several health outcomes, such as cardiovascular disease, HIV, and maternal health. The Tough Talks COVID (TT-C) study was a randomized controlled trial of a DHI designed to empower Black young adults in the United States South to make informed, autonomous decisions about COVID-19 vaccine uptake by addressing structural barriers and misinformation about vaccines.

Objective: Our objective was to identify subgroups of Black young adults with various vaccine attitudes at baseline and determine the subgroups for which the TT-C DHI was most impactful.

Methods: Black young adults aged 18‐29 years in Alabama, Georgia, and North Carolina who were unvaccinated or insufficiently vaccinated against COVID-19 completed three online surveys over three months (N=360). Latent profile analysis was used to identify subgroups based on general vaccine attitudes at baseline, including hesitancy, confidence, knowledge, conspiracy beliefs, and mistrust. Logistic regression was used to examine the associations between latent profiles and vaccine uptake, and linear regression was used to examine changes in vaccine attitudes at three months post-randomization. Modification of the TT-C DHI's effects was assessed by latent profiles.

Results: Three latent profiles emerged: vaccine-receptive (n=124), vaccine-neutral (n=155), and vaccine-resistant (n=81). Political affiliation, income, social support, and recent flu vaccination differed significantly between the three subgroups (P<.05). Vaccine uptake was not significantly different by subgroup, and the TTC-DHI did not have differing effects on uptake across subgroups. However, the DHI had the strongest effect—with statistically significant measures of association (P<.05) and interaction P values (P<.10)—among the baseline vaccine-resistant and vaccine-neutral subgroups compared to the vaccine-receptive subgroups at three months in improving vaccine hesitancy, confidence, and conspiracy beliefs at three months: vaccine-resistant difference: −0.40 (−0.76 to −0.37), 0.39 (0.02 to 0.75), and −0.47 (−0.86 to −0.09); vaccine neutral difference: −0.36 (−0.52 to −0.19), 0.35 (0.18 to 0.51), and −0.24 (−0.44 to −0.03). The DHI had no effects on these outcomes among the vaccine-receptive subgroup.

Conclusions: Our findings revealed subgroups of Black young adults in the United States South with different vaccination attitudes, for which the TT-C intervention had differing effects. Black young adults who are vaccine-resistant or vaccine-neutral

XSL•FO
RenderX

may experience larger gains from a digital vaccine intervention. Future work aimed at improving vaccination outcomes could target these populations to maximize resource efficiency and drive the greatest improvements in vaccine outcomes.

KEYWORDS

COVID-19; mHealth; African American and Black; young adults; vaccination; mobile health

Introduction

The World Health Organization declared the outbreak of novel COVID-19, a global pandemic in early 2020, caused by SARS-CoV-2 [1]. By the end of the year, two COVID-19 vaccines had been issued emergency use authorizations in the United States [2,3]. At the time, nearly three in five Americans reported intentions to be vaccinated for COVID-19; however, African American or Black (Black) Americans reported intentions to vaccinate approximately 30% lower than that of White Americans and 50% lower than that of Asian Americans [4]. Hesitancy toward COVID-19 vaccination was particularly high among Black young adults and residents of the United States South [5,6], which translated into lower uptake of the COVID-19 vaccine and a disproportionately high mortality rate for Black Americans early in the pandemic [7,8].

Negative attitudes toward vaccines and suboptimal vaccination rates among Black Americans have been influenced by a history of medical racism and human rights violations in the United States [9-14]. Continued harmful experiences with the health care system and government motivate hesitancy toward public health programs, such as vaccination, as a self-protective coping mechanism [15]. Studies have consistently shown this hesitancy, with reported lower vaccine uptake among Black communities for the annual flu shot due to distrust of medical institutions and concerns for safety [16-18]. Additionally, disparities in human papillomavirus vaccination have been observed among young Black girls, which is reflected in higher rates of cervical cancer incidence and mortality later in life [19,20]. During the COVID-19 pandemic, these experiences were exacerbated for Black young adults by the spread of misinformation and conspiracy theories online and on social media [21,22].

Digital health interventions (DHIs) have been successful in addressing racial disparities in health by creating culturally tailored messaging, inclusive programming, and more accessible services for disease prevention, ranging from cardiovascular disease to HIV to maternal health [23-27]. DHIs are particularly helpful for young adults, given the high proportion of Americans aged 18‐28 years with smartphones who report using web-based news and social media sites to access information about COVID-19 [28,29]. However, few DHIs to date have been developed specifically for COVID-19 vaccination among Black young adults in the United States South.

The Tough Talks COVID (TT-C) study was a randomized controlled trial of a DHI designed to empower Black young adults in the United States South to make informed, autonomous decisions about COVID-19 vaccine uptake (ClinicalTrials.gov NCT05490329) [30]. The TT-C intervention was cocreated using community-based participatory research methods to address structural barriers and misinformation about vaccines through interactive activities and digital storytelling [31,32]. Assuming heterogeneity among the study population, we aimed to use a latent profile analysis (LPA) to identify subgroups of Black young adults with different baseline vaccine attitudes and identify subgroups for whom TT-C was most impactful, to allow for better-informed community-based policies, practices, and messaging related to vaccine uptake and attitudes.

Methods

Participants

We used data from the TT-C randomized control trial, which included Black young adults aged 18‐29 years who were unvaccinated or insufficiently vaccinated against COVID-19 in Alabama, Georgia, and North Carolina. Participants were recruited online or via social media and randomized 1:1 to either the TT-C DHI, a self-directed asynchronous app developed to enable Black young adults in Southern United States to make decisions about COVID-19 vaccine receipt via nonstigmatizing and tailored messaging, or an information standard-of-care control consisting of COVID-19 vaccine materials adapted from the Centers for Disease Control and Prevention for three months. Surveys were completed at baseline, one month, and three months after randomization. Additional details about the study, which was conducted between March and December 2023, have been published previously [30] .

Latent Indicators

Five baseline variables related to general vaccine attitudes at baseline were used as latent indicators in the LPA: vaccine hesitancy, vaccine confidence, vaccine-related conspiracy beliefs, vaccine knowledge, and group-based medical mistrust. Each variable was assessed using a previously validated scale with a standardized continuous score as input using z-scores, such that the mean score transformed to zero to remove the impact of any baseline differences in means or variances across the variables before they were used in the LPA. This approach helps mitigate the influence of baseline distribution differences in the clustering process by making the variables comparable. The measures used in this LPA were prespecified in the study protocol and tested in formative surveys with Black young adults [30,33]. Vaccine hesitancy was a mean score of a 9-item scale with Likert responses ranging from 1‐5, where higher scores indicated greater hesitancy [34]. Vaccine confidence was a mean score of a 7-item scale with Likert responses ranging from 1‐5, where higher scores indicated greater confidence [35]. Vaccine-related conspiracy beliefs were a mean score of an adapted 5-item scale with Likert responses ranging from 1‐4,

XSL•FO
RenderX

where higher scores indicated greater belief in conspiracy [36]. Vaccine knowledge was a sum score of an adapted 4-item scale with "yes" or "no" responses for each item, where higher scores indicated greater knowledge [37]. Group-based medical mistrust was a sum score of a 12-item scale with Likert responses ranging from 1 - 5, where higher scores indicated greater mistrust [38]. For mean scores, if a response was missing for more than one scale item, the mean score was set as missing and not calculated. For summed scores, if a response was missing for any scale item, the summed score was set as missing and not calculated.

Additional Measures

Once latent profiles were established, differences in several baseline sociodemographic variables and other measures were assessed between the profiles. These included self-reported: sex assigned at birth, gender, age, education (ie, 9th-12th grade; no diploma; high school graduate or GED completed; some college level or technical or vocational degree; bachelor's degree; other advanced degree), political affiliation (ie, Democrat, Republican, Independent, other), employment status (eg, full-time; part-time; student; not working; disabled, permanently or temporarily), annual income, insurance coverage (eg, public, private, none), social support (continuous scale) [39], and previous flu and human papillomavirus vaccination.

Outcomes

The primary outcome was uptake of a COVID-19 vaccine anytime during the 3-month follow-up period, based on uploaded vaccine cards or, if not uploaded, self-report at one month and three months. Secondary outcomes included vaccine hesitancy, vaccine confidence, vaccine-related conspiracy beliefs, and vaccine knowledge, which were reported at 3 months. These secondary measures were assessed in the same manner as the baseline latent indicators explained above. Latent profiles were used to assess effect measure modification (EMM) of the TT-C DHI on both primary and secondary outcomes.

Statistical Analysis

Latent profile analysis allows us to gain insights into "hidden" subgroups in a study sample using person-centered mixture modeling. This approach models how indicator variables relate to each other by estimating different profiles (or classes) and determining the best-fitting model [40,41]. In LPA, model parameters include the probability of an individual belonging to a given profile, and each profile can have its own set of means and variances.

We evaluated two different model specifications: (1) equal variance and covariance across profiles and (2) varied variances and covariances across profiles. For each specification, we tested models with two, three, and four profiles. Model fit was assessed using an analytical hierarchy process based on the following information criteria: Akaike information criterion, Bayesian information criterion, Approximate Weight of Evidence, consistent likelihood criterion, and Kullback information criterion [42]. Lower values indicate a better fit for each criterion. Additional criteria including the sample size-adjusted Bayesian information criterion, entropy, and the bootstrap likelihood ratio (BLRT) were used to assess overall model quality. For these criteria, a lower sample size-adjusted Bayesian information criterion, higher entropy, and statistically significant BLRT indicate a good fit. The best model was selected using an analytical hierarchical process that balanced low values of Akaike information criterion, Bayesian information Criterion, Approximate Weight of Evidence, consistent likelihood criterion, and Kullback information criterion, which indicate a more parsimonious model, with fewer parameters while still accounting for data complexity, with higher entropy to ensure distinct profile separation and a significant BLRT to confirm robustness [42]. After model selection, we assigned study participants to the profile with the highest posterior probability based on their pattern of responses across the variables. Descriptive statistics were then calculated for the sociodemographic and additional variables within each profile. Differences in continuous variables across profiles were tested using ANOVA, while differences in categorical variables were assessed with the χ^2 test of independence.

The primary outcome of vaccine uptake at three months was assessed using a logistic regression model. The odds ratio approximates the risk ratio, as the probability of vaccine uptake was not common (<15%). For secondary outcomes—vaccine hesitancy, vaccine confidence, and vaccine-related conspiracy beliefs—we used linear regression to determine differences in outcomes at three months. Poisson regression was used to test for differences in the secondary outcome of vaccine knowledge score at three months. The main effects of the TT-C DHI intervention on vaccine uptake and vaccine attitudes will be reported in the primary manuscript of the study (Budhwani et al, PhD, unpublished data, 2024). The EMM of the effect of the TT-C DHI intervention on primary and secondary outcomes by profile group was assessed in this study by including the study arm and latent profile at baseline as both main effects and interaction terms. The EMM assesses whether an intervention effect (ie, the effect of the intervention on the outcome in the intervention group compared to the control group) differs across a variable of interest (in this case, the LPA groups). Interaction terms with a P value <.10 were considered indicators of significant effect measure modification. For all models, the state of residence was controlled to account for its inclusion in the stratified randomization study design. We did not control for other variables as they were balanced by the randomized design. All analyses were conducted using R software (version 4.4.1; R Foundation for Statistical Computing) [43].

Sensitivity Analysis

A sensitivity analysis was conducted using latent class analysis (LCA), typically used with categorical variables, where all indicator variables were dichotomized at appropriate cut-points for each validated scale [44]. We tested LCA models with two, three, and four classes and used similar criteria to assess fit. We then compared the number of classes identified by LCA to the number of profiles identified by LPA, as well as the total variance explained and general sociodemographic differences across the classes/profiles. We chose to report LPA as the main analysis to maintain the continuous nature of the originally validated measures used as indicator variables and because of the added model flexibility of LPA with varying variances and covariances across profiles.

Ethical Considerations

All study materials and procedures were reviewed and approved by the Institutional Review Boards of the University of North Carolina, Chapel Hill (21 - 1746) and Florida State University (STUDY00003617). Informed consent was collected digitally from all study participants before data collection and randomization. All data were deidentified to safeguard participant information.

Results

A total of 360 Black young adults were included in this study, of whom 76% (n=272) identified as cisgender or transgender women. The median age was 24 (IQR 21 - 27) years, and approximately one-third of participants (n=122) had a bachelor's degree or higher. Overall vaccine uptake at month 3 was low (n=21) and did not significantly differ between the intervention and control arms (odds ratio [OR] 1.88, 95% CI 0.76 to 4.69).

Latent Profile Analysis

Using the prespecified fit criteria with the analytic hierarchy process, we found that the model with three profiles and varied variances and covariances across profiles provided the best fit (Table 1). The profiles in Figure 1 were named based on the mean values of the five indicator variables, all of which were significantly different (P<.001) between the profiles (Table 2). The vaccine-receptive group (Profile 2) included 124 participants (34%) and had the lowest mean scores for medical mistrust, conspiracy beliefs, and vaccine hesitancy and the highest mean score for vaccine confidence and knowledge of vaccines compared to other profiles. The vaccine-resistant group (Profile 3) included 81 participants (23%) and had the highest mean score for medical mistrust, conspiracy beliefs, and vaccine hesitancy and the lowest mean score for confidence and knowledge of vaccines compared to other profiles. The vaccine-neutral group (Profile 1) included 155 participants (43%) and had mean scores between those of the vaccine-receptive and vaccine-resistant groups for all indicator variables.

[a]TT-C: Tough Talks COVID

Individuals in the vaccine-receptive group was significantly more likely to have been vaccinated for the flu in the past 12 months (n=40, 41%) compared with those in the vaccine-neutral (n=33, 29%) and the vaccine-resistant (n=7, 15%) groups (*P*=.01). Additionally, the vaccine-receptive group was more likely to report Democratic political affiliation (n=74, 60%) compared to the vaccine-neutral (n=70, 45%) and vaccinate-resistant (n=27, 33%) groups (*P*=.001). Reported annual income and insurance coverage were highest among the vaccine-receptive group; however, there were no significant differences in educational attainment or employment status across profiles. The vaccine-receptive group also tended to be younger (mean age, 23.3, SD 3.7) years and reported more social support (mean score, 4.1, SD 0.8) compared with both the vaccine-neutral (mean age, 23.6, SD 3.3 years; mean social support score, 3.8, SD, 0.9) and vaccine-resistant (mean age, 24.5, SD 3.1 years; mean social support score, 3.6, SD 1.1) groups (*P*=.05).

EMM by Baseline Vaccine Attitude Profile

Effect measure modification analysis showed that the TT-C DHI did not have a different effect on vaccine uptake across latent profile subgroups (Table 3). For secondary outcomes, EMM showed that the TT-C DHI had differing effects among those identified as vaccine-resistant compared with those classified as vaccine-receptive at baseline for the outcomes of vaccine hesitancy (interaction *P*=.07), vaccine confidence (interaction *P*=.06), and vaccine-related conspiracy beliefs (interaction *P*=.04) at 3 months (Table 3). There were also differing effects between vaccine-neutral and vaccine-receptive groups from baseline for the outcomes of vaccine hesitancy (interaction *P*=.05) and vaccine confidence (interaction *P*=.05) at 3 months. The vaccine-resistant group showed the greatest effect from the TT-C DHI, with a reduced mean vaccine hesitancy score of −0.40 (95% CI −0.76 to −0.37), an increased mean vaccine confidence score of 0.39 (95% CI 0.02 to 0.75), and a reduced conspiracy belief score of −0.47 (95% CI −0.86 to −0.09). The vaccine-neutral subgroup experienced moderate effects, including a reduced mean vaccine hesitancy score of −0.36 (95% CI −0.52 to −0.19) and an increased mean vaccine confidence score of 0.35 (95% CI 0.18 to 0.51). The TT-C DHI had no significant effect on any of the secondary vaccine-related outcomes among the vaccine-receptive subgroup.

Sensitivity Analysis

When using the prespecified fit criteria with the analytic hierarchy process, we found the LCA model with the best fit to include three classes, similar to the LPA results. Similar to our LPA results, the three classes represented subgroups of study participants who were either: (1) vaccine-receptive, with low mean scores for mistrust, conspiracy beliefs, or hesitancy and high mean scores for knowledge and confidence; (2) vaccine-resistant, with high mean scores for mistrust, conspiracy beliefs, and hesitancy and low mean scores for knowledge or confidence; or (3) somewhere in between the two, as vaccine-neutral. The classes from the LCA had similar differences as the profiles in the LPA analysis with respect to political affiliation, income, insurance coverage, and flu vaccination. Thus, LCA results reinforce the findings from the LPA.

Discussion

Our LPA of Black young adults participating in an RCT for the TT-C DHI found three distinct subgroups of individuals with different baseline vaccine attitudes. The three subgroups ranged from vaccine-receptive to vaccine-resistant and differed on several sociodemographic variables, such as political affiliation, income, and social support. While there were no significant differences in vaccine uptake by intervention arm between the three subgroups, we identified modification whereby the TT-C DHI had the largest improvement in hesitancy, confidence, and conspiracy beliefs at 3 months among the subgroups who were vaccine-resistant and vaccine-neutral at baseline compared to those who were vaccine-receptive.

To our knowledge, this is the first study to use LPA to explore the efficacy of DHIs for improving vaccine outcomes among Black young adults in the United States South, a population understudied and underserved in vaccine research. Our results

XSL•FO
RenderX

from TT-C align with those of several social media and video-based educational DHIs across different populations, which showed the biggest improvements in vaccine outcomes among those with poor vaccine attitudes at baseline [45,46]. Because the TT-C DHI was cocreated with youth from the community and incorporated digital storytelling—a method well suited for marginalized communities [32]—we believe we prevented experiences of "backfiring" or reverse effects seen in more generalized vaccine-related DHIs where vaccine attitudes worsened among those with poor attitudes at baseline [47,48]. Additionally, the vaccine-receptive subgroup in this study had high confidence and knowledge in vaccines, with little hesitancy, mistrust, or conspiracy beliefs despite being insufficiently vaccinated. These baseline scores left limited room for improvement at month 3, which likely explains why TT-C differs from some other vaccine DHIs that saw the largest improvements in vaccine outcomes among those with more positive attitudes at baseline [49,50].

The success of this community-based participatory research project in developing a DHI for Black young adults in the United States South mirrors that of other DHIs aimed at acknowledging and addressing the historical injustices and ongoing inequities that drive distrust within communities of color, while using culturally appropriate messages and existing community infrastructure to address concerns about COVID-19 vaccine safety and access [51-55]. By using digital storytelling to convey accurate, relatable, and culturally resonant messages, DHIs can foster trust and engagement in positive vaccine beliefs, which can serve as a model for improving vaccination among other underserved or vaccine-resistant populations, both for COVID-19 and other vaccines. This work provides a blueprint for public health initiatives to adapt and implement culturally sensitive vaccine interventions that help build the capacity to identify inaccurate or misleading information online and to encourage individuals to make informed decisions. However, it also highlights the challenges of translating changed attitudes into actions.

Despite the significant improvements seen in vaccine attitudes, the lack of impact from the TTC-DHI on actualized vaccination behavior among any subgroup of Black young adults in this study may be attributed to a number of external factors. One key factor was the availability and access of COVID-19 vaccines during the study period of late 2023, when primary series promotion was shifting to boosters. Changing public health guidelines and the short 3-month timeframe in the study may have resulted in a lack of opportunity for behavioral action to get vaccinated, as the recommended frequency of boosters was greater than 3 months and it may have been less likely for clinics to offer the primary vaccination series. Indeed, only 21 (6.4%) participants received a new COVID-19 vaccine over the 3-month follow-up period. Additionally, the Health Belief Model has shown that a change in attitudes is not always enough to effect behavior change; certain conditions, such as perceived risk of infection and resource mobilization, are also required [56,57]. Lastly, other external influences, such as ongoing misinformation and continued structural inequalities in access, may have dampened the direct impact of the intervention on behavior, even as attitudes shifted positively.

This study draws on a large sample of Black young adults from the United States South, and we used a comprehensive range of validated vaccine scales as constructs to conduct the LPA. However, there are several limitations to this work. First, the landscape of COVID-19 science was changing quickly while the app was being developed and implemented (2021 - 2024); although app content was responsive to these changes, not all components were adjustable once developed, which may limit the generalizability and overall effectiveness of app messaging. This evolving context may have influenced participants' attitudes and behaviors in ways that are difficult to fully capture, as new information or policy changes could have overshadowed the effects of the intervention itself. Second, information about vaccine attitudes was collected via self-report, which may be misreported due to social desirability bias. Lastly, the use of LPA does not guarantee proper creation or assignment of subgroups and overlap between identified profiles may impact findings. However, our sensitivity analysis resulted in the same number of subgroups with similar distributions and effect measures, strengthening our confidence in these results and our study conclusions.

This analysis found that Black young adults who are vaccine-resistant or vaccine-neutral may experience larger improvements in vaccine outcomes when using DHIs like TT-C. Future researchers and policymakers can use this knowledge to create better-informed community-based policies, practices, and messaging related to vaccine uptake and attitudes while understanding subpopulations to target for resource efficiency and to drive the biggest improvement in vaccine outcomes. However, vaccine-receptive individuals may experience other benefits from these types of DHIs not assessed, such as improved linkage to vaccine resources or social support and thus should not be excluded. Vaccine-receptive individuals could also be leveraged as peer leaders or vaccine advocates in their respective communities to further increase uptake and acceptability of DHIs among Black young adults in the United States South.

Abstract

Background: Violence against women (VAW) is a major public health and human rights concern with profound mental health consequences. However, the association between specific VAW forms and mental health, particularly among left-behind women in rural China, remains unclear.

Objective: This study aimed to identify the associations of VAW with depression, anxiety, and comorbid symptoms and to explore the potential roles of resilience and social support.

Methods: The cross-sectional survey was conducted in Y City, Henan Province, China, in July 2023. A multistage stratified random sampling method was used to recruit left-behind women, resulting in a final sample of 1503 participants. Data on participants and their VAW were collected through a face-to-face questionnaire survey. The forms of VAW assessed were nonpartner violence (NPV) and intimate partner violence (IPV; including remote IPV). Depressive symptoms were evaluated using the 10-item Center for Epidemiological Studies Depression Scale, while anxiety symptoms were assessed with the Generalized Anxiety Disorder-7. The comorbid symptoms of depression and anxiety (CDA) were ascertained as the simultaneous presence of depressive and anxiety symptoms. A multivariable logistic regression model was used to estimate the odds ratio and 95% CIs. A 4-way decomposition analysis was conducted to test the mediation roles and interactions of resilience and social support between VAW and mental health outcomes. Population attributable fractions and pathway-specific population attributable fractions were calculated to estimate the burden of mental health outcomes attributable to VAW.

Results: Lifetime VAW (adjusted odds ratio [aOR] 1.84, 95% CI 1.32 - 2.54) was associated with an increased risk of CDA. Women who were exposed to lifetime IPV (aOR 1.84, 95% CI 1.32 - 2.56), remote IPV (aOR 2.79, 95% CI 1.60 - 4.74), and NPV (aOR 2.63, 95% CI 1.58 - 4.26) had an increased likelihood of reporting CDA. Similar associations could also be found for depressive symptoms and anxiety symptoms. In the 4-way decomposition analysis for VAW and CDA, mediation effects of low resilience and social support were statistically significant (P<.05), whereas none of the interactions reached significance (P>.05). The pure mediation proportion was 28.2% for the low resilience and 18.6% for the social support between VAW and CDA. A total of 20.8% of CDA cases, 15.1% of depressive symptoms cases, and 22.7% of anxiety symptoms cases were attributable to VAW. Among these, low resilience accounted for 7.2% and low social support accounted for 4.7% of CDA cases as mediators.

Conclusions: Lifetime VAW, including IPV (and remote IPV) and NPV, shows significant associations with CDA and depressive and anxiety symptoms among rural left-behind women in China. The associations are partly mediated by low resilience and social support. Targeted strategies, including efforts to reduce violence against rural left-behind women, enhance their resilience and strengthen their social support networks, are urgently needed.

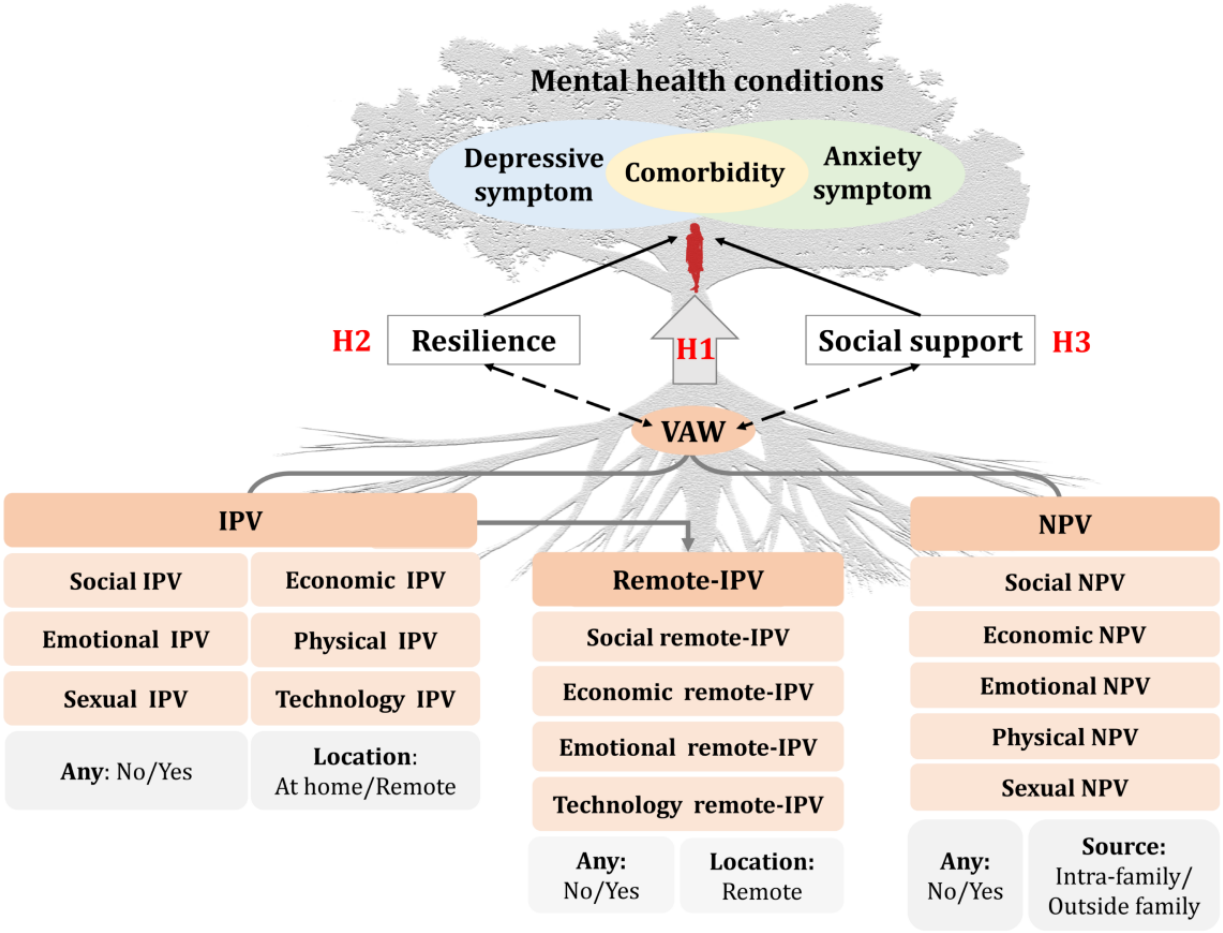
Introduction

With rapid urbanization and economic reforms, rural left-behind women—those whose husbands migrate to urban areas for employment—are becoming increasingly common in many low- and middle-income countries [1-3]. In China, over 50 million women are left behind in rural areas due to internal migration [4]. This demographic shift is shaped by structural inequalities, such as women's disadvantaged position, underdeveloped social services, and cultural norms like familism, which often prioritize family needs over individual desires [5]. As a result, left-behind women bear a "triple burden" of caring for children, supporting older family members, and managing agricultural responsibilities in the absence of their spouses [6]. The prolonged separation from their spouses, combined with socioeconomic pressures, raises concerns about their mental health [3].

Mental disorders, particularly depression and anxiety, have become increasingly prevalent and are now major global mental health concerns [7]. Previous studies showed that depression and anxiety frequently co-occur, sharing common symptoms and risk factors like adverse life events [8]. Comorbid symptoms of depression and anxiety (CDA) are more debilitating than either condition alone, leading to greater psychosocial impairment and poorer health outcomes [9]. Among left-behind women, these disorders are of particular concern due to the compounded stressors they face. The absence of a spouse, social isolation, and the potential for increased economic pressure can create an environment that fosters psychological distress [10,11]. Thus, attention to the mental health of left-behind women is essential, particularly given the limited availability of mental health services in rural settings [12].

A crucial, yet often overlooked, determinant of mental health is violence against women (VAW). VAW is a pervasive global issue encompassing physical, emotional, and sexual abuse, with intimate partner violence (IPV) being the most commonly studied form [13,14]. Although the physical absence of a husband might suggest reduced exposure to IPV, left-behind women are susceptible to experiencing remote IPV, a form of abuse facilitated by technology, where geographically distant partners exert control through harassment, threats, or emotional abuse via phone calls, messaging, or social media [15,16]. Moreover, nonpartner violence (NPV) should be given attention among left-behind women since they experience prolonged periods of living alone or with other family members [17,18]. A growing body of literature demonstrates that exposure to VAW, particularly IPV, is strongly associated with adverse mental health outcomes, including depression and anxiety [19,20]. For example, for women in Afghanistan under the Taliban government, exposure to traumatic events such as violence can contribute to depressive and anxiety symptoms, ultimately diminishing their quality of life [21-23]. However, significant gaps remain in our understanding of how different forms of VAW, specifically IPV, remote IPV, and NPV, impact mental health outcomes among left-behind women.



Resilience is the ability to adapt positively in the face of adversity [24]. Social support, similarly, is considered a positive role in improving mental health outcomes [25]. Despite their known protective effects, the roles of resilience and social support as mediators or moderators in the relationship between VAW and mental health, particularly among rural left-behind women, remain unclear.

This study aimed to address these gaps by investigating the associations of VAW with depressive, anxiety, and comorbid symptoms among left-behind women in rural China, and to explore the potential roles of resilience and social support. Specifically, this study sought to test the following three primary hypotheses (Figure 1):

1. Hypothesis 1 (H1): VAW is positively associated with depressive and anxiety symptoms, with different forms, types, and periods of violence exhibiting various associations.
2. Hypothesis 2 (H2): Resilience serves as a mediator and moderates the association between VAW and mental health conditions.
3. Hypothesis 3 (H3): Social support acts as a mediator and moderates the association between VAW and mental health conditions.

Figure 1. Conceptual framework illustrating the hypothesized associations between various forms and types of violence and mental health outcomes among rural left-behind women in China, with resilience and social support as potential mediators. In this figure, the tree trunk represents mental health status composed of depressive and anxiety symptoms, while the roots symbolize various forms of violence as underlying factors. The tree as a whole illustrates how these root-level exposures may influence the development of mental health outcomes. H1: hypothesis 1; H2: hypothesis 2; H3: hypothesis 3; IPV: intimate partner violence; NPV: nonpartner violence; VAW: violence against women.

Methods

Study Design and Participants

The cross-sectional survey was conducted in Y City, Henan Province, China, in July 2023, where there is frequent labor migration to urban areas for work (Figure S1 in Multimedia Appendix 1). For participant recruitment, a multistage stratified random sampling method was used. First, 7 towns were chosen: 3 low-, 2 medium-, and 2 high-economic towns. Second, 102 survey sites were selected within these towns. With support from local Women's Federation staff or social workers of these selected survey sites, participants were invited to complete a face-to-face questionnaire administered by trained field investigators in meeting rooms of village committee service centers. Data on women's sociodemographic and lifestyle information, violence exposure, and mental health outcomes were self-reported and collected following the World Health Organization recommendations to maximize participant safety and disclosure [26]. To ensure data quality, daily debriefing sessions were held with all field investigators to address potential questions arising from interviews based on their submitted questionnaires. The statistics team performed daily checks on antifraud questions, minimum completion time thresholds, and logical consistency checks (eg, implausible age values).

Eligible participants were rural married women aged 18 years or older with normal communication and understanding ability, whose husbands had been absent for at least 6 months within the past year. A total of 1525 questionnaires were finally retained for the survey, of which 1519 were valid. Participants with missing or ambiguous data on violence (n=3) or mental health outcomes (n=13) were excluded, resulting in a final sample of 1503 women (Figure S1 in Multimedia Appendix 1).

Ethical Considerations

The study protocol was approved by the Ethics Review Committee of Zhejiang University School of Public Health (approval number: ZGL202306-5). All participants provided written informed consent for participation and publication. Study data were anonymized prior to analysis. Each participant received a health gift package valued at approximately ¥20 (approximately US $2.80). No identifiable images of participants are included in the manuscript or Multimedia Appendix files.

Assessment of VAW

The questionnaire used to assess various forms of VAW in this study was developed based on the World Health Organization's VAW Instrument [27]. The adapted questionnaire was validated through a 2-round Delphi survey with 18 experts, ensuring its credibility. The lifetime VAW was divided into 2 primary forms according to the sources: IPV (violence from partners) and NPV (violence from other family members or outside the family) (Figure 1). Given that technology-driven, geographically distant abuse is unique for rural left-behind women, remote IPV was specifically measured. IPV was measured using 25 items across 6 types (social IPV, economic IPV, emotional IPV, physical IPV, sexual IPV, and technology-facilitated IPV). Remote IPV was assessed using 16 items across 4 types (social remote IPV, economic remote IPV, emotional remote IPV, technology-facilitated remote IPV). NPV was measured through 19 items across 5 types (social NPV, economic NPV, emotional NPV, physical NPV, and sexual NPV) (Table S1 in Multimedia Appendix 1).

Assessment of Mental Health Outcomes

Depressive symptoms were measured using the 10-item Center for Epidemiological Studies Depression scale [28], which demonstrated good internal consistency (Cronbach α=0.80) [29]. Participants were asked how frequently they experienced a series of depressive symptoms over the past week, with response options ranging from 0 (rarely or none of the time) to 3 (most or all of the time). The total 10-item Center for Epidemiological Studies Depression Scale score ranged from 0 to 30, with a cutoff score of 10 indicating the presence of depressive symptoms [30].

Anxiety symptoms were assessed using the generalized anxiety disorder-7 scale [31,32], which also showed excellent internal consistency (Cronbach α=0.92) [33]. The Generalized Anxiety Disorder-7 includes 7 items rated on a 4-point scale: 0 (not at all) to 3 (nearly every day), with a cutoff score of 5 indicating anxiety symptoms [34].

CDA was defined as the simultaneous presence of both depressive and anxiety symptoms. In this study, CDA, depressive symptoms, and anxiety symptoms were the primary mental health outcomes of interest.

Assessment of Resilience and Social Support

Resilience was measured using the 10-item Connor-Davidson Resilience Scale [24,35,36], with a Cronbach α of 0.98. Items were rated on a 0 - 4 scale, with higher scores indicating greater resilience (range 0 - 40). Social support was measured using the Social Support Rating Scale, including objective support (3 items), subjective support (4 items), and utilization of support (3 items), with a total score of 66 points. The Social Support Rating Scale has demonstrated acceptable internal consistency and reliability, with a Cronbach α of 0.70 in this study [37].

Ascertainment of Covariates

Covariates include women's sociodemographic, lifestyle, and left-behind related variables. The age of women was assessed as a continuous variable. Education was classified into primary school and below, middle school, and high school and above. Work was categorized into no job, farmer, formal job, casual job, or others. Annual household income in CNY was divided into below ¥30,000, ¥30,001 - 50,000, and ¥50,001 and above (all currency values in Chinese yuan [¥] are based on the conversion rate of ¥7.1 = US $1, the approximate exchange rate at the time of the study). An unhealthy lifestyle consists of smoking, drinking, and poor sleep quality. BMI was calculated as weight divided by the square of height and categorized into 3 levels (normal weight or under: <23.9 kg/m^2, overweight: 23.9 - 27.8 kg/m^2, and obesity: ≥27.9 kg/m^2) [38]. Chronic disease history was self-reported physician diagnosis of the common noncommunicable diseases, including hypertension, dyslipidemia, diabetes or hyperglycemia, gastrointestinal disorders, liver diseases, heart diseases, stroke, urological disorders, respiratory system diseases, arthritis, or rheumatism. Length of being left behind was divided into below 3 years, 3 - 6 years, 6 years and above.

Statistical Analysis

Descriptive statistics summarized rural left-behind women's characteristics by CDA, depressive, and anxiety symptoms. Skewed continuous variables were reported as medians (IQRs) and compared via the Wilcoxon rank-sum test. Categorical variables were presented as frequencies (%) and analyzed using Pearson chi-square or Fisher exact tests.

Multivariable logistic regressions were used to analyze associations of any VAW and its forms (IPV [including remote IPV] and NPV) as well as specific types with CDA, depressive, and anxiety symptoms. Models were adjusted for age, education, occupation, household income, healthy lifestyle, BMI, chronic disease history, and length of being left behind. Restricted cubic splines were used to investigate the dose-response associations between the number of VAW items and mental health outcomes.

A 4-way decomposition analysis was performed to quantify how much of the association between VAW and mental health outcomes could be attributed to mediation (the sum of the mediated interaction and the pure indirect effect) or interaction (the sum of the reference interaction and the mediated interaction) of low resilience and social support [39]. In addition, separate mediation and additive and multiplicative interaction analyses were also performed. Detailed methods are described in Multimedia Appendix 1.

Population attributable fractions (PAFs) were calculated to estimate the proportion of CDA, depressive symptoms, and anxiety symptoms cases that could potentially be attributable to VAW based on the following equation[40]: PAF=Pe(RR-1)1+PeRR-1. Our study replaced risk ratios (RRs) in the formula with odds ratios (ORs) obtained in the above logistic regression. The fraction of participants being exposed to the risk factor (Pe) and the OR of the outcome associated with the corresponding factors were derived from the study. The 95% CI of PAF was calculated using bootstrap [41]. Furthermore, we explored pathway-specific PAFs of potential mediators between VAW and outcomes, which indicated the relative reduction in outcome prevalence if a certain mediating pathway was disabled. The "graphPAF" R package was used to obtain pathway-specific PAFs [42,43].

XSL•FO
RenderX

All statistical analyses were performed using R software (version 4.2.1; R Foundation for Statistical Computing). Statistical significance was considered to be <.05 with a 2-sided, or 95% CIs of OR that did not cross 1.00.

Results

Characteristics

The characteristics of rural left-behind women stratified by CDA are shown in Table 1. Of the 1503 rural left-behind women, 12.8% (n=192) had CDA. Women with CDA were more likely to experience VAW (43.8% vs 29.4%), IPV (40.1% vs 26.6%), remote IPV (12.0% vs 4.4%), and NPV (14.6% vs 5.9%), compared with those without CDA (all *P*<.05). For VAW types, similar comparisons are also evident.

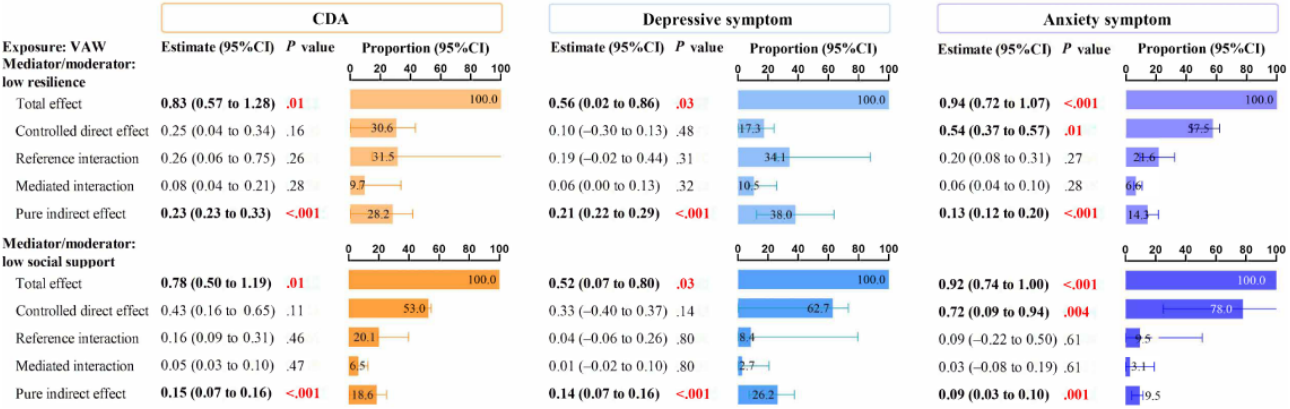
Associations Between VAW and Mental Health Outcomes

In the multivariable logistic models presented in Figure 2 and Table S2 in Multimedia Appendix 1, compared with no VAW, VAW exposure was associated with an increased CDA risk (adjusted odds ratio [aOR] 1.84, 95% CI 1.32 - 2.54), and this risk rose with each additional VAW item (aOR 1.21, 95% CI 1.13 - 1.29). When VAW was categorized by item count, women with 3 or more VAW items showed a markedly higher risk of CDA (aOR 3.41, 95% CI 2.25 - 5.15). Similar associations were also observed for depressive and anxiety symptoms in relation to VAW (Figure 2 and Table S2 in Multimedia Appendix 1). Restricted cubic spline curves exhibited dose-response associations between increased VAW numbers and elevated risks of mental health outcomes (Figure S2 in Multimedia Appendix 1).

For the 3 forms of VAW, lifetime IPV (aOR 1.84, 95% CI 1.32 - 2.56), remote IPV (aOR 2.79, 95% CI 1.60 - 4.74), and NPV (aOR 2.63, 95% CI 1.58 - 4.26) were all associated with higher odds of CDA. Among the types of IPV, only economic IPV did not show a significant association with mental health outcomes. Social remote IPV (aOR 3.39, 95% CI 1.71 - 6.48), technology-facilitated remote IPV (aOR 5.95, 95% CI 1.07 - 30.12), economic NPV (aOR 6.10, 95% CI 1.19 - 26.48), and emotional NPV (aOR 3.15, 95% CI 1.86 - 5.24) were all associated with higher odds of CDA. Similar findings were observed for depressive symptoms and anxiety symptoms, respectively (Figure 2 and Table S2 in Multimedia Appendix 1).

XSL•FO
RenderX

Figure 2. Heat maps of aOR from multivariable logistic regression analyses examining associations between various forms and types of violence and mental health outcomes among Chinese rural left-behind women, based on a cross-sectional study conducted in China in 2023. A darker color in a gradient from white to blue shows a higher aOR of corresponding outcomes. All models were adjusted for age, education, occupation, household income, unhealthy lifestyle (smoking, drinking, poor sleep quality), BMI, chronic disease history, and length of being left behind. aOR: adjusted odds ratio; CDA: comorbid symptoms of depression and anxiety; IPV: intimate partner violence; NPV: nonpartner violence; VAW: violence against women.



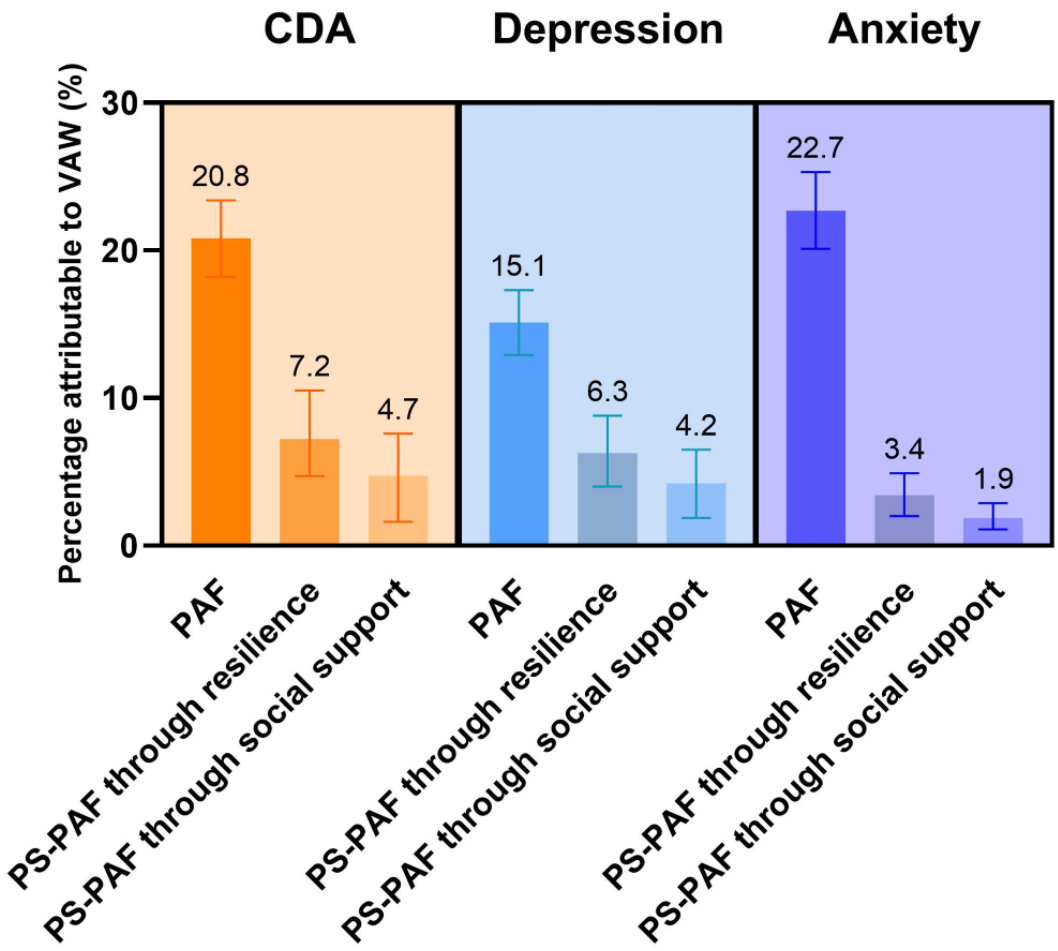
Mediation and Interaction Effects

In a 4-way decomposition analysis, all mediation effects were statistically significant (P<.05), whereas none of the interactions reached significance (P>.05). Overall, 69.4% of the association between VAW and CDA could be explained by low resilience, with 37.9% of this effect attributable to total mediation. Similarly, 45.2% of the association between VAW and CDA could be explained by low social support, with 25.1% attributable to total mediation (Figure 3 and Table S3 in Multimedia Appendix 1).

Separate mediation and interaction analyses validated similar conclusions. Mediation analysis also showed that low resilience and low social support partially mediated the associations between VAW and mental health outcomes (Table S4 in Multimedia Appendix 1). While the additive and multiplicative interactions of "VAW*resilience" and "VAW*social support" on mental health outcomes were not significant, as the 95% CI of relative excess risk due to interaction crossed 0 and the 95% CI of multiplicative scales crossed 1 (Table S5 in Multimedia Appendix 1).

XSL•FO
RenderX

Figure 3. Four-way decomposition analysis of the associations between violence and mental health outcomes with low resilience or social support as mediators among Chinese rural left-behind women, based on a cross-sectional study conducted in China in 2023. Controlled direct effect indicates association not caused by mediation or interaction, reference interaction indicates association due to interaction only, mediated interaction indicates association due to mediation and interaction, and pure indirect effect indicates association due to mediation only. The total mediation proportion comprises the combined effects of the mediated interaction and the pure indirect effect. Similarly, the total interaction proportion is determined by the sum of the reference interaction and the mediated interaction. All models were adjusted for age, education, occupation, household income, unhealthy lifestyle (smoking, drinking, and poor sleep quality), BMI, chronic disease history, and length of being left behind. CDA: comorbid symptoms of depression and anxiety; VAW: violence against women.



Population Attributable Fractions

A total of 20.8% of CDA cases, 15.1% of depressive symptoms cases, and 22.7% of anxiety symptoms cases were attributable to VAW (Figure 4). Among the 3 forms of VAW, the PAF of IPV on depressive symptoms (13.9%) is lower than on anxiety symptoms (23.6%), while the PAF of NPV on depressive symptoms (7.7%) is higher than on anxiety symptoms (5.9%) (Table S6 in Multimedia Appendix 1). The pathway-specific PAFs of CDA, depressive symptoms, and anxiety symptoms attributable to VAW through resilience or social support are presented (Figure 4 and Table S6 in Multimedia Appendix 1). As a mediator, resilience accounted for 7.2%, 6.3%, and 3.4% of CDA, depressive symptoms, and anxiety symptoms with VAW, respectively. The pathway-specific PAFs of social support between VAW and CDA, depressive symptoms, and anxiety symptoms were 4.7%, 4.2%, and 1.9%, respectively.

Figure 4. PAF and PS-PAF for violence on mental health outcomes for Chinese rural left-behind women, based on a cross-sectional study conducted in China in 2023. CDA: comorbid symptoms of depression and anxiety; PAF: population attributable fraction; PS-PAF: pathway-specific population attributable fraction; VAW: violence against women.

Discussion

Principal Findings

Chinese rural left-behind women's exposure to lifetime VAW, including IPV (and remote IPV) and NPV, is strongly associated with adverse mental health outcomes, including CDA, depressive, and anxiety symptoms. These associations were partially mediated by low resilience and social support, though interactions were nonsignificant. VAW accounted for a substantial proportion of CDA, depressive, and anxiety symptoms, with differing attributable fractions for IPV and NPV, and resilience and social support partially mediated these attributable proportions.

This study aligns with previous research, reinforcing the association between lifetime VAW and adverse mental health outcomes, including its cumulative effects [44,45]. The left-behind situation among women in rural areas has lasted several decades in China due to disproportionate male labor migration to advanced economic regions. In such a context, women are particularly vulnerable without support from their husbands. Stereotypical gender norms and prevailing beliefs that family matters are private in rural areas constrain women's autonomy and perpetuate violence [46,47]. Moreover, this vulnerability can be further exacerbated by women's economic dependence and limited mental health services resources, further deepening their mental health issues [48]. These associations between VAW and mental health issues can also be supported by biological evidence. Repeated violence exposure may lead to dysregulation of the hypothalamic-pituitary-adrenal axis, a critical pathway in the body's stress response system, contributing to long-term adverse health effects [49]. Moreover, violence exposure can alter neural circuits involved in emotional learning, resulting in impaired memory, heightened threat vigilance, and exaggerated emotional responses to environmental stimuli [50].

The increased risk of adverse mental health outcomes for women exposed to lifetime IPV and NPV is well established and extended by our findings [20,51,52]. Remote IPV has also been found to be an important factor affecting left-behind women's mental health, calling attention to technology-facilitated remote IPV [16,53]. All IPV types, except economic IPV, were significantly associated with mental health outcomes. The lack of a significant association for economic IPV might be due to the socioeconomic context of rural left-behind women, many of whom are in lower economic strata and depend primarily on

XSL•FO
RenderX

their husbands for financial support. Additionally, social and technology-facilitated remote IPV, along with economic and emotional NPV, was associated with higher CDA odds. Our findings expand previous research by comprehensively assessing a broader range of VAW forms, types, and their associations with mental health outcomes.

The associations between VAW and mental health outcomes were partially mediated by low resilience and social support, aligning with previous research. Resilience is thought to buffer the psychological effects of violence, given its ability to access various resources to adapt positively in the face of adversity [54,55]. A study found that empowering women to develop resilience-based coping strategies significantly mediated the impact of IPV on mental health outcomes [56]. Social support is also a vital source of empowerment for women provided by a network of relationships, which helps them cope with stress and maintain well-being. Consistent with our findings, research shows that higher social support buffers the negative impacts of adverse events, helping individuals maintain physical and mental well-being [57,58]. This highlights the importance of strengthening social support networks and fostering resilience as potential interventions to reduce the psychological burden of VAW among rural left-behind women.

Our study estimated that 20.8% of CDA cases, 15.1% of depressive symptoms cases, and 22.7% of anxiety symptoms cases were attributable to VAW. Depressive symptoms were predominantly attributed to IPV, while anxiety symptoms were mainly attributed to NPV. These findings underscore the significant mental health burden associated with VAW, emphasizing the need for clinicians, psychotherapists, and social workers to recognize it as a critical risk factor in rural left-behind women with depression or anxiety. Additionally, pathway-specific PAF revealed that psychological resilience accounted for a greater fraction of mental health outcomes attributable to VAW than social support. This suggests that enhancing resilience may be more effective in reducing the mental health impact of VAW than solely focusing on social support. These findings underscore the importance of incorporating both resilience and social support into public health interventions to address the mental health consequences of VAW.

Implications for Policy
