The study also reinforces a broader principle in public health surveillance: no single data source should be treated as complete population truth. CHS provides observed survey information and official small-area health indicators, but it remains a complex-sample survey with sampling uncertainty and sparse high-dimensional cells. KOSIS provides official aggregate statistics, but its denominators do not always match synthetic

XSL•FO
RenderX

adult rows and KOSIS/public statistics were among the persona seed sources. In this setting, synthetic personas are best understood as a complementary analytic layer whose value depends on explicit validation and calibration, not as a replacement for survey or official statistics.

This interpretation is consistent with statistical quality frameworks that distinguish output quality, process quality, coherence, and fitness for intended use [25]. For a public statistics–based synthetic persona dataset, fitness for use should therefore be judged against the specific surveillance task: broad descriptive planning, profile construction, calibration, or inferential small-area estimation. These findings support the first 2 uses more strongly than the latter 2.

For public health informatics, the results support a cautious but constructive role for synthetic personas. They should not be used as stand-alone substitutes for observed CHS indicators, because CHS already provides observed small-area health measures and synthetic rows are not survey observations. A more defensible use is to support simulation, scenario analysis, vulnerability profiling, dashboard prototyping, and calibration workflows when benchmark differences, sparse-cell flags, and denominator caveats are visible to users.

A practical implication is that marginal agreement is not enough. Close alignment for age, sex, province, and living-alone status does not guarantee alignment for profiles such as older low-education adults living alone or for combinations of age, sex, marital status, education, and living arrangement. The exhaustive audit of all 39 family-type labels and the alternative recoding analysis supported retaining living-alone status in the core analysis, whereas occupation remained sensitive to keyword mapping.

For implementation, the results support a tiered approach to use. Basic demographic margins and regional aging-related rankings may be appropriate for descriptive planning and regional prioritization. Policy-relevant vulnerable profiles may support scenario generation if benchmark differences and uncertainty diagnostics are reported. The national high-dimensional profile requires calibration, whereas municipal profiles require both calibration and explicit consideration of CHS sampling noise before inferential use.

For future validations of public-statistics-based synthetic populations, basic margins are a necessary first check but not a sufficient one. Joint distributions are essential because they reveal discrepancies that marginal comparisons can hide. Policy-relevant vulnerable profiles should be reported alongside high-dimensional metrics because they are easier for surveillance users to interpret than thousands of sparse cells. Sparse-cell sensitivity should accompany CHS comparisons at detailed profile levels. Variables requiring substantial harmonization, such as occupation, should be separated into sensitivity analyses. Finally, distributional discrepancies should be interpreted against benchmark uncertainty and temporal stability where possible, rather than against arbitrary cutoffs.

The framework also points to where calibration should be directed. For variables with strong public statistics benchmarks, raking or poststratification could be used to align synthetic rows to selected CHS or KOSIS margins [26,27]. For surveillance tasks that depend on vulnerable profiles, iterative proportional fitting or related calibration methods could target selected joint distributions rather than all possible sparse cells [26,28]. This role is closer to formal small-area estimation and calibration workflows than direct use of synthetic rows as evidence; recent small-area estimation work illustrates how survey data and auxiliary population information can be combined to improve estimates for small domains [29]. Occupation requires a separate harmonization strategy, ideally validated against external labor statistics benchmarks before being used as a core surveillance variable. At the municipal level, calibrated outputs should retain sparse-cell flags and uncertainty annotations so that synthetic profiles are not overinterpreted as direct local population estimates.

The study used multiple benchmark layers, including CHS survey benchmarks, seed-source–informed KOSIS public statistics benchmarks, comparison-specific denominators, stratified cluster bootstrap intervals, sparse-cell and temporal-stability diagnostics, split-half and independence-baseline references, occupation and living-alone recoding checks, and regional downstream compositional sensitivity. This layered approach reduces the risk that conclusions are driven by a single benchmark or harmonization choice and makes the intended use of each result more explicit.

Several limitations remain. First, CHS is a complex-sample survey benchmark rather than a population gold standard. Second, CHS high-dimensional cells are sparse, especially at the municipal level; scalar TVD and Jensen-Shannon divergence intervals quantify CHS sampling variability but not uncertainty in the fixed persona generation, and repeated synthetic generations or model-based uncertainty estimates would be needed to evaluate that component. Third, KOSIS indicators and persona rows have different denominators, and KOSIS/public statistics were among the persona seed sources; KOSIS comparisons are therefore seed-source–informed consistency checks rather than independent validation. Fourth, the dataset card identifies 2024 reference information for some seed sources but not a common vintage for all inputs, so temporal mismatch with pooled 2021-2025 CHS cannot be fully resolved. Fifth, persona living-alone status remains a proxy derived from the structured family-type field, although all 39 labels were audited and the single ambiguous label did not materially affect the results (Table S9 in Multimedia Appendix 1); economic activity and occupation had greater harmonization uncertainty and were treated as sensitivity domains. Sixth, the regional downstream analysis standardized CHS outcome rates over alternative compositions and did not validate persona-generated health outcomes.

In this benchmark-consistency study, public statistics–based synthetic personas represented several basic demographic margins and regional aging-related patterns reasonably well but did not fully reproduce the high-dimensional profiles needed for subgroup surveillance. The national discrepancy was clear, whereas municipal evidence was limited by sparse cells and CHS sampling noise. Synthetic personas may be useful for composition-based scenario development and dashboard prototyping but should not be treated as stand-alone sources for

XSL•FO
RenderX

local surveillance or health-outcome inference without additional calibration and validation.

## Acknowledgments

The author acknowledges the Korea Disease Control and Prevention Agency for providing access to Korea Community Health Survey data through official data-use procedures, the Korean Statistical Information Service (KOSIS) for providing publicly accessible statistical indicators, and NVIDIA for publicly releasing Nemotron-Personas-Korea through Hugging Face. ## Abstract

**Background:** Health information–seeking behavior (HISB) is a critical component of personal health management. Health literacy (HL) shapes whether and how people seek health information, but its role across age groups remains underexplored. Korea's highly digitalized information environment and rapidly aging population provide an important context for examining age-group differences in HL and HISB.

**Objective:** This study examined age-group differences in the association of HL with 2 related stages of HISB—HISB experience and, conditional on engagement, source-based HISB type—and assessed whether the roles of HL, education, and health-related factors differed across age groups.

**Methods:** Cross-sectional data from the 2020 - 2021 Korea Health Panel and 2021 HL Supplementary Survey (N=7910) were analyzed. HL was measured using the European Health Literacy Survey Questionnaire-16-item (HLS-EU-Q16). HISB type was classified as source-based "active seeking" or "passive acquisition" according to the respondents' top-ranked information source. Age-stratified multivariable logistic regression was used for HISB experience and type, and sensitivity analyses examined age×HL interactions and potential selection into the HISB type sample.

**Results:** Mean HL scores were lower in older age groups (14.10, SD 2.94 in ages 19 - 44 years vs 8.34, SD 4.65 in ≥65 years). HISB prevalence was highest in the youngest group (1072/1608, 66.7%) and lowest in the oldest group (1052/3487, 30.2%). Among those who engaged in HISB, 92.7% (993/1072) of the youngest group and 48.2% (507/1052) of the oldest group were classified in the active-seeking category. Primary age-stratified and interaction analyses showed that HL was significantly associated with HISB experience and type among adults aged 45 - 64 and ≥65 years, but not among those aged 19 - 44 years, whereas education and health-related factors were more salient among younger adults. The HL-HISB type association was sensitive to modeling selection.

**Conclusions:** Age-group patterns were evident in HISB experience and source-based type. HL was a more prominent correlate among middle-aged and older adults, while education and health-related factors were more salient among younger adults. Age-tailored strategies that also consider structural, motivational, and digital-access factors alongside HL are needed.

## Introduction

### Background

Health information–seeking behavior (HISB) is a fundamental component of personal health management and a recognized social determinant of health. In an increasingly digital environment, individuals are expected to engage proactively with diverse sources to make informed decisions on prevention, diagnosis, and treatment [1-3]. Health information seeking has been linked to increased health knowledge, improved decision-making, healthier behaviors, and favorable health outcomes [1-8].

Health literacy (HL) is critical in shaping individuals' HISB [1,5]. HL affects whether individuals seek information, how

XSL•FO
RenderX

actively they engage with it, and whether they can evaluate and apply what they find [6,8]. Those with higher HL tend to use more diverse and credible information sources, demonstrate greater initiative in information seeking, and report higher confidence in managing their health [9,10]. Conversely, individuals with low HL may encounter barriers in navigating health systems, communicating with providers, or even recognizing the need for additional information [7,11-13].

Among multiple dimensions of HISB, the type of behavior, particularly the distinction between active information seeking and passive information acquisition, has been used as an important analytical lens [5,7,8]. At the conceptual level, active seeking refers to purposeful, goal-directed efforts to find health information, whereas passive acquisition refers to incidental exposure without deliberate information seeking [5,7,14]. This distinction is analytically useful because active and passive forms of information engagement may differ in their associations with health-related outcomes. HL is thus considered a predictor of whether people seek health information and how they do so [8].

Age-group differences in HL and HISB have been widely documented: older adults generally have lower HL, which may reflect educational, cognitive, and technological factors [13-16], and, despite having greater health needs, are less likely to actively seek information [17-19]. Although typically higher in HL, younger adults may rely on less vetted sources or exhibit superficial engagement with information [20]. These contrasting patterns underscore the importance of examining age-specific dynamics in the HL-HISB relationship. They can be interpreted through the lens of information-seeking frameworks such as the Comprehensive Model of Information Seeking (CMIS), which emphasizes that information seeking is shaped by individual characteristics, perceived health-related relevance, and information-source factors [21]. This perspective is useful for understanding why HL, education, and perceived health needs may play different roles in active versus passive HISB across age groups [21,22].

### Objectives

Previous studies have primarily focused on HL or HISB, either separately or within specific subgroups [23,24]. Few have analyzed their relationship using nationwide adult panel data [15,25,26], and even fewer have explored age-specific differences, despite clear theoretical and empirical reasons to do so [27]. Building on the distinction between active information seeking and passive information acquisition [5,7], this study addresses this gap by examining not only whether HL is associated with HISB, but also whether the correlates of HISB type differ across age groups. We focus on whether HL, educational attainment, and perceived health needs are differentially associated with active versus passive HISB across age groups. The South Korean context, characterized by rapid population aging alongside a highly digitalized health information environment, provides a relevant setting for examining these age-specific dynamics. Using data derived from a nationally designed panel, we investigate (1) how HISB patterns vary by age group, (2) whether HL is associated with an individual's likelihood of engaging in HISB, and (3) whether the source-based HISB type (active vs passive) varies according to HL within each age group.

## Methods

### Data

This cross-sectional study used data from the 2020 - 2021 Korea Health Panel (KHP) and 2021 HL Supplementary Survey, which were collected within a nationally designed panel framework. The KHP, jointly administered by the Korea Institute for Health and Social Affairs and the National Health Insurance Service, is an annual longitudinal survey that assesses patterns of health care utilization, expenditures, and key determinants, including individual health conditions and socioeconomic characteristics. The sampling frame was derived from the 2016 Korean Population and Housing Census for the second panel cohort, introduced in 2020, to ensure broad national coverage.

The KHP data structure combines cross-sectional and longitudinal elements, with repeated annual measurements collected via face-to-face interviews and self-reported questionnaires. As a longitudinal panel dataset, the KHP can capture both between-individual variation at specific time points and within-individual changes over time. However, for this study, only between-individual variation at a single time point was examined. A single cross-sectional wave was used to align with the HL survey period and to assess age-group differences in HL and health behavior.

The HL Supplementary Survey was conducted between March and July 2021 among respondents who had completed the KHP. This supplemental module included a validated and standardized tool for assessing HL among respondents from nationally designed KHP. Approximately 9530 adults aged 19 years or older completed the HL module. To ensure completeness and consistency, 1620 individuals were excluded due to missing responses on key variables, including health care utilization (n=1482), private health insurance status (n=95), high-risk drinking (n=38), smoking status (n=4), and type of health coverage (n=1). The final analytic sample consisted of 7910 adults. A flow diagram of the sample selection process is shown in Figure S1 in Multimedia Appendix 1.

### Operational Definitions of HISB Experience and Type

To assess HISB in greater detail, participants were first asked whether they had sought any health-related information during the past 12 months. This binary (yes or no) variable defined the overall presence of HISB. Among those who responded affirmatively, the type of HISB was categorized as either active seeking or passive acquisition based solely on the respondent's top-ranked information source from a predefined list of 9 options. We treated this source as the respondent's primary health information source. Drawing on prior literature, we classified the sources by the mode of access typically associated with each source [3,14,26,28-31]. Information sources such as health care professionals, government websites, hospital websites, internet portal searches, and targeted searches on platforms like YouTube (Google) were assigned to the active-seeking category [3,14,28,29]. In contrast, sources such as television, radio, newspapers, magazines, books, and

XSL•FO
RenderX

interpersonal channels such as family or friends were classified under the passive acquisition category [26,29-31]. The classification scheme used to determine HISB type is summarized in Table 1. The KHP HL Supplement identified respondents' primary health information source but did not assess whether the reported source was intentionally accessed or merely encountered incidentally. Accordingly, this classification should be interpreted as a source-based proxy for active seeking and passive acquisition rather than a direct measure of behavioral intentionality. For example, some sources, including YouTube, newspapers and magazines, and interpersonal channels, may involve either active searching or passive exposure depending on the context of use.

**Table .** Classification of health information sources into health information–seeking behavior (HISB) types among Korean adults: a cross-sectional analysis of the 2020 - 2021 Korea Health Panel and 2021 Health Literacy Supplementary Survey[a].

| Type | Sources |
|---|---|
| Active information–seeking category | • Health care professionals (doctors, nurses, pharmacists, etc) [29]<br>• Government public sector channels (website, YouTube, and SNS[b]) [3,14]<br>• Hospital or public health center channels (website, YouTube, and SNS) [3,14]<br>• Internet portals [14]<br>• YouTube (various sources) [28] |
| Passive information acquisition category | • Television [26,29,31]<br>• Radio [26,29]<br>• Newspapers, magazines, or books (print and online) [29]<br>• Family, friends, colleagues, and acquaintances [29,30] |

[a]HISB type was classified based on the respondent's top-ranked information source and represents a source-based proxy rather than a direct measure of intentionality.

[b]SNS: social network service.

## Variables and Measurements

HL was measured using the European Health Literacy Survey Questionnaire-16-item (HLS-EU-Q16), a validated instrument adapted for the Korean population. This tool comprises 16 items covering health care, disease prevention, and health promotion domains. Respondents were asked to rate each item based on perceived difficulty using a four-point Likert scale: "very difficult," "difficult," "easy," and "very easy," with an additional "do not know" option. In this study, responses were dichotomized into "easy" (1 point) and "difficult" (0 points), while "do not know" responses were treated as missing. The total score ranged from 0 to 16, with higher scores indicating greater HL. The overall HL score was considered missing if a respondent had any missing values. For descriptive purposes, HL scores were categorized as inadequate (0 - 8), problematic (9-12), or adequate (13-16) [32], but in multivariable analyses, HL was used as a continuous variable.

A range of covariates was selected based on prior research linking them to HL and HISB and included to account for potential confounding. Sociodemographic variables comprised gender, age group, marital status, educational attainment, household income, employment status, type of health coverage, and private health insurance enrollment [26,33-35]. Age was categorized into three groups: 19 - 44 years (young adults), 45 - 64 years (middle-aged adults), and 65 years and older (older adults). Given the cross-sectional design, these age groups were interpreted as reflecting age-cohort differences rather than pure physiological or cognitive aging effects, because chronological age and birth cohort could not be disentangled in the current data [36,37]. Educational attainment was grouped into elementary school or less, middle or high school, and college or above. Household income was equivalized by dividing total monthly household income by the square root of the number of household members. Employment status was categorized as economically active or inactive. Health coverage included National Health Insurance and Medical Aid. Health behavior variables included current smoking, high-risk drinking, and walking [25,33,34]. Current smoking was defined as the use of conventional cigarettes or nicotine-containing electronic cigarettes at the time of the survey. High-risk drinking was defined as consuming 7 or more drinks per occasion for men (5 or more for women) at least twice a week during the prior year. Walking behavior was defined as walking for 30 minutes or more at least 5 days per week. Health status and health care utilization variables included self-rated health (SRH; on a five-point Likert scale), number of chronic diseases (categorized as none, one, or two or more), health-related quality of life (assessed using the EQ-5D index), disability status, number of outpatient visits, hospitalization experience, and whether the respondent had a usual source of care [15,26,33,35]. Unless otherwise specified, all covariates reflected values as of December 31, 2020.

## Statistical Analysis

Descriptive statistics summarized participants' demographic, behavioral, and health-related characteristics. Chi-square tests were used to examine the distribution of key variables across age groups, including health information–seeking experience and behavior type. The KHP provides survey weights for the full-panel cohort, but none were calibrated specifically for the restricted analytic sample of respondents who completed the 2021 HL Supplementary Survey and had complete data on all analytic variables. Applying the full-panel weights to this complete-case subsample could yield weighted estimates that

XSL•FO
RenderX

do not accurately represent either the original target population or the final analytic sample. We therefore retained unweighted analyses as the primary approach.

Primary inferential analyses distinguished two related stages of HISB: whether respondents reported any HISB experience, and, among those who did, the source-based type of HISB. This reflected the outcome data structure, in which HISB experience was observed for the full analytic sample, whereas HISB type was defined only for respondents who reported HISB experience. First, multivariable logistic regression was used to examine the association between HL and the likelihood of seeking health information in the past 12 months (yes or no). Second, among respondents who had engaged in information seeking, an additional multivariable logistic regression model was used to assess the association between HL and the source-based HISB type (active seeking vs passive acquisition). These stage-specific models constituted the primary analyses because they addressed complementary inferential objectives: HISB engagement in the full analytic sample and HISB type conditional on engagement. For each stage, models were estimated for the relevant overall sample and separately within each age group (19‐44, 45‐64, and ≥65 years).

To examine whether the association between HL and each outcome differed across age groups, two pooled multivariable logistic regression models incorporating age×HL interaction terms were estimated in a separate sensitivity analysis: one for HISB experience in the full analytic sample and one for HISB type among respondents who had engaged in HISB. The overall significance of the age×HL interaction terms was evaluated using joint Wald $\chi^2$ tests, and age-specific associations between HL and each outcome were estimated from the pooled interaction models. Separately, potential selection into the HISB type analytic sample was evaluated using a separate Heckman-type 2-step sensitivity analysis. Covariate coding for this sensitivity analysis was harmonized with that used in the primary HISB type model. In the first step, a probit model was used to estimate the probability of selection into the HISB type analytic sample. In the second step, the inverse Mills ratio (IMR) derived from the first-step probit model was included in a logistic regression model comparing active seeking with passive acquisition. Although the original Heckman model was developed for continuous second-stage outcomes, related extensions have been applied to binary second-stage outcomes [38-40]. All analyses were conducted using Statistical Analysis System (SAS) version 9.4 (SAS Institute Inc.), and statistical significance was determined using a two-tailed *P* value threshold of .05.

### Ethical Considerations

The study was conducted in accordance with the principles outlined in the Declaration of Helsinki. The study was approved by the Institutional Review Board of the Catholic University of Korea (MC24ZASI0109), and informed consent was waived because publicly available secondary data were used. To ensure privacy and confidentiality, all data were fully anonymized and deidentified prior to access. Participant compensation was not applicable because this study involved a secondary analysis of survey data.

## Results

### Participant Characteristics

Among the 7910 participants, the largest proportion (3487/7910, 44.1%) was aged 65 years and older, followed by 35.6% (2815/7910) aged 45‐64 years and 20.3% (1608/7910) aged 19‐44 years. Education level differed significantly by age, with nearly half (1734/3487, 49.7%) of the oldest group having completed elementary school or below, compared with just 0.3% (4/1608) in the youngest group. Age differences were also observed in private health insurance enrollment rates, which were approximately 90% (4015/4423) among participants aged 19‐64 years but dropped to 53.1% (1852/3487) among those aged 65 years or older. A similar pattern appeared in economic activity: 68.1% (1095/1608) of individuals aged 19‐44 years were economically active, compared to 42.4% (1479/3487) of the oldest group. Health behaviors and SRH also varied with age. The oldest adults reported the highest rate of walking (1697/3487, 48.7%) and the lowest prevalence of current smoking (334/3487, 9.6%) and high-risk drinking (142/3487, 4.1%). Older age groups reported poorer SRH, with a lower proportion reporting good health and a higher proportion with multiple chronic conditions.

### HISB Prevalence and Type

HISB also showed notable age-group differences. While 66.7% (1072/1608) of adults aged 19‐44 years had sought health information, only 30.2% (1052/3487) of those aged 65 years and older had done so. Furthermore, among those who had sought information, 51.8% (545/1052) of the oldest group was classified in the passive acquisition category, compared with only 7.3% (78/1072) of the youngest group. The overall mean HL score was 10.96 (SD 4.79), and mean scores were lower in older age groups (Table 2).

## Factors Associated With HISB Experience by Age Group

In the first stage of the primary analysis, a logistic regression analysis was used to examine factors associated with HISB experience. HL was significantly associated with HISB experience; participants with higher HL scores had higher odds of seeking health information (odds ratio [OR] 1.139, 95% CI 1.123 - 1.154; *P*<.001). Other variables significantly associated with HISB experience included age, gender, marital status, education, income, private health insurance, current smoking status, health-related quality of life, and having a usual source of care. Compared with adults aged 65 years and older, those aged 19 - 44 years had more than twice the odds of seeking health information (OR 2.072, 95% CI 1.690 - 2.541), and those aged 45 - 64 years also had higher odds (OR 1.728, 95% CI 1.502 - 1.988). Conversely, men, individuals with lower education levels, current smokers, and those with higher EQ-5D scores had lower odds of seeking health information. Age-stratified logistic regression analyses showed different patterns of association across age groups. Among participants aged 19 - 44 years, information seeking was more likely among women, married participants, those with two or more chronic conditions, and those with a usual source of care. Significant correlates of HISB experience in the 45 - 64 age group included gender, education level, household income, current smoking, SRH, health-related quality of life, having a usual source of care, and HL. Among adults aged 65 years and older, education level, private health insurance, current smoking, number of outpatient visits, and HL were significantly associated with HISB experience (Table 3).

## HL Scores by HISB Type and Information Source

Figures 1 and 2 illustrate differences in HL according to HISB type and information source. Overall, individuals classified in the active-seeking category had higher mean HL scores (mean 13.50, SD 3.18) than those in the passive acquisition category (mean 11.06, SD 4.17), with the highest mean score observed among users of internet portals (13.82, SD 2.94). Within the passive acquisition category, printed media users had the highest mean HL score (13.52, SD 2.99), whereas those relying on interpersonal sources (eg, family or acquaintances) had the lowest mean score (9.88, SD 4.26; Figure 1). Across age groups, mean HL scores were higher among individuals classified in the active-seeking category than among those in the passive acquisition category. However, the difference was smallest among adults aged 19 - 44 years and was virtually absent in this group (14.122 vs 14.115; Figure 2).

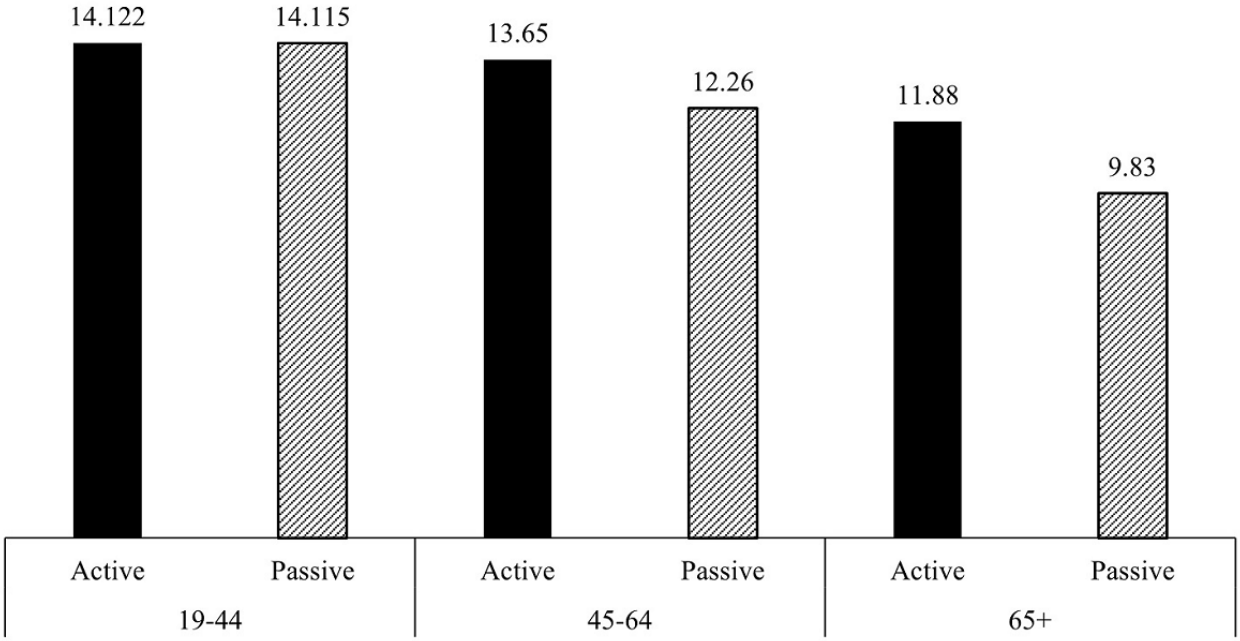

**Figure 1.** Health literacy scores by source-based health information–seeking behavior type and source among Korean adults: a cross-sectional analysis of the 2020 - 2021 Korea Health Panel and 2021 health literacy supplementary survey. Active: active information seeking: (a) health care professionals (doctors, nurses, pharmacists, etc); (b) government or public sector channels (website, YouTube, and social network service); (c) hospital or public health channels (website, YouTube, social network service); (d) internet portals; e: YouTube (various sources). Passive: passive information acquisition: (f) television; (g) radio; (h) newspapers, magazines, or books (print and online); (i) family, friends, colleagues, and acquaintances.

**Figure 2.** Health literacy scores by age group and source-based health information–seeking behavior type among Korean adults: a cross-sectional analysis of the 2020 - 2021 Korea Health Panel and 2021 Health Literacy Supplementary Survey. Active: active information seeking; passive: passive information acquisition; age groups (years): 19 - 44, 45 - 64, and 65+.

## Factors Associated With HISB Type by Age Group

In the second stage of the primary analysis, logistic regression showed that participants with higher HL scores had higher odds of classification in the active-seeking category (OR 1.105, 95% CI 1.080-1.131; *P*<.001). Other significant correlates of HISB type included age, education level, SRH, number of chronic diseases, and health-related quality of life. Participants with higher education, fewer chronic diseases, and poorer SRH had higher odds of being classified as active-seeking. Compared with adults aged 65 years and older, individuals aged 19 - 44 years had more than six times the odds of active-seeking classification (OR 6.072, 95% CI 4.374 - 8.428), while those aged 45 - 64 years had more than twice the odds (OR 2.582, 95% CI 2.096 - 3.180). Age-stratified models showed further differences. In the youngest group, education level, SRH, and disability were significantly associated with HISB type, while HL was not. In this group, individuals with disabilities had higher odds of classification in the active-seeking category. Among adults aged 65 years and older, higher HL and higher EQ-5D scores were significant correlates of classification in the active-seeking category (Table 4).

### Sensitivity Analyses

In pooled multivariable logistic regression models including age×HL interaction terms, the joint test of the interaction terms was statistically significant for both HISB experience (Wald $\chi^2_2$=57.84; *P*<.001) and HISB type (Wald $\chi^2_2$=7.79; *P*=.02). Age-specific estimates showed that HL was significantly associated with HISB experience and classification in the active-seeking category among adults aged 45 - 64 and ≥65 years, but not among those aged 19 - 44 years. These findings were consistent with the age-stratified primary analyses (Table S1 in Multimedia Appendix 2).

In a separate sensitivity analysis, the Heckman-type 2-step analysis showed that respondents with higher HL scores had higher odds of classification in the active-seeking category in the primary conditional logistic model among those who engaged in HISB (OR 1.105, 95% CI 1.080 - 1.130; *P*<.001). After the IMR was included in the second-stage logistic model, the IMR was statistically significant (OR 0.147, 95% CI 0.062 - 0.348; *P*<.001), whereas the estimate for HL was attenuated and no longer statistically significant (OR 0.995, 95% CI 0.945 - 1.048; *P*=.86). These findings indicate that the estimated association between HL and HISB type was sensitive to accounting for potential selection into the HISB type analytic sample (Table S2 in Multimedia Appendix 3).

## Discussion

### Principal Findings

This study demonstrated a distinct age-group pattern in HL, with higher mean HL scores among younger adults and lower mean scores among older adults. Given the cross-sectional design, this pattern should be interpreted as reflecting a combination of age and cohort differences rather than as evidence of HL decline caused by aging alone [36]. Differences in cognitive and sensory functions [16] and communication barriers in health care settings may partly contribute to the lower HL scores observed among older adults [24]. At the same time, cohort-specific differences in educational opportunities and formative exposure to digital technologies may also have contributed to distinct historical and technological environments [41]. These factors may also shape whether individuals engage in HISB and, among those who do, the source-based type of HISB observed in this study.

Table 5 provides an integrative summary of the main age-group patterns observed in this study. The matrix shows that the main correlates of HISB varied across age groups, with education level and health-related needs more salient among younger adults and HL emerging as a more prominent correlate among middle-aged and older adults, particularly for classification in the active-seeking category in the primary analyses. These contrasts may reflect both age-related differences in health needs and cohort-specific educational and information environments [36,37], consistent with recent evidence that information-source preferences differ across generations [41]. Viewed through the CMIS, these findings can be understood as age-group differences in the relative importance of individual antecedents, perceived health-related salience, and information-source factors rather than as a direct test of the full model [21,22]. In younger adults, education and perceived health needs may represent key antecedents and salience-related factors associated with information seeking, whereas HL may represent a more prominent cognitive and experiential resource among middle-aged and older adults, potentially supporting the recognition of information needs, evaluation of available channels, and engagement with health information (Table 5).

**Table .** Summary matrix of main correlates of health information–seeking behavior by age group among Korean adults: a cross-sectional analysis of the 2020 - 2021 Korea Health Panel and 2021 Health Literacy Supplementary Survey.

| Age group (years) | Observed HISB[a] pattern | Main correlates | Interpretive summary |
|---|---|---|---|
| 19 - 44 | Predominantly active seeking | Education level; health-related needs[b] | HISB was common and active, but HL[c] was not significantly associated with HISB. |
| 45 - 64 | Predominantly active seeking, with transitional features | HL; Education level; health-related needs[b] | HL was a significant correlate, alongside education and health-related needs[b]. |
| 65+ | Higher reliance on passive acquisition | HL; health-related quality of life | HL was significantly associated with classification in the active-seeking category. |

[a]HISB: health information–seeking behavior.

[b]Health-related needs refer to health status indicators such as self-rated health, number of chronic diseases, disability status, or health-related quality of life, which were associated with HISB in different ways across age groups.

[c]HL: health literacy.

Building on these patterns, this analysis examined how HL, sociodemographic factors, and health-related factors were associated with the HISB experience and source-based HISB type across age groups. In the primary age-stratified analyses, HL was significantly associated with both HISB experience and classification in the active-seeking category among adults aged 45 years and older, but not among those aged 19 - 44 years. The significant age ×HL interaction further supported heterogeneity in these associations across age groups. However, in the Heckman-type sensitivity analysis, the association between HL and HISB type was attenuated after accounting for potential selection into the HISB type analytic sample. Taken together, these findings suggest that HL may play a more prominent role in HISB among middle-aged and older adults, while the independent association between HL and HISB type should be interpreted cautiously because it was sensitive to the modeling of selection. This age-group pattern may reflect differences in cognitive processing needs, reliance on health care services, or familiarity with different information channels. The latter may also reflect cohort-specific exposure to changing media and digital environments [41]. In this context, HL may function not merely as a set of skills or knowledge but as a cognitive asset that facilitates engagement with, retention of, and application of health information [41,42]. This interpretation is consistent with a recent scoping review identifying eHealth literacy as an important individual resource for online HISB, but also showing that its role is embedded within broader educational, socioeconomic, health care, and digital-environmental conditions [43]. Prior evidence also points to a close relationship between HL and HISB, although its direction remains uncertain. Information seeking was more strongly associated with healthy lifestyle behaviors among individuals with higher HL [9], while older adults who regularly sought health content online had higher HL [10].

Among adults aged 19 - 44 years, health information seeking was widespread, and more than 90% (993/1072) of seekers were classified in the active-seeking category. Despite this high engagement, HL was not significantly associated with either HISB experience or source-based HISB type in this group. Instead, the correlates differed by outcome: gender, marital status, multiple chronic conditions, and having a usual source of care were associated with HISB experience, whereas education level, SRH, and disability were associated with HISB type. While HL and education are often correlated, education, but not HL, was associated with classification in the active-seeking category, possibly reflecting broader educational resources, health awareness, or confidence in navigating information sources rather than specific information-processing skills [44]. Additionally, among those who engaged in HISB, individuals with better SRH had lower odds of classification in the active-seeking category, suggesting that perceived health-related need may be relevant to source-based information seeking [45,46]. These findings suggest that health-related needs and sociodemographic factors may be more salient correlates than HL among younger adults. However, because passive acquisition was uncommon in this age group, estimates for HISB type should be interpreted cautiously, and the nonsignificant association with HL should not be interpreted as evidence that HL is unimportant. A similar caveat applies to the predominance of classification in the active-seeking category among younger adults: this source-based classification does not directly capture intentionality, and frequent digital health information seeking does not necessarily translate into greater health empowerment or effective health management [47]. Therefore, interventions for this age group may benefit from emphasizing preventive care and future health risks while also strengthening the appraisal of digital health information and connections between digital information-seeking environments and professional guidance, including offline or telehealth-based support [47,48].

In the 45 - to 64-year age group, the primary age-stratified analyses showed that HL and education were significantly associated with both HISB experience and source-based HISB type, whereas the number of chronic diseases was associated with HISB type. In the HISB type model, higher HL and education were associated with higher odds of classification in the active-seeking category [14,49], whereas a greater number of chronic diseases was associated with lower odds of such classification [2,50,51]. This finding contrasts with prior research and may reflect a gap between the need for information

XSL•FO
RenderX

and the capacity to engage, potentially due to information overload, limited digital skills, or cognitive fatigue among individuals managing multiple health conditions [17,19]. These barriers are likely to be more pronounced among socioeconomically disadvantaged groups, where resource constraints can hinder the meaningful use of information [18]. In this context, HL may serve as an important resource for navigating information-access and processing challenges. Thus, strengthening HL, including digital HL, and ensuring access to accessible, trustworthy offline resources, such as community clinics and health centers, could support effective engagement with health information [52,53]. Tailored interventions are particularly relevant for middle-aged adults with limited incomes and lower education levels, who often face greater barriers to effective health communication [44].

Adults aged 65 years and older exhibited markedly lower levels of HISB, both in prevalence and in the proportion classified in the active-seeking category, compared with younger groups. In the primary age-stratified HISB type model, higher HL and EQ-5D scores were significantly associated with higher odds of classification in the active-seeking category. The association with EQ-5D suggests that overall functional health may be relevant to the capacity to engage with health information [2,51]. These findings indicate that HISB among older adults may be shaped not merely by perceived health needs, but also by the availability of cognitive and structural resources [14,50]. Consistent with the CMIS-informed interpretation introduced above, HL can be understood as an important resource for navigating cognitive, functional, and channel-related barriers to active engagement with health information [22,54]. At the same time, the higher proportion classified in the passive-acquisition category among older adults warrants attention, as prior media research has shown that health-related news may frame health problems in ways that emphasize individual responsibility over broader social determinants [55]. Such framing may be especially consequential for older adults with lower HL, who may have fewer opportunities or resources to verify, compare, or contextualize health information [54,56]. Therefore, interventions for older adults could combine efforts to strengthen HL with the reduction of access barriers through user-friendly technologies and community-based education tailored to their needs [53].

Taken together, these findings point to the value of strategies tailored to the needs and information environments of different age groups to support equitable and effective engagement with health information [48], consistent with recent evidence that health information source preferences differ across generations [41]. For older adults, who showed lower HISB prevalence and a higher proportion classified in the passive-acquisition category, interventions should not simply encourage more digital information seeking [54]. Rather, health systems could provide accessible proactive communication methods, such as short message service health alerts or automated reminders, while reducing digital barriers through user-friendly national health portals, community-based digital education, and peer-based technology mentoring programs [54,56]. These approaches may offer trusted entry points for older adults to gradually engage with digital health information while maintaining support from the community and health care professionals [48]. For younger adults, among whom most seekers were classified in the active-seeking category, the priority should shift from increasing information seeking itself to strengthening their ability to assess the credibility of, interpret, and apply the information they encounter [47]. Linking commonly used digital platforms with professional guidance, such as telehealth services or verified clinician-led information channels, may support more informed and effective use of health information [47,48]. As digital health environments increasingly include generative AI tools for health-related inquiries, tailored digital HL education may also be important for helping users critically evaluate AI-generated health information and reducing the risk of emerging informational inequalities across age groups [57].

## Limitations

This study has several limitations. First, because of its cross-sectional design, causal inferences cannot be drawn, and the temporal relationships between HL and HISB remain unclear. Because chronological age and birth cohort cannot be disentangled in cross-sectional data, the observed age-group pattern should be interpreted as potentially reflecting both age and cohort differences, rather than as evidence of physiological or cognitive changes attributable to aging alone [36]. For example, the lower prevalence of HISB and the higher proportion classified in the passive-acquisition category among older adults may partly reflect cohort differences in formative exposure to the internet and digital technologies, rather than aging alone [47].

Second, the analysis was limited to respondents who participated in the HL supplement of the KHP and had complete data for the variables included in the analyses, a subsample of the broader national cohort. As appropriate weights specifically constructed for this restricted analytic subsample were not available, the analyses were conducted without applying survey weights. Therefore, the reported estimates should be interpreted as unweighted associations within the analytic sample rather than as nationally representative population estimates, and their generalizability may be limited.

Third, unmeasured confounding may persist despite adjustment for several socioeconomic and baseline health status variables. In particular, the KHP dataset did not include detailed measures of physical access to digital devices, internet affordability, or perceived accessibility and usability of online health information channels, all of which may influence both HL and HISB, particularly among older adults and other groups with limited digital resources [22,47,54,56]. Other potentially relevant factors, such as digital self-efficacy, prior experience with online health services, trust in specific information sources, and cognitive functioning, were also not directly measured. A recent scoping review among individuals with diabetes identified multilevel determinants of online HISB spanning individual, interpersonal, health care, and digital-environmental domains, further underscoring the possibility that relevant contextual factors were not fully captured in the present analysis [43].

Fourth, HISB type was operationalized as a source-based proxy using the respondent's highest-ranked information source. This approach did not directly assess intentionality and could not

XSL•FO
RenderX

capture the simultaneous use of multiple sources, changes in information-seeking mode across situations, or variation in how actively individuals engaged with a given source. This binary classification into active seeking and passive acquisition may not fully capture the complexity of real-world HISB.

Fifth, the HISB type analysis was conditional on respondents having engaged in HISB, creating the possibility of selection into the analytic sample. In the Heckman-type sensitivity analysis, the estimated association between HL and HISB type was attenuated after the IMR was included. Accordingly, the primary findings regarding HL and HISB type should be interpreted with caution because they were sensitive to modeling potential selection.

Sixth, passive acquisition was uncommon among adults aged 19‐44 years. The relatively small number of observations in this outcome category may have reduced the precision and stability of estimates in the youngest age group. Consequently, the nonsignificant association between HL and HISB type in this group should not be interpreted as evidence that no association exists.

Seventh, although HL was treated as a focal independent variable in this study, its role may be more nuanced, potentially functioning as a mediator or moderator in broader health engagement pathways. The analyses also could not evaluate reciprocal relationships in which engagement with health information may itself contribute to HL over time. Additionally, the assumption that classification in the active-seeking category is inherently beneficial warrants caution, as active engagement with health information may sometimes lead to information overload or exposure to misinformation [52].

Eighth, the dataset did not allow us to account for potentially important age-varying factors, including eHealth literacy and trust in specific media or information sources, that may shape the association between HL and HISB. Among younger adults, the ability and confidence to navigate online platforms may be more salient than general HL, whereas older adults' greater reliance on passive acquisition may partly reflect trust in familiar sources such as television or interpersonal networks [29,41]. Older adults' engagement with digital health services may also be constrained by technology-related anxiety, privacy concerns, and concerns that digitally mediated care could weaken interpersonal connections, which may reinforce a preference for in-person care [58]. The analyses did not capture patient activation or discussions of online health information with health care providers, which may influence whether information seeking translates into patient-centered communication [59]. Future studies should incorporate these digital, psychological, and interpersonal factors to clarify the mechanisms underlying age-group differences in HL and HISB. Finally, data were collected during the COVID-19 pandemic, and changes in health service accessibility and communication patterns may have influenced HL and information-seeking behaviors.

## Conclusions

This study identified clear age-group patterns in the association between HL and HISB among Korean adults, underscoring that the role of HL and source-based HISB type differed across age groups. In the primary analyses, higher HL was associated with HISB experience and classification in the active-seeking category among middle-aged and older adults, whereas educational attainment and health-related needs were more salient among younger adults. However, because the association between HL and HISB type was sensitive to accounting for potential selection into the HISB type analytic sample, this specific association should be interpreted cautiously. At the same time, the broader age-group patterns observed across HISB experience and source-based HISB type highlight the value of designing strategies tailored to the needs and information environments of different age groups to improve access to and effective use of health information. Rather than focusing solely on strengthening HL, future interventions should also consider structural, motivational, and digital access factors to promote equitable engagement with health information across age groups.

## Acknowledgments

During the revision process, the authors used generative AI (ChatGPT) to assist with language editing, the restructuring of selected passages, and the refinement of table, figure, and text presentation. ChatGPT was not used to generate or analyze data, conduct statistical analyses, interpret the results independently, or create references. It was not treated as a source of evidence; all factual statements, interpretations, citations, and reference details were reviewed and verified by the authors against the underlying data and original sources. ## Abstract

**Background:** Throughout the COVID-19 pandemic, regular population testing for SARS-CoV-2 was crucial for disease monitoring and management. Initially, reverse transcriptase–polymerase chain reaction tests were primarily used for identifying new cases, but their high cost and delayed results, combined with laboratory capacity and supply chain limitations, led to the adoption of antigen-detection rapid diagnostic tests (Ag-RDTs) at point-of-care locations. On August 11, 2022, the US Food and Drug Administration (FDA) issued a safety communication recommending serial Ag-RDT testing to reduce the risk of false-negative results from singular testing and combat disease spread, followed by a revision letter on November 1, 2022, to manufacturers to update their authorized product labeling.

**Objective:** This study evaluates adherence to serial testing using data from the Centers for Disease Control and Prevention (CDC) Increasing Community Access to Testing, Treatment, and Response (ICATT) program.

**Methods:** This national, retrospective cohort study analyzed ICATT program line-level testing records from August 12, 2022, to January 14, 2025. Patients were included if they had at least 1 Ag-RDT. Adherence was determined based on whether patients followed FDA guidance after a negative test. Multivariable logistic regression models were used to identify demographic features associated with adherence, with an expanded model to identify the impact of additional clinical variables. Rates of testing positive after an initial negative Ag-RDT were also calculated for ICATT pharmacy testing.

**Results:** There were 2,189,464 patients included in the second-test adherence analysis, and 6813 included in the third-test adherence analysis. Less than 1% (20,290/2,189,464) of patients were adherent to the instructions to use a second Ag-RDT, and 98.2% (2,149,292/2,189,464) had no second test documented in ICATT and therefore were classified as nonadherent in this analysis. Second-test adherence was higher among Asian (adjusted odds ratio [AOR] 1.28, 95% CI 1.21-1.36) and Black (AOR 1.17, 95% CI 1.12-1.23) patients and lower among children (AOR 0.48, 95% CI 0.45-0.51). In the expanded model, recent COVID-19 contact increased adherence odds (AOR 1.87, 95% CI 1.64-2.13), whereas recent COVID-19 infection decreased them (AOR 0.66, 95% CI 0.56-0.76). Among patients with symptoms initially testing negative with an Ag-RDT, 24.9%

XSL•FO
RenderX

(7310/29,315) tested positive on their second test, and 57.4% (4195/7310) of these episodes were adherent. For patients without symptoms, 4.2% (60/1435) tested positive on their third test after testing negative on their first 2 tests, with 60% (36/60) adherence.

**Conclusions:** This study is the first to evaluate adherence to the FDA instructions to perform serial Ag-RDTs. Overall, adherence was low among patients seeking testing at community sites. Recent COVID-19 exposure was associated with the highest odds of serial testing adherence. These insights can inform targeted public health strategies to improve adherence and reduce the risk of false-negative results from Ag-RDTs in future pandemics.

## Introduction

Throughout the COVID-19 pandemic, regular population testing for SARS-CoV-2 was a cornerstone of disease monitoring and management. Early in the pandemic, nucleic acid amplification tests (NAATs), which include reverse transcriptase–polymerase chain reaction (RT-PCR) tests, were relied upon as the sole way to identify new cases because they were the first diagnostic tests developed and authorized by the US Food and Drug Administration (FDA). While highly sensitive, RT-PCR tests were expensive, and results may not be available for several days due to shipping delays, staffing shortages, supply chain shortages, and reporting backlogs [1,2]. The emergence of antigen-detection rapid diagnostic tests (Ag-RDTs) improved the accessibility and timeliness of SARS-CoV-2 testing, and these tests were less sensitive than their NAAT counterparts [3].

On August 11, 2022, the US FDA issued a new safety communication for serial Ag-RDT testing for SARS-CoV-2 to reduce the risk of false-negative results for COVID-19 [4-6]. The safety communication instructed individuals with COVID-19–like symptoms who received negative test results to test 48 hours after the first test. Asymptomatic individuals with a negative result were instructed to test 48 hours after the first test and then again after 48 hours if the first repeat test was also negative. Confirmatory "laboratory molecular-based" testing, including RT-PCR, was also encouraged, when possible, to further reduce the risk of false-negative Ag-RDT results. For both symptomatic and asymptomatic individuals, a positive result in any repeat test was considered indicative of a case of COVID-19. A comprehensive study of more than 7000 participants was used to establish these instructions and determined that serial Ag-RDT testing improved sensitivity for both Delta and Omicron SARS-CoV-2 variants [7,8].

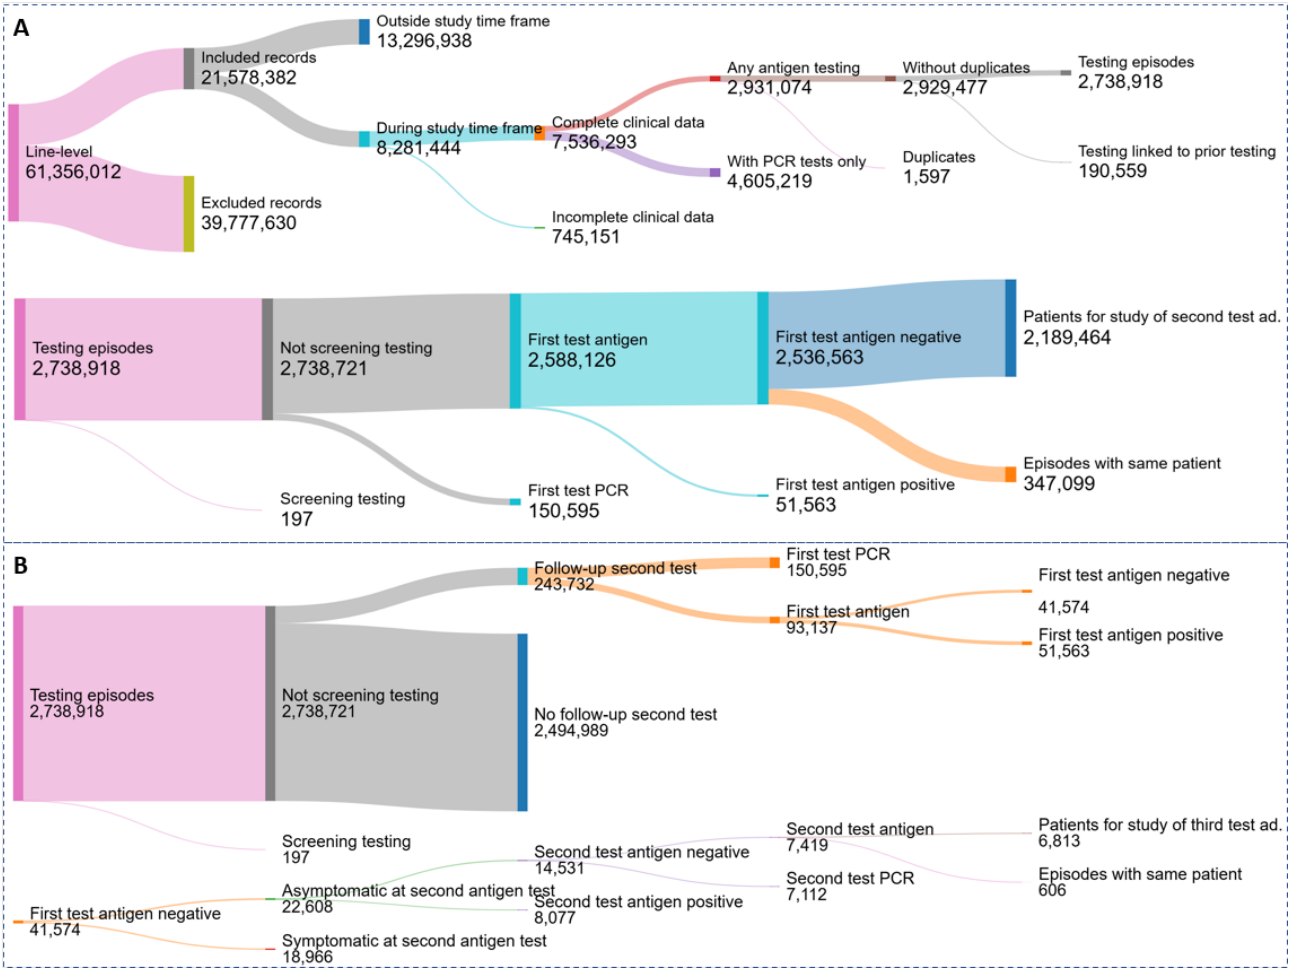
The degree to which the US population followed the FDA's instructions has not been studied, primarily because most Ag-RDTs were performed at home, making studies of Ag-RDT testing more difficult to conduct. While it was possible for patients to voluntarily report at-home test results for 4 Ag-RDT manufacturers, that reporting was only a fraction of the total testing volume, and most results were self-interpreted and self-reported [9]. This was partially rectified by the MakeMyTestCount program launched by the US National Institutes of Health's Rapid Acceleration of Diagnostics Tech program in December 2022 [10]. However, there have been no studies to date that have evaluated adherence to serial Ag-RDT testing within that program. Studies that have evaluated serial test adherence have either been outside the United States, within a closed cohort, or have been small, limiting understanding of how the specific FDA instructions generalize to a broader US population [11-15]. Understanding whether COVID-19 testing among the public adhered to the authorized instructions for use of antigen tests would provide important information for public health officials and epidemiologists to optimize diagnostic testing for future respiratory outbreaks.

The US Centers for Disease Control and Prevention (CDC) Increasing Community Access to Testing, Treatment, and Response (ICATT) program began in April 2020 to provide no-cost SARS-CoV-2 testing through a public-private partnership with participating pharmacy vendors, including CVS, Rite Aid, Walgreens, and eTrueNorth, among others [16]. Since its creation, the ICATT program has collected data on 61 million SARS-CoV-2 tests at more than 19,000 locations in all 50 states, Puerto Rico, and Washington DC. Of the 61 million tests, 49.4 million were categorized as "ICATT paid" or "ICATT conducted," and 12 million were categorized as "non-ICATT test" records performed at ICATT locations. Thus, the ICATT dataset captures testing that occurred at participating vendor sites and does not capture at-home testing or testing performed at non-ICATT sites. In July 2022, ICATT program testing vendors began assigning unique patient identification numbers to individual testing records, allowing for a large-scale, longitudinal study of adherence to FDA serial testing instructions. In addition, the ICATT dataset included symptom status, demographic information, and clinical features for each testing record to study factors that affect adherence. This study aims to identify patient-level demographic and clinical features associated with adherence to FDA serial Ag-RDT testing guidelines within a national retrospective cohort.

## Methods

### Data and Key Variables

ICATT-funded line-level testing records were used as the primary source of data (49.4 million), in addition to Medicare, Medicaid, private insurers, Health Resources and Services Administration (HRSA), and cash-paid pharmacy test records (11.9 million) at ICATT locations. These records reflect on-site



XSL•FO
RenderX

testing at participating ICATT vendor locations and therefore do not include at-home tests or testing performed at non-ICATT sites. ICATT testing records were provided by ICATT testing sites to CDC as part of CDC's One CDC Data Platform (1CDP). Individual testing records were combined into testing events (testing records from the same patient and the same vendor on the same day). Testing events that occurred within 10 days of each other were collapsed into testing episodes via daisy-chaining to link distinct testing events for each patient. Adherence with serial testing was then determined for each testing episode. Finally, summaries of adherence were created for each patient, demographic and clinical features were joined to patient records, and inclusion/exclusion criteria were applied.

There were 745,151 testing records excluded because the symptom status was unreported, and it was used to determine whether a patient was required to take 2 or 3 Ag-RDTs according to the authorized instructions for use. Patients were included if they had at least 1 Ag-RDT between August 12, 2022, and January 14, 2025, at a CVS, Walgreens, or eTrueNorth facility. If the duration of a patient's testing episode exceeded 30 days and the number of tests per day exceeded 0.2, the episode was excluded from the study (197 episodes), as this was considered to be indicative of regular screening testing and not diagnostic testing for acute illness. Since the primary outcome of interest was adherence with FDA serial Ag-RDT testing instructions after a negative first test, patients were also excluded if their first test was a NAAT/RT-PCR test (150,595 episodes) or if their first test result was positive (51,563 episodes). In addition, 347,099 testing episodes were merged with other episodes with the same patient ID, and averages were calculated for each patient's numeric or binary variables, leaving 2,189,464 patients eligible for second-test adherence analysis. The number of tests included and excluded based on different criteria is shown in Figure 1.

In an expanded model, available self-reported clinical variables, including recent contact with a patient infected with COVID-19, vaccination status, COVID-19 infection within the past 90 days, and symptom status at the time of testing, were examined alongside demographic features including age, sex, race, ethnicity, insurance status, test vendor (eg, CVS or Walgreens), and location (collapsed into US Census regions). To account for multiple testing episodes by the same patient, demographic variables for each testing episode were assigned based on the demographic information available for the first test of the testing episode. Clinical variables were represented as the rate of episodes in which that clinical variable occurred (eg, the proportion of episodes where the patient was symptomatic).

**Figure 1.** Tests-to-patients flow diagram for second-test and third-test adherence analyses. (A) Flow for the second-test adherence analysis; (B) Flow for the third-test adherence analysis. The term polymerase chain reaction (PCR) is used in the figure to denote any nucleic acid amplification test (NAAT).

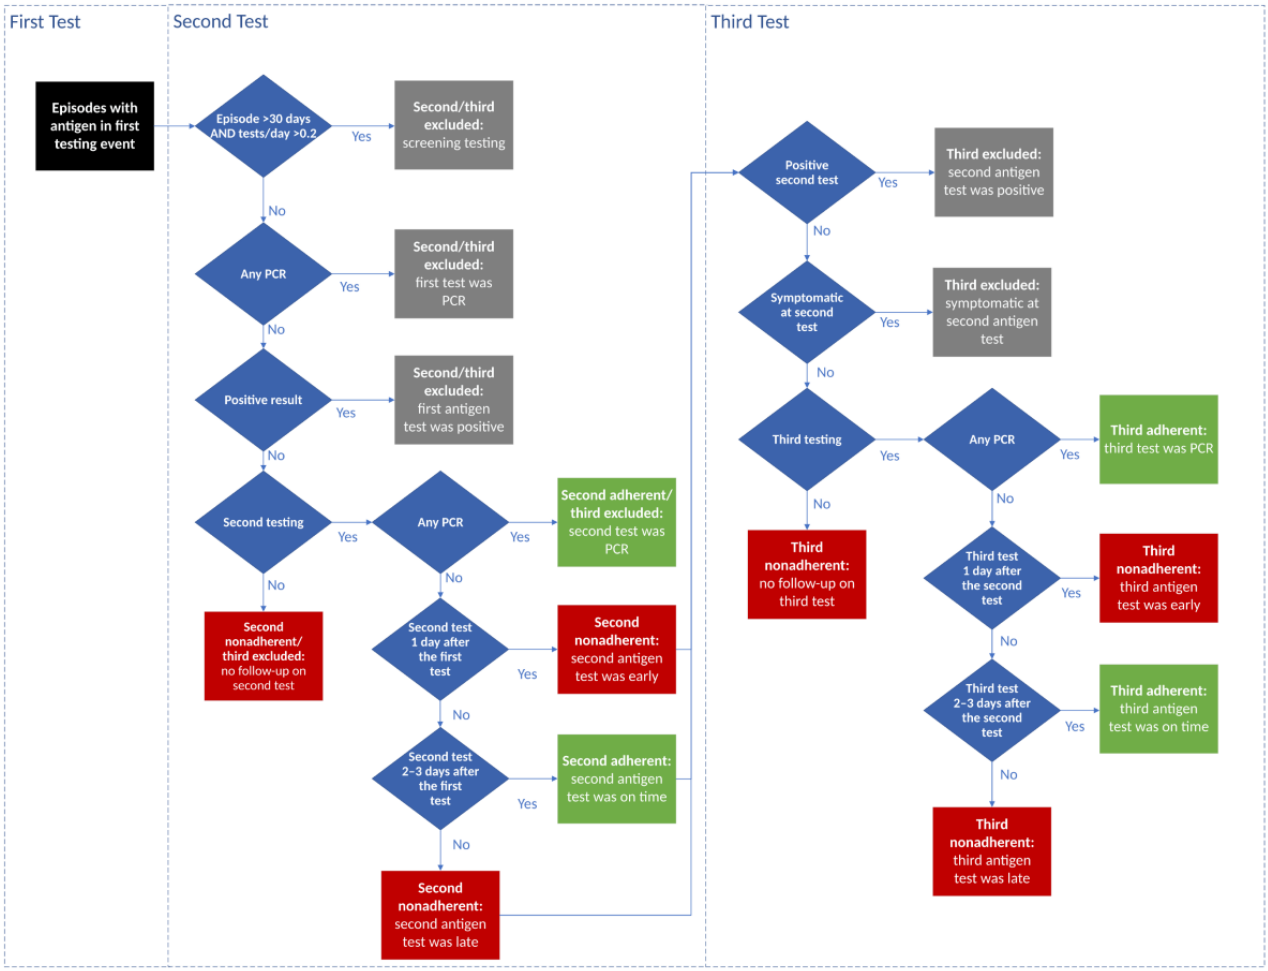
### Patient Summary Adherence Determination

Adherence was defined at the testing-episode level. A testing episode included all tests for the same patient that occurred within 10 days of one another. Episodes were excluded if they lasted more than 30 days and reflected frequent screening (>0.2 tests per day), began with a NAAT/RT-PCR test, or began with a positive Ag-RDT result. A series of complex branching logic (Figure 2) was then applied to the episodes to determine adherence with serial testing.

For second-test adherence, the first eligible test had to be a negative Ag-RDT. An episode was classified as second-test adherent if the next documented ICATT test was either (1) a NAAT/RT-PCR test or (2) a second Ag-RDT performed 2-3 days after the first negative Ag-RDT. An episode was classified as second-test nonadherent if no follow-up test was documented in ICATT, if the second Ag-RDT was performed 1 day after the first test, or if it was performed 4 or more days later.



For third-test adherence, only episodes in which the patient was asymptomatic and the second Ag-RDT was negative were eligible. These episodes were classified as third-test adherent if the next documented ICATT test was either (1) a NAAT/RT-PCR test or (2) a third Ag-RDT performed 2-3 days after the second negative Ag-RDT. They were classified as third-test nonadherent if no third test was documented in ICATT, if the third Ag-RDT was performed 1 day after the second test, or if it was performed 4 or more days later. Episodes with patients with symptoms or a positive second test were excluded from the third-test analysis because a third test was not recommended under FDA instructions [4]. For example, a patient without symptoms with negative Ag-RDTs on day 0, day 2, and day 4 would be classified as adherent for both the second and third tests; if the second test occurred on day 1 or day 4, or if no follow-up test was documented in ICATT, the episode would be classified as nonadherent.

Because some patients contributed more than 1 eligible testing episode, second-test adherence and third-test adherence were summarized at the patient level as the proportion of that patient's eligible episodes that were adherent. This approach was used to avoid overweighting patients with repeated episodes and to reduce bias that could arise from treating correlated episodes from the same individual as independent observations. Although this aggregation may smooth within-patient variability across episodes, it allowed each patient to contribute a single outcome value to the regression analyses. For example, a patient with 2 adherent testing episodes and 1 nonadherent testing episode was considered 66.67% adherent.

XSL•FO
RenderX

**Figure 2.** Serial testing adherence logic flowchart. The term polymerase chain reaction (PCR) is used in the figure to denote any nucleic acid amplification test (NAAT). Testing results were collapsed into episodes by grouping patient tests that occurred within 10 days of each other. Testing episodes exceeding both 30 days and 0.2 tests per day were excluded. After the initial test, testing was considered second-test adherent or third-test adherent based on the FDA safety communication [4]. Blue diamonds represent decision points, gray boxes indicate excluded testing episodes, red boxes indicate nonadherent episodes, and green boxes indicate adherent episodes.

## Statistical Modeling

Two separate generalized linear models with a binomial family and logit link function were fit to model the second- and third-test Ag-RDT serial testing adherence. For each model, the outcome variable was the patient-level proportion of eligible testing episodes that were adherent. A patient-level analytic approach was selected because some individuals contributed multiple testing episodes; analyzing episodes as independent observations could disproportionately weight frequent testers and underestimate within-patient correlation. All demographic variables and symptom status were included in the model as candidate predictors. To understand whether the time since the initial safety communication affected adherence, we also included calendar quarters since the initial announcement in the model. In an expanded model, the remaining 3 clinical variables were included in the model; these were included separately due to the high degree of missingness to avoid skewing results in the main analysis. An $\alpha$ of .05 was used to determine statistical significance. Bonferroni corrections were employed to compensate for family-wise error associated with 35 comparative odds ratios.

## Rate of Testing Positive After Initially Testing Negative

To assess the actual impact of adherence with serial testing, 2 rates (1 for patients with symptoms and 1 for patients without symptoms) were calculated to determine the percentage of COVID-19 cases that were not detected on the first Ag-RDT but were detected subsequently by serial testing.

## Serial Testing of Patients With Symptoms

To estimate the rate of episodes whereby patients with symptoms and initially negative Ag-RDTs subsequently tested positive during serial testing, testing episodes with a first Ag-RDT in a patient with symptoms that were followed by any second test were compiled. Then, the fraction of the second tests that were positive and negative was calculated, and the fraction of each group (positive and negative second tests) that was adherent to the FDA serial testing instructions was calculated.

## Serial Testing of Patients Without Symptoms

To estimate the rate of episodes whereby patients with initially negative Ag-RDTs subsequently tested positive during serial testing, testing episodes with patients without symptoms who had negative first and second Ag-RDTs, and a third test were compiled. Then, the fraction of the third tests that were positive

XSL•FO
RenderX

was calculated, and the fraction of each group (positive and negative third tests) that was adherent to the FDA serial testing instructions was calculated.

### Software

We used R (version 4.4.1, R Foundation for Statistical Computing, Vienna, Austria) for all statistical analyses.

### Ethical Considerations

This study is not human subjects research because it only used data from public health surveillance activities [17]. Therefore, this study was exempt from requiring the Johns Hopkins University's Institutional Review Board approval. This activity was reviewed by CDC, deemed not research, and was conducted consistent with applicable federal law and CDC policy [18].

## Results

### Patient Characteristics

Of the 61,356,012 ICATT testing records, a total of 2,929,477 unique records representing 2,189,464 patients with Ag-RDTs between August 12, 2022, and January 14, 2025, were included in the analysis of second-test adherence (Figure 1). The majority of records were excluded for falling outside the study window (n=13,296,938), followed by missing clinical data on self-reported symptom status (n=745,151), and only having NAAT/RT-PCR tests (n=4,605,219). Included records were then collapsed into 2,738,918 "testing episodes." There were an additional 197 episodes removed since they were assumed to be screening testing because the total duration of the testing episode exceeded 30 days and the number of tests per day within the episode exceeded 0.2. In addition, testing episodes were excluded if the first test was a NAAT/RT-PCR test (n=150,595) or a positive antigen test (n=51,563). Finally, episodes were summarized by patient ID, with 347,099 episodes associated with another testing episode with the same patient ID, leaving 2,189,464 patients for analysis of second-test adherence. To summarize episodes by patient ID, rates were calculated for the fraction of testing episodes in which the patient was symptomatic and adherent for the second test or third test. In addition, the first testing record in the line-level dataset with a given patient ID was used as the source of all demographic information.

Of the patients included in the final analytic sample of second-test adherence (Table 1), the majority were adults (1,676,033/2,189,464, 76.5%), non-Hispanic or Latino (1,583,019/2,189,464, 72.3%), and tested at a CVS location (2,153,391/2,189,464, 98.4%; Table 1). Approximately 60% (1,312,464/2,189,464) of patients were women, and 14% (296,851/2,189,464) were Black or African American. Geographically, the majority of patients were from the South (1,251,495/2,189,464, 57.2%), followed by the Midwest (441,296/2,189,464, 20.2%) and the Northeast (297,278/2,189,464, 13.6%). Patients with private insurance comprised 70.5% (1,543,902/2,189,464) of the patient cohort. Uninsured patients represented 12.1% (264,071/2,189,464), Medicaid patients represented 7.9% (173,486/2,189,464), and Medicare patients represented 8% (176,015/2,189,464).

The analysis of third-test adherence followed the same process as second-test adherence for compiling testing episodes (Figure 1), but additional criteria were applied to exclude episodes inappropriate for analysis of third-test adherence. These exclusion criteria included having no follow-up second test (n=2,494,989), being symptomatic at the second antigen test (n=18,966), having a positive second antigen test (n=8077), and having a second NAAT/RT-PCR test (n=7112). Finally, episodes were summarized by patient ID, with 606 episodes associated with another testing episode with the same patient ID, leaving 6813 patients for analysis of third-test adherence.

Of the 6813 patients included in the final analytic sample of third-test adherence (Table 2), the majority were adults (5237/6813, 76.9%), non-Hispanic or Latino (4465/6813, 65.5%), and tested at a CVS location (6664/6813, 97.8%; Table 2). Approximately 60% (3939/6813) of participants were women, and 23% (1560/6813) were Black or African American. Geographically, the largest proportion of patients was from the South (3202/6813, 47%), followed by the Northeast (1570/6813, 23%) and the Midwest (1116/6813, 16.4%). Patients with private insurance comprised 56% (3812/6813) of the patient cohort, uninsured patients represented 18.6% (1265/6813), Medicaid patients represented 12.4% (842/6813), and Medicare patients represented 12.4% (846/6813).

### Patient and Testing Episode Adherence

At the patient level, second-test adherence was rare. Less than 1% (20,290/2,189,464) of patients included in the second-test adherence analysis were adherent to the instructions for a second test after an initial negative Ag-RDT, and 98.2% (2,149,292/2,189,464) had no second test documented in ICATT and therefore were classified as nonadherent in this analysis. At the testing-episode level, of the 2,536,563 testing episodes eligible for second-test adherence analysis, over 98% (n=2,494,989) were not adherent for either the second or third test (Table 3). The reason for lack of adherence was almost entirely a lack of documented follow-on testing in ICATT (2,494,989/2,536,563, 98.4% for the second test and 5894/7419, 79.4% for the third test), which may reflect loss to follow-up or follow-up testing done outside the program in addition to true nonadherence. Among testing episodes with a second test and only a negative Ag-RDT (n=41,574), the average time between tests was 4.15 (SD 2.59) days. Roughly half (20,481/41,574, 49.3%) of those testing episodes were adherent, either with a second Ag-RDT performed 2-3 days after the first negative Ag-RDT (13,369/41,574, 32.2%) or with a NAAT/RT-PCR test (7112/41,574, 17.1%). However, of the remaining 50.7% of included tests, 40.2% (16,700/41,574) received the follow-up Ag-RDT after the required window, while 10.6% (4393/41,574) received the follow-up Ag-RDT too soon. Patients who received a second Ag-RDT waited an average of 4.15 (SD 2.59) days after their first Ag-RDT.

Among the 7419 testing episodes with a recommended third test per FDA instructions, a total of 20.6% (1525/7419) had a third test. Of those, 75.9% (1157/1525) were nonadherent due to late Ag-RDT testing, 4.5% (69/1525) were nonadherent due to early antigen testing, 14% (214/1525) were adherent from on-time antigen testing, and 5.6% (85/1525) were adherent from NAAT/RT-PCR testing at the third testing encounter. Patients who received a third Ag-RDT waited an average of 5.84 (SD 2.25) days after their second Ag-RDT.

Similar results (Table 4) were found for serial testing adherence of testing episodes used for the expanded model that restricted the inclusion criteria to testing records with complete reporting for the following clinical variables: symptom status, recent COVID-19 contact, having had COVID-19 within 90 days, and having received a vaccine.

XSL•FO
RenderX

**Table 3.** A summary of testing episode adherence for the second and third test analyses. Episodes with no documented follow-up test in Increasing Community Access to Testing, Treatment, and Response (ICATT) were classified as nonadherent for analytic purposes; this category may include loss to follow-up or follow-up testing outside ICATT.

| Characteristic | Value |
|---|---|
| **Second-test adherence, n/N (%)** | |
| Adherent: second test antigen on-time | 13,369/2,536,563 (0.5) |
| Adherent: second test PCR[a] | 7112/2,536,563 (0.3) |
| Nonadherent: no follow-up second test | 2,494,989/2,536,563 (98.4) |
| Nonadherent: second test antigen early | 4393/2,536,563 (0.2) |
| Nonadherent: second test antigen late | 16,700/2,536,563 (0.7) |
| **Third-test adherence, n/N (%)** | |
| Adherent: third test antigen on-time | 214/7419 (2.9) |
| Adherent: third test PCR | 85/7419 (1.1) |
| Nonadherent: no follow-up third test | 5894/7419 (79.4) |
| Nonadherent: third test antigen early | 69/7419 (0.9) |
| Nonadherent: third test antigen late | 1157/7419 (15.6) |
| **Timing between tests, mean (SD)** | |
| Days between test 1 and 2 | 4.15 (2.59) |
| Days between test 2 and 3 | 5.84 (2.25) |

[a]PCR: polymerase chain reaction.

**Table 4.** Serial testing adherence of testing episodes for the expanded model, which required clinical variables in addition to symptom status to be reported. Episodes with no documented follow-up test in Increasing Community Access to Testing, Treatment, and Response (ICATT) were classified as nonadherent for analytic purposes; this category may include loss to follow-up or follow-up testing outside ICATT.

| Characteristic | Value |
|---|---|
| **Second-test adherence, n/N (%)** | |
| Adherent: second antigen test, on time | 572/140,461 (0.4) |
| Adherent: second PCR[a] test | 547/140,461 (0.4) |
| Nonadherent: no follow-up second test | 138,330/140,461 (98.5) |
| Nonadherent: second antigen test, early | 252/140,461 (0.2) |
| Nonadherent: second antigen test, late | 760/140,461 (0.5) |
| **Third-test adherence, n/N (%)** | |
| Adherent: third antigen test, on time | 8/450 (1.8) |
| Adherent: third PCR test | 3/450 (0.7) |
| Nonadherent: no follow-up third test | 343/450 (76.2) |
| Nonadherent: third antigen test, early | 6/450 (1.3) |
| Nonadherent: third antigen test, late | 90/450 (20) |
| **Time between tests, mean (SD)** | |
| Days between tests 1 and 2 | 3.85 (2.26) |
| Days between tests 2 and 3 | 3.53 (2.26) |

[a]PCR: polymerase chain reaction.

## Second-Test Adherence: Demographic Variables

Multiple clinical and patient demographics were significantly associated with second-test adherence (Table 5). Patients with symptoms had 47% lower odds (adjusted odds ratio [AOR] 0.53, 95% CI 0.51-0.55; $P$<.001) of adherence compared with those who were without symptoms. Both children (AOR 0.48, 95% CI 0.45-0.51; $P$<.001) and adults aged 65 years and older (AOR 0.83, 95% CI 0.77-0.88; $P$<.001) had lower odds of adherence compared with adults. In contrast, both Asian (AOR

XSL•FO
RenderX

1.28, 95% CI 1.21-1.36; *P*<.001) and Black (AOR 1.17, 95% CI 1.12-1.23; *P*<.001) individuals had higher odds of adherence compared with White individuals. Hispanic or Latino individuals had 9% higher odds of adherence (AOR 1.09, 95% CI 1.03-1.16; *P*=.003) compared with non-Hispanic individuals; however, this association did not remain statistically significant after correction for multiple comparisons. All geographic regions had lower odds of adherence than the Northeast, with the largest difference observed in the South (AOR 0.82, 95% CI 0.79-0.86; *P*<.001). Women had 8% higher odds of adherence (AOR 1.08, 95% CI 1.05-1.11; *P*<.001) compared with men. Both patients with Medicare (AOR 1.11, 95% CI 1.03-1.20; *P*=.005) and patients with Medicaid (AOR 1.14, 95% CI 1.07-1.20; *P*<.001) had higher odds of adherence than those with private insurance; however, the association for Medicare did not remain statistically significant after correction for multiple comparisons. Estimates for the site contractor eTrueNorth (Table 5) are based on small sample sizes (Table 1), as reflected by wider CIs. Adherence significantly attenuated over time since guideline implementation, ranging from 17% lower odds in the quarter immediately following guideline implementation (AOR 0.83, 95% CI 0.79-0.87; *P*<.001) to 92% lower odds of adherence more than 2 years later (AOR 0.08, 95% CI 0.05-0.13; *P*<.001).

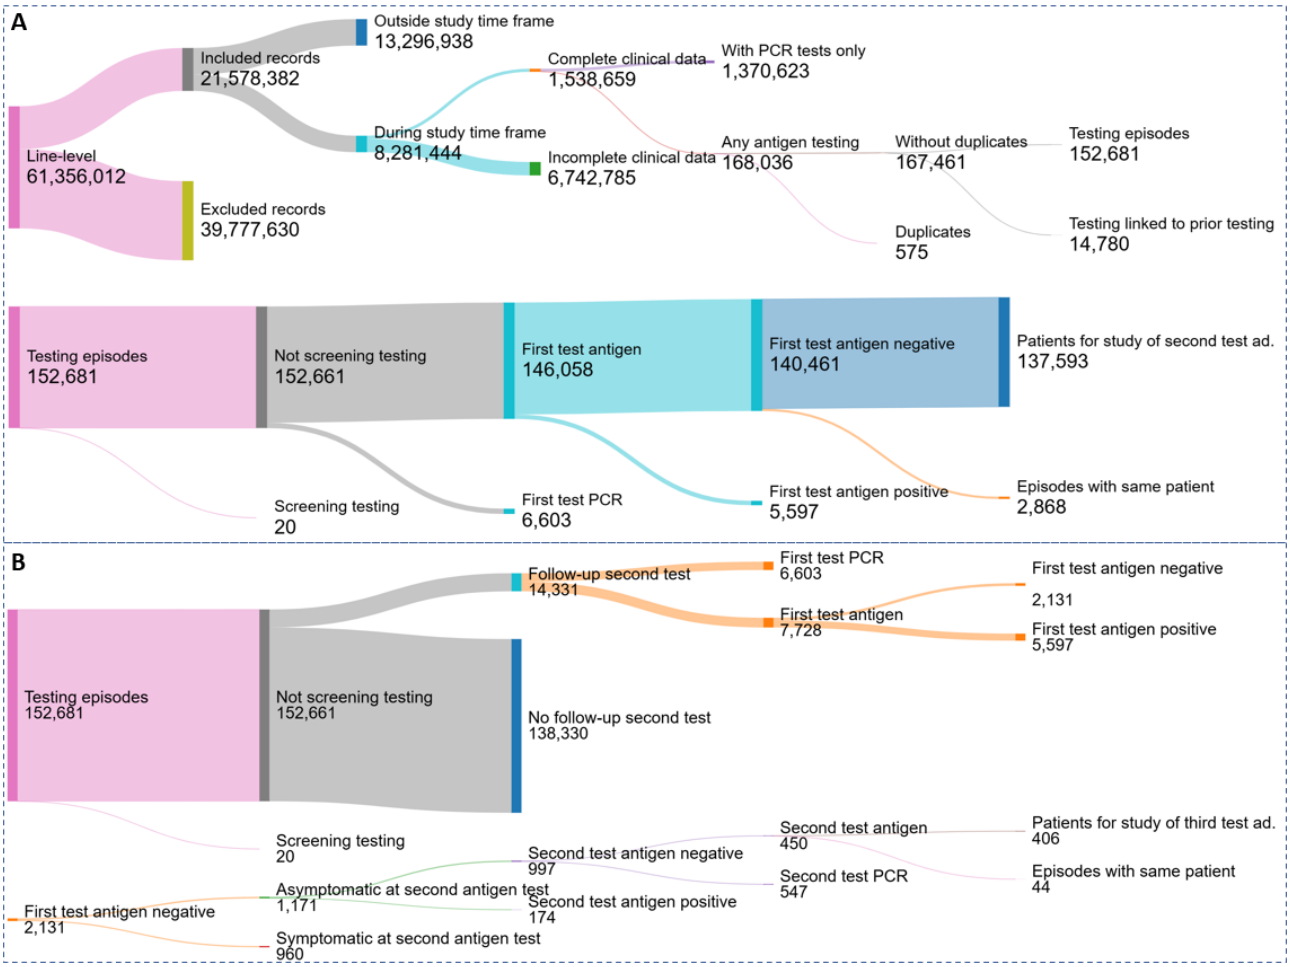
### Second-Test Adherence Expanded Model: Demographic and Clinical Variables



There were 137,593 patients (Figure 3) included in the expanded model with complete demographic and clinical information (Table 6), representing a substantially smaller complete-case subset of the primary analytic sample. After reducing the model to this sample and adding in the 3 clinical variables (recent COVID-19 contact, COVID-19 within 90 days, and vaccination status), many of the demographic variables (sex, insurance status, and symptom status) were no longer statistically significant (Table 7). However, the newly added clinical variables were significantly associated with the outcome. For example, testing episodes among patients with a recent COVID-19 contact had 87% higher odds (AOR 1.87, 95% CI 1.64-2.13; *P*<.001) of adherence compared with patients without recent COVID-19 contact. In contrast, testing episodes among patients who had COVID-19 within the past 90 days had 34% lower odds (AOR 0.66, 95% CI 0.56-0.76; *P*<.001) of adherence. Vaccination status (AOR 1.07, 95% CI 0.92-1.26; *P*=.40) was not significantly associated with adherence.

Among demographic variables, children had 46% lower odds of adherence than adults (AOR 0.54, 95% CI 0.40-0.72; *P*<.001), while older adult patients were no longer statistically different from adults (AOR 0.89, 95% CI 0.68-1.16; *P*=.40). Asian individuals had 33% higher odds of adherence (AOR 1.33, 95% CI 1.05-1.67; *P*=.02) compared with White individuals; however, this association did not remain statistically significant after correction for multiple comparisons, and all other racial categories were not statistically significant. Testing episodes in the quarter immediately following the issuance of the FDA recommendations showed the opposite direction of association, with 20% higher odds of adherence (AOR 1.20, 95% CI 1.04-1.38; *P*=.01) compared with the quarter of policy implementation; however, this association did not remain statistically significant after correction for multiple comparisons.

### Third-Test Adherence: Demographic Variables

Some similar trends among demographic variables were observed for third-test adherence (Table 8). Patients with symptoms had 35% lower odds of adherence compared with those without symptoms (AOR 0.65, 95% CI 0.45-0.91; *P*=.02), and children had 50% lower odds of adherence than adults (AOR 0.50, 95% CI 0.24-0.94; *P*=.05); however, these associations did not remain statistically significant after correction for multiple comparisons. Asian individuals had 53% lower odds of adherence than White individuals (AOR 0.47, 95% CI 0.24-0.82; *P*=.01); however, this association did not remain statistically significant after correction for multiple comparisons, and all other racial categories were not statistically significant. Among geographic regions, the only significant difference was observed in the West, which had 47% higher odds of adherence than the Northeast (AOR 1.47, 95% CI 1.00-2.15; *P*=.048); however, this association did not remain statistically significant after correction for multiple comparisons. Ethnicity, sex, insurance status, site contractor, and temporality were not statistically significant. Similar to second-test adherence, the odds of third-test adherence also declined over time.

### Third-Test Adherence Expanded Model: Demographic and Clinical Variables

There were 406 patients included in the expanded model with complete demographic and clinical variables (Table 9), reflecting a markedly reduced complete-case sample. After adding additional clinical variables into the model and restricting the analysis to this sample, the majority of demographic variables were no longer statistically significant (Table 10). The only significant relationship was observed for recent COVID-19 contacts, as those individuals had 1643% higher odds of adherence (AOR 17.43, 95% CI 2.14-546.41; *P*=.03); however, the wide CI around this estimate indicates limited precision, and the association did not remain statistically significant after correction for multiple comparisons.

### Analysis of the Rate of Testing Positive After Initially Testing Negative

#### *Serial Testing of Patients With Symptoms*

Among 2,025,975 episodes with a negative first Ag-RDT, 1,742,160 (86%) were symptomatic at the first test. Of the episodes with patients with symptoms, a total of 29,315 (1.7%) had a second test, and 7310 (24.9%) of those receiving a second Ag-RDT were positive. Among this group, a total of 4195 (57.4%) of the episodes were adherent with serial testing (eg, an Ag-RDT taken 2-3 days after the first test or an RT-PCR test). Of the 22,005 (75.1%) episodes with a negative second Ag-RDT, a total of 10,818 (49.2%) were adherent with serial testing. Therefore, 24.9% (7310/29,315) of episodes among patients with symptoms tested negative on the first antigen test (95% CI 24.4%-25.4%) and positive on the second test when performing serial testing with 2 antigen tests.

#### *Serial Testing of Patients Without Symptoms*

Among 2,025,975 episodes with a negative first Ag-RDT, a total of 7792 (0.39%) were asymptomatic at the first and second tests, and 5957 (0.29%) were also negative at the second Ag-RDT. Among the 5957 episodes among patients without symptoms and with 2 negative Ag-RDTs, a total of 1435 (24.1%) had a third test, of whom 60 (4.2%) were positive, and 1375 (95.8%) were negative for the third Ag-RDT. Of the 60 episodes with a positive third test, 36 (60%) were adherent with serial testing. Of the 1375 episodes with a negative third test, 246 (17.9%) were adherent with serial testing. Therefore, the rate of testing positive through serial testing for this population was 4.2% (60/1435, 95% CI 3.2%-5.2%). In addition, serial testing was also effective for 24 patients without symptoms who were positive on the third test but nonadherent, indicating that serial testing can still be effective in situations where patients do not strictly adhere to testing timelines.

## Discussion

### Overview

This study is the first to evaluate serial Ag-RDT testing adherence following the FDA's safety communication issued in August 2022. Among 2,189,464 patients who received at least 1 Ag-RDT through the CDC ICATT program, less than 2% also received a follow-up test captured by the program. Accordingly, the large group classified as nonadherent because no follow-up test was observed likely includes a mixture of true nonadherence, loss to follow-up, and follow-up testing done outside ICATT. Multiple demographic variables (including age, race, and region) were significantly associated with adherence, although some variables (eg, insurance, sex, or timeliness relative to the issuance of the recommendations) were only significant for second-test adherence. In the expanded model that included 3 clinical variables, however, the majority of demographic variables were no longer statistically significant. Instead, interaction with a recent COVID-19 contact significantly increased the odds of second- and third-test adherence, while patients who had COVID-19 themselves within the past 90 days were less likely to be adherent. Taken together, these results suggest that clinical variables and temporal nearness to policy issuance and likelihood of exposure (due to a substantial reduction in cases since policy issuance [19,20]) are more closely related to adherence than nonclinical demographic variables.

Within this study, there were only a few demographic differences associated with serial testing adherence, and these distinctions differed from those identified in other studies. In university environments, women were more likely than men to adhere to serial testing policies [11,14], while Asian and Black individuals were less likely to adhere [11]. This partially aligned with the results presented here; while women were also found to be more adherent than men for their second test, so were Asian and Black individuals (although both became statistically insignificant after adjusting for additional clinical variables). These differences may be attributable to the setting of the study (eg, a university setting in a relatively closed environment vs a broader geographic sample) or the time frame in which the studies occurred and the corresponding availability of resources. In particular, over-the-counter Ag-RDT tests were not approved by the FDA until December 2020, which was after the Wisconsin university study occurred [11,21]. As a result, patients in that study may have been more likely to adhere to serial testing because they did not have accessible over-the-counter tests.

In contrast, patients in this study may appear to be nonadherent with serial testing when, in actuality, they took a second Ag-RDT that was not captured by the ICATT program. As a result, the availability of at-home Ag-RDTs is a notable confounding variable. However, it is unlikely that all patients who did not receive a follow-up Ag-RDT within the ICATT data took an at-home Ag-RDT. A previous cross-sectional online survey found that approximately 20% of participants had engaged in at-home COVID-19 testing by March 2022, especially those who had either a COVID-19 exposure or COVID-19-like symptoms [22]. Even if a similar proportion of testing episodes without a second Ag-RDT in the ICATT data had an Ag-RDT, that would still leave over 1,995,991 testing episodes without a follow-up test. This may still be an underestimation because a significant portion of test takers were uninsured, and at-home testing rates are lower among these individuals [16,22].

In the expanded model that included only persons with complete clinical data, the majority of the demographic variables were no longer statistically significant (especially within the second-test adherence model). This suggests that a patient's recent COVID-19 environment is more of a driver to testing than various demographic variables. Furthermore, the conflicting directionality of recent COVID-19 contact (which was associated with higher adherence) and recent COVID-19 status (which was associated with lower adherence) could be attributable to the rationale behind why an individual sought ICATT testing. For example, a patient who recently had

XSL•FO
RenderX

COVID-19 may seek out an ICATT test to confirm that they no longer have the disease, as opposed to testing for a new instance of the disease. In contrast, patients with a recent COVID-19 contact may be more motivated to test because of concern that they may actively have COVID-19. These expanded-model findings should be interpreted cautiously because they were based on complete-case analyses using substantially smaller samples than the primary models. If the completeness of the clinical variables was nonrandom, the expanded-model estimates may be subject to selection bias. The smaller analytic samples, particularly for third-test adherence, also reduced precision and statistical power and may partly explain why some associations were attenuated or no longer statistically significant.

Interestingly, symptom status and vaccination status were not significant after adjusting for COVID-19 contact status, suggesting that actual contact with another patient may be more motivating than a person's own symptoms or vaccination history. This aligns with findings from a scoping review that found that a person's perception of having COVID-19 and motivation for testing are heavily influenced by their social environment [23]. This may also explain why adherence declined over time relative to the announcement of a new safety communication, as motivation to comply may be higher directly after the initial announcement occurs. In addition, independent pharmacies (eTrueNorth sites) showed significantly higher odds of test adherence than chain pharmacies. Similar results have been found in terms of medication adherence by independent pharmacy users [24]. Because all ICATT vendors were required to follow FDA regulations and manufacturers' instructions for use, this difference is unlikely due to procedural variations and warrants further investigation. Overall, these results suggest the need for public health officials to make frequent reminders about changes in instructions to stress their importance and reinforce positive behaviors, although additional work is needed to understand the most effective messaging strategy and how over-the-counter testing may have played a role in serial testing adherence. Although we did not directly measure exposure to public health messaging or pharmacist (testing-site) counseling, the low adherence observed here suggests a need for future work on how serial-testing guidance is communicated to patients and how access to convenient follow-up testing can be improved during future pandemics. Although several ORs were statistically significant, many were close to 1 and therefore likely represent modest practical differences at the individual level. The more important public health finding is the uniformly low uptake of serial testing across the cohort, suggesting broad barriers to adherence rather than large disparities concentrated in a few subgroups. Taken together, these findings suggest that low adherence likely reflects a combination of behavioral factors, including perceived exposure risk and declining motivation over time, and structural factors, including the availability of at-home testing, differences in access, and possible variation in counseling across testing sites.

The analysis on the rate of testing positive through serial testing indicated that serial testing can reduce the risk of false-negative Ag-RDT results, aligning with the FDA safety communication. For patients with symptoms, serial testing (eg, a follow-up Ag-RDT or NAAT/RT-PCR test after the initial test) identified 24.9% of initially negative cases as positive upon retesting, underscoring the importance of multiple tests to catch infections missed by earlier tests. Adherence with serial testing was higher among those who tested positive on the second test (57.4%) compared with those who remained negative (49.2%). Of the 60 episodes with a positive third test, 36 (60%) were adherent with serial testing. Of the 1375 episodes with a negative third test, 246 (17.9%) were adherent with serial testing. For patients without symptoms, the rate of testing positive via serial testing was lower at 4.2%. This lower rate of testing positive for patients without symptoms is logical, as patients without symptoms are less likely to have COVID-19.

## Limitations

This study's strength is its large sample size of over 2 million patients over a multiyear time frame. However, there are several limitations that are important to note. Testing data are limited to tests that occurred at vendor sites and do not include at-home tests or tests performed outside of ICATT, creating the potential for misclassification bias in the adherence outcome. As a result, some patients classified as nonadherent may in fact have completed follow-up testing outside the observed pharmacy network. Similarly, it is assumed that the first ICATT test is the start of an individual's testing episode, when a patient may be using ICATT as a follow-up for a test they took at home or at a non-ICATT facility. In addition, observation of repeat testing was limited within the pharmacy chain because patient IDs were generated separately by vendors and were not used across vendors, so linking testing records for the same patient between different pharmacy chains was not possible. Finally, vendors performed testing according to the authorized instructions for use and counseled patients on the serial testing protocol; however, there was no measure of vendor compliance or patient compliance, and there was no measure of whether patients knew the importance of serial testing. Future work could seek to validate the findings presented here by measuring at-home testing rates or examining testing in other health care settings among demographic groups targeted by the ICATT program, as well as measuring knowledge of the serial testing safety communication.

Furthermore, ICATT is a nonprobability sample that targets underresourced communities; as a result, the findings presented here may not be representative of the broader US population. In addition, the study's cut-off date extends well beyond the issued safety communication date, and it is possible that the likelihood of adherence due to the safety communication was lower for dates further out from the announcement. Third, a gender variable closely linked to sex was used to determine a patient's sex because sex was not collected by the ICATT vendors. Finally, there was a high degree of missingness among self-reported clinical variables. Consequently, the expanded models were restricted to complete cases, and if the completeness of the clinical variables was nonrandom, those estimates may be affected by selection bias. The markedly smaller complete-case samples—especially for the third-test expanded model—also reduced precision and statistical power.

## Conclusion

This study is the first to evaluate adherence with SARS-CoV-2 serial Ag-RDT testing following the issuance of an FDA safety communication. Our results highlight the value of public-private programs such as ICATT, which not only directly delivered testing services to uninsured individuals during the COVID-19 pandemic but also provided a detailed source of data to evaluate the effectiveness of government safety communications, such as serial testing instructions for Ag-RDTs, as well as the real-world performance of medical countermeasures such as diagnostic testing. The CDC ICATT program can serve as a model for public health programs and data infrastructure that can improve the readiness, response, and monitoring of the US public health authorities to future biological threats.

Using a large national dataset, this study demonstrates that nearly all patients did not have follow-up testing captured in the dataset according to the FDA's test instructions. It is possible that this result may be attributable to the increased availability of at-home tests over time, and it justifies the further development of data systems that can track individual patient testing across modalities for additional study. Despite low adherence to testing and noncompliant timing of testing, serial testing successfully identified infections missed by earlier tests at significant rates, indicating the public health benefit of serial testing.

With the availability of at-home testing, a significant proportion of second- and third-test patients likely used at-home tests rather than going back to the pharmacy, reducing the rates of detection through serial testing compared with those observed in this study. There was significant variability in second-test and third-test adherence rates among distinct demographic groups. Individuals with symptoms and children had lower odds of both second- and third-test adherence; Asian individuals had higher odds of second-test adherence but lower odds of third-test adherence; and individuals in the West had lower odds of second-test adherence but higher odds of third-test adherence. When clinical factors were incorporated into the model, adherence was significantly higher among patients with recent COVID-19 contact, but lower among those who had COVID-19 within the past 90 days. The rate of testing positive through serial testing was 24.9% for patients with symptoms on the second test and 4.2% for patients without symptoms on the third test. Finally, adherence was greater at community pharmacy sites compared with chain pharmacies, and second-test adherence for all test takers declined steadily over time. Altogether, these findings emphasize the need for additional targeted public health strategies to improve adherence, particularly among groups, sites, and later time periods with lower rates, to improve overall disease detection and management in future outbreaks.

## Acknowledgments

We appreciate the millions of patients and thousands of health care providers who pursued and conducted testing during the pandemic. The authors would also like to thank the following people for their assistance in reviewing the manuscript: Dr Matthew Bevan, Dr Lucy Carruth, Dr Zahra Chaudhry, Mr Jim Hess, Dr Travis Lim, Mr Edward McDonald, and Mr Michael Obringer from the Johns Hopkins University Applied Physics Laboratory. Finally, we would like to acknowledge the initial vision for the Community-Based Testing program by Admiral Brett Giroir, Admiral Erica Schwartz, and Lieutenant Colonel Tiffany Bilderback.

The authors declare the use of generative AI (GenAI) in the research and writing process. According to the GAIDeT taxonomy (2025), the following tasks were delegated to GenAI tools under full human supervision: text generation, refinement of the layout of Figure 2, proofreading and editing, and summarizing text. The GenAI tools used were Gemini 2.0, GPT 5.2, GPT 5.4 Pro, and GPT 5.5 Pro. Responsibility for the final manuscript lies entirely with the authors. GenAI tools are not listed as authors and do not bear responsibility for the final outcomes. Declaration submitted by: collective responsibility.

## Funding

This study was funded by the US Centers for Disease Control and Prevention (CDC) Increasing Community Access to Testing, Treatment, and Response (ICATT) program.

## Data Availability

The datasets analyzed during this study are available in the One CDC Data Platform (1CDP). Due to the sensitivity of the public health data and privacy regulations, the datasets are not publicly available but may be requested from the CDC. Anonymized line-level data are available upon request to the corresponding author and subject to an approved data use agreement.

## Authors' Contributions

MZM, EAC, ZRS, ACG, and JDM were significantly involved in the conception of the study. MZM and CCP wrote the manuscript and conducted all statistical analyses. ACG, MS, GMT, RMS, TCT, MFI, and JDM provided critical intellectual revisions to the content. All authors reviewed and approved the final manuscript.

## Conflicts of Interest

ZRS was employed at Walgreens Co. at the date of article publication.

## Abstract

**Background:** Routine surveillance is important for understanding hand, foot, and mouth disease (HFMD) after monovalent enterovirus 71 (EV71) vaccine introduction, but interpretation is difficult when etiologic typing is sparse and the COVID-19 pandemic overlaps with the postvaccine era.

**Objective:** This study described surveillance-derived changes in HFMD burden and typed serotype composition in Anhui Province, China, after EV71 vaccine introduction and during the COVID-19 pandemic.

**Methods:** We conducted a retrospective ecological surveillance study using HFMD records from January 2008 to December 2023. The primary analysis used negative-binomial interrupted time series (ITS) counterfactual models for all reported HFMD cases and typed EV71 monthly counts. Vaccine-era models were trained using data from January 2013 through May 2016; the previous specification covering January 2010 through May 2016 was retained as a sensitivity analysis. COVID-19–period models were trained using data from January 2008 through December 2019. Secondary analyses assessed spatial, temporal, and age patterns. Vaccine coverage histories, individual vaccination records, specimen submission metadata, and laboratory platform-change metadata were unavailable; therefore, models estimated calendar-based surveillance deviations rather than vaccine effectiveness.

**Results:** Anhui reported 1,292,579 HFMD cases from 2008 to 2023, including 47,990 (3.7%) typed cases. EV71 declined from 45.8% (8479/18,534) of typed cases before vaccine introduction to 3.4% (578/16,930) during COVID-19, while other enteroviruses increased from 29.6% (5487/18,534) to 81.8% (13,848/16,930). There were 123 deaths from 2008 to 2023, corresponding to 9.52 deaths per 100,000 reported cases; no deaths were recorded from 2020 to 2023. In primary vaccine-era ITS models, typed EV71 counts remained below the predicted trajectory in 2017 to 2019: 470 observed vs 659 predicted cases (95% prediction interval [PI] 467-933) in 2017, 181 vs 531 (95% PI 379-798) in 2018, and 63 vs 427 (95% PI 305-662) in 2019. All reported HFMD cases were not uniformly below the vaccine-era counterfactual. During the COVID-19 pandemic, all reported HFMD cases remained below prediction through 2023, with the largest relative difference in 2022 (28,385 observed vs 175,601 predicted; 95% PI 111,465-268,202). The proportion of reported children aged ≥4 years increased from 19% (50,503/266,132) during 2017 to 2019 to 29.1% (44,133/151,795) during 2021 to 2023 (odds ratio 1.75, 95% CI 1.72-1.78; $P$<.001).

**Conclusions:** Typed EV71 surveillance signals declined after EV71 vaccine introduction, and overall HFMD burden was strongly disrupted during the COVID-19 pandemic. However, sparse typing, unavailable vaccination and testing policy metadata,

XSL•FO
RenderX

and the aggregated other enteroviruses category limit causal interpretation. These findings should be read as surveillance signals, not as direct estimates of population-level serotype replacement or individual-level vaccine protection.

## Introduction

Hand, foot, and mouth disease (HFMD) remains an important childhood infection in China and is caused by multiple enteroviruses [1,2]. Enterovirus 71 (EV71) has long been of particular concern because it is disproportionately associated with severe neurological complications and death [3-5]. Since inactivated monovalent EV71 vaccines were introduced in China in 2016, postlicensure surveillance has been used to examine whether typed HFMD patterns have shifted away from EV71 and toward non-EV71 enteroviruses [6-9].

Routine surveillance is essential for detecting population-level signals, but it is not equivalent to an individually linked vaccine effectiveness study [10]. HFMD surveillance systems do not type every reported case, and the typed subset may be affected by case selection, disease severity, reagent availability, local laboratory capacity, and changes in diagnostic platforms [11,12]. These constraints are especially important when broad categories such as “other enteroviruses” are used because changes in testing breadth may alter which infections become visible to the surveillance system [12-16].

Interpretation became more difficult after January 2020, when the COVID-19 pandemic altered health care use, child contact patterns, and disease reporting [17-23]. Intensive nonpharmaceutical interventions (NPIs) coincided with sharp short-term reductions in HFMD in multiple settings [17-20], while the later rebound has been interpreted as compatible with renewed transmission and an expanded susceptible pool [21-23]. In practice, EV71 vaccine introduction and the COVID-19 period are temporally contiguous disruptions in the same surveillance series. For an ecological dataset, this overlap limits the clean separation of vaccine-era trend shifts from pandemic-era perturbation.

Many province-level HFMD reports have described declining EV71 detection and rising non-EV71 detection after vaccine introduction [6,19,24-26]. What is often less explicit is the inferential boundary: with sparse typing and incomplete testing metadata, typed serotype composition is a surveillance signal rather than a direct estimate of population serotype structure [27]. Long-term provincial surveillance remains valuable because it can show how routine reporting, etiologic typing, seasonality, spatial heterogeneity, severe outcomes, and pandemic-era rebound evolved in the same public health system.

Using provincial HFMD surveillance data from Anhui Province from 2008 to 2023, we aimed to describe how reported burden and typed serotype composition changed after EV71 vaccine introduction and during the COVID-19 period. We prioritized ecological interrupted time series (ITS) counterfactual analyses of all reported HFMD cases and typed EV71 cases, while treating spatial analyses, county-level typed-dominance summaries, seasonality assessment, and joinpoint regression as secondary descriptive analyses. Because individual vaccination records and province-wide vaccine coverage histories were unavailable, the study was framed as an ecological surveillance analysis rather than a causal assessment of vaccine effectiveness.

## Methods

### Study Design and Data Source

We conducted a retrospective ecological surveillance study using deidentified HFMD records provided by the Anhui Provincial Center for Disease Control and Prevention. The analytic window was January 1, 2008, through December 31, 2023. Anhui Province comprises 16 prefecture-level cities and 104 county-level administrative units. Because different surveillance outputs were available at different spatial resolutions, analyses were conducted at mixed levels by design: prefecture-level city units were used for incidence mapping and spatiotemporal cluster detection; county-level units were used for typed-dominance mapping; and province-level aggregation was used for seasonality, joinpoint, and ITS analyses.

The surveillance extract included date of symptom onset, administrative unit, age, sex, clinical severity, and etiologic typing result when available. Population denominators were obtained from the Anhui Statistical Yearbook [28]. HFMD cases were reported through the statutory notifiable disease surveillance system. Clinical diagnosis followed the national HFMD diagnostic standard, which requires compatible symptoms, such as fever with rash or vesicles affecting the hands, feet, mouth, or buttocks; cases without rash are not clinically diagnosed as HFMD [29]. We followed the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) reporting principles, where applicable, to an aggregated surveillance analysis [30].

### Surveillance and Testing Context

Under the national diagnostic standard, severe HFMD includes central nervous system involvement, such as poor mental status, somnolence, startle, delirium, headache, vomiting, limb tremor, myoclonus, nystagmus, ataxia, weakness, acute flaccid paralysis, convulsions, or meningeal signs; critical disease includes severe central nervous system injury, respiratory dysfunction, or circulatory dysfunction [29]. In this analysis, severe cases were records marked as severe in the surveillance extract. The extract contained a death-date field but did not contain follow-up information on neurological sequelae.

XSL•FO
RenderX

Several surveillance features define the boundary of interpretation. June 1, 2016, was used as the EV71 vaccine–era boundary, and January 1, 2020, to December 31, 2023, was treated as the COVID-19 period. Etiologic typing was incomplete and time varying: 47,990 (3.7%) of 1,292,579 reported cases had a recorded etiologic result, with annual typing fractions ranging from 0.3% (76/26,359) in 2008 to 8.4% (4429/52,712) in 2020. Typed analyses therefore describe surveillance-derived typed composition rather than population serotype structure. The surveillance extracts also lacked individual vaccination records, province-wide vaccine coverage histories, annual specimen submission criteria, and laboratory platform-change records. These gaps precluded direct estimation of vaccine effectiveness, adjustment for testing policy changes, or attribution of changes in the aggregated other enteroviruses category to true population-level serotype replacement.

### Outcomes and Definitions

The primary burden end point was the monthly number of reported HFMD cases. The primary typing end point was the monthly number of typed EV71 cases. Typed cases were also categorized as coxsackievirus A16 (CV-A16) or other enteroviruses. In this surveillance extract, other enteroviruses represented typed results recorded as neither EV71 nor CV-A16; the category could not distinguish coxsackievirus A6 (CV-A6), coxsackievirus A10 (CV-A10), or other individual serotypes. Deaths were identified from nonmissing death dates, and case fatality was summarized as deaths per 100,000 reported cases.

For descriptive analyses, we summarized annual reported cases, annual incidence, typing fractions, typed serotype composition, sex distribution, age distribution, severe cases, deaths, and case fatality. Age-shift analyses grouped cases with known age as children aged ≤1 year, aged 2 to 3 years, or aged ≥4 years. For county-level typed-dominance maps, we masked county-year observations with <10 typed cases because dominant-serotype assignments based on small number of typed cases are not epidemiologically stable.

### Statistical Analysis

We first described overall burden, typed composition, and age-sex structure over time. Seasonality was summarized with epidemic curves and a wavelet analysis of weekly reported cases. Annual incidence maps at the prefecture-level city scale, spatiotemporal scan statistics, Moran *I*, and joinpoint regression were retained as secondary descriptive analyses. Retrospective spatiotemporal scan statistics used a discrete Poisson model, a maximum spatial cluster size of 15% of the population at risk, a maximum temporal window of 1 year, and monthly temporal aggregation. Cluster-size sensitivity analyses used maximum spatial windows of 10% and 20%. Joinpoint models were used to summarize annual trend inflections for all reported HFMD incidence, sex-specific incidence, age group counts, and typed serotype counts.

The primary analysis used negative-binomial ITS counterfactual models with month-specific seasonal terms. Following recent counterfactual-prediction guidance, we specified the target observed series, intervention dates, training windows, evaluation metrics, and prediction-interval summaries before interpreting postintervention contrasts [31,32]. For vaccine-era primary models, we used a shorter and more stable preintervention window (January 2013 to May 2016) and specified a linear secular trend to avoid overfitting the short training set. The previous January 2010 to May 2016 quadratic specification was retained as a sensitivity analysis to preserve comparability with previous analyses. For COVID-19–period models, we trained models using data from January 2008 to December 2019 with a linear secular trend. To assess whether the COVID-19 counterfactual depended on including vaccine-era months in the baseline, we also fit a prevaccine sensitivity model using January 2008 to December 2015 as the training window.

Model performance was evaluated on the training period by comparing observed monthly counts with model-fitted counts. We reported mean absolute error (MAE) and root mean square error (RMSE) as primary fit diagnostics because they are expressed in the same count scale as the modeled outcomes; mean absolute percentage error (MAPE) was also tabulated but interpreted cautiously because sparse-typed monthly counts can inflate percentage errors. For each fitted model, we generated postintervention counterfactual predictions and estimated 95% prediction intervals (PIs) by simulating negative-binomial monthly counts from the fitted model and aggregating simulated postintervention counts by year. We summarized observed counts, point predictions, PIs, signed count differences, and relative differences by year. Because province-wide monthly denominators for specimen submission and testing were unavailable, we did not include typing fractions as regressors in the primary models. Instead, we retained previously generated typing-fraction sensitivity analyses as context in Multimedia Appendix 1.

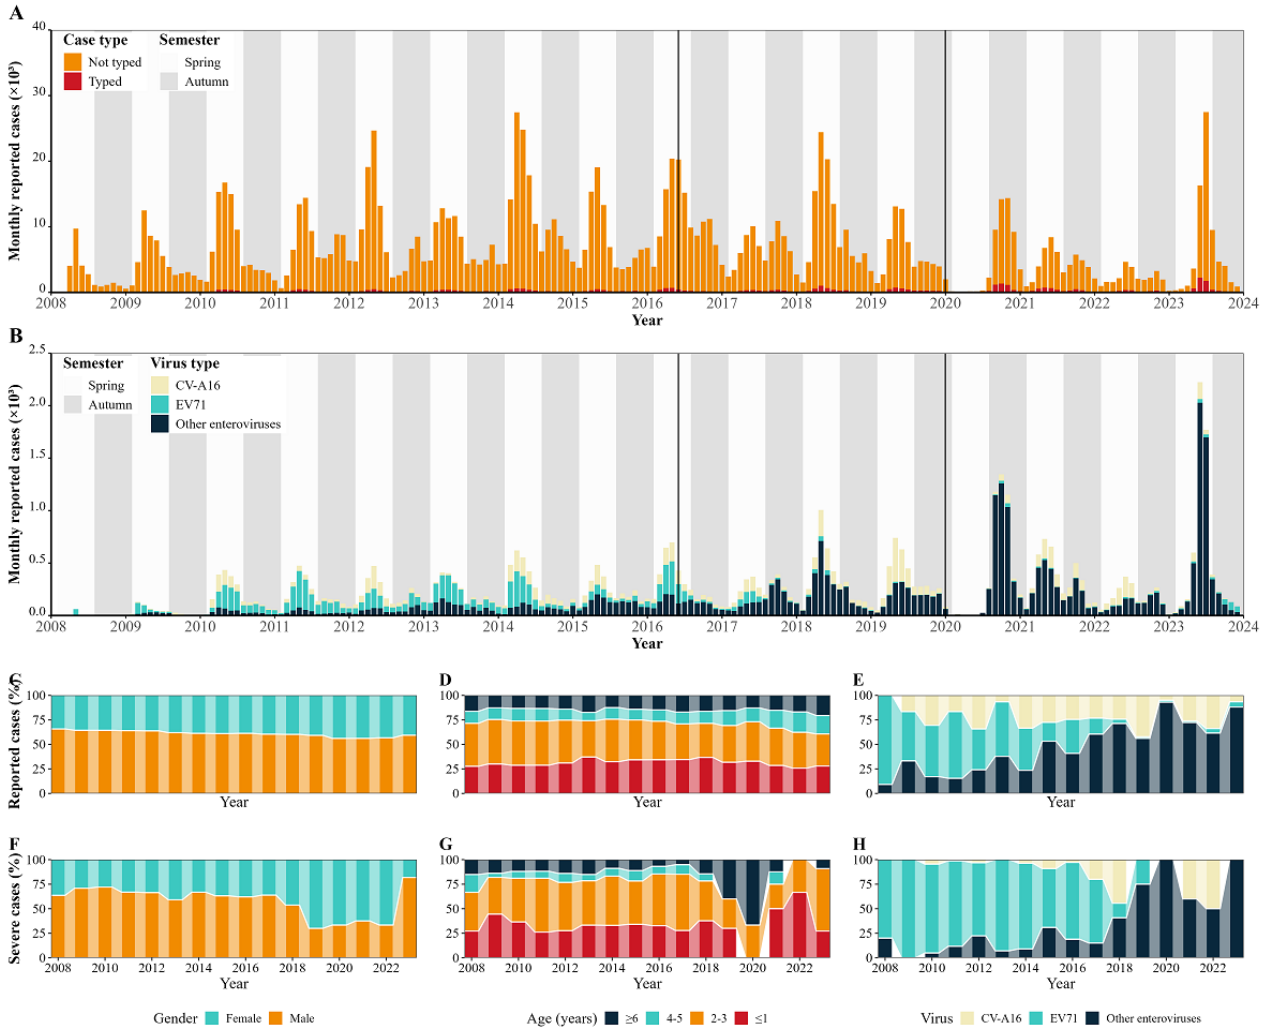
To assess potential severity-related differences within the typed subset, we compared EV71 proportions between severe and mild typed records and fitted adjusted multinomial models of typed serotype category with calendar year, sex, age group, and severity as covariates. To examine the postpandemic age shift, we compared the age composition of reported HFMD cases with known age from 2017 to 2019 vs from 2021 to 2023, performed a chi-square test across age group distributions, and fitted a binomial model comparing the odds that a reported case belonged to the ≥4-year age group of children from 2021 to 2023 vs from 2017 to 2019.

All analyses were performed in R (version 4.5.2; R Foundation for Statistical Computing). Spatiotemporal scan statistics used SaTScan (version 10.2.5; Martin Kulldorff and Information Management Services Inc), and joinpoint analyses used the *nih.joinpoint* R package.

### Ethical Considerations

This study analyzed deidentified routine HFMD surveillance data provided by the Anhui Provincial Center for Disease Control and Prevention as part of the statutory notifiable infectious disease surveillance system. Permission to use the deidentified surveillance data for retrospective analysis was granted by the Anhui Provincial Center for Disease Control and Prevention. The study involved secondary analysis of anonymized records, without direct participant contact, intervention, recruitment, or compensation. No names,

XSL•FO
RenderX



identification numbers, addresses, telephone numbers, or other direct personal identifiers were available to the authors, and all public outputs are reported as aggregated temporal or spatial summaries. Under local requirements for routine public health surveillance data [33], separate ethics committee approval and individual informed consent were not required.

## Results

### Overview of Reported and Typed HFMD Cases

From January 2008 through December 2023, Anhui reported 1,292,579 HFMD cases, including 47,990 (3.7%) typed cases. Annual incidence peaked in 2014, with 145,528 reported cases (241 per 100,000 population), while the lowest annual incidence occurred in 2022, with 28,385 reported cases (46 per 100,000 population; Table S1 in Multimedia Appendix 1). Monthly burden retained a bimodal seasonal pattern, with a larger spring–early summer peak and a smaller autumn peak (Figure 1A; Figure S1 in Multimedia Appendix 1). Wavelet analysis identified significant 6- and 12-month periodicities in the reported case series (Figure S2 in Multimedia Appendix 1). The single highest monthly count occurred in July 2023, with 27,489 reported cases.

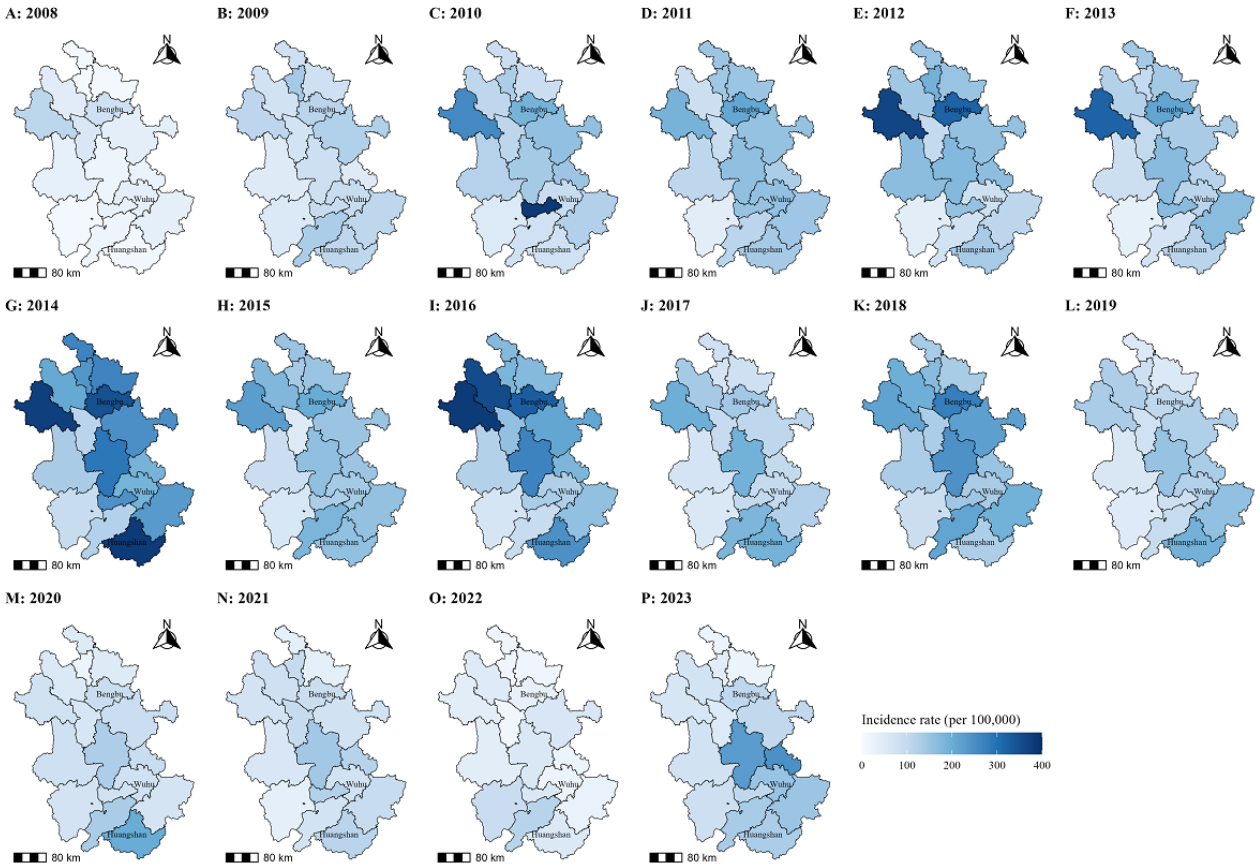
**Figure 1.** Epidemic curves and case composition of hand, foot, and mouth disease (HFMD) in Anhui Province (2008-2023). (A) Monthly reported HFMD cases, categorized as typed or not typed; (B) monthly typed HFMD cases, displayed as enterovirus 71 (EV71), coxsackievirus A16 (CV-A16), and other enteroviruses; (C, D, and E) annual proportions of cases by sex, age group, and typed serotype, respectively, among all reported cases or typed cases, as appropriate; and (F, G, and H) annual proportions of cases by sex, age group, and typed serotype, respectively, among all severe cases or typed severe cases, as appropriate. Vertical lines indicate June 1, 2016 (EV71 vaccine–era analytic boundary), and January 1, 2020 (start of the COVID-19 period).

HFMD remained concentrated in young children across the full study period. Among the 1,292,579 reported cases, 540,368 (41.8%) occurred among children aged ≤1 year, 517,445 (40%) among children aged 2 to 3 years, and 234,766 (18.2%) among children aged ≥4 years. Male participants accounted for 791,458 (61.2%) reported cases, compared with 501,121 (38.8%) among female participants. Overall, 3064/1,292,579 (0.24%) severe cases were recorded during 2008 to 2023. Severe cases became rare after 2018, with 10/70,759 (0.014%) severe cases in 2019 and 3 to 11 severe cases annually from 2020 to 2023. The death-date field identified 123 deaths during 2008 to 2023, corresponding to 9.52 deaths per 100,000 reported cases; no deaths were recorded during 2020 to 2023 (Figure S5 and Tables S6 and S7 in Multimedia Appendix 1).

XSL•FO
RenderX

## Typed Serotype Composition

Among typed cases, the January 2008 to May 2016 period included 18,534 typed detections: EV71 represented 8479 (45.8%), CV-A16 represented 4568 (24.6%), and other enteroviruses represented 5487 (29.6%; Figure 1B; Table S5 in Multimedia Appendix 1). The immediate postrollout prepandemic period (June 2016 to December 2019) included 12,526 typed detections: EV71 accounted for 1114 (8.9%), CV-A16 accounted for 3718 (29.7%), and other enteroviruses accounted for 7694 (61.4%). The COVID-19 period (January 2020 to December 2023) included 16,930 typed detections: other enteroviruses accounted for 13,848 (81.8%), EV71 accounted for 578 (3.4%), and CV-A16 accounted for 2504 (14.8%) (Figure S3 in Multimedia Appendix 1).



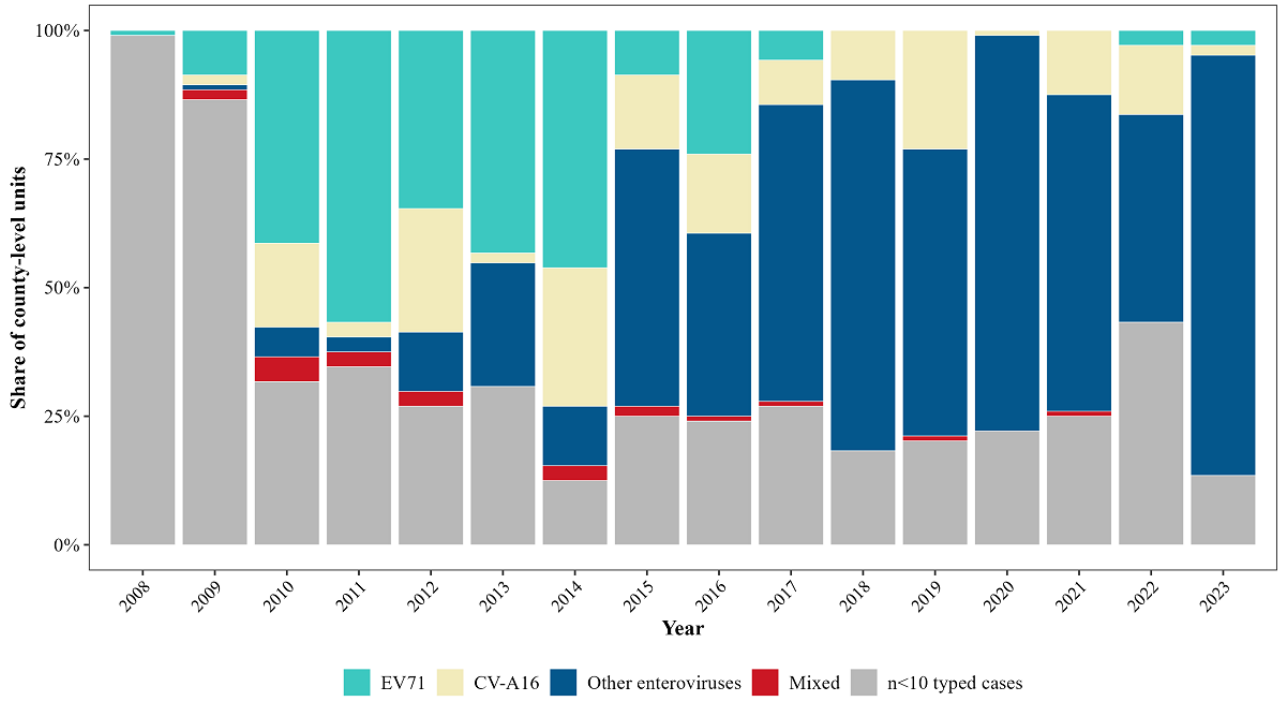
The annual proportion of reported cases with typing increased from 0.3% (76/26,359) of reported cases in 2008 to 5.5% (3919/70,759) in 2019, 8.4% (4429/52,712) in 2020, and 8.4% (5884/70,288) in 2023. In annual typed composition, EV71 accounted for 90.8% (69/76) of typed records in 2008, 34.6% (1266/3664) in 2016, 16.3% (470/2885) in 2017, and 1.6% (63/3919) in 2019. Other enteroviruses accounted for 93.1% (4122/4429) of typed records in 2020 and 88.1% (5186/5884) in 2023 (Table S5 in Multimedia Appendix 1).

In an adjusted multinomial model of typed records, severe cases were more likely than mild cases to be typed as EV71 rather than other enteroviruses (relative risk ratio 7.08, 95% CI 6.01-8.34; Table S5, and Table S8 in Multimedia Appendix 1). Older age groups (2-3 years and ≥4 years) were also more likely than the reference group (≤1 year) to be typed as EV71 or CV-A16 rather than other enteroviruses, while male sex had little association with EV71 classification (relative risk ratio 1.01, 95% CI 0.95-1.07).

## Secondary Spatial and Temporal Analyses

Annual incidence maps showed persistent geographic heterogeneity across Anhui (Figure 2; Figure S4 in Multimedia Appendix 1). Retrospective spatiotemporal scan statistics identified 26 cluster windows, of which 25 were significant at $P<.05$ (Table S2 in Multimedia Appendix 1). Wuhu was the most frequently identified cluster center (11 windows), followed by Huangshan, Ma'anshan, and Bengbu (4 windows each). The largest log-likelihood cluster was centered in Huangshan from April to October 2014, with 18,324 observed cases vs 5195 expected cases (relative risk 3.56). The highest relative risk cluster was centered in Ma'anshan from April to June 2012, with 11,585 observed cases vs 2444 expected cases (relative risk 4.77). Annual global Moran $I$ was significant in 2008 (Moran $I$=0.43; $P<.001$), 2016 (Moran $I$=0.38; $P$=.002), and 2021 (Moran $I$=0.26; $P$=.02), but not in most other years (Table S3 in Multimedia Appendix 1).

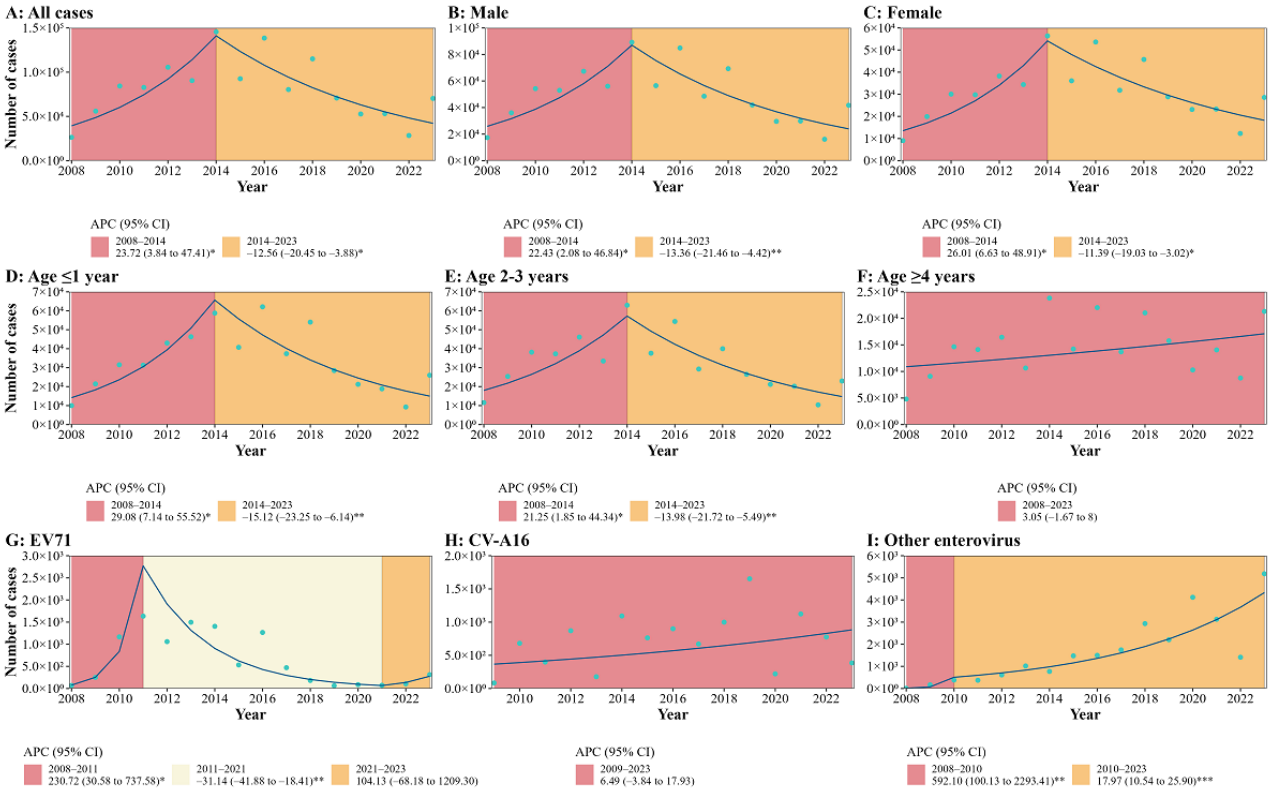
**Figure 2.** Annual incidence maps of reported hand, foot, and mouth disease (HFMD) in Anhui Province, China (2008-2023). Each panel shows the incidence rate for each prefecture-level city in the corresponding year. Labels for Bengbu, Wuhu, and Huangshan are added as spatial references because these locations are discussed in the text.



XSL•FO
RenderX

County-level typed-dominance summaries showed that apparent EV71-dominant county-years decreased over time, while other enterovirus–dominant county-years became more frequent (Figure 3; Figure S8 in Multimedia Appendix 1). County-year observations with <10 typed cases were masked. Dominant-serotype labels indicate only the largest typed category in a county-year and do not measure the margin between the leading and second-leading typed categories.

**Figure 3.** Annual county-level dominance of typed serotype after masking sparse observations in Anhui Province, China (2008-2023). The 100% stacked bar chart shows the share of county-level units classified as enterovirus 71 (EV71)–dominant, coxsackievirus A16 (CV-A16)–dominant, other enterovirus–dominant, mixed, or masked because of <10 typed cases. Counties with <10 typed cases in a given year were not assigned a dominant typed serotype and are shown as masked observations. Dominance indicates the largest typed category in a county-year and should not be interpreted as evidence that one serotype was substantially more frequent than the next most common typed serotype.



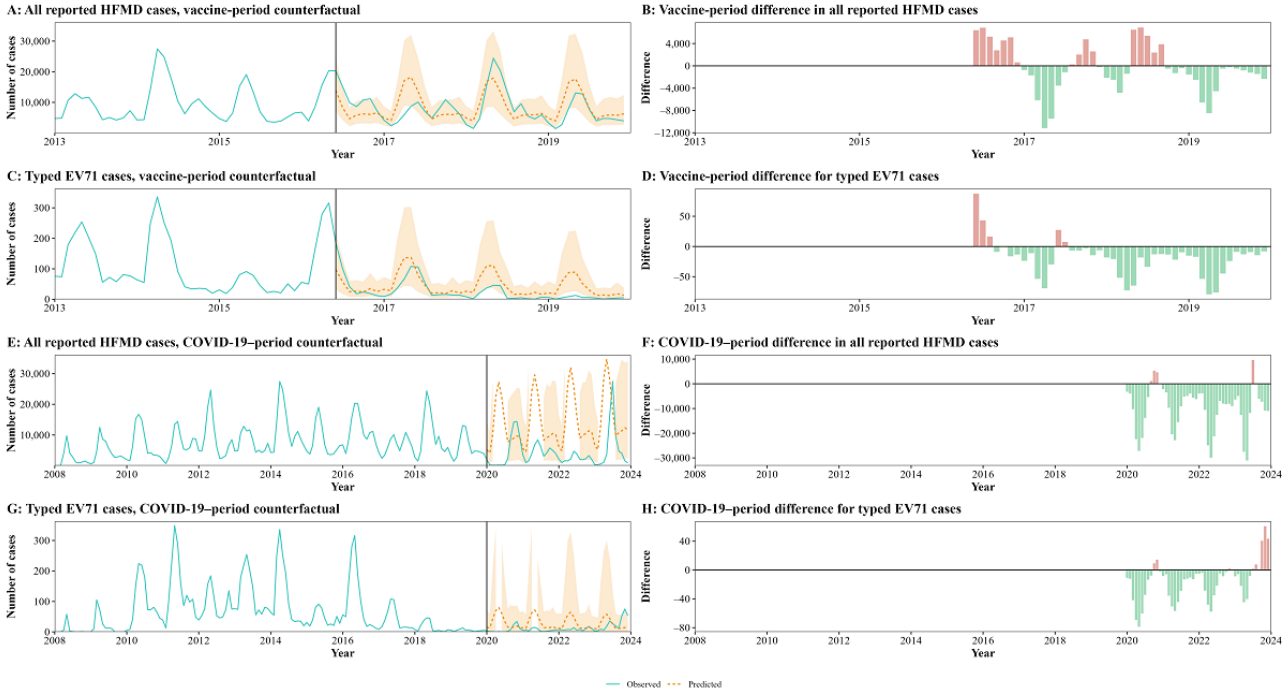
Joinpoint regression suggested a province-wide inflection around 2014 for all reported HFMD incidence and a sustained decline thereafter, whereas typed EV71 counts showed a downward long-term pattern after the early years of laboratory expansion (Figure 4). Count-regression sensitivity analyses for annual typed counts showed a negative annual trend for EV71 in the negative-binomial model (annual percentage change −14.4%, 95% CI −22% to −6%), a positive annual trend for other enteroviruses (annual percentage change 19.5%, 95% CI 19.2%-19.9%), and no statistically clear annual trend for CV-A16.

XSL•FO
RenderX

**Figure 4.** Joinpoint regression of annual hand, foot, and mouth disease (HFMD) trends in Anhui Province, China (2008-2023). (A) Overall incidence, (B) male incidence, (C) female incidence, (D) age ≤1 year, (E) age 2 to 3 years, (F) age ≥4 years, (G) typed enterovirus 71 (EV71) counts, (H) typed coxsackievirus A16 (CV-A16) counts, and (I) typed other enterovirus counts. Dots indicate observed values, and lines indicate fitted segments with 95% CIs. APC: annual percent change. P<0.05, P<0.01, P<0.001.

## ITS Analyses of Vaccine-Era Models

Primary vaccine-era ITS models were trained using data from January 2013 to May 2016 and included a linear secular trend (Figures 5A and 5B). Training-period MAE and RMSE were 2065.5 and 2950.6 monthly cases, respectively, for all reported HFMD cases and 35.5 and 53.4 monthly cases, respectively, for typed EV71 cases. Observed annual typed EV71 counts remained below the predicted trajectory throughout 2017 to 2019 (Figures 5C and 5D; PI summaries are provided in Table S4 in Multimedia Appendix 1): 470 observed vs 659 predicted cases (95% PI 467–933) in 2017, 181 vs 531 (95% PI 379–798) in 2018, and 63 vs 427 (95% PI 305–662) in 2019. These corresponded to annual relative differences of −28.7%, −65.9%, and −85.2%, respectively.



For all reported HFMD cases, observed burden was lower than predicted in 2017 (80,344 observed vs 104,712 predicted; 95% PI 84,388-129,080) and 2019 (70,759 observed vs 101,494 predicted; 95% PI 82,487-132,654), but higher than the point prediction in 2018 (115,029 observed vs 103,091 predicted; 95% PI 82,975-130,561; Figures 5A and 5B). Secondary typed series showed lower-than-predicted CV-A16 counts in 2017 to 2019, while typed other enterovirus counts were below prediction in 2017 and 2019 but above the point prediction in 2018 (Table S3, Table S4 and Figure S7 in Multimedia Appendix 1).

Sensitivity analyses using the previous January 2010 to May 2016 quadratic training window preserved the same direction of post-2016 negative divergence for typed EV71, although effect magnitudes were attenuated compared with the primary model (Table S9 in Multimedia Appendix 1). The longer-window specification yielded 2017 to 2019 typed EV71 counts that were 17%, 49.7%, and 70% below prediction, respectively, compared with 28.7%, 65.9%, and 85.2% in the primary short-window model.

XSL•FO
RenderX

**Figure 5.** Primary ecological interrupted time series counterfactual analyses for hand, foot, and mouth disease (HFMD) surveillance in Anhui Province, China. The primary models focused on all reported HFMD cases and typed enterovirus 71 (EV71) cases. Panels show observed monthly case counts, predicted counterfactual trajectories, and 95% prediction intervals (PIs), along with postintervention difference plots. (A-D) Vaccine-era models (trained January 2013–May 2016) showing (A, B) all reported HFMD cases and (C, D) typed EV71 cases. (E-H) COVID-19–period models (trained January 2008–December 2019) showing (E, F) all reported HFMD cases and (G, H) typed EV71 cases.

## ITS Analyses of COVID-19–Period Models

COVID-19–period ITS models were trained from January 2008 to December 2019. Training-period MAE and RMSE were 2756.2 and 3821.3 monthly cases, respectively, for all reported HFMD and 47.4 and 70.0 monthly cases, respectively, for typed EV71. All reported HFMD cases remained below the pre-2020 counterfactual throughout 2020 to 2023 (Figures 5E and 5F; Table S4 in Multimedia Appendix 1): 52,712 observed vs 149,675 predicted (95% PI 96,603-222,919) in 2020, 53,122 vs 162,121 (95% PI 105,863-243,423) in 2021, 28,385 vs 175,601 (95% PI 111,465-268,202) in 2022, and 70,288 vs 190,201 (95% PI 127,746-284,820) in 2023. The corresponding annual relative differences were −64.8%, −67.2%, −83.8%, and −63%.

Typed EV71 counts were also below predicted values in 2020 to 2022 (Figure 5G and 5H): 87 observed vs 395 predicted in 2020, 72 vs 355 in 2021, and 106 vs 319 in 2022. In 2023, typed EV71 was slightly above the point prediction but remained within the 95% PI (313 observed vs 287 predicted; 95% PI 113-678). Typed CV-A16 and typed other enterovirus counts were below predicted values throughout 2020 to 2023 in the primary COVID-19–period models (Table S4 and Figure S7 in Multimedia Appendix 1).

A sensitivity model trained only on the prevaccine period (January 2008 to December 2015) yielded the same direction of post-2020 suppression for all reported HFMD and the typed serotype series (Table S10 in Multimedia Appendix 1).

## Postpandemic Age Shift

The age composition of reported HFMD cases shifted upward after the most restrictive pandemic period (Figure S6 in Multimedia Appendix 1). Among cases with known age, the proportion of children aged ≥4 years increased from 19% (50,503/266,132) in 2017 to 2019 to 29.1% (44,133/151,795) in 2021 to 2023, while the proportion aged ≤1 year decreased from 45% (119,868/266,132) to 35.6% (54,102/151,795). The ≥4-year age group accounted for 26.5% (14,060/53,122) in 2021, 30.9% (8765/28,385) in 2022, and 30.3% (21,308/70,288) in 2023.

The age distribution comparison between 2017 and 2019 and 2021 and 2023 was statistically significant ($\chi^2_2$=6417.0; $P$<.001). The odds that a reported case belonged to the ≥4-year age group were higher in 2021 to 2023 than in 2017 to 2019 (odds ratio 1.75, 95% CI 1.72-1.78).

# Discussion

## Principal Results

This study should be read as a long-term surveillance analysis, not as a formal assessment of vaccination-related protection. The main findings were that typed EV71 surveillance signals declined after EV71 vaccine introduction, overall reported HFMD burden did not show a uniform postrollout decrease, and the COVID-19 pandemic created a large disruption in the same ecological time series. The revised analyses also showed that severe and fatal outcomes became rare in the later years, that other enterovirus records became dominant within the typed subset, that spatial clustering persisted in selected years and

XSL•FO
RenderX

locations, and that the postpandemic rebound was accompanied by an older age distribution among reported cases.

The most important interpretive boundary is the typed subset. Only 3.7% (47,990/1,292,579) reported cases had etiologic typing. Individual vaccination records, province-wide vaccine coverage histories, testing policy metadata, and laboratory platform-change records were unavailable. In addition, severe cases were more likely than mild cases to be classified as EV71 rather than other enteroviruses among typed records. These features mean that the typed EV71 series cannot be treated as an unbiased proxy for community serotype incidence.

### Interpretation of Typed EV71 and Vaccine-Era Signals

Within those limits, the vaccine-era primary ITS models showed a sustained negative divergence of typed EV71 counts below the counterfactual trajectory during 2017 to 2019. This pattern is directionally consistent with reports from other Chinese provinces after EV71 vaccine introduction [6,24-26]. However, the magnitude of our typed EV71 counterfactual contrast was larger than several published population-level estimates. Guangdong reported a 41.4% reduction in EV71-associated HFMD in 2017 to 2019 with increasing vaccine coverage, and Jiangsu reported an estimated 45.6% reduction with a wide credible interval [24,25]. By comparison, our primary short-window model estimated that typed EV71 counts were 28.7%, 65.9%, and 85.2% below predicted values in 2017, 2018, and 2019, respectively, while the longer-window sensitivity analysis estimated smaller reductions of 17%, 49.7%, and 70%, respectively.

Several mechanisms could make the Anhui-typed EV71 contrast appear larger than a true population-level vaccine effect. Early typing fractions were low, the typed subset may have overrepresented severe cases, severe EV71-associated disease may have been preferentially depleted after vaccine rollout, and changes in specimen submission or laboratory platforms could have altered the case mix entering the typed series. For that reason, the relevant message is not that Anhui had unusually high vaccine impact, but that routine typed surveillance recorded a sustained decline in EV71 signals while the overall reported HFMD burden remained substantial.

The aggregated other enteroviruses category requires similar caution. In this dataset, other enteroviruses were recorded only as typed results that were neither EV71 nor CV-A16. That grouping does not identify which serotypes drove the increase, and it could be sensitive to changes in diagnostic breadth over time [12,15,16]. If multiplex polymerase chain reaction became more common during the later study period, previously underdetected CV-A6, CV-A10, or other enteroviruses could have been more readily classified into the other enteroviruses group [12-16]. We therefore interpret the rise of other enteroviruses as a change in typed surveillance composition rather than definitive evidence of population-level serotype replacement.

### COVID-19 Disruption and Postpandemic Age Shift

The COVID-19 period created a distinct ecological disruption. All reported HFMD counts remained far below the pre-2020 counterfactual through 2023, consistent with documented suppression of contact-based infectious diseases during intensive NPIs [17-22]. The same direction held when the COVID-19 counterfactual was anchored only to prevaccine data, reducing concern that the pandemic signal was an artifact of including vaccine-era months in the baseline. At the same time, the postpandemic age composition shifted toward older children. This local age shift is compatible with an immunity-gap or immunity-debt interpretation, but the evidence remains indirect because the surveillance system does not measure susceptibility or prior infection history [23,34-37]. We therefore present this mechanism as a plausible interpretation supported by age-structured surveillance patterns, not as a proven causal explanation. A pre-vaccine meta-analysis from China documented increasing EV71 antibody seroprevalence with age among preschool children [38], providing historical context for age-related immunity rather than direct evidence of a pandemic-related immunity gap. From a policy perspective, the age shift suggests that postpandemic HFMD preparedness should not focus only on infants and very young preschool children. If linked vaccination and coverage data become available, Anhui could evaluate whether unvaccinated older preschool or school-entry children would benefit from catch-up EV71 vaccination; however, such a strategy cannot be recommended from the current ecological data alone, especially because absolute typed EV71 counts remained low and the vaccine does not protect against non-EV71 HFMD [3-8].

### Spatial and Seasonal Surveillance Findings

The secondary spatial and seasonal analyses add descriptive context to the ITS findings. The bimodal seasonal pattern and significant 6- and 12-month periodicities indicate that seasonal forcing remained a recurring feature of Anhui HFMD activity across the long surveillance window [34,35]. Spatiotemporal scan statistics repeatedly identified clusters centered in Wuhu, Huangshan, Bengbu, and Ma'anshan, but annual Moran *I* was significant only in selected years. These findings indicate spatial heterogeneity in reported burden, but they do not identify causal drivers such as mobility, school calendars, climate, health care access, socioeconomic conditions, or vaccine uptake [34,35].

County-level typed-dominance maps should be read even more cautiously than incidence maps. The dominance label is categorical, depends only on typed records, and can be unstable when typed counts are small. Masking county-years with <10 typed cases reduces the most extreme instability, but it does not remove selection into testing or measure how close the leading typed category was to the next most common category. These maps are therefore best used to flag areas for enhanced surveillance rather than to infer local replacement of serotypes.

### Comparison With Prior Work

Our findings overlap with prior Chinese surveillance studies showing reduced EV71 detection after vaccine introduction and persistent circulation of non-EV71 enteroviruses [6,9,19,24-26]. The added value of the current study is not mechanistic discovery or broad causal generalization beyond Anhui. Instead, it is the explicit framing of what surveillance data can and cannot support when typing is sparse, when the non-EV71 category is aggregated, and when the COVID-19 period interrupts the same time series [10,12,13,27]. This framing aligns more closely with

XSL•FO
RenderX

public health surveillance priorities than with causal inference regarding vaccine impact.

The findings also align with broader reports that COVID-19 pandemic control measures suppressed multiple pediatric and contact-transmitted infections, followed in some settings by rebound or altered age distributions when contact patterns normalized [17-23]. Anhui adds a province-level example in which pandemic-era suppression occurred against the background of an already changing EV71 vaccine–era surveillance series.

### Limitations

This study has several limitations. First, the absence of individual vaccination records and province-wide vaccine coverage histories means that we could not account for actual vaccine uptake, estimate vaccine effectiveness, or distinguish vaccine-program effects from other contemporaneous changes [10,24,25]. Second, the surveillance system was passive, so reporting may have been influenced by health care–seeking behavior and pandemic-era service disruption. Third, etiologic typing remained sparse and likely nonrandom, with severe cases more likely to be typed and the association between severity and typing changing over time. We did not have province-wide metadata on specimen submission criteria, the balance between mild and severe cases selected for testing, or annual changes in laboratory platform use [10-13]. Fourth, the aggregated other enteroviruses category may have been influenced by diagnostic drift; wider adoption of multiplex polymerase chain reaction could make CV-A6, CV-A10, or other previously underdetected serotypes more visible without proving population-level niche replacement [12-16,27]. Fifth, because the postvaccine period and the COVID-19 period are contiguous in the same ecological series, no stable interdisruption interval was available for formal statistical separation of their independent effects. Sixth, although the death-date field allowed us to summarize fatal outcomes, the surveillance extract did not include follow-up information on neurological sequelae, so we could not estimate the proportion of survivors with neurological sequelae after severe HFMD. Finally, county-level dominant-serotype maps are sensitive to sparse-typed counts even after masking county-year cells with <10 typed cases.

### Public Health Implications

The practical contribution of this analysis is a surveillance blueprint rather than an estimate of vaccine effectiveness. Future HFMD surveillance would be more interpretable if specimen submission rules were standardized across sites and years; if sentinel hospitals routinely used multiplex polymerase chain reaction or sequencing capable of distinguishing CV-A6, CV-A10, and other non-EV71 serotypes; and if surveillance extracts preserved the denominator of submitted and successfully tested specimens [11-16]. Linkage to immunization registries would be needed before the same surveillance system could support vaccine effectiveness analyses [10,24,25]. Wastewater or environmental surveillance could provide an additional low-cost early-warning stream for non-EV71 enteroviruses, especially when clinical typing remains sparse [39,40].

### Conclusions

Routine HFMD surveillance in Anhui showed a decline in typed EV71 surveillance signals after EV71 vaccine introduction, a concurrent rise in typed other enterovirus detections, and strong pandemic-era suppression of overall HFMD burden followed by partial rebound and an older-age shift. These findings support extending surveillance priorities beyond EV71 alone. For practice, this means standardizing specimen submission rules, introducing routine multiplex polymerase chain reaction in eligible sentinel hospitals, preserving testing denominators and vaccination histories in surveillance extracts, and considering wastewater surveillance as a lower-cost supplementary early-warning approach. For interpretation, this requires maintaining ecological humility: changes in typed surveillance composition can illuminate temporal patterns but cannot, on their own, establish vaccine-attributable protection or population-level serotype replacement.

## Acknowledgments

The authors thank the Anhui Provincial Center for Disease Control and Prevention for data access and surveillance support. During revision, the authors used ChatGPT (version 5.6; OpenAI) to assist with language editing and consistency checks across the manuscript and multimedia appendix. The authors reviewed and verified all generated text, analyses, and interpretations and take full responsibility for the final content.

## Funding

This research was supported by the National Science and Technology Major Project (grant 2027ZD01999504), the Major Project of Guangzhou National Laboratory (grant GZNL2024A01004), and the National Key Research and Development Program of China (grant 2024YFE0214800).

## Data Availability

Supplementary figures and tables are provided in Multimedia Appendix 1. Aggregated analytic data, analysis scripts, and analytic outputs supporting this study are publicly available in our GitHub repository [41]. The individual-level surveillance records are not publicly available because they contain sensitive statutory notifiable disease surveillance information and are governed by the Anhui Provincial Center for Disease Control and Prevention; requests for additional access would require approval from the

XSL•FO
RenderX

data custodian. Publicly released materials contain aggregated temporal and spatial counts rather than individual-level surveillance records.

## Authors' Contributions

KL, Jiadong Wu, and Tianmu Chen conceptualized the study. Jiadong Wu and KL developed the analytic strategy, wrote the analysis code, performed the formal analyses, validated the results, and prepared the figures and tables. WM, Jiabing Wu, Tao Chen and YZ curated the surveillance data, verified variable definitions, and provided context on the surveillance system. JR contributed to epidemiological interpretation and review of the ecological inference framework. ZZ contributed to the interpretation of spatial and population data and reviewed the mapping analyses. Jiabing Wu oversaw surveillance data access, data governance, and interpretation of the Anhui reporting context. Tianmu Chen provided overall supervision, project administration, and funding acquisition. KL, Jiadong Wu, and WM drafted the manuscript. Jiadong Wu, ZZ, Jia Rui, Jiabing Wu, and Tianmu Chen critically revised the manuscript for important intellectual content. All authors approved the final version and agreed to be accountable for the work.

## Conflicts of Interest

None declared.

## Abstract

**Background:** Despite extensive vaccination efforts, pertussis has experienced a global resurgence, with China alone reporting over 470,000 cases in 2024. The age distribution of cases has shifted markedly from infants to school-age children and adults, likely driven by waning acellular pertussis vaccine (DTaP [Diphtheria, Tetanus Toxoids, and Acellular Pertussis Vaccine])–induced immunity. In response, China revised its immunization schedule in 2025 to include a booster dose at the age of 6 years; however, the population-level impact of this strategy on age-specific transmission dynamics remains unclear.

**Objective:** This study aimed to characterize the shifting age-specific transmission dynamics of *Bordetella pertussis* under changing immunization landscapes and evaluate the population-level impact of the 2025 Chinese immunization schedule.

**Methods:** An age-structured Vaccinated-Susceptible-Exposed-Infectious-Recovered model incorporating vaccination, waning immunity, and demographic structures was calibrated using surveillance data from Hunan Province (2010-2025). The next-generation matrix approach estimated the effective reproduction numbers across 5 epidemic phases. Multiscenario simulations were used to assess the impact of a 6-year booster dose at varying coverage levels.

**Results:** Among 47,300 reported cases (2010-2025), a marked resurgence peaked at 6743 cases in April 2024, with consistent spring seasonality. The case distribution shifted from infant-dominated (0-6 months: 293/552, 53.07%, 2010-2017) to school-age-dominated (6-10 years: 9814/30,589, 32.08%, 2024-2025). This study period was stratified into 5 temporal phases based on the epidemic dynamics: phase 1 (2010-2017), phase 2 (2018-2019), phase 3 (2020-2023), phase 4 (2024), and phase 5 (2025). Segmented fitting analyses were conducted for monthly pertussis cases across age groups within each phase of this study. The model demonstrated high fitting consistency across all age groups, with an overall $R^2$ of 0.96. Adults emerged as the dominant transmission source in 2023-2024 ($R_{eff}$ to infants: 2.717). A booster administered at the age of 6 years with full coverage is expected to decrease the 10-year cumulative incidence by 24.15% (24,972.58/103,408.95). Children between 6 and 10 years of age are expected to experience the most significant monthly decrease, at 45.06% (335.49/744.51), whereas infants are predicted to gain 28.91% (170.92/591.19) indirect protection.

XSL•FO
RenderX

**Conclusions:** Pertussis resurgence is driven by age-structured heterogeneity and waning immunity. Administering a booster shot to children at the age of 6 years can reduce the spread of infections across different age groups and offer indirect protection to infants who are at high risk. However, for long-term control, it may be necessary to implement broader strategies that involve vaccinating adolescents, adults, and pregnant women.

## Introduction

Pertussis, caused by *Bordetella pertussis*, is a highly contagious acute respiratory disease with a basic reproduction number ($R_0$) estimated at 5.5-17 [1,2]. However, as vaccination coverage expands, the effective reproduction number ($R_{eff}$)—which accounts for population immunity—becomes a more informative metric for tracking transmission dynamics under real-world immunization conditions. In China, pertussis is classified as a class B notifiable infectious disease, with children under 5 years of age constituting the primary susceptible population [3]. Among them, infants younger than 1 year are disproportionately affected, accounting for the highest incidence and the majority of severe cases [4]. Clinically, the disease is characterized by paroxysmal spasmodic cough with a distinctive inspiratory whoop, and the course of illness may last for 2-3 months [5,6]. Although the case fatality rate is low (0.01% in China during 2018-2021) [7], the disease burden remains considerable due to its high transmissibility and concentration in vulnerable populations, particularly in incompletely vaccinated infants [4].

From an epidemiological perspective, before the widespread use of vaccines, pertussis exhibited cyclical outbreaks occurring every 3-5 years [8]. This periodicity was substantially attenuated following the incorporation of pertussis vaccines into national immunization programs. However, since the early 21st century, a resurgence of pertussis has been reported in multiple regions worldwide, including countries with high vaccination coverage [9]. Similar trends have been observed in China, where the reported incidence has increased steadily since 2014, except for a temporary decline during the COVID-19 pandemic owing to nonpharmaceutical interventions (NPIs). Notably, reported cases rose sharply during the large 2024 outbreak, with more than 470,000 cases reported in China [8].

Concomitant with this resurgence, the age distribution of pertussis cases in China has substantially shifted [10]. Since 2017, the proportion of cases among adolescents and adults has increased markedly, resulting in a bimodal age distribution characterized by peaks in both infants and older age groups. This pattern suggests that, in addition to infants, older individuals may play an increasingly important role in sustaining transmission. Notably, this epidemiological trend intensified in 2024, when both China and multiple regions worldwide experienced large-scale pertussis outbreaks. Despite consistently high vaccination coverage exceeding 99% [3], severe disease remains concentrated among young infants who have not completed the vaccination schedule [6], while most cases in other age groups are mild and recover with appropriate treatment.

The observed resurgence and age shift of pertussis have been widely attributed to waning vaccine-induced immunity, pathogen adaptation, and improved surveillance and diagnostic capacities. Among these factors, the durability of vaccine-induced immunity is considered a key driver of changes in transmission dynamics [7,11,12]. In China, the pertussis vaccination strategy has evolved from DTwP (Diphtheria, Tetanus, and Whole-Cell Pertussis Vaccine) to DTaP (Diphtheria, Tetanus Toxoids, and Acellular Pertussis Vaccine), with progressive optimization of the immunization schedule. The incorporation of DTwP into the national immunization program in 1978, with a 4-dose schedule, led to a substantial decline in the disease incidence. The subsequent replacement with DTaP between 2007 and 2013 improved vaccine safety and acceptability but has been associated with more rapid waning of immunity [12,13], potentially contributing to increased susceptibility in older age groups [14].

To address these challenges, China further optimized its pertussis immunization schedule in 2025 by advancing the first DTaP dose to 2 months of age and introducing an additional booster dose at 6 years, resulting in a 5-dose regimen (2, 4, and 6 months; 18 months; and 6 years) [15]. This adjustment is intended to enhance early life protection and mitigate the role of school-age children in transmission. However, the population-level impact of this updated strategy, particularly its effects on age-specific transmission dynamics, remains unclear. Age-structured mathematical models, particularly the Vaccinated-Susceptible-Exposed-Infectious-Recovered (VSEIR) framework, have been widely applied to characterize pertussis transmission dynamics and evaluate vaccination strategies, with consistent evidence that waning immunity in older age groups sustains transmission toward vulnerable infants [16-20].

Building on this evidence, the present study pursued 3 specific objectives. First, we aimed to characterize the phase-dependent evolution of age-specific pertussis transmission dynamics in Hunan Province over the period 2010-2025 using a 5-phase segmented VSEIR modeling framework with next-generation matrix (NGM) analysis. Second, we sought to quantify the shifting contributions of different age groups, particularly older children, adolescents, and adults, to sustained pertussis transmission under progressively waning vaccine-induced immunity. Third, we evaluated the potential population-level impact of China's 2025 immunization schedule revision, with a focus on the newly introduced booster dose at the age of 6 years, across a range of coverage scenarios and time horizons.

XSL•FO
RenderX

Together, these analyses provide a quantitative basis for optimizing age-targeted pertussis vaccination strategies and informing future immunization policy in China.

## Methods

### Data Sources

This study used publicly available surveillance data from the Chinese Disease Surveillance System. No individual-level personal data were collected or used, and no human subjects were directly involved in this research. Therefore, ethical approval and informed consent were not required. All analyses were conducted in accordance with the Declaration of Helsinki.

Hunan Province, located in central China, was selected as the study area owing to its large demographically representative population, well-established infectious disease surveillance system, and high compliance with national immunization policies. Individual-level pertussis case records reported between January 2010 and December 2025 were obtained from the Hunan Provincial Center for Disease Control and Prevention. Each record included the date of illness onset and the patient's age at diagnosis.

Age was recorded in months for children under 1 year of age and in years for individuals aged 1 year and older. Cases were aggregated into 6 age groups based on immunization schedule relevance and epidemiological characteristics: 0-6 months, 6 months-2 years, 2-6 years, 6-10 years, 10-20 years, and ≥20 years. These age boundaries were chosen to align with the Chinese national immunization schedule: 0-6 months corresponds to the window before completion of the primary DTaP series (doses at 2, 4, and 6 months); 6 months-2 years spans the period from completion of the primary series through the 18-month booster dose; 2-6 years represents the preschool period; 6-10 years isolates the cohort eligible for the booster dose introduced at the age of 6 years in 2025; 10-20 years covers adolescence; and ≥20 years represents adults. This definition ensures that each age group corresponds to a distinct vaccination status, enabling the model to directly capture the epidemiological impact of changes in the immunization schedule.

The 2025 immunization schedule revision encompassed 2 modifications: advancing the primary series from 3, 4, and 5 months to 2, 4, and 6 months of age, and introducing an additional booster dose at 6 years of age. This study focused exclusively on evaluating the epidemiological impact of the booster dose at 6 years of age, which targets an age group of increasing importance in sustaining pertussis transmission.

### Descriptive Analysis

Temporal trends in monthly reported cases and age-specific incidence rates were examined across the study period. Age-specific incidence rates were calculated using population structures derived from China's national population censuses conducted at 5-year intervals. For each census year, age-specific population counts reported at 5-year age bands were used to construct a reference population structure, with uniform distribution assumed within each 5-year interval. Annual provincial population totals were obtained from the Hunan Provincial Statistical Yearbook, and age-specific population denominators were estimated by applying the census-derived proportional age structure to the corresponding annual total population figures. Intercensal years were handled by applying the population structure from the most recent preceding census.

To characterize the seasonal distribution of pertussis incidence, calendar months were classified into 4 meteorological seasons: spring (March-May), summer (June-August), autumn (September-November), and winter (December-February). For each season, cases were aggregated across all observation years, and the annual mean monthly incidence was estimated by dividing the cumulative case count by the corresponding number of observation years. Age-specific seasonal patterns were subsequently examined by computing the annual mean case count stratified by age group, season, and epidemic phase, with phase-specific denominators applied to account for the varying duration of each phase.

The study period (January 2010-December 2025) was divided into 5 phases based on key epidemiological transitions and national policy events. Phase 1 (2010-2017) corresponds to a prolonged period of relatively low pertussis incidence following the introduction of DTaP vaccination. Phase 2 (2018-2019) marks the onset of a marked resurgence, coinciding with the increased application of polymerase chain reaction (PCR) and serological PT-IgG antibody testing for laboratory confirmation [21]. Phase 3 (2020-2023) covers the COVID-19 pandemic period, during which NPIs substantially suppressed pertussis transmission [22]. Phase 4 (2024) captures the post-NPI relaxation period characterized by a historic outbreak peak, and phase 5 (2025) reflects the implementation of the revised national immunization schedule that introduced a 6-year booster dose.

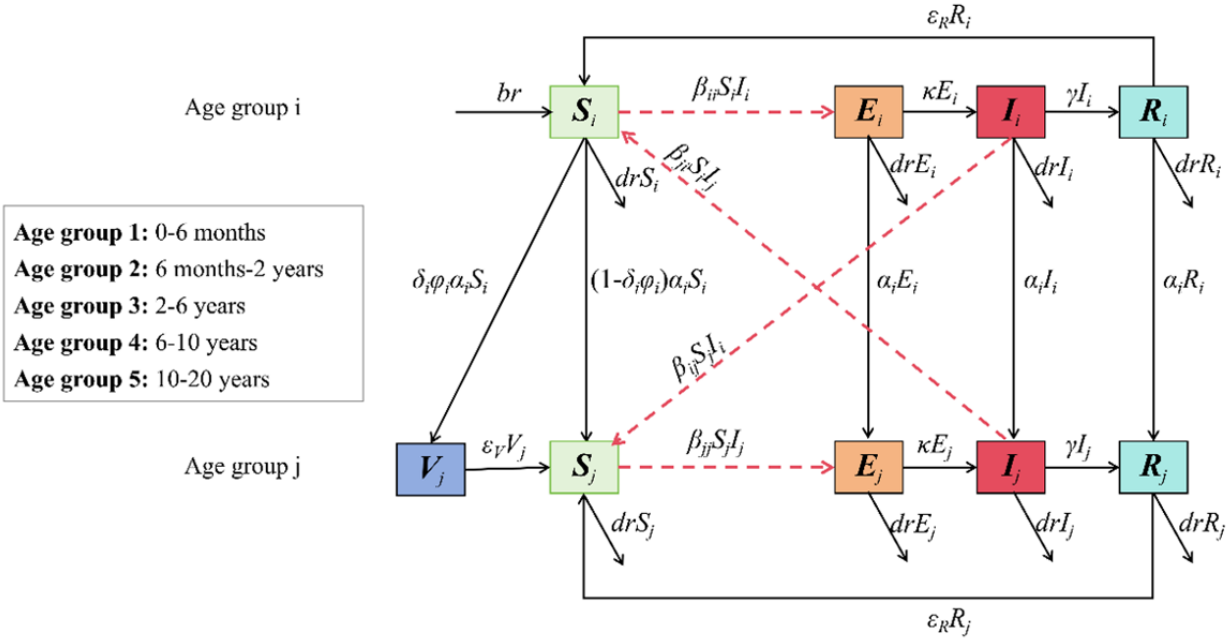
Throughout the study period, pertussis was reported through the standardized National Notifiable Infectious Disease Reporting System. The diagnostic criteria followed the national standard WS 274, with the 2019 revision (WS 274-2019) adding PCR-based confirmation alongside clinical and serological criteria. These criteria were applied uniformly across all age groups and throughout the study period in Hunan Province, with no province-specific protocol changes that would introduce discrete discontinuities at the phase boundaries.

To objectively validate the phase definitions, we conducted change point detection analyses using 3 established algorithms, Pruned Exact Linear Time, cumulative sum, and Bayesian information criterion, applied independently to monthly case counts for each of the 6 age groups. Full results are presented in Figure S1A-E and Table S1 in Multimedia Appendix 1.

To assess whether sex-specific stratification would inform the transmission model, sex-stratified descriptive analyses of case counts, incidence rates, and age at onset, together with formal tests for sex differences, were performed as exploratory analyses (Figure S2A-D and Table S2 in Multimedia Appendix 1).

### Model Structure

An age-structured VSEIR compartmental model was developed to characterize pertussis transmission dynamics. The population was stratified into 6 age groups aligned with the national immunization schedule: 0-6 months (group 1), 6 months-2 years



XSL•FO
RenderX

(group 2), 2-6 years (group 3), 6-10 years (group 4), 10-20 years (group 5), and ≥20 years (group 6). Within each age group, individuals were classified into 5 mutually exclusive epidemiological compartments: susceptible (S), vaccinated with waning immunity (V), exposed (E), infectious (I), and recovered (R).

The model incorporates age-specific demographic processes, including live births entering group 1, natural mortality, and aging transitions between adjacent groups at constant rates. Disease-induced mortality was not modeled given the negligible case fatality rate of pertussis. Population closure was assumed, with no migration (Figure 1).

**Figure 1.** Structure of the age-structured VSEIR transmission model for pertussis. The population in each age group (i,j) is divided into 5 compartments: susceptible (S), vaccinated but not fully protected (V), exposed (E), infectious (I), and recovered (R). VSEIR: Vaccinated-Susceptible-Exposed-Infectious-Recovered.

1. Force of infection: Transmission follows a frequency-dependent mechanism. The force of infection on age group i is:

Where $\beta_{ij}$ represents the transmission rate from age group *j* to age group *i*, $I_j(t)$ denotes the number of infectious individuals in group *j*, and $N_j(t)$ is the total population in group j. The term $f_{season}(t)$ captures seasonal variation in transmission.

2. Latent and infectious periods: Exposed individuals are noninfectious and transition to the infectious compartment at rate $\kappa$ (mean latent period $1/\kappa$). Infectious individuals recover at rate $\gamma$ (mean infectious period $1/\gamma$).

3. Waning immunity: Postinfection immunity wanes at rate $\varepsilon_R$, vaccine-derived immunity wanes at rate $\varepsilon_V$, returning individuals to the susceptible compartment. This reflects the incomplete and temporary nature of pertussis immunity.

4. Vaccination: Vaccination is modeled from group 2 onward. Age-specific vaccination coverage ($\phi_i$) and vaccine efficacy ($\delta_i$) jointly determine the proportion of individuals entering the vaccinated compartment upon aging into each group. Coverage for the 6-year booster, administered upon entry into group 4 (6-10 years), is the primary parameter modified in scenario analyses.

5. Reporting: An age-group-specific reporting rate $\rho_i$ links model output to surveillance data. Reported incidence is defined as:

6. Phase-specific parameters: The study period is partitioned into 5 fitting phases, within which transmission parameters are assumed constant and estimated independently.

The complete differential equation system for each age group is presented below. For group 1 (0-6 months):

For group 2 (6 months-2 years):

XSL•FO
RenderX

For groups 3-5 ($i$=3,4,5), the transition equations follow an analogous structure:

For group 6 (≥20 years), the aging-out term is omitted:

Natural history parameters ($\kappa$, $\gamma$, $\varepsilon_R$, $\varepsilon_V$) were informed by published literature, and demographic parameters including age-specific mortality and aging rates were derived from national census data. All fixed parameters and their sources are summarized in Table 1.

**Table 1.** VSEIR[a] model parameters.

| Parameter | Description | Unit | Value | Source |
|---|---|---|---|---|
| $\beta_{ij}$ | Transmission rate | person$^{-1}$*month$^{-1}$ | —[b] | Fitting |
| $f_{season}$ | Seasonal modulation factor | 1 | — | Fitting |
| $N$ | Population size (age group i) | 1 | Summed | Statistical Yearbook [23] |
| $br$ | Number of newborns | month$^{-1}$ | Summed | Statistical Yearbook [23] |
| $\mu_i$ | Natural mortality rate | month$^{-1}$ | Summed | Statistical Yearbook [23] |
| $\rho_i$ | Case reporting rate | 1 | — | Fitting |
| $\alpha_i$ | Aging rate (transition between age groups) | month$^{-1}$ | 1/6, 1/18, 1/48, 1/60 | Reported data |
| $\kappa$ | Progression rate from exposed to infectious | month$^{-1}$ | 3 | US Centers for Disease Control and Prevention [24] |
| $\gamma$ | Recovery rate (inverse of infectious period) | month$^{-1}$ | 30/35 | Finger and von Koenig [25] |
| $\delta$ | Projected intervention effectiveness | 1 | 0.95, 0.90, 0.85 | Decker and Edwards, Wilkinson et al, Zhu et al, Gambhir et al, Chit et al, Zhang et al [5,26-29] |
| $\phi_i$ | Projected vaccination coverage rate | 1 | 0.99, 0.73 | Zhu et al, Zhang et al [27,30] |
| $\varepsilon_V$ | Vaccine-induced immunity waning rate | month$^{-1}$ | 1/60 | Chen and He [11] |
| $\varepsilon_R$ | Natural immunity waning rate | month$^{-1}$ | 1/120 | Wendelboe et al [31] |

## Model Fitting

Model parameters were estimated independently within each of 5 consecutive fitting phases (January 2010-December 2025) using a bounded nonlinear least-squares algorithm. Within each phase, the estimated parameter vector comprised a 6 × 6 age-structured transmission rate matrix $B$= [$\beta_{ij}$] and age-group-specific reporting rates $\rho$= ($\rho_1$, $\rho_2$, $\rho_3$, $\rho_4$, $\rho_5$, $\rho_6$). The objective function minimized weighted squared residuals between model-predicted and observed monthly incidence across all 6 age groups simultaneously, with observation weights defined as a monotone function of phase-mean incidence to down-weight groups with extreme case counts.

Reporting rates were regularized through 2 penalty components. A Beta-distribution prior was applied to constrain reporting rate estimates toward biologically plausible values. For phases 2-5, an additional smoothing penalty was imposed to prevent abrupt discontinuities between adjacent phases, while preserving flexibility to capture genuine shifts in surveillance sensitivity. The seasonal forcing amplitude was specified independently for each phase.

XSL•FO
RenderX

Model fitting was implemented sequentially across phases. For phase 1, initial compartment sizes were constructed heuristically from observed incidence at the start of the study period and age-specific vaccination coverage assumptions. For phases 2-5, the terminal compartment state of the preceding fitted phase was carried forward as the initial condition for the subsequent phase, ensuring demographic and immunological continuity across phase boundaries. The ordinary differential equation system was solved numerically using the RK45 algorithm with strict convergence tolerances, and state variables were constrained to nonnegative values throughout integration. Model fit was evaluated using the coefficient of determination ($R^2$) computed separately for each age group. For projection analyses, transmission parameters, reporting rates, and the terminal compartment state estimated from phase 5 were carried forward to simulate pertussis dynamics from January 2026 onward.

### Estimation of the Effective Reproduction Number

The effective reproduction number Reff was estimated for each fitting phase using an NGM framework adapted to incorporate age-specific susceptibility [32]. For phase k, the age-structured NGM $K^{(k)}$ was constructed as:

Where  is the transmission rate from age group j to i in phase k,  denote the susceptible population and total population of age group i, respectively. $D_{INF}$ represents the mean infectious period. The effective reproduction number for phase k is calculated as the spectral radius of the matrix $K^{(k)}$:

This formulation explicitly incorporates both age-specific transmission heterogeneity (through $\beta_{ij}$), and time-varying susceptibility structure (through ), ensuring mathematical consistency between matrix-level visualization and overall epidemic potential.

### Sensitivity Analysis

Sensitivity analyses were conducted to evaluate the robustness of transmission estimates and vaccine impact projections to uncertainty in case ascertainment and immunity-related parameters.

To assess parameter identifiability and the robustness of projections, we performed a parametric bootstrap for phases 4 and 5. Synthetic monthly case counts were generated from the fitted phase-specific incidence curves (negative binomial), and the full estimation procedure was repeated under the original constraints for 30 replicates. The replicate parameter sets were used to derive bootstrap 95% CIs for the effective reproduction number, aggregate transmission measures, and projected outcomes (Tables S2 and S3 in Multimedia Appendix 1).

To examine the influence of age-dependent underreporting on inferred transmission dynamics, the phase 4 NGM was recalculated under 4 alternative ascertainment scenarios. Because pertussis cases in older individuals are more likely to present with mild or atypical symptoms and therefore remain undetected, age-specific reporting rates were progressively reduced across older age groups relative to the fitted baseline values. The baseline scenario assumed no additional adjustment, whereas the remaining scenarios imposed increasingly stronger reporting gradients, with adult multipliers decreasing to 0.25, 0.12, and 0.08, respectively. For each scenario, the effective reproduction number and major age-specific transmission pathways were re-estimated and compared.

Sensitivity analyses for vaccine impact projections were performed using a full-factorial design across 3 key parameters, including vaccine-derived immunity duration of 3, 5, and 10 years, natural immunity duration of 5, 10, and 20 years, and 6-year booster vaccine efficacy of 71%, 85%, and 95%. All parameter combinations were evaluated under 6 booster coverage scenarios ranging from 0% to 100%, resulting in 162 independent simulation runs. Projected intervention effectiveness was defined as the proportional reduction in cumulative reported cases over a 10-year projection period relative to the 0-coverage baseline. Uncertainty bounds for each coverage scenario were derived from the full range of simulated outcomes across all parameter combinations.

### Vaccine Impact Projection

To evaluate the potential epidemiological impact of the 6-year booster dose introduced under the 2025 immunization schedule revision, projection analyses were conducted from January 2026 onward using parameters estimated from the final fitting phase. The baseline scenario assumed 0 booster coverage, representing the counterfactual in which the additional dose is not implemented. Five intervention scenarios were defined with booster coverage levels of 30%, 50%, 70%, 80%, 85%, 90%, 95%, 99%, and 100% applied to the 6-year-old cohort entering group 4, with all other model parameters held constant. The 100% coverage scenario represents a theoretical upper bound included to characterize the maximum achievable impact under ideal conditions.

For each scenario, projected intervention effectiveness was quantified as the proportional reduction in cumulative projected reported cases relative to the baseline, calculated both overall and separately for each age group. Short-term (3-year) and long-term (10-year) effectiveness estimates were derived to characterize the temporal dynamics of impact. Monthly peak case reduction was additionally calculated as the proportional difference in maximum monthly projected incidence between the 0% and 100% coverage scenarios within each age group.

### Statistical Analysis and Visualization

Percentages for projected scenarios represent relative reductions in the cumulative number of reported cases, computed for each parameter combination as (N0% – Nscenario)/N0%, where N0% is the projected cumulative case count under 0% booster coverage. Values reported for the sensitivity analysis are means across the specified parameter combinations, with the range across combinations given in parentheses. Descriptive analyses and data visualization were performed in R (version 4.5.1). Model simulations and projection analyses were implemented in Python (version 3.12.4).

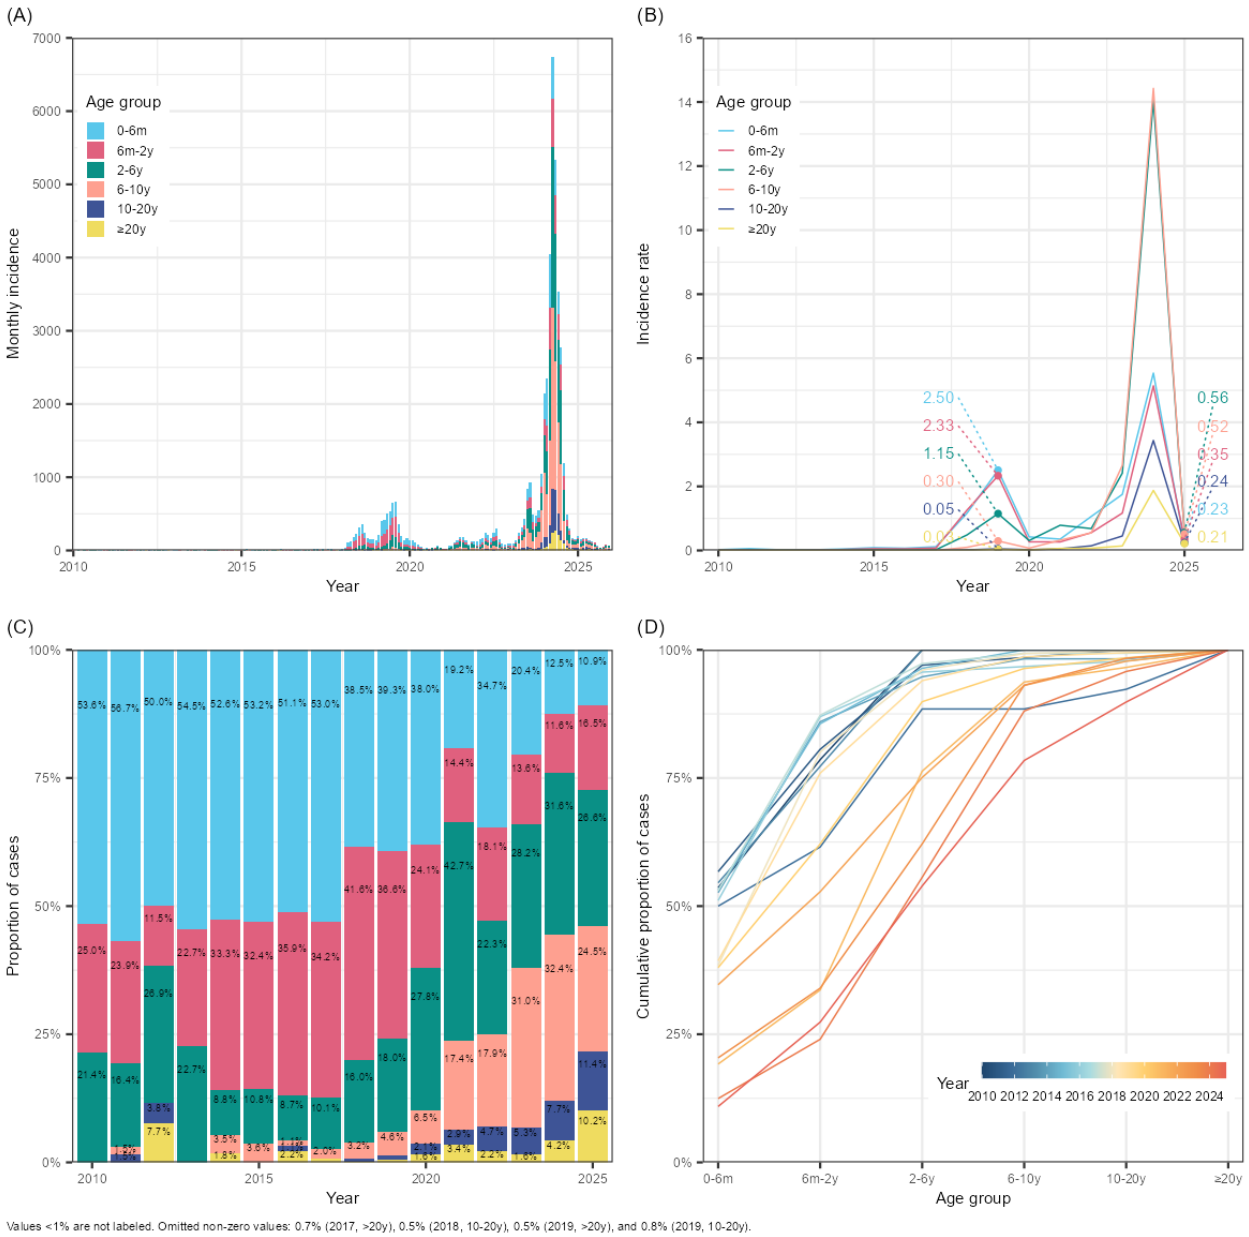
XSL•FO
RenderX

### Ethical Considerations

The data were obtained from the Chinese Information System for Disease Control and Prevention, within the Hunan Provincial Center for Disease Control and Prevention's (Hunan Provincial Academy of Preventive Medicine) surveillance project on key acute respiratory infectious diseases, which is one of the funding sources of this work. The source data in the national surveillance system contain personal identifiers; an exemption from ethics review was therefore not applicable under Chinese regulations, and formal ethics review was mandatory. Because personal identifiers were removed from the extracted records during the analysis phase and only de-identified records were analyzed, and because the study involved no direct patient involvement, medical intervention, or biological samples, the Ethics Review Committee of the Hunan Provincial Center for Disease Control and Prevention exempted the authors from obtaining informed consent. The study was reviewed retrospectively, after the data had already been collected, and was approved by the committee (approval 湘疾控IRD-2025-013-01; October 20, 2025). All results are reported as aggregated, population-level counts; no individual-level or identifiable data are presented in the manuscript or in any publicly available material.

## Results

### Overall Temporal Trend



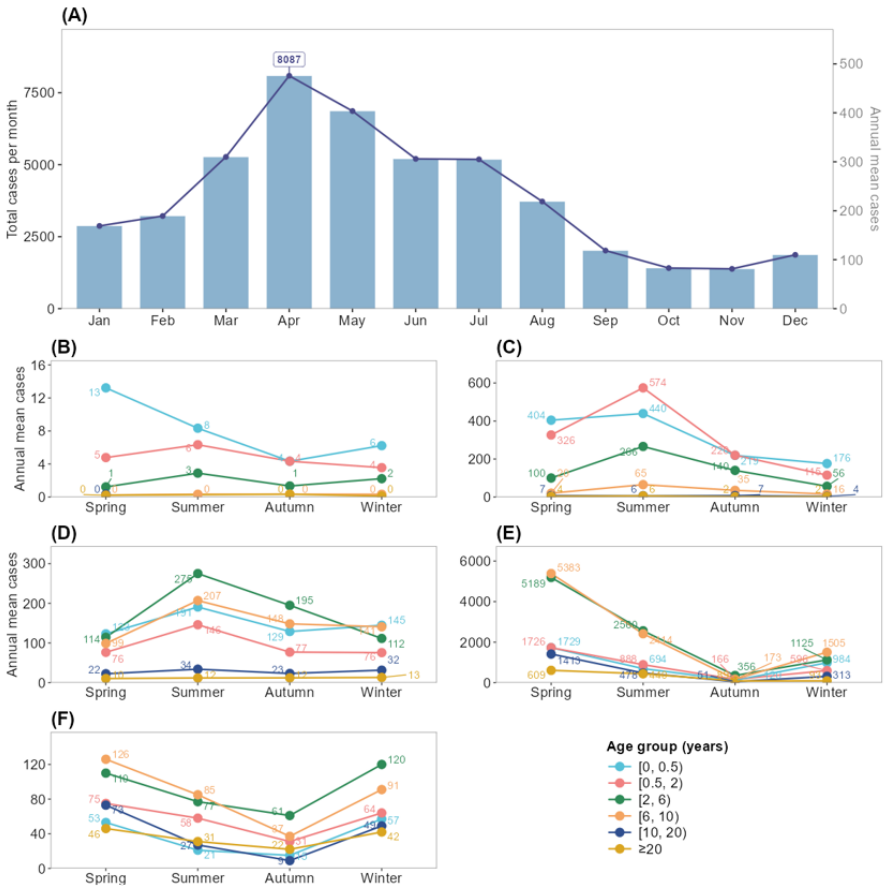
Between 2010 and 2025, a total of 47,300 pertussis cases were reported in Hunan Province. Age-specific case distributions included: 0-6 months (n=8994), 6 months-2 years (n=7747), 2-6 years (n=13,576), 6-10 years (n=12,477), 10-20 years (n=2909), and ≥20 years (n=1597). Monthly reported cases and age-specific incidence rates (Figure 2A and B) revealed distinct temporal patterns. During 2010-2017, monthly reported cases were maintained between 0 and 30, with an age-specific incidence rate of 2.18 per 100,000 in 2017. A minor resurgence occurred in 2018-2019, with peak monthly cases reaching 271. During 2020-2022, monthly cases remained below 92. From 2023 onward, cases increased synchronously across all age groups, reaching the study-period peak in April 2024, with 6743 total monthly cases (age-group specific: 578, 647, 2197, 2472, 606, and 243, respectively). By late 2025, monthly reported cases had fallen below 56.

Age composition of cases demonstrated marked temporal variation (Figure 2C and D). During 2010-2017, cases predominantly concentrated in the 0-6 months age group (293/552, 53.07%), followed by 6 months-2 years (170/552, 30.79%) and 2-6 years (69/552, 12.50%), with other age groups each accounting for <2.00%. In 2018-2019, the proportion of 0-6-month cases decreased to 39.05% (2526/6469), while proportions of 6 months-2 years and 2-6 years groups increased to 38.21% (2472/6469) and 17.39% (1125/6469), respectively. During 2020-2023, the 0-6 months proportion further declined to 24.63% (2387/9690), whereas 2-6 years and 6-10 years groups increased to 28.73% (2784/9690) and 24.57% (2381/9690), respectively. In 2024-2025, younger age groups showed markedly reduced case proportions: 0-6 months (3788/30,589, 12.38%), 6 months-2 years (3604/30,589, 11.78%); while proportions in 2-6 years (9598/30,589, 31.38%), 6-10 years (9814/30,589, 32.08%), 10-20 years (2413/30,589, 7.89%), and ≥20 years (1372/30,589, 4.49%) increased substantially.

XSL•FO
RenderX

**Figure 2.** Pertussis incidence in Hunan Province, 2010-2025. (A) Cumulative reported cases by age group; (B) annual trend of age-specific incidence rates (annual cases per age group divided by total population in the corresponding year); (C) annual age composition of cases; and (D) cumulative age distribution of reported cases by year (2010-2024).

## Seasonal Distribution



Pertussis incidence in Hunan Province demonstrated a consistent seasonal pattern throughout the study period. The highest monthly case burden was recorded in April (8087 total cases across all years), with spring (March-May) representing the primary epidemic season, followed by a secondary peak in June-July. The lowest incidence occurred in autumn and winter, particularly in October and November (Figure 3A).

This spring-dominant pattern was maintained across all epidemic phases, though the age-group contributions varied markedly. During 2010-2017, the 0-6 months group contributed the highest spring burden (annual mean: 13.2 cases, SD 12.8 cases; Figure 3B). During 2018-2019, the 6 months-2 years group emerged as the dominant contributor in summer (annual mean: 574.5 cases, SD 219.9 cases; Figure 3C). During 2020-2023, summer became the peak season for most age groups, with the 2-6 years group showing the highest summer burden (annual mean: 275.0 cases, SD 287.9 cases; Figure 3D). During 2024, the 2-6 years group recorded the highest summer burden (2560 cases), while the 6-10 years group contributed substantially in spring (5383 cases; Figure 3E). During 2025, the 6-10 years group recorded the highest spring burden (126 cases), while the 2-6 years group contributed substantially in winter (120 cases; Figure 3F). Across all phases, autumn consistently represented the low-transmission season.

XSL•FO
RenderX

**Figure 3.** Seasonal distribution of pertussis cases across age groups in Hunan Province. (A) Total monthly cases and annual mean cases by calendar month. (B) Seasonal variation in annual mean cases by age group during phase 1 (2010-2017). (C) Seasonal variation in annual mean cases by age group during phase 2 (2018-2019). (D) Seasonal variation in annual mean cases by age group during phase 3 (2020-2023). (E) Seasonal variation in annual mean cases by age group during phase 4 (2024). (F) Seasonal variation in annual mean cases by age group during phase 5 (2025). In panels (B-F), seasons are defined as spring (March-May), summer (June-August), autumn (September-November), and winter (December-February).

## Model Performance

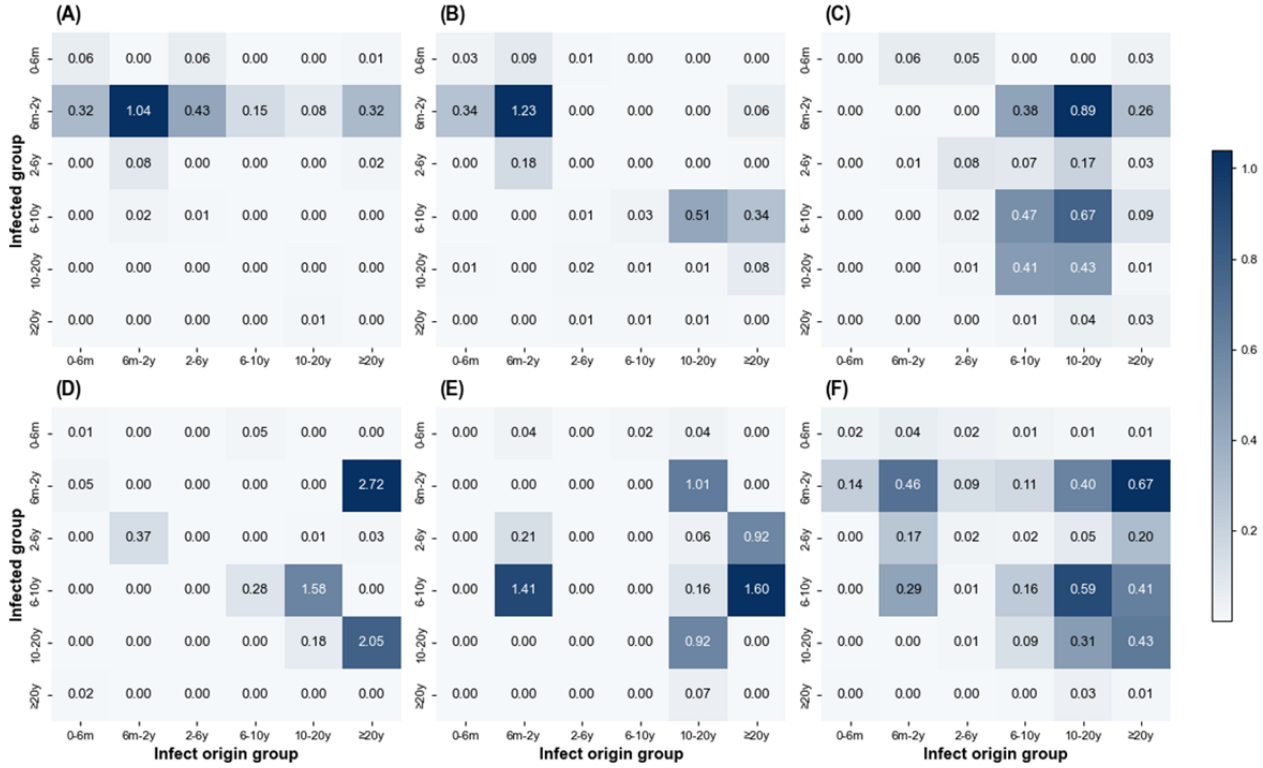
The study period was stratified into 5 temporal phases based on epidemic dynamics: phase 1 (2010-2017), phase 2 (2018-2019), phase 3 (2020-2023), phase 4 (2024), and phase 5 (2025). Segmented fitting analyses were conducted for monthly pertussis cases across age groups within each phase (Figure S3 in Multimedia Appendix 1). Groups 1-6 corresponded to ages 0-6 months, 6 months-2 years, 2-6 years, 6-10 years, 10-20 years, and ≥20 years, respectively. The model demonstrated high fitting consistency across all age groups, with coefficients of determination ($R^2$) of 0.86 (group 1), 0.88 (group 2), 0.95 (group 3), 0.94 (group 4), 0.95 (group 5), and 0.82 (group 6). The overall $R^2$ was 0.96.

Local identifiability diagnostics indicated that individual age-specific transmission coefficients were not fully identifiable in the short phases 4 and 5 (condition numbers of J'J on the order of $10^{13}$-$10^{14}$ and near-0 eigenvalues for 29/42 and 19/42 parameters, respectively; Table S3 in Multimedia Appendix 1). In the parametric bootstrap, aggregate measures were more stable: the effective reproduction number was 1.24 (95% CI 0.92-1.86) in phase 4 and 1.15 (95% CI 0.73-1.40) in phase 5. Propagating the bootstrap parameter sets through the projection model yielded a 10-year reduction in reported cases of 20% (95% CI 11.3%-65.1%) at 70% coverage, with effectiveness increasing monotonically with coverage (Figure S4 and Table S4 in Multimedia Appendix 1).

## Transmissibility Dynamic Analysis

Cross-age-group $R_{eff}$ demonstrated phase-dependent shifts in pertussis transmission patterns. During phase 1 (2010-2017), transmission was concentrated among younger age groups, with the 6 months-2 years group recording the highest within-group $R_{eff}$ (1.039; Figure 4A). In phase 2 (2018-2019), within-group transmissibility in the 6 months-2 years group increased to 1.234, with elevated cross-age transmission from the 10-20 years to 6-10 years group ($R_{eff}$ = 0.510; Figure 4B).

During phase 3 (2020-2023), the highest cross-age $R_{eff}$ shifted to transmission from the 10-20 years to 6 months-2 years group (0.895), followed by 10-20 years to 6-10 years transmission (0.669; Figure 4C). In phase 4 (2024), transmission from the ≥20 years group became predominant, with $R_{eff}$ reaching 2.717 to the 6 months-2 years group and 2.050 to the 10-20 years group (Figure 4D). By phase 5 (2025), a bimodal transmission pattern emerged: the ≥20 years to 6-10 years pathway showed the highest $R_{eff}$ (1.603), while the 6 months-2 years to 6-10 years pathway also increased substantially ($R_{eff}$ = 1.411; Figure 4E). Concurrently, monthly reported cases declined to below 56 by late 2025.



XSL•FO
RenderX

The overall transmission matrix for the full study period (2010-2025) showed that transmission was primarily concentrated among school-age children and older age groups (Figure 4F). The strongest transmission pathways included within-group transmission in the 6 months-2 years group ($R_{eff}$ = 0.463), transmission from 10-20 years to 6-10 years ($R_{eff}$ = 0.593), and transmission from ≥20 years to 6-10 years ($R_{eff}$ =0.412). Cross-age transmission from older age groups to younger children remained consistently evident across the aggregated matrix.

Based on estimated transmission parameters, we projected pertussis incidence over the next decade (2026-2035) under 6 booster vaccination coverage scenarios at the age of 6 years: 0%, 30%, 50%, 70%, 90%, and 100%, assuming vaccine efficacy per dose remains at historical levels.

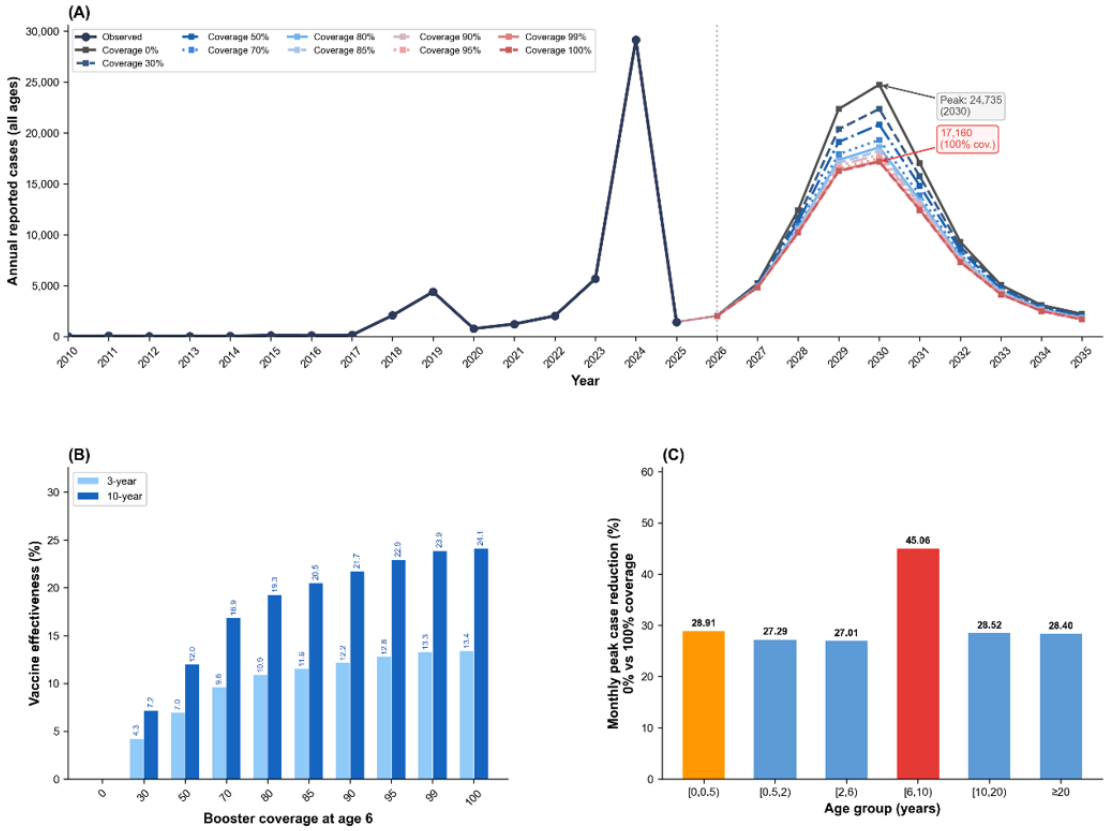
**Figure 4.** Transmissibility across age groups in Hunan Province, 2010-2025. (A) Age-structured NGMnext-generation matrix for phasePhase 1 (2010-2017); (B) phasePhase 2 (2018-2019); (C) phasePhase 3 (2020-2023); (D) phasePhase 4 (2024); (E) phasePhase 5 (2025); and (F) overall matrix for the full study period (2010-2025). In each panel, the horizontal axis represents the age group of infection origin and the vertical axis represents the age group of infected individuals. Each cell value represents the expected number of secondary cases in the recipient age group generated by one infectious individual in the source age group. Color intensity reflects transmission magnitude, with darker shading indicating higher values. The effective reproduction number ("R" _"eff" ) for each phase is given by the spectral radius of the corresponding matrix.

## Simulation of Vaccination Intervention Effectiveness

Monthly case projections (Figure S5 in Multimedia Appendix 1) showed that increasing booster coverage progressively reduced incidence peaks across all age groups. The most pronounced direct effect was observed in the 6-10 years age group, where 100% coverage reduced the projected monthly peak from 744 to 409 cases. Notably, the 0-6 months age group, ineligible for the booster, showed a monthly peak reduction from 591 to 420 cases under 100% coverage, indicating substantial indirect protection.

Annual incidence projections showed a consistent epidemic cycle across all vaccination scenarios, with incidence peaking in 2030 (Figure 5A). Under the no-booster scenario, the projected annual peak reached 24,734 cases. Increasing booster coverage progressively reduced the projected epidemic peak to 22,346, 20,803, 19,306, 18,576, 18,217, 17,861, 17,508, 17,229 and 17,160 cases at coverage levels of 30%, 50%, 70%, 80%, 85%, 90%, 95%, 99%, and 100%, respectively, corresponding to peak reductions of 9.65% (2387.90/24,734.53), 15.89% (3931.43/24,734.53), 21.95% (5428.48/24,734.53), 24.90% (6157.73/24,734.53), 26.35% (6517.24/24,734.53), 27.79% (6873.23/24,734.53), 29.21% (7225.64/24,734.53), 30.34% (7504.94/24,734.53), and 30.62% (7574.39/24,734.53).

Projected intervention effectiveness increased with both booster coverage and follow-up duration (Figure 5B). Over a 3-year horizon, cumulative reported cases were reduced by 4.25% (836.34/19,670.07), 6.98% (1372.89/19,670.07), 9.62% (1893.13/19,670.07), 10.92% (2147.27/19,670.07), 11.55% (2272.87/19,670.07), 12.19%(2397.49/19,670.07), 12.82% (2521.14/19,670.07), 13.32% (2619.37/19,670.07), and 13.44% (2643.84/19,670.07) under coverage levels of 30%, 50%, 70%, 80%, 85%, 90%, 95%, 99%, and 100%, respectively. Over a 10-year horizon, the corresponding reductions increased to 7.20% (7449.55/103,408.95), 12.04% (12,451.80/103,408.95), 16.89% (17,466.73/103,408.95), 19.32% (19,973.50/103,408.95), 20.53% (21,225.61/103,408.95), 21.74% (22,476.40/103,408.95), 22.94%



XSL•FO
RenderX

(23,725.52/103,408.95), 23.91% (24,723.35/103,408.95), and 24.15% (24,972.58/103,408.95). Compared with the no-booster scenario, the projected number of averted cases over 10 years ranged from 7449 at 30% coverage to 24,972 at 100% coverage.

Age-specific analyses demonstrated substantial heterogeneity in intervention effects (Figure 5C). The largest reduction was observed in the vaccinated 6-10 years age group, where monthly peak incidence decreased by 45.06% (335.49/744.51) under the 100% coverage scenario, representing the direct effect of the booster strategy. Indirect protection was also observed in younger children, particularly among infants aged 0-6 months, in whom monthly peak incidence decreased by 28.91% (170.92/591.19). Reductions in monthly peak incidence in the remaining age groups ranged from 27.01% (233.93/865.97) to 28.52% (286.68/1005.08).

**Figure 5.** Annual predicted pertussis incidence and intervention effectiveness under gradient booster coverage. (A) Annual observed cases (2010-2025) and projected cases (2026-2035) under different vaccination coverage scenarios. (B) Effectiveness by vaccination coverage level and time horizon. (C) Age-specific peak reduction under 100% coverage, where red bars indicate the directly targeted age group, and orange and blue bars represent indirect protection, with orange indicating the most pronounced indirect effect. The vertical dashed line separates the observation period from the projection period.

## Sensitivity Analysis

Varying natural immunity duration from 5 to 20 years produced minimal changes in projected effectiveness within the same vaccine immunity scenario. Across the evaluated vaccine efficacy range of 71%-95%, projected effectiveness under 70% coverage ranged from 14.3% (range 8.0%-21.7%) to 19% (range 10.7%-28.4; Figure S6A in Multimedia Appendix 1). In contrast, under the 70% coverage scenario, the projected 10-year reduction in cumulative cases increased from approximately 9.5% (range 8.0%-11.1%) to 25% (range 21.1%-28.4%) as vaccine-derived immunity duration increased from 3 to 10 years (Figure S6B in Multimedia Appendix 1). Age-specific analyses showed the largest reduction in the 6-10 years age group, with a mean reduction of 26.5% (range 15.9%-39.4%), while the 0-6 months age group showed a reduction of 16.3% (range 7.2%-28.4%; Figure S6C in Multimedia Appendix 1). Sensitivity analyses showed that projected intervention effectiveness was most sensitive to assumptions regarding vaccine-derived immunity duration (Figure S6D in Multimedia Appendix 1).

To quantify the uncertainty of the projected outcomes, the parameter sets obtained from the parametric bootstrap were propagated through the projection model. The projected monthly reported cases under the 70% booster coverage scenario and the current 18-month booster coverage are shown in Figure S4A in Multimedia Appendix 1 with the bootstrap median and the corresponding 95% CI. The projected cumulative reductions in reported cases over 3-year and 10-year horizons increased monotonically with booster coverage, with the medians and 95% CIs summarized in Figure S4B and Table S4 in Multimedia Appendix 1. Specifically, the median 10-year reduction was 20% (IQR 15.5%-34.5%; 95% CI 11.3%-65.1%) at 70% coverage and 27.8% (IQR 22.3%-45.9%; 95% CI 15.8%-74.1%) at 100% coverage.

## Discussion

### Principal Findings

Based on surveillance data from Hunan Province between 2010 and 2025, this study identified clear phase-dependent changes in pertussis epidemiology, including temporal trends, seasonal patterns, age distribution, and transmission dynamics. The epidemic trajectory was characterized by a prolonged low-incidence period (2010-2017), a moderate increase (2018-2019), a decline during the COVID-19 period (2020-2022), and a marked resurgence in 2023-2024, followed by a decline in 2025. This pattern is consistent with recent global observations [33].

During the COVID-19 pandemic, NPIs such as social distancing, mask use, and school closures substantially reduced opportunities for the transmission of respiratory pathogens, leading to a marked decline in reported pertussis cases in many countries [22,34,35]. With the gradual relaxation of these measures, population contact rates rebounded, while reduced natural infection during the pandemic period led to the accumulation of susceptible individuals. Consequently, pertussis incidence increased significantly after 2023. This phenomenon has been described as the "immunity debt" effect [36], whereby reduced pathogen exposure in a low-transmission environment results in diminished population-level immunity, facilitating epidemic rebound after the lifting of control measures. Nationwide, approximately 0.48 million pertussis cases were reported in 2024 [33], indicating a large-scale resurgence compared to previous years. In addition, waning vaccine-induced immunity and potential genetic variation of *Bordetella pertussis* may have further contributed to the observed increase in incidence [28].

It is also possible that part of the sharp increase in reported incidence, from 0.75 per 100,000 in 2017 to 33.37 per 100,000 in 2024, reflects improvements in surveillance and diagnostic capacity rather than a true rise in transmission. In 2019, the national diagnostic criteria (WS 274-2019) were revised to formally incorporate PCR-based laboratory confirmation [3,8], and the increasing availability of PCR and serological testing over the study period may have enhanced the detection of mild and atypical cases, particularly among older children and adults. Several considerations nonetheless suggest that the resurgence was largely genuine. Reporting rates were estimated separately for each phase, so that gradual shifts in surveillance sensitivity would be absorbed into the reporting-rate parameters rather than into the estimated transmission rates, and the phase boundaries were independently supported by a data-driven change-point analysis. In addition, the 2024 surge coincided with a large-scale pertussis resurgence observed in many countries during 2023-2024, and the shift in the age distribution of cases remained robust under alternative ascertainment assumptions in our sensitivity analyses [19,37]. The absolute magnitude of the increase should therefore be interpreted with caution; its timing, direction, and accompanying age shift nevertheless appear to reflect genuine changes in pertussis epidemiology.

Our findings demonstrated a stable and consistent seasonal pattern throughout the study period, with peak incidence during spring and a secondary peak in summer, and lowest transmission during autumn. This seasonal signature persisted despite substantial changes in overall incidence magnitude and age distribution, suggesting that climatic and behavioral factors exert a consistent influence on pertussis transmission dynamics in Hunan Province. Similar seasonal patterns have been reported in multiple regions [38]. Increased indoor crowding during colder months and elevated contact rates associated with school terms may create favorable conditions for transmission [39,40].

Age-specific analysis revealed a substantial shift in case distribution over time. In the early study period (2010-2017), cases were predominantly concentrated among infants and young children [41], with the 0-6 months group accounting for 53.07% of cases. However, the proportion of cases among school-age children and adolescents has progressively increased over time. This trend is consistent with observations from other countries [42]. Infants remain the most vulnerable population because of their immature immune systems and incomplete vaccination status. The increasing proportion of cases among older children and adolescents may be attributable to the more rapid waning of immunity induced by acellular pertussis vaccines, as well as pathogen evolution affecting vaccine-induced protection. The accumulation of susceptible individuals during the COVID-19 pandemic may have further amplified these trends [10].

Our results demonstrate clear temporal shifts in the age-specific transmission dynamics. During the early phase (2010-2017), transmission was primarily concentrated within younger age groups, with infants and preschool children forming the core transmission networks. In the subsequent period (2018-2019), transmission within younger age groups further intensified, while transmission involving school-age children began to increase, indicating an expansion of the transmission network across broader age strata. During the COVID-19 period (2020-2023), transmission among younger age groups declined markedly, whereas relative transmission among older age groups increased. This shift is likely attributable to changes in contact patterns induced by NPIs [43]. Following the relaxation of these measures, a substantial resurgence occurred in 2024 [44], during which the relative contribution of older age groups increased significantly. Notably, transmission pathways from adults to children exhibited a high estimated transmission potential [45], though these estimates should be interpreted with caution given that adult cases are systematically underascertained; sensitivity analyses incorporating age-graded detection corrections suggested that the absolute magnitude of adult transmission contributions may be attenuated under higher underreporting assumptions, while the directional shift toward older age groups remained consistent across scenarios.

By 2025, the transmission structure evolved further, with adults and infants emerging as 2 key nodes in the transmission network, and cross-age transmission played a more prominent role in sustaining the epidemic spread. This is consistent with the well-documented role of household transmission, in which parents and older siblings are frequently the source of infection for unprotected infants [5,46-49]. Because immunity induced by acellular vaccines wanes within a few years, many adults and adolescents experience mild or atypical infection that is frequently unrecognized and untreated; they nevertheless shed

XSL•FO
RenderX

*Bordetella pertussis* and can transmit to susceptible household contacts [50]. In addition, school-age children, owing to their high contact rates in school settings, may act as "bridges" connecting different age groups, thereby facilitating sustained community transmission [48,51]. The rebound of social contact after the relaxation of NPIs in 2024, together with the accumulation of susceptible adolescents and adults during the pandemic, plausibly amplified these cross-age pathways and contributed to the age-shift observed in the present study.

Notably, the ≥20 years group contributed only 1597 (3.4%) of the 47,300 reported cases over the study period, ranking lowest among all age groups; given its considerably larger population size, its reported incidence was correspondingly low. This sparsity largely reflects underascertainment rather than a true absence of transmission: adults are less likely to seek medical care, undergo diagnostic testing, or be captured by surveillance when presenting with mild disease. The sparse and 0-inflated reporting in this group therefore cannot represent its true transmission potential, and further subdivision into adult and older adult subgroups would yield case series dominated by 0 counts that cannot support reliable estimation. The ≥20 years group was accordingly retained as a single category, and estimates involving this group should be interpreted with caution; nevertheless, the direction of the age shift—increasing transmission from older age groups—remains robust.

Although a DTaP booster at the age of 6 years has only recently been introduced in China, immunogenicity studies in 6-year-old Chinese children have demonstrated robust serological responses following an additional DTaP dose, with seroconversion rates exceeding 80% for key pertussis antigens [52]. Furthermore, the well-documented waning of protection following the fifth DTaP dose [53], combined with the disproportionate burden of pertussis among school-age children in China [54], provides a strong epidemiological rationale for targeting this age group with a booster dose. The simulation results support the epidemiological rationale for a booster dose at the age of 6 years as a strategic intervention to disrupt cross-age transmission. At 100% coverage, the 6-10 years group showed the greatest monthly peak reduction (45.06%), while vaccine-ineligible infants also benefited through indirect protection (28.91% peak reduction). This pattern of herd protection is particularly important given that infants below 6 months carry the highest risk of severe pertussis and are too young to complete primary vaccination [55]. The surveillance dataset used in this study contains aggregated, age-stratified case counts without clinical severity indicators, so temporal trends in infant disease severity cannot be quantified directly from these data. Nevertheless, severe and fatal pertussis has remained rare and concentrated among unvaccinated or incompletely vaccinated young infants since the nationwide introduction of routine pertussis vaccination in 1978, and the DTwP-to-DTaP transition did not alter this pattern. Most cases in older age groups are mild and recover with appropriate treatment [56]. Marginal effectiveness analysis indicated that achieving and sustaining coverage at or above 70% should be the priority public health target, as this threshold captures the majority of achievable benefit. The temporal dynamics of effectiveness further demonstrate that the value of the booster strategy is realized progressively over time. Nevertheless, even at 100% coverage, the projected 10-year effectiveness of 24.1% indicates that a single-age booster alone cannot fully interrupt transmission [57]. Complementary strategies, such as booster doses of Tdap (Tetanus, Diphtheria, and Acellular Pertussis) vaccine for boosters for adolescents and adults and maternal immunization during pregnancy, warrant integration into future immunization policy frameworks [58-60].

## Limitation

Several limitations should be acknowledged. First, phases 4 and 5 each comprise only 13-15 monthly observations, which limited the identifiability of the individual age-specific transmission coefficients in these phases, as reflected in the flat directions of the fitting objective and the wide bootstrap intervals for individual parameters. Our conclusions therefore rely primarily on aggregate transmission measures, the effective reproduction number, and projected outcomes, for which bootstrap CIs are reported; the qualitative finding that higher booster coverage confers a greater reduction in reported cases remained consistent across the bootstrap replicates. Second, surveillance-based pertussis data are likely affected by age-dependent underreporting, particularly among adolescents and adults who often present with mild or atypical symptoms. Although sensitivity analyses showed that the overall transmission pattern remained stable across different ascertainment assumptions, the absolute magnitude of transmission estimates may still be uncertain. Third, several model parameters, including immunity duration and vaccine efficacy, were derived from published literature rather than directly estimated from local immunological data. Fourth, the projection analyses assumed stable demographic structure and contact patterns over time and did not incorporate behavioral changes, pathogen evolution, or future modifications to vaccination policy. Finally, the study was based on data from a single province and may not fully represent transmission dynamics in other regions of China.

## Conclusions

This study demonstrated a progressive shift in pertussis transmission toward older age groups, with increasing cross-age transmission to younger children and infants. Simulation analyses suggested that introduction of a booster dose at the age of 6 years could reduce overall pertussis incidence and provide indirect protection to infants, although the projected impact of a single school-age booster alone remained moderate. These findings provide quantitative evidence for optimizing age-targeted pertussis vaccination strategies in China.

## Abstract

**Background:** Vaccination in early childhood is essential to prevent serious infectious diseases and protect community health. In the United States, 7 vaccines (diphtheria, tetanus, and acellular pertussis; polio; measles, mumps, and rubella; *Haemophilus influenzae* type b; hepatitis B; varicella; and pneumococcal conjugate) are recommended by the Centers for Disease Control and Prevention for children aged 19-35 months, along with 3 others (hepatitis A, influenza, and rotavirus), which are recommended for full protection. Despite these guidelines, recent measles outbreaks in the United States have drawn attention to persistent gaps in coverage.

**Objective:** This cross-sectional study explores immunization patterns among children aged 19-35 months using provider-verified data from the National Immunization Survey-Child between 2010 and 2023.

**Methods:** Survey-weighted logistic regression models were used to assess associations between vaccination status and social determinants of health, including child age group, maternal education, insurance status, birth order, and region. Separate survey-weighted logistic regression models were fit for each survey year from 2010 to 2023. We considered the complex survey design to calculate vaccination coverage rates and their CIs, accounting for clustering and stratification in the sampling methodology. A composite variable was created to measure full coverage of the 7 recommended vaccines, and within each year, models were estimated separately for each individual vaccine and for the 7-vaccine series composite outcome to identify vaccine-specific barriers to immunization.

**Results:** Provider-verified response rates declined from 70.8% (17004/24013) in 2010 to 47.7% (18412/38619) in 2023, although the analytic sample size remained stable. Coverage for the Combined 7-Vaccine Series increased from 70.8% (11893/16798) in 2010 to 77.4% (13957/18032) in 2023. Older age was consistently associated with higher odds of complete vaccination (2010: odds ratio [OR] 1.10, 95% CI 1.02-1.19; 2023: OR 1.24, 95% CI 1.13-1.35), whereas lack of insurance and Hispanic origin were associated with lower uptake for selected vaccines. In 2022, uninsured children had 26% lower odds of complete vaccination compared with insured children (OR 0.74, 95% CI 0.65-0.84). Higher income-to-poverty ratio was consistently associated with increased vaccination uptake, including influenza vaccination in 2020 (OR 1.25, 95% CI 1.13-1.39). Regional and language-related disparities persisted across survey years.

**Conclusions:** Persistent socioeconomic and structural gradients in childhood vaccination coverage highlight the need for equity-focused immunization strategies that address insurance access, language barriers, and geographic disparities.

# Introduction

## Background

Vaccination programs have transformed child health outcomes by lowering the incidence of vaccine-preventable diseases worldwide. These efforts prevent an estimated 2-3 million deaths annually across all age groups, making childhood immunization one of the most effective public health interventions to date [1]. Despite decades of global investment in vaccination infrastructure, gaps remain in immunization coverage, particularly among marginalized communities and for specific vaccines [2]. In the United States, early childhood vaccinations protect against conditions such as measles, pertussis, and polio. Yet, recent resurgence of measles in the United States, along with suboptimal uptake of influenza and hepatitis A vaccines, underscore persistent disparities. These patterns raise concern about whether emerging infectious threats, vaccine hesitancy, and systemic inequities are eroding past gains in population protection [3]. The persistence of undervaccination calls for a deeper understanding of social and structural barriers to vaccine access and trust [4]. Understanding the factors that limit complete immunization is essential for improving equitable vaccine delivery and maintaining high coverage across the population [5].

## Prior Work

Social determinants of health (SDoH) are increasingly recognized as critical drivers of health outcomes, including vaccine access and uptake [6,7]. These determinants include socioeconomic status, maternal education, employment, household size, geographic location, access to health care, and cultural or language barriers [8-10], among others. Financial constraints and limited-service availability are common barriers for low-income families, particularly those without private insurance or who reside in underserved areas. County-level data from the United States have revealed pronounced geographic disparities in immunization, often related to income and education levels [11]. In such settings, tools like small area estimation have been applied to identify pockets of low coverage and guide outreach strategies [11]. These disparities often intersect with race, ethnicity, and immigration status, further limiting vaccination access in vulnerable populations [12]. Together, these interrelated structural and socioeconomic factors shape access to pediatric services and influence the likelihood of full immunization [13,14].

In parallel, vaccine hesitancy, defined as a delay in acceptance or refusal despite availability, remains a serious threat to public health and can exacerbate inequities [15]. Misinformation, perceived safety concerns, and social influences have been identified as key factors in vaccine decision-making [2]. Hesitancy tends to cluster within populations and regions, making it harder to maintain herd immunity [16,17]. When combined with structural disadvantages, these behavioral factors further widen gaps in immunization coverage.

Recognizing and addressing these social and structural factors is central to reducing health inequities. Research incorporating SDoH into public health analysis has demonstrated that targeted interventions, including Medicaid expansion, community-based care investment, culturally tailored communication strategies, and patient navigation services, can improve vaccine uptake [18,19]. Community-driven models that consider cultural norms, transportation access, and flexible scheduling have shown promise in overcoming barriers to care and should be prioritized in public health planning [20]. Partnerships between public health officials, policymakers, researchers, and local organizations are essential to operationalize solutions that account for the full social context in which health decisions occur [21,22]. Integrating SDoH into immunization research not only informs policy decisions but also helps develop more tailored interventions that are likely to succeed across diverse populations [14,23]. Furthermore, vaccination efforts contribute directly to broader Sustainable Development Goals of the United Nations by reducing disease burden, supporting educational attainment, and enabling economic participation [6].

Although prior research has documented associations between social determinants and childhood vaccination coverage, many studies rely on pooled multiyear data, limited time windows, or focus on single vaccine outcomes. Less is known about the temporal stability of these associations across independent survey cycles, particularly before and after the COVID-19 pandemic, and about whether disparities differ systematically across specific vaccine types. Addressing these gaps is essential for understanding whether observed inequities represent persistent structural patterns or time-specific disruptions.

## Study Objective

This study conducts year-specific survey-weighted analyses of National Immunization Survey-Child (NIS-Child) data from 2010 to 2023 to examine the temporal stability, pandemic-related shifts, and vaccine-specific heterogeneity of associations between social determinants and childhood immunization coverage. Focusing on children aged 19-35 months, we assess how maternal education, insurance status, income-to-poverty ratio, language, and geographic region are associated with individual vaccine uptake and completion of the Combined 7-Vaccine Series. These analyses provide updated evidence on disparities in childhood immunization coverage across prepandemic and postpandemic periods.

# Methods

## Data

This cross-sectional study uses data from the NIS-Child, which is publicly available through the Centers for Disease Control and Prevention (CDC) [24,25]. The NIS-Child is an annual, nationally representative survey conducted by the CDC using a random digit–dial sampling design of landline and cellular telephone numbers. Households with children aged 19-35

XSL•FO
RenderX

months are identified through telephone screening interviews. With parental consent, vaccination providers are contacted by mail to obtain official immunization records. Final survey weights adjust for sampling probability, nonresponse, and poststratification to US population benchmarks. The survey produces reliable, population-based estimates at the national, state, and selected local levels using a consistent sampling and verification process. The survey is administered by the University of Chicago under the direction of the CDC [26]. This study used all available NIS-Child data meeting inclusion criteria from 2010 to 2023. No formal sample size calculation was performed as this was a secondary analysis of existing surveillance data. The final analytic sample included all children aged 19-35 months with provider-verified immunization records across the 13-year study period.

## Variables

To assess childhood immunization trends and disparities, we selected key variables grounded in demographic, socioeconomic, and household contexts. These variables align with SDoHs identified in prior literature as influential factors in vaccine uptake. In addition to child characteristics like age group, sex, and birth order, we considered household and maternal variables, such as maternal education, income-to-poverty ratio, and language of interview, to capture broader influences on immunization behavior.

For every year from 2010 to 2023, we derived new binary coverage variables indicating whether a child received the minimum required doses based on provider-verified data (adequate provider data identifier [PDAT]). These thresholds were based on the CDC's standard immunization schedule. The thresholds recommended by the CDC for children aged 19-35 months are diphtheria, tetanus, and acellular pertussis (DTaP) ≥4 doses, polio ≥3 doses, measles, mumps, and rubella (MMR) ≥1 dose, *Haemophilus influenzae* type b (Hib) ≥3 doses, hepatitis B ≥3 doses, varicella ≥1 dose, and pneumococcal conjugate (PCV) ≥4 doses. These dose thresholds were based on CDC recommendations for children aged 19-35 months and were applied consistently across all survey years (2010-2023) to ensure comparability over time.

The outcome of interest throughout our analysis was whether the child was up to date on individual vaccines. All other variables are listed in Table S1 in Multimedia Appendix 1, which were treated as covariates for understanding patterns in coverage across years. In addition to individual vaccine indicators, we created a composite variable denoted as the Combined 7-Vaccine Series, capturing whether a child was fully vaccinated with all 7 core vaccines (DTaP, polio, MMR, Hib, hepatitis B, varicella, and PCV) as defined by the CDC for national coverage monitoring. Although school entry vaccine requirements vary by state and year, this composite reflects the standardized CDC core series definition rather than uniform state mandates. Additional vaccines (hepatitis A, influenza, and rotavirus) were analyzed separately as individual outcomes. This composite variable served as a unified measure of complete immunization and played a key role in year-over-year comparisons.

Observations were restricted to children with provider-verified immunization records (using PDAT=1 as a filter), consistent with the study eligibility criteria. No additional manual row deletion was performed. Across study years, vaccine coverage variables exhibited no missing values, and most covariates demonstrated <6% missingness. Survey-weighted logistic regression models were estimated using complete-case analysis inherent to the modeling procedure, whereby observations with missing covariate values were excluded automatically at the model estimation stage.

One variable, representing the participation in the Supplemental Nutrition Program for Women, Infants, and Children (WIC) and denoted as CWIC_02, however, exhibited a markedly higher proportion of missing responses, ranging approximately from 50% to 60% across years. This pattern reflects survey flow structure and item-level nonresponse within the NIS-Child rather than data processing decisions. Because WIC participation is captured through multiple related indicators within the survey, including an alternative measure (CWIC_01) with lower missingness and comparable conceptual relevance, sensitivity analyses were conducted to evaluate whether associations were robust to alternative WIC specifications and resulting differences in analytic sample size.

## Survey Design

We incorporated the core survey design variables required to ensure valid, nationally representative estimates across all years of analysis. To maintain data integrity, only records with provider-verified data were included, reflecting the study's eligibility criteria: children aged 19-35 months with completed NIS-Child interviews and verified immunization records from health care providers. Each year's dataset was structured using a consistent survey design framework that aligned with the NIS-Child's complex sampling methodology. The unique child identification was used as the primary sampling unit to account for clustering within the sample, ensuring that variance estimates reflected the survey's multistage sampling design. A stratification variable was used to optimize precision and reduce sampling error in national estimates. Sampling weights for the children were applied to each observation to adjust for unequal probabilities of selection, survey nonresponse, and to align the weighted data with US population totals.

## Bias

Several measures were implemented to minimize potential bias. Provider verification of immunization records reduced recall and reporting bias compared to parental self-report. Survey weights accounted for differential selection probabilities and nonresponse bias. It is important to mention that the restriction to provider-verified data may have introduced selection bias toward children with better health care access.

## Analysis

Statistical analyses were conducted using survey-weighted methods to account for the complex sampling design of NIS-Child. Complete-case analysis was used within each survey-weighted model, excluding records with missing survey weights or covariate values at the estimation stage. Out of all 15 independent variables, the income-to-poverty ratio was the

XSL•FO
RenderX

only variable analyzed as continuous, while the remaining 14 predictors were treated as categorical variables with predefined NIS-Child groupings. No interaction terms were included in the primary models. However, subgroup analyses and sensitivity analyses were conducted to evaluate the robustness of findings with the inclusion of interaction effects. Subgroup analyses examining associations across key demographic strata are presented in Multimedia Appendix 1. To examine annual trends in childhood immunization and assess how they relate to demographic and social factors, we used survey-weighted logistic regression models. Two sets of analyses were conducted. The first focused on the Combined 7-Vaccine Series, which is the binary variable created to reflect whether a child received all 7 core vaccines recommended by the CDC. The second set of models was run for each individual vaccine, allowing us to explore differences in coverage patterns across specific immunizations. We applied the same modeling process across all years from 2010 to 2023. This ensured consistent treatment of variables, uniform survey design application, and systematic evaluation of associations across time. All models used the appropriate sampling weights, clustering, and stratification variables provided by the NIS-Child to produce estimates that represent the US child population.

To evaluate the stability of associations related to WIC participation, 3 model specifications were examined. A base model excluded WIC participation entirely. A second model included CWIC_01, an indicator of WIC participation with lower missingness. The third model included CWIC_02, denoting current participation. Comparing these specifications allowed assessment of whether associations between vaccination coverage and social determinants were sensitive to WIC measurement and resulting analytic sample size differences.

To ensure methodological transparency, categorical predictors were coded using treatment contrasts in R software (version 2024.12.1+563; R Foundation for Statistical Computing), with the first-factor level serving as the reference category. Variables were harmonized across survey years to maintain consistent category definitions and reference groups. The income-to-poverty ratio was modeled as a continuous predictor to preserve information. Although formal spline-based testing of the linearity assumption was not performed, coefficient stability across years did not suggest substantial deviation from linearity on the logit scale. Formal variance inflation factors were not calculated within the survey-weighted framework; however, inspection of coefficient and SE stability indicated no evidence of meaningful multicollinearity. Statistical significance was evaluated at $\alpha$=0.05 without formal adjustment for multiple comparisons, as each year-specific model addressed a substantively distinct survey population and temporal comparison. Interpretation focused on effect sizes, CIs, and consistency of associations across survey years rather than isolated *P* values.

The survey-weighted logistic regression models estimate the likelihood of a child being up to date on recommended vaccines while accounting for the complex sampling design of the NIS-Child. The mathematical formulation of the survey-weighted logistic regression models is provided in Section S1 in Multimedia Appendix 1.

All data processing and statistical analyses were conducted using R statistical programming [27]. The *survey* package was used to implement complex survey design and fit survey-weighted logistic regression models [28]. From this, it is important to note that variance estimation was obtained from using Taylor linearization via the indicated R package. For each survey year, a year-specific survey design object was created, and associations between vaccination coverage and contextual factors (as listed in Table S1 in Multimedia Appendix 1) were examined. This modeling process was conducted separately for each vaccine outcome variable, including the derived Combined 7-Vaccine Series indicator. To visualize trends across years, we used heat maps showing the direction and significance of associations at the 5% significance level, where green indicates statistically significant effects in the positive direction, red indicates statistically significant effects in the negative direction, and gray indicates nonsignificant results. Additional gradient heat maps were generated to display the magnitude and direction of statistically significant log-odds estimates across model specifications. Separate heat maps were also created for each vaccine. Selected figures are included in the main text of this manuscript, and additional figures are present in Multimedia Appendix 1.

### Ethical Considerations

The Indiana University Human Research Protection Program staff determined that the analysis done in this study was not human subject research and did not require further institutional review board (IRB) review before conducting the study.

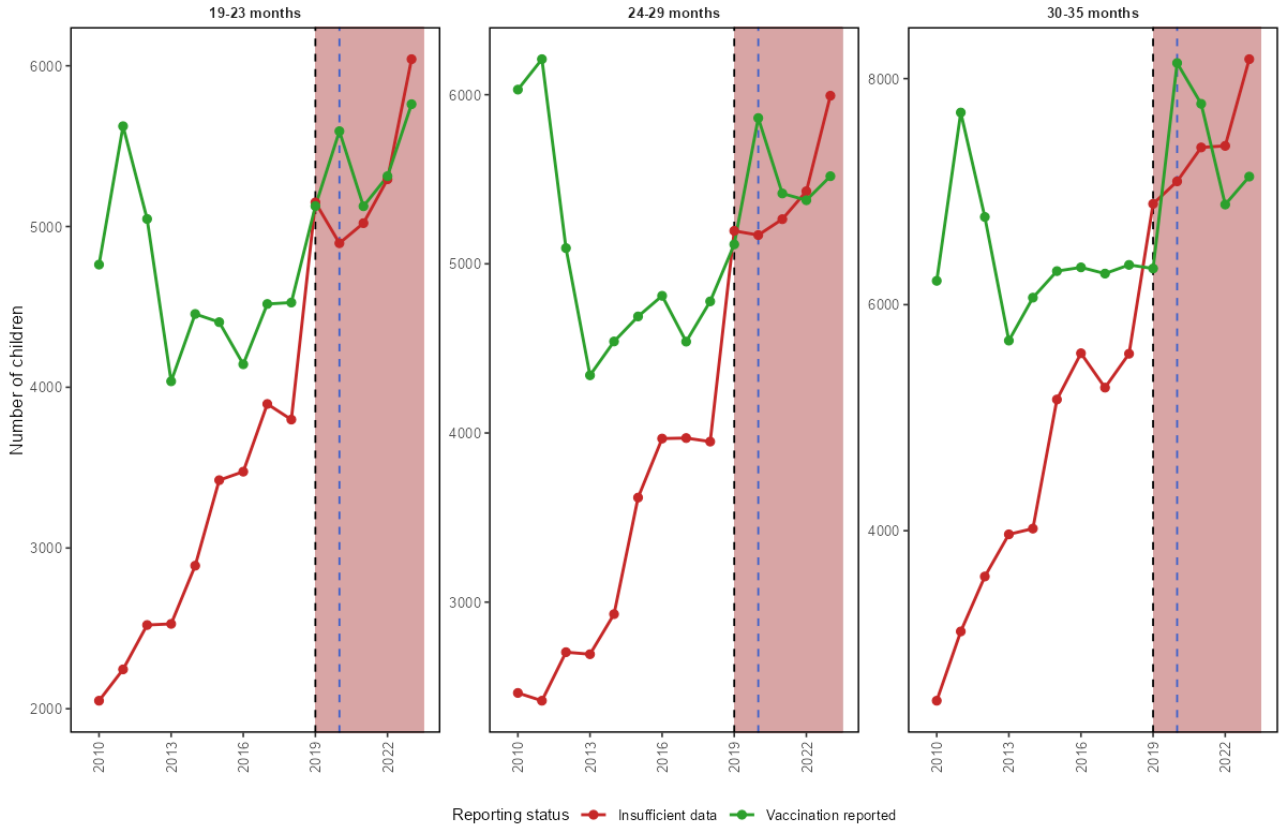
This study used publicly available, deidentified data from the NIS-Child, conducted annually by the CDC. The NIS-Child protocol is reviewed and approved by the CDC IRB, and informed consent is obtained from participating households, with additional parental consent for provider record verification. Because this analysis relied on secondary, deidentified data that is publicly available, IRB review was not required. The dataset contains no personally identifiable information, and no participant compensation was provided as part of this secondary analysis.

## Results

Figure 1 shows the trends in the number of children with provider-verified vaccination data (green) versus those with insufficient provider data (red), stratified by age groups (19-23, 24-29, and 30-35 months). A notable shift is observed during the COVID-19 pandemic (highlighted region in red), with a marked increase in missing provider data across all age groups starting in 2020, which coincides with the emergence of COVID-19 in the United States. By 2023, the number of unverified records surpassed verified ones in all age categories, especially among older children (30-35 months), suggesting disruptions in provider follow-up and data collection practices during and after the pandemic. This pattern is further corroborated by Figure 2, which shows a sharp rise in insufficient provider data following the pandemic across all age groups, particularly for children aged 30-35 months. Vaccination reporting by age group, as seen in Figure 2, shows that children aged 30-35 months consistently had higher rates of up-to-date

XSL•FO
RenderX

vaccination, while children aged 19-23 months lagged. The disparity widened after 2020, possibly reflecting pandemic-related disruptions to scheduled vaccinations among younger children.



Maternal education levels, a key variable in our models, showed consistent regional differences across time. Figure 3 illustrates that the Northeast and Midwest regions had a higher proportion of college-educated mothers, with an upward trend over time. By contrast, the South had persistently higher proportions of mothers with less than 12 years of education. These regional disparities in maternal education may contribute to the observed geographic differences in vaccination outcomes. Figure 4 presents the mean number of vaccines received per child by region. The Northeast consistently achieved higher average vaccine counts compared to other regions, while the South and West trailed behind.

Figures S5 and S6 in Multimedia Appendix 1 illustrate trends in the language of interview among Hispanic respondents and the weighted proportion of Hispanic to non-Hispanic children included in the NIS-Child survey over time. Figure S5 shows a marked shift from Spanish to English interviews among Hispanic families between 2010 and 2023. Early in the time series, Spanish-language interviews comprised a considerable proportion of the total, suggesting a need for linguistically appropriate outreach. The increasing predominance of English-language responses in later years may reflect demographic transitions or changes in data collection protocols, but could also indicate reduced inclusion of less acculturated families. Figure S6 demonstrates a gradual decline in the number of Hispanic children included in the weighted sample over the years. This trend raises questions about representation and potential undercounting of vulnerable subgroups.

Figure 5 shows year-wise vaccination coverage trends for each individual vaccine. While coverage remained above 90% for core vaccines such as polio, MMR, and PCV, substantial gaps persisted for influenza and hepatitis A. Rotavirus and influenza saw visible declines in 2022 and 2023, diverging from otherwise stable trajectories. Figure 6 reinforces these trends, showing relatively tight 95% CIs for high-coverage vaccines, but wider intervals for hepatitis A and influenza.

To illustrate model-based coverage estimates, a sample of 2022 CIs is shown in Table 1. This includes estimated means and 95% CIs for each vaccine coverage. For example, polio had a mean coverage of 93.5% (95% CI 92.7%-94.3%), while influenza had 72.9% (95% CI 71.6%-74.3%). Complete year-specific coverage estimates for all vaccines are provided in Table S3 in Multimedia Appendix 1.

**Figure 1.** Provider-verified (green) versus insufficient provider data (red) before and after COVID-19 emergence in the United States. Insufficient provider data refers to completed interviews without adequate provider-verified vaccination records. The dashed line marks 2020; the shaded region indicates the post–COVID-19 period.

[f]HepA: hepatitis A.

The primary multivariable model included demographic, socioeconomic, household, and maternal factors as detailed in Table S1 in Multimedia Appendix 1, alongside an indicator reflecting whether the child had ever received benefits through the WIC program. This specification was selected due to lower missingness and broader representation of cumulative program exposure across survey years. Sensitivity analyses were conducted using an alternative indicator reflecting current WIC participation, which exhibited substantial structural missingness and resulted in a marked reduction in analytic sample size. A third model excluded WIC participation entirely while retaining all other social and demographic covariates to evaluate whether inclusion of WIC altered associations among core predictors. Across specifications, the direction and magnitude of non-WIC predictors remained largely consistent, supporting the stability of the primary model.

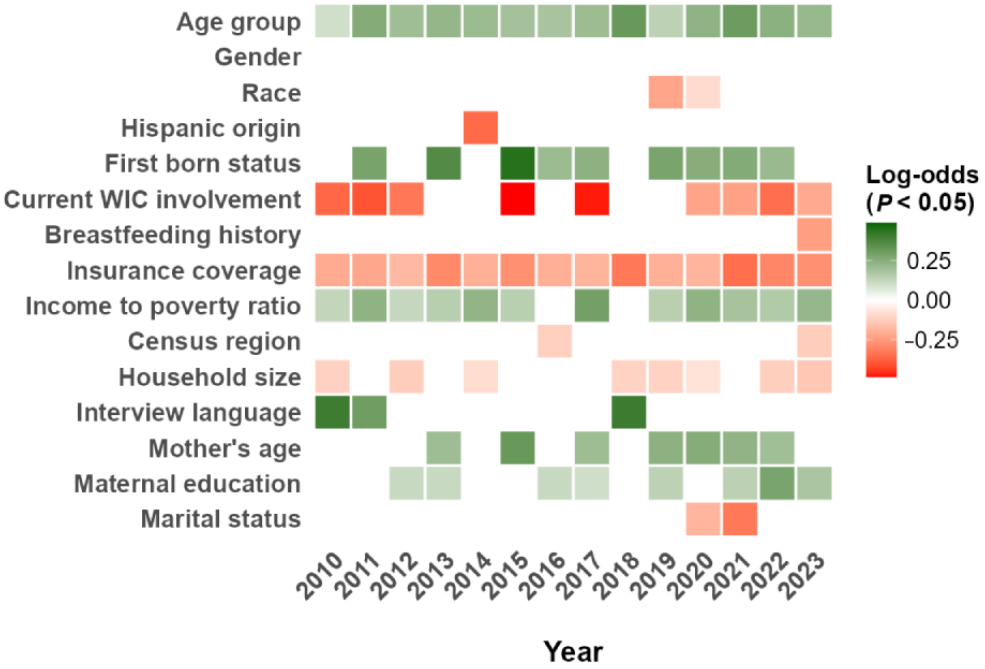
XSL•FO
RenderX

By 2023, coverage for the Combined 7-Vaccine Series reached 77.4% (14107/18032). In 2010, estimated coverage was 70.8% (SE 0.006), increasing to 71.5% (SE 0.007) by 2012 and continuing to rise thereafter.

In the primary model, older child age was consistently associated with higher odds of being fully vaccinated across the study period (2010: odds ratio [OR] 1.10, 95% CI 1.02-1.19, SE 0.040; *P*=.02; 2023: OR 1.24, 95% CI 1.13-1.36, SE 0.047; *P*<.001). Larger household size was associated with lower odds of vaccination completion in early years (2010: OR 0.89, 95% CI 0.85-0.94, SE 0.027; *P*<.001) and remained a persistent barrier across multiple survey cycles. The language of the interview demonstrated positive associations in selected years. For example, in 2010, children from households interviewed in English had higher odds of complete vaccination (OR 1.50, 95% CI 1.18-1.90, SE 0.123; *P*<.001), and this association reemerged in 2018 (OR 1.50, 95% CI 1.15-1.95, SE 0.407; *P*=.003).

Insurance coverage became increasingly influential in later years. In 2022, insured children had higher odds of complete vaccination compared with uninsured children (OR 0.74, 95% CI 0.65-0.84, SE 0.063; *P*<.001). Maternal education similarly demonstrated positive associations in recent years, indicating a widening gradient by educational attainment. Regional disparities intensified after 2020, with certain geographic regions exhibiting lower odds of complete vaccination (OR 0.74, 95% CI 0.65-0.84, SE 0.063; *P*<.001). Hispanic origin showed intermittent negative associations across survey years but was not uniformly significant throughout the study period. Overall, age-related advantages and household size barriers were the most stable predictors across time.

Influenza coverage improved from 65.9% (11470/16798) in 2010 to 77.5% (13408/17232) in 2022 before plateauing. In 2020, marital status (OR 0.75, 95% CI 0.63-0.90, SE 0.087; *P*=.001) and income-to-poverty ratio (OR 1.25, 95% CI 1.13-1.39, SE 0.054; *P*<.001) were significantly associated with influenza vaccination. Insurance coverage and regional disparities also became more prominent after 2020. In 2010, hepatitis A coverage was 49.7% (SE 0.007). Older age (2010: OR 1.94, 95% CI 1.80-2.09, SE 0.038; *P*<.001), smaller household size (2010: OR 0.90, 95% CI 0.85-0.94, SE 0.027; *P*<.001), Hispanic origin (2010: OR 0.75, 95% CI 0.63-0.89, SE 0.086; *P*=.001), language of interview (2010: OR 1.39, 95% CI 1.13-1.73, SE 0.108; *P*=.002), insurance coverage (2010: OR 0.81, 95% CI 0.80-0.98, SE 0.049; *P*=.001) and WIC benefits (2010: OR 0.69, 95% CI 0.56-0.87, SE 0.107; *P*<.001) were significantly associated with uptake. These disparities persisted in 2022 and 2023, indicating continued structural and access-related inequities. PCV and rotavirus vaccines showed persistent negative associations with increasing household size (2010; rotavirus: OR 0.74, 95% CI 0.65-0.84, SE 0.063; *P*<.001; PCV: OR 0.88, 95% CI 0.82-0.93 SE 0.030; *P*<.001), which are highly significant, suggesting logistical challenges among larger families. Regional disparities and Hispanic origin effects were also evident for these vaccines, particularly after 2020.



For MMR vaccination, the strength of age-related associations declined over time. In 2018, age group was strongly associated with higher odds of vaccination (OR 1.37, 95% CI 1.20-1.57, SE 0.069; *P*<.001), and this association remained significant in 2022 (OR 1.34, 95% CI 1.14-1.57, SE 0.081; *P*<.001). However, by 2023, the association weakened and became nonsignificant (OR 1.12, 95% CI 0.97-1.31, SE 0.076; *P*=.12). Participation in WIC demonstrated notable temporal shifts. In 2013, WIC participation was associated with significantly lower odds of MMR vaccination (OR 0.63, 95% CI 0.44-0.90, SE 0.180; *P*=.01). This inverse association attenuated in subsequent years and was not statistically significant in 2016 (OR 0.64, 95% CI 0.40-1.03, SE 0.241; *P*=.06). During the COVID-19 period, the direction of association shifted toward higher vaccination likelihood among WIC participants, although not reaching statistical significance in 2022 (OR 0.72, 95% CI 0.49-1.05, SE 0.194; *P*=.09) and 2023 (OR 0.83, 95% CI 0.62-1.11, SE 0.151; *P*=.21). These temporal fluctuations suggest that socioeconomic program engagement and age-based eligibility effects on MMR vaccination evolved over the study period, particularly during the pandemic years. Additional heat maps for individual vaccines are presented in Figures S6-S15 in Multimedia Appendix 1, demonstrating statistical significance patterns of SDoH across each vaccine type. These disparities remained evident across the study period when looking at the Combined 7-Vaccine Series, reinforcing the persistence of structural and access-related barriers, as seen in Figure 7. Complete table of effect sizes, CIs, and *P* values is provided in Multimedia Appendix 1.

Sensitivity analyses using the current-participation WIC measure yielded comparable directional effects but wider CIs due to reduced sample size. The base model excluding WIC showed no material changes in non-WIC predictor associations, indicating that WIC inclusion did not distort relationships among core social determinants. Detailed model comparisons and corresponding association patterns are provided in Multimedia Appendix 1, where year-specific estimates across WIC specifications are presented.

## Discussion

### Principal Findings

This cross-sectional analysis of provider-verified NIS-Child data from 2010 to 2023 documents persistent associations between childhood vaccination coverage and multiple SDoH across the United States. Although coverage for several core vaccines remained high, consistent socioeconomic, regional, and language-related gradients were observed across survey years. These findings describe associations rather than causal effects and highlight structural patterns that may contribute to inequities in immunization uptake.

Maternal education was consistently associated with higher odds of being up to date on vaccines. This pattern aligns with global evidence identifying maternal education as an important determinant of child health outcomes, including immunization coverage [29]. Higher educational attainment may reflect differences in health literacy, access to reliable information, and the ability to navigate health care systems. Caregivers with more education may be better positioned to understand vaccine schedules, communicate with providers, and respond to reminders, which may facilitate timely immunization.

Household income-to-poverty ratio was similarly associated with vaccination coverage, consistent with prior research documenting economic disparities in immunization [30]. Financial constraints may limit transportation access, appointment flexibility, and continuity of care. Even when vaccines are available at low or no cost, structural barriers such as unstable employment, limited clinic availability, and neighborhood-level resource gaps may shape preventive service use. Insurance status demonstrated strong associations, particularly in later survey years. According to a nationwide analysis, children from higher-income families were more likely to complete the full vaccine schedule on time compared to those in lower-income households. Insurance status was another factor with a strong association [31]. Uninsured children were less likely to be fully vaccinated compared to those with public or private coverage. CDC reports have similarly noted lower immunization rates among uninsured children despite the presence of the Vaccines for Children program [32]. Insurance coverage may therefore reflect broader system engagement and continuity of pediatric care.

Ethnicity-related differences were observed for several vaccines, including hepatitis A, influenza, and rotavirus. Hispanic origin was intermittently associated with lower vaccination odds, though not uniformly across all years. These findings are consistent with the literature attributing disparities in preventive care to structural barriers, including language discordance, immigration-related concerns, and differential provider engagement. The Hispanic paradox, which refers to the phenomenon in which Hispanic individuals experience health outcomes that are unexpectedly favorable relative to their socioeconomic status, has been well documented in outcomes such as mortality and chronic disease. However, these results indicate that this paradox does not extend to preventive care measures like childhood immunization, where disparities in access and use remain prominent [33,34]. Preventive services such as vaccination require active health care system engagement and documentation, which may be more sensitive to structural access barriers than mortality outcomes.

Language of interview was associated with vaccination coverage in selected years, with non–English-speaking households less likely to achieve complete immunization. This supports evidence that language discordance between caregivers and providers may contribute to miscommunication, reduced trust, and missed vaccination opportunities [35]. However, the language of the interview likely reflects broader structural barriers beyond

XSL•FO
RenderX

communication alone and should be interpreted as a proxy marker rather than a purely linguistic effect. Improvements in culturally and linguistically appropriate services may therefore play an important role in reducing disparities.

Regional variation persisted throughout the study period and appeared more pronounced after 2020. Differences across census regions likely reflect variation in health care infrastructure, provider density, rural-urban distribution, and state-level immunization policies. Lower vaccination coverage in certain regions may be related to previously documented geographic disparities in pediatric service access, particularly in rural or underserved areas where limited provider availability and long travel distances create barriers to timely immunization [36]. Regional heterogeneity in vaccination coverage may therefore represent structural differences in health care delivery rather than individual-level preferences alone. While regional analyses provide stable comparisons across years, they may mask meaningful state-level variation; future research should examine state-specific differences to better inform policy decisions.

Household size was consistently associated with lower vaccination completion for several vaccines, including PCV and rotavirus. Larger households may face logistical challenges related to scheduling, transportation, and competing caregiving demands. Age-related differences in coverage likely reflect timing of eligibility and health care encounters rather than behavioral differences.

The COVID-19 period coincided with increased insufficient provider data and widening disparities for selected vaccines, particularly influenza and hepatitis A. Disruptions in routine care and shifts in health care use during this period may have influenced vaccination patterns. Recent CDC reports indicate declines in kindergarten vaccination coverage and rising exemption rates, reinforcing concerns about sustained population-level protection. MMR coverage dropped from 93.1% (17931/19342) to 92.7% (17931/18032), a decrease of 0.4 percentage points), while DTaP coverage fell from 92.7% (14909/17232) to 92.3% (15903/18032), also a 0.4 percentage point decline) between the 2022-2023 and 2023-2024 school years. Simultaneously, exemption rates reached a record high of 3.3%, up from 3.0% the previous year [37]. The findings of this study reinforce the need to address coverage disparities through targeted public health strategies. Although the analytic sample size remained stable and standard survey weighting procedures were applied, estimates from 2020-2023 should be interpreted with caution, given potential shifts in provider participation and survey response dynamics during the pandemic period.

As a cross-sectional analysis, this study documents associations between social determinants and vaccination coverage but cannot establish causal relationships. Longitudinal or quasi-experimental studies are needed to determine whether interventions targeting identified social and structural barriers would improve immunization uptake. Given the number of year-specific models estimated, findings should be interpreted in the context of temporal consistency rather than reliance on isolated statistical significance. Overall, the persistence of disparities across education, income, insurance, language, and region suggests that structural inequities remain central to understanding gaps in childhood vaccination coverage.

## Limitations

This study has several limitations. First, the cross-sectional design limits inference to associations and does not establish causality. Second, analyses were restricted to children with provider-verified vaccination records, consistent with NIS-Child guidance; however, if children without verified records differ systematically in health care access or sociodemographic characteristics, disparities may be underestimated. Survey-weighted regression models were estimated using complete-case analysis. Although most covariates had low missingness, bias may occur if the data were not missing at random. WIC participation required additional consideration. While the primary WIC indicator used in the main models had relatively low missingness, an alternative WIC variable exhibited substantial structural missingness due to survey design. Sensitivity analyses indicated that this missingness influenced certain associations, particularly involving insurance status, suggesting that the missingness mechanism was not random. However, associations for other core social determinants remained stable across alternative model specifications, including a model excluding WIC, supporting the robustness of the primary findings.

Changes in provider verification patterns and health care use during 2020 to 2023 may affect the interpretation of year-specific estimates, even though provider-phase weights and a consistent analytic framework were applied across all years. Several relevant factors, including immigration status, health literacy, vaccine confidence, and access barriers, were not captured in the public dataset, raising the possibility of unmeasured confounding. Regional variables were measured at an aggregate level and may be subject to ecological bias. Statistical significance was assessed at 5% without formal adjustment for multiple comparisons, and findings should be interpreted with emphasis on effect sizes and consistency over time. Finally, generalizability is limited to US children aged 0-35 months with provider-verified records and may not extend to other populations or health systems.

## Future Work

Future research should build on these findings by using longitudinal and quasi-experimental approaches to better understand how structural and policy changes influence vaccination disparities over time. Qualitative and mixed method studies may help clarify mechanisms not captured in NIS-Child, including health literacy, cultural mistrust, transportation barriers, and health care navigation challenges that may contribute to undervaccination among Hispanic, uninsured, and low-income families [38]. State-level and geospatial analyses are also needed to examine within-region heterogeneity and link disparities to policy environments such as Medicaid eligibility, exemption laws, and public health funding differences across states [39]. Incorporating interaction analyses in future models as part of a formal causal inference model, such as ethnicity by language or insurance by income, may further identify subgroups experiencing compounded barriers and inform more targeted interventions.

XSL•FO
RenderX

## Conclusion

This study used nationally representative, provider-verified NIS-Child data from 2010 to 2023 to examine associations between SDoH and early childhood vaccination coverage of CDC recommended vaccines, including completion of a Combined 7-Vaccine Series. Across survey years, vaccination coverage was consistently patterned by maternal education, insurance status, household income, language of interview, and region, with particularly persistent gaps for hepatitis A, influenza, and rotavirus. Although provider verification decreased after 2020, the analytic sample of children with adequate provider data remained stable, and results were generally robust across sensitivity specifications. These findings support the need for equity-focused immunization strategies that address structural barriers to accessing preventive care, including insurance coverage, culturally and linguistically appropriate services, and geographically tailored outreach. Continued surveillance and policy-relevant analyses are needed to monitor whether disparities narrow over time and to guide interventions that improve protection against vaccine-preventable diseases for all children.

## Funding

The authors declared no financial support was received for this work.

## Data Availability

The data used for this study were sourced from the National Immunization Surveys database, available on the Centers for Disease Control and Prevention (CDC) website. Access to the dataset can be obtained from the CDC's official data repository, ensuring transparency and reproducibility in research findings. The study involved secondary analysis of publicly available, deidentified surveillance data. No new datasets were generated. Statistical code used for data processing and analysis is available from the corresponding author on reasonable request.

## Authors' Contributions

Conceptualization: RKM, YZ, FMPR
Data curation: RKM, FMPR
Formal analysis: RKM
Methodology: RKM, YZ, FMPR
Software: RKM
Visualization: RKM
Supervision: YZ, FMPR
Validation: YZ, FMPR
Project administration: YZ, FMPR

## Abstract

**Background:** Blood exposure accidents (BEAs) remain a major occupational hazard for health care providers, particularly in low-resource settings. Despite their preventable nature, BEAs continue to occur frequently due to gaps in compliance with standard precautions and limited institutional surveillance.

**Objective:** This study aimed to determine the prevalence and factors associated with BEAs among health care providers in Kalemie, Tanganyika Province, Democratic Republic of the Congo.

**Methods:** A cross-sectional study was conducted in March 2024 among 316 health care providers randomly selected from 34 health facilities: public facilities (20/34, 58.8%), private facilities (9/34, 26.5%), and faith-based facilities (5/34, 14.7%). Data were collected using a structured questionnaire adapted from World Health Organization and Centers for Disease Control and Prevention tools. Logistic regression was performed to identify predictors of BEAs, with adjusted odds ratios (AORs), 95% CIs, and *P* values reported.

**Results:** The lifetime prevalence of BEAs was 65.8% (208/316), and the 12-month prevalence was 60.4% (191/316). The most frequent causes were unexpected patient movement (81/191, 42.4%) and lack of attention (66/191, 34.6%). Needlestick injuries accounted for 59.2% (113/191) of exposures. Only 36.1% (69/191) of incidents were formally reported. Multivariate analysis identified two independent predictors: (1) noncompliance with standard precautions (AOR 2.921, 95% CI 1.503-5.677; *P*=.001) and (2) facility type (working in secondary-level facilities was protective; AOR 0.310, 95% CI 0.144-0.670; *P*=.003).

**Conclusions:** BEAs were highly prevalent among health care providers in Kalemie. Most incidents were preventable, and noncompliance with standard precautions significantly increased risk. Strengthening infection prevention and control measures, ensuring consistent availability of personal protective equipment, and establishing effective surveillance systems are urgently needed to protect health care workers and reinforce health system resilience.

## Introduction

Occupational exposure to blood and infectious body fluids remains a major public health concern, particularly for health care workers in low-resource settings. Blood exposure accidents (BEAs) are defined as any accidental percutaneous or mucocutaneous contact with blood or biological fluids potentially contaminated with pathogens such as bacteria, viruses, parasites, or fungi [1,2]. These exposures typically occur through needlestick injuries, cuts, or splashes during clinical procedures. Beyond blood, other biological fluids—including cerebrospinal, synovial, amniotic, and genital secretions—may also transmit infections even when not visibly contaminated [3]. According to the World Health Organization (WHO), approximately 3 million of the 35 million health care workers worldwide are exposed to bloodborne pathogens annually [4,5]. Recent global evidence confirms the persistence of this risk: a meta-analysis published in 2022 reported a lifetime prevalence of occupational blood exposure of 56.6% and a 12-month prevalence of 39% among health care workers worldwide [6]. More recent studies highlight organizational and systemic determinants: a longitudinal cohort in France identified irregular schedules and reliance on external staff as predictors of BEAs [7], whereas a systematic review in 2023 found a pooled global prevalence of needlestick injuries of 40.9% among nurses, with higher rates in low- and middle-income countries [8]. In addition, the WHO reported in 2023 that 41% of health workers in Africa experience at least one percutaneous injury annually, underscoring the magnitude of the problem [9]. The risk of transmission varies by pathogen: 10% to 40% for hepatitis B virus, approximately 2% for hepatitis C virus, and approximately 0.3% for HIV following a needlestick injury [10,11]. The WHO estimates that nearly 2 million needlestick injuries occur annually among health care workers, with 40% to 60% of hepatitis B and hepatitis C virus infections in this population being occupationally acquired [12]. Recent studies confirm the persistence of BEAs: prevalence rates have reached 93% in Cameroon [13], 78.9% among nursing students in Morocco [14], and 31% in India [15]. In Ethiopia and Nigeria, lifetime prevalence exceeds 60% [16,17]. In the Democratic Republic of the Congo (DRC), the problem is particularly acute. A study in Lubumbashi reported a prevalence of 73.2% among health care workers [18,19]. Noncompliance with standard precautions was identified as the strongest predictor (adjusted odds ratio [AOR] 2.921, 95% CI 1.503-5.677), confirming that most BEAs could be prevented through simple measures such as consistent use of personal protective equipment (PPE) and avoidance of needle recapping [19]. These findings highlight systemic gaps in infection prevention and control across provinces in the DRC. Multiple factors contribute to BEAs, including insufficient infection prevention training, inadequate PPE, poor compliance with standard precautions, absence of infection control committees, and overcrowded or poorly designed workspaces [20,21]. While high-income countries have implemented surveillance systems and continuous training programs [22], many African countries still face underreporting and poor documentation of BEAs [23]. This study aimed to determine the factors associated with BEAs among health care providers in Kalemie, DRC, hypothesizing that noncompliance with standard precautions significantly increases the occurrence of BEAs.

## Methods

### Study Design and Setting

We conducted a cross-sectional study in March 2024 among health care providers in Kalemie, Tanganyika Province, eastern DRC. The city comprises 2 health zones (Kalemie and Nyemba) covering 11 health areas and a total of 45 public, private, and faith-based health facilities.

### Sample Size and Sampling Technique

The sample size was calculated using the single population proportion formula [24]: $n = [(z\alpha/2)^2 \times p\ (1 - p)]/d^2$, where $z$=1.96 (for 95% confidence), $p$=73.2% (estimated BEA prevalence from the aforementioned Lubumbashi study), and $d$=0.05 (margin of error). After accounting for a 10% nonresponse rate, the final sample size was 335.

A 2-stage sampling approach was applied. Although clustering was considered, no formal adjustment for design effect was performed as the calculated sample size was deemed sufficient to ensure representativeness. The final number of respondents was 316, corresponding to a response rate of 94.3% (316/335); the difference was due to nonresponses.

### Recruitment Procedure

From the 45 health facilities listed in the National Health Information System (NHIS), 34 (75.6%) were randomly selected using a computer-generated list, ensuring proportional representation of public, private, and faith-based institutions. Within each selected facility, staff rosters were systematically validated by managers against official NHIS records to guarantee accuracy and completeness. The number of participants per facility was determined proportionally to staff size, and providers were then chosen using a random number generator. This systematic validation of lists and proportional allocation ensured representativeness and minimized selection bias.

### Inclusion and Exclusion Criteria

Inclusion criteria were nurses, physicians, midwives, and laboratory technicians with direct contact with blood or body fluids. Exclusion criteria were providers with less than 1 month of professional experience to reduce onboarding variability.

### Data Collection Tools and Procedures

Data were collected using a structured questionnaire adapted from validated WHO and Centers for Disease Control and Prevention (CDC) instruments [25-27]. The tool comprised closed-ended items covering sociodemographic characteristics,

XSL•FO
RenderX

knowledge of BEAs, attitudes toward reporting and prevention, compliance with standard precautions, and history of occupational exposure. Prior to implementation, the questionnaire was pilot-tested at Baraka Health Post and Shalom Polyclinic to ensure clarity and contextual relevance. Seven data collectors and 1 supervisor received 2 days of standardized training focused on interview techniques, ethical considerations, and data quality assurance. Reliability testing yielded a Cronbach α coefficient of 0.766, indicating acceptable internal consistency. Data collection was conducted through face-to-face interviews using the KoboCollect (Kobo) software installed on tablets. Each interviewer completed approximately 10 provider interviews per day over a 5-day period. Supervisory checks were performed daily to validate the completeness and accuracy of entries. The use of electronic data capture minimized transcription errors and ensured secure storage of anonymized records.

### Variables

The dependent variable was occupational exposure to blood within the previous 12 months, defined as any percutaneous or mucocutaneous contact with potentially infectious biological fluids. Independent variables included the type of health facility, categorized as secondary level (general referral hospitals, referral health centers, and polyclinics) vs primary level (health centers, health posts, and dispensaries). Compliance with standard precautions was dichotomized as “always” vs “not always.” Needle recapping was assessed through self-reported frequency and classified as “never” vs “ever.” Availability and use of PPE were measured on an ordinal scale (“rarely,” “usually,” and “always”). Syringe reuse was recorded as a binary variable (“yes” or “no”). Sociodemographic characteristics were also collected, including age (categorized), sex, marital status, professional category, years of professional experience, and daily working hours.

### Statistical Analysis

Data were exported from KoboCollect to Microsoft Excel 2016 and analyzed using SPSS (version 25.0; IBM Corp). Descriptive statistics were computed, including frequencies, percentages, medians, and IQRs. Normality of continuous variables was assessed using the Kolmogorov-Smirnov test [28]. Knowledge scores were derived from 31 items and categorized as optimal (>85%), moderate (70%-85%), or poor (<70%). Bivariate analyses were performed using chi-square tests, and variables with a *P* value of .20 or lower were retained for multivariate modeling. Logistic regression was conducted to identify independent predictors of BEAs, with AORs and 95% CIs reported. Both crude (odds ratio) and adjusted (AOR) estimates were presented, and potential confounding factors were explicitly discussed. Model diagnostics included assessment of multicollinearity using the variance inflation factor (<2), evaluation of model fit using the Hosmer-Lemeshow goodness-of-fit test, and discrimination using the area under the receiver operating characteristic curve [29]. Statistical significance was set at a *P* value below .05.

### Ethical Considerations

This study was conducted and reported in accordance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines [30]. Ethics approval was obtained from the ethics committee of the School of Public Health, University of Kinshasa (reference ESP/CE/38/2024). Written informed consent was obtained from all participants prior to their inclusion. Confidentiality was safeguarded by anonymizing the data and storing them securely, accessible only to authorized researchers. No financial compensation was provided to participants for their involvement in the study.

## Results

### Sociodemographic and Professional Characteristics

A total of 316 health care providers participated (response rate: 316/335, 94.3%). Most (n=256, 81%) worked in secondary-level facilities (general referral hospitals, referral health centers, and polyclinics). Most were female (n=179, 56.6%), married (n=230, 72.8%), and aged 40 years or older (n=128, 40.5%). Nurses represented 78.2% (n=247) of the sample. Median professional experience was 9 (IQR 5-15) years, and median workload was 8 (IQR 7-9) hours per day, as shown in Table 1.

| Workload (h), median (IQR) | 8 (7-9) |
| ≤8, n (%) | 209 (66.1) |
| >8, n (%) | 107 (33.9) |

## Prevalence and Circumstances of BEAs

Overall, 65.8% (208/316) reported at least one BEA during their career, and 60.4% (191/316) reported one within the previous 12 months. The leading causes were unexpected patient movement (81/191, 42.4%) and lack of attention (66/191, 34.6%). Most incidents occurred in treatment rooms (64/191, 33.5%), delivery rooms (33/191, 17.3%), and operating rooms (27/191, 14.1%).

Needlestick injuries accounted for 59.2% (113/191) of exposures, followed by splashes on damaged skin (43/191, 22.5%) and on mucous membranes (18/191, 9.4%). Hollow needles (77/191, 40.3%) and defective surgical equipment (49/191, 25.7%) were the objects most frequently responsible, as shown in Table 2. Only 36.1% (69/191) of BEAs were formally reported; among the 122 non-reported cases, the main reason was the perception that the incident was not risky (70/122, 57.4%).

### Knowledge, Attitudes, and Practices

Nearly all participants (309/316, 97.8%) had heard of BEAs, mainly through formal education (125/316, 40.5%) and training (125/316, 40.5%). However, 72.8% (230/316) had never received specific training on standard precautions, and 94.3% (298/316) demonstrated poor knowledge levels.

Attitudes were mixed: 48.4% (153/316) strongly agreed on the importance of reporting BEAs, 72.2% (228/316) emphasized the importance of knowing the patient's serological status, and 73.4% (232/316) expressed willingness to initiate postexposure prophylaxis.

In practice, 76.6% (242/316) claimed to always follow standard precautions, but only 25% (79/316) consistently washed their hands before and after patient contact. Needle recapping was reported by 27.8% (88/316), PPE was always used by 19.6% (62/316), and syringe reuse occurred in 16.5% (52/316) of cases, as shown in Table 3.

## Factors Associated With BEAs

Bivariate analysis identified 6 factors associated with BEAs, with exact *P* values: facility type (*P*<.001), daily working hours (*P*=.001), compliance with standard precautions (*P*<.001), needle recapping (*P*<.001), PPE availability (*P*=.03), and PPE use (*P*=.003).

Multivariate logistic regression confirmed two independent predictors: (1) noncompliance with standard precautions (AOR 2.921, 95% CI 1.503-5.677; *P*=.001) and (2) facility type (AOR 0.310, 95% CI 0.144-0.670; *P*=.003), as shown in Table 4.

# Discussion

## Summary of Key Findings

This study highlights that BEAs remain a major occupational hazard among health care providers in Kalemie, Tanganyika Province, DRC. The strongest predictor was noncompliance with standard precautions [15], whereas working in secondary-level facilities appeared protective.

## Interpretation and Comparison With Previous Studies

Our findings are consistent with those of recent African studies reporting high BEA prevalence: 93% in Cameroon [10], 78.9% in Morocco [11], more than 60% in Ethiopia [13,17], and more than 60% in Nigeria [14]. The Kalemie results reinforce the persistence of occupational risks across sub-Saharan Africa.

The protective effect of secondary-level facilities may be explained by better infrastructure, availability of PPE, and more structured infection prevention programs, as observed in Ethiopia [17] and Benin [18]. Conversely, primary-level facilities often lack resources, increasing exposure risks [20].

The association between noncompliance with standard precautions and BEAs has been consistently documented [27]. In Kalemie, this factor nearly tripled the risk, confirming that most accidents are preventable through adherence to basic infection control measures. The apparent contradiction between bivariate and multivariate analyses regarding facility type likely reflects confounding factors: secondary facilities host more complex procedures and higher patient volumes, increasing crude risk, but once adjusted for PPE availability, training, and compliance, their structured infection control systems reduced overall risk. Similar methodological challenges have been highlighted in recent epidemiological modeling studies [31].

## Strengths and Limitations

The methodological rigor of this study, including the use of a validated questionnaire adapted from WHO and CDC tools [22,26], random sampling, and robust statistical diagnostics such as the Hosmer-Lemeshow test and the area under the receiver operating characteristic curve [28,29], supports the representativeness of the findings. Nevertheless, limitations must be acknowledged. Reliance on self-reported data may have introduced social desirability bias, as suggested by the discrepancy between the high proportion of providers claiming to "always" follow standard precautions (242/316, 76.6%) and the finding that noncompliance was the strongest predictor. Recall bias may also have affected lifetime prevalence estimates. Measurement limitations exist because exposure was assessed exclusively through self-report without external validation, and the cross-sectional design precludes causal inference. Finally, generalizability is limited as this study was conducted in Kalemie and may not fully represent health care providers in other provinces of the DRC.

## Broader Implications

BEAs remain highly prevalent among health care providers in Kalemie. Most incidents are preventable through adherence to standard precautions, adequate provision of PPE, and establishment of surveillance systems. Strengthening institutional policies and continuous training are essential to reduce occupational risks and safeguard health care workers.

Beyond Kalemie, these findings highlight systemic gaps in infection prevention and control across sub-Saharan Africa. Addressing these gaps requires coordinated action: investment in PPE, integration of infection control committees, and reinforcement of reporting and monitoring systems. At the global level, the persistence of BEAs underscores the need for harmonized occupational health policies and stronger advocacy for health care worker safety.

## Conclusions

BEAs remain a major occupational hazard for health care providers in Kalemie, DRC. With nearly two-thirds of providers reporting lifetime exposure and more than half exposed within the past year, the burden is substantial. Most incidents were preventable, and noncompliance with standard precautions emerged as the strongest predictor. Conversely, working in secondary-level facilities appeared protective once confounding factors were accounted for.

XSL•FO
RenderX

These findings underscore the urgent need to strengthen infection prevention and control measures, ensure consistent availability and use of PPE, and establish effective surveillance and reporting systems. Beyond Kalemie, the results highlight systemic gaps across sub-Saharan Africa, calling for coordinated national and international efforts to safeguard health care workers. Protecting those at the frontline is essential not only for their safety but also for the resilience of health systems.

## Acknowledgments

The authors thank the Tanganyika Provincial Health Division for administrative support, the managers of the participating health facilities for their collaboration, and the health care providers who generously contributed their time and insights to this study. All authors declared that they had insufficient funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee support for the publication of this article. No generative AI tools were used in the design, conduct, analysis, or writing of this study. All content was produced by the authors, and responsibility for the accuracy and integrity of the work rests entirely with them.

## Data Availability

The datasets generated and analyzed during the current study are not publicly available due to confidentiality agreements with participating health facilities. However, anonymized data can be obtained from the corresponding author on reasonable request and with approval from the institutional ethics committee.

## Funding

The authors declared no financial support was received for this work.

## Abstract

**Background:** Mental health disorders represent a growing global challenge, particularly in low- and middle-income countries, where women are disproportionately affected by social and structural inequalities. Although women's empowerment has been increasingly recognized as a strategy to improve physical health, its relationship with mental health remains less well understood.

**Objective:** This study examined the association between women's empowerment and mental health symptoms among ever-married women in Bangladesh.

**Methods:** A cross-sectional analysis was conducted using data from the 2022 Bangladesh Demographic and Health Survey. Women's empowerment was measured using the Survey-Based Women's Empowerment (SWPER) Global index across 3 domains: attitudes toward violence, social independence, and decision-making. Associations between empowerment domains and depressive symptoms, anxiety, and any mental health symptoms were assessed using multivariable logistic regression.

**Results:** Empowerment in the attitudes toward violence domain was significantly associated with mental health outcomes. Women with low empowerment in this domain had higher odds of depression (adjusted odds ratio [aOR] 1.81, 95% CI 1.16-2.81), anxiety (aOR 1.46, 95% CI 1.10-1.94), and any mental health symptoms (aOR 1.63, 95% CI 1.27-2.10). No significant associations were found for the social independence or decision-making domains.

**Conclusions:** Higher empowerment in the "attitudes toward violence" domain was associated with a lower prevalence of common mental health symptoms, suggesting that addressing gender-based violence norms may improve women's mental health in Bangladesh.

## Introduction

Mental health disorders are an increasingly critical global health concern, accounting for an estimated 17.2% of disability-adjusted life years (DALYs) in 2021 [1]. The burden is disproportionately high in low- and middle-income countries (LMICs), where limited health care access, stigma, and economic barriers restrict both prevention and treatment [2]. Women in LMICs experience a disproportionate burden of common mental disorders because of intersecting social, economic, and gender-related disadvantages, including poverty, limited educational and employment opportunities, restricted decision-making autonomy, gender discrimination, social isolation, intimate partner violence (IPV), and inadequate access to mental health services [2-4]. In South Asia, these structural inequities collectively contribute to depression, anxiety, and other common mental disorders among women [4]. Although IPV is a well-established determinant of women's mental health, it represents only 1 pathway through which gender inequality may influence psychological well-being [5].

Women's empowerment has emerged as an important social determinant of health and is recognized as a key component of Sustainable Development Goal (SDG) 5, which seeks to achieve gender equality and empower all women and girls [6]. Women's empowerment is a multidimensional construct encompassing access to resources, decision-making autonomy, freedom of movement, social independence, and the ability to challenge inequitable gender norms [7]. Greater empowerment has been associated with improved reproductive, maternal, and child health outcomes, increased health care use, and enhanced overall well-being [8]. Emerging evidence also suggests that women's empowerment may influence mental health by increasing

XSL•FO
RenderX

autonomy, self-efficacy, and social support while reducing exposure to adverse social and gender-related stressors [9].

Although an increasing number of studies have examined the relationship between women's empowerment and mental health, findings remain inconsistent across countries and empowerment domains. Some studies have reported that greater empowerment is associated with lower risks of depression and anxiety, whereas others have found weak or domain-specific associations [10-12]. These inconsistencies may partly reflect differences in the conceptualization and measurement of empowerment, as well as variation in sociocultural contexts. Consequently, examining empowerment as a multidimensional construct may provide a more comprehensive understanding of its relationship with women's mental health.

In Bangladesh, these structural disadvantages are particularly salient. The country has made substantial progress in women's education and maternal health, yet persistent gender inequalities continue to affect women's social and economic opportunities [13]. Women continue to face barriers related to employment, household decision-making, child marriage, and gender-based violence [13]. Social norms that justify violence against women remain prevalent in many communities, and IPV remains widespread, with 23.2% of women aged 15 to 49 years reporting physical or sexual violence in the past year [14]. These structural disadvantages may adversely affect both women's empowerment and their mental and physical health. Previous studies conducted in Bangladesh have primarily reported that lower autonomy, limited decision-making power, and exposure to gender-based violence are associated with poorer mental health outcomes [12,15-18]. However, these studies generally focused on specific dimensions of empowerment or selected populations, limiting our understanding of how multidimensional empowerment influences mental health at the national level.

Various indices have been used to measure empowerment, including the Women's Empowerment in Agriculture Index [19], the Gender Development Index [20], and the Gender Inequality Index [21]. Although useful at national and regional levels, these tools offer limited applicability for subnational or subgroup analyses. To address this gap, the Survey-Based Women's Empowerment (SWPER) Global index was developed in 2017 using Demographic and Health Survey (DHS) data from 34 African countries [22]. The index identifies 3 domains of empowerment—attitudes toward violence, social independence, and decision-making—and has since been adapted as the SWPER Global index for use across world regions [22,23]. The SWPER Global index provides a standardized multidimensional measure of women's empowerment across these 3 domains [23]. Although the relationship between IPV victimization and women's mental health has been extensively documented, considerably less is known about whether women's attitudes toward the acceptability of violence—measured as an empowerment domain rather than as exposure to IPV—are independently associated with mental health [24,25]. Understanding this relationship may provide new insights into how gender norms and women's empowerment influence psychological well-being beyond direct experiences of violence.

Evidence on women's empowerment and mental health in South Asia remains limited. A recent study in Nepal, using the SWPER Global index, found that social independence was protective against depression and anxiety, whereas decision-making was associated with increased risk [26]. Previous studies across various contexts have reported mixed effects; some have identified empowerment—particularly autonomy and agency—as protective against mental health symptoms [19,27-29], while others have reported detrimental effects linked to specific domains such as decision-making [11,26]. Such findings highlight the complexity and context-specific nature of the relationship between empowerment and mental health.

Despite growing evidence linking women's empowerment and mental health, important knowledge gaps remain. Few nationally representative studies have examined multidimensional women's empowerment in relation to mental health in Bangladesh, and the relative contributions of different empowerment domains remain unclear, particularly the role of attitudes toward the acceptability of violence. Given persistent gender inequalities and limited mental health resources in Bangladesh, understanding these relationships is essential for informing gender-responsive public health interventions. Therefore, this study examined the associations between the 3 SWPER Global empowerment domains and symptoms of depression, anxiety, and overall mental health among ever-married women in Bangladesh. We hypothesize that lower levels of empowerment across the attitudes toward violence, social independence, and decision-making domains would be associated with greater odds of adverse mental health outcomes.

## Methods

### Data Source

This study analyzed secondary data from the women's individual recode (IR) file of the nationally representative 2022 Bangladesh Demographic and Health Survey (BDHS). The BDHS was conducted in urban and rural areas across all 8 administrative divisions of Bangladesh between June and December 2022. It used a 2-stage stratified cluster sampling design based on the 2011 national census. In the first stage, 675 enumeration areas were selected with probability proportional to size. In the second stage, an average of 45 households per cluster were selected systematically, yielding a sample of 30,330 households. Ever-married women aged 15 to 49 years who were usual residents of, or who stayed in, selected households on the night before the survey were eligible for the interview. Thirty of the 45 selected households in each cluster were randomly allocated to the long women's questionnaire, which included the Patient Health Questionnaire–9 (PHQ-9) and Generalized Anxiety Disorder–7 (GAD-7) mental health modules. For this analysis, only women with complete data for SWPER Global empowerment indicators and mental health measures were included (N=17,027). Details of the BDHS methodology are available elsewhere [30].

### Exposure Variable

Women's empowerment was the exposure variable, assessed using the SWPER Global index, which was constructed from 14 standardized DHS items available in the women's IR file

XSL•FO
RenderX

for married women. The index includes 3 domains: attitudes toward violence, social independence, and decision-making. The attitudes toward violence domain reflects women's acceptance or rejection of justifications for wife beating; the social independence domain captures women's education, age at marriage or first birth, age difference with the partner, and media exposure; and the decision-making domain reflects participation in household decisions. Domain scores were generated using principal component analysis and then categorized into tertiles (low, medium, and high) following established SWPER Global methodology [22,23].

### Outcome Variables

This study evaluated 3 mental health outcomes: depression, anxiety, and any mental health symptoms. Anxiety was assessed using the GAD-7 scale [31]. Participants reported the frequency of their symptoms on a scale from 0 ("never") to 3 ("always") over the preceding 2 weeks, with responses to the 7 questions aggregated to yield a total score between 0 and 21. Respondents were categorized as exhibiting anxiety symptoms if they achieved a GAD-7 score of ≥6. This cutoff was used for the present population-based analysis as a symptom-screening definition rather than a clinical diagnosis. Depression was assessed using the PHQ-9 [32]. Participants reported the occurrence of their symptoms on a scale from 0 ("never") to 3 ("always"), with responses to the 9 questions aggregated to yield a cumulative score between 0 and 27. Respondents were categorized as exhibiting depressive symptoms if they achieved a PHQ-9 score of ≥10. Respondents were classified as exhibiting "any mental health symptoms" if they reported experiencing ≥1 symptom of anxiety and/or depression. This study categorized mental health symptoms according to methodologies established in prior research [26]. Although the PHQ-9 and GAD-7 are screening rather than diagnostic instruments, Bangladeshi validation studies have supported their reliability and validity in local samples, including evidence for unidimensionality and acceptable internal consistency [33].

### Covariates

This study included various sociodemographic covariates such as age, place of residence, division, highest level of education, number of children, wealth index, religion, the respondent's employment status, the partner's employment status, and the respondent's BMI. These variables were selected a priori as potential confounders because they may be associated with both women's empowerment and mental health. Religion was included to account for cultural and normative differences that may shape gender roles and attitudes toward women's autonomy; partner employment status was included as a marker of household economic stability and financial stress; and BMI was included as an indicator of women's physical and nutritional status, which may be linked to both psychological well-being and social disadvantage. Age was classified into 3 groups: 15 to 29 years, 30 to 39 years, and 40 to 49 years. Residence was classified as urban or rural according to country-specific criteria [30]. Bangladesh comprises 8 divisions: Barishal, Chattogram, Dhaka, Khulna, Mymensingh, Rajshahi, Rangpur, and Sylhet. Education level was classified according to the highest level of schooling completed: no education, primary, secondary, or higher education. Children were classified into 3 categories: 0 or 1 child, 2 children, and ≥3 children, according to population distribution. The wealth index was developed through principal component analysis, a statistical technique frequently used to create composite indicators of economic status derived from household assets and characteristics. The population was subsequently categorized into quintiles, from the poorest to the richest [30]. The respondent's reported religion was categorized as either "Islam" or "Other." The employment status of both the respondent and their partner was categorized as binary variables: employed or unemployed. BMI was classified according to World Health Organization (WHO) standards: underweight (<18.5 $kg/m^2$), normal weight (18.5 $kg/m^2$-24.9 $kg/m^2$), overweight (25.0 $kg/m^2$-29.9 $kg/m^2$), and obese (≥30.0 $kg/m^2$). This study categorized BMI into 2 groups: "normal" (18.5 $kg/m^2$-24.9 $kg/m^2$) and "underweight/overweight" (<18.5 $kg/m^2$ or ≥25.0 $kg/m^2$) to identify individuals outside the conventional "normal" range.

### Statistical Analysis

Descriptive statistics were used to summarize sample characteristics, with proportions estimated for categorical variables and means and SDs reported for continuous variables. The prevalence of anxiety, depression, and any mental health symptoms was calculated by sociodemographic characteristics and SWPER Global domains. Bivariate associations were evaluated using chi-square tests. Associations between empowerment levels and mental health outcomes were examined with bivariate and multivariate logistic regression; covariates with $P<.25$ in bivariate analyses were included in the multivariate models. Collinearity among covariates was assessed using variance inflation factors. Adjusted odds ratios (aORs) with 95% CIs were reported. Statistical significance was determined using an $\alpha$ level of .05, with all tests being 2-sided. Model fit was assessed using the Archer-Lemeshow *F*-adjusted goodness-of-fit test for survey-weighted logistic regression; a nonsignificant result indicated no evidence of lack of fit. All analyses were conducted in Stata (version 18.5; StataCorp) using survey commands (*svy*) to apply the BDHS sampling weights, strata, and primary sampling unit, thereby producing nationally representative estimates and valid SEs.

### Sensitivity Analyses

We re-estimated all associations using survey-weighted Poisson regression with a log link to obtain adjusted prevalence ratios (aPRs) and 95% CIs. These models included the same exposures and covariates as the primary logistic regression models and accounted for the BDHS sampling weights, stratification, and clustering. This analysis was undertaken because odds ratios (ORs) can overstate the magnitude of association when outcomes are common in cross-sectional studies [34].

### Ethical Considerations

The 2022 BDHS protocol was reviewed and approved by the Institutional Review Board of Inner City Fund (ICF) International and the Bangladesh Medical Research Council (BMRC). The publicly available BDHS documentation does not report the corresponding approval numbers. Before

XSL•FO
RenderX

participation, all respondents provided informed consent to take part in the survey. The present study was a secondary analysis of deidentified BDHS data obtained through the DHS program. The analytic dataset contained no direct personal identifiers, and the research team had no access to information that could identify individual participants. Therefore, no additional participant contact, recruitment, or consent was required for this analysis. No compensation was provided to participants for this secondary analysis. The manuscript and supplementary materials contain no identifiable participant information, including names, photographs, addresses, or other potentially identifying details. Detailed ethical aspects and consent forms are available on the BDHS website and in the report.

## Results

This study included a total of 17,027 respondents, representing a population of ever-married women aged 15 to 49 years who responded to the questions required for calculating the SWPER Global index and assessing mental health in the 2022 BDHS. Table 1 presents a summary of the sociodemographic characteristics of the respondents included in the study.

XSL•FO

| BMI of respondents (kg/m$^2$),[a] mean (SD) | 23.97 (4.31) |
| BMI group[a], n (%) | |
| Normal (18.5 kg/m$^2$-24.9 kg/m$^2$) | 4462 (52.5) |
| Abnormal (<18.5 kg/m$^2$ or ≥25.0 kg/m$^2$) | 4029 (47.5) |

[a]Some sociodemographic characteristics were not reported by all respondents; therefore, the total for these variables may not be equal to the sample size (N=17,027).

Mental health outcomes were stratified by sociodemographic characteristics and summarized in Table 2. Across the sample, 4.9% of respondents were classified as having depression, 19.5% as having anxiety, and 31.9% as having at least 1 mental health symptom in the 2022 BDHS. Education was inversely associated with the prevalence of anxiety, depression, and any mental health symptoms, with lower levels of education associated with a higher prevalence of mental health symptoms. Similarly, the household wealth index was inversely associated with mental health outcomes, with poorer individuals more likely to experience depression, anxiety, and any mental health symptoms. Being underweight or overweight was associated with a higher prevalence of anxiety, depression, and any mental health symptoms (Table 2).

**Table .** Unweighted frequencies and weighted prevalence of depression, anxiety, and any mental health symptoms (MHSs) by women's empowerment domain.[a]

[a]Frequencies are unweighted numbers of women with depression, anxiety, or at least 1 mental health symptom. Percentages are weighted estimates accounting for the 2022 Bangladesh Demographic and Health Survey sampling weights, stratification, and clustering. *P* values were calculated using design-based Pearson chi-square tests.

[b]SWPER: Survey-Based Women's Empowerment.

The distribution of respondents' empowerment levels varied across the 3 SWPER Global domains. Most women had high empowerment in the "attitudes toward violence" (86.2%) and decision-making (60.7%) domains, whereas nearly half had low empowerment in the social independence domain (46.3%). Overall, higher empowerment across the 3 domains was more common among women who lived in urban areas, had higher educational attainment, and belonged to wealthier households. Detailed distributions of empowerment levels according to sociodemographic characteristics are presented in Tables S1A to S1C in Multimedia Appendix 1.

Unadjusted ORs for the associations between women's empowerment domains and mental health outcomes are summarized in Table 3. Figure 1 presents graphical representations of aORs after adjustment for covariates including age, residence type, division, education level, number of children, wealth index, religion, work status, and BMI. Results indicated a significant association between mental health outcomes and empowerment in the "attitudes toward violence" domain. Women with low empowerment in this domain had higher odds of depression (aOR 1.81, 95% CI 1.16-2.81), anxiety (aOR 1.46, 95% CI 1.10-1.94), and any mental health symptoms (aOR 1.63, 95% CI 1.27-2.10). Medium empowerment in this domain was also associated with higher odds of anxiety (aOR 1.26, 95% CI 1.04-1.53) and any mental health symptoms (aOR 1.56, 95% CI 1.32-1.85). No significant association was observed between empowerment in the social independence or decision-making domains and mental health

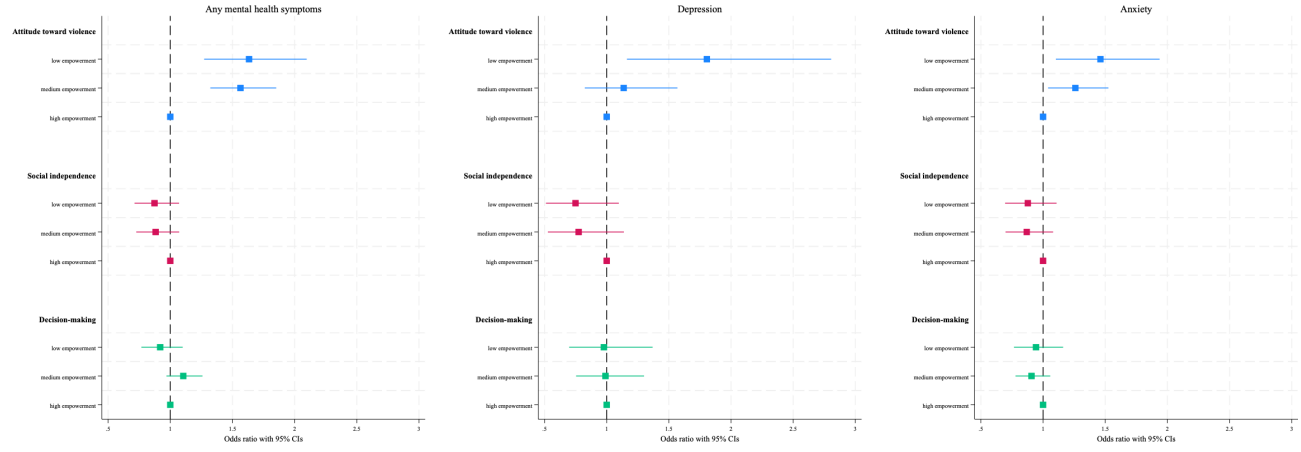
XSL•FO
RenderX

outcomes in this study. The Archer-Lemeshow *F*-adjusted goodness-of-fit test indicated no evidence of lack of fit for all final models ($P>.05$), except for the model examining depression in relation to the "Attitude to Violence" domain ($P=.03$).

**Table .** Unadjusted associations of SWPER (Survey-Based Women's Empowerment) Global index domains and mental health symptoms (MHSs) among women in Bangladesh[a].

| Empowerment domains or categories | Depression, OR[b] (95% CI) | Anxiety, OR (95% CI) | Any MHSs, OR (95% CI) |
|---|---|---|---|
| SWPER—attitudes toward violence | | | |
| Low | 2.05 (1.46-2.87)[c] | 1.78 (1.44-2.22)[c] | 1.72 (1.41-2.11)[c] |
| Medium | 1.36 (1.08-1.71)[d] | 1.41 (1.22-1.64)[c] | 1.58 (1.40-1.80)[c] |
| High | 1.00 | 1.00 | 1.00 |
| SWPER—social independence | | | |
| Low | 1.39 (1.07-1.79)[d] | 1.40 (1.23-1.60)[c] | 1.24 (1.11-1.39)[c] |
| Medium | 1.13 (0.87-1.45) | 1.09 (0.95-1.25) | 1.12 (1.00-1.25)[e] |
| High | 1.00 | 1.00 | 1.00 |
| SWPER—decision-making | | | |
| Low | 0.89 (0.69-1.19) | 0.83 (0.71-0.98)[e] | 0.93 (0.81-1.06) |
| Medium | 0.92 (0.74-1.14) | 0.94 (0.84-1.05) | 1.14 (1.04-1.25)[d] |
| High | 1.00 | 1.00 | 1.00 |

[a]Statistical significance was determined using 2-sided tests with an α of .05. Empowerment levels were calculated using the SWPER Global index and categorized using the original studies' methodologies [22,23].



[b]OR: odds ratio; unadjusted ORs are based on bivariate logistic regression models.

[c]$P<.001$.

[d]$P<.01$.

[e]$P<.05$.

**Figure 1.** Adjusted odds ratios presenting the associations between women's empowerment domains and mental health symptom prevalence. Odds ratios were adjusted for age, residence type, division, education level, number of children, religion, employment status (respondent and partner), and BMI.

Sensitivity analyses using survey-weighted Poisson regression produced aPRs that were consistent in direction and statistical significance with the primary logistic regression findings (Tables S2A-S2C in Multimedia Appendix 1).

## Discussion

### Principal Findings

This study found a significant association between women's empowerment in the "attitudes toward violence" domain and mental health outcomes among Bangladeshi women, whereas no significant association was observed for the social independence or decision-making domains. These findings indicate that the relationship between empowerment and mental

XSL•FO
RenderX

health is multidimensional and may vary according to the specific dimension of empowerment being assessed.

The present findings are broadly consistent with evidence from neighboring South Asian countries, although the patterns are not uniform across settings. A recent nationally representative study from Nepal reported that greater social independence was associated with lower odds of anxiety and depression, whereas higher decision-making empowerment was associated with increased odds of these symptoms [26]. Similarly, prospective evidence from rural India suggests that the relationship between women's agency and mental distress is complex and context-dependent rather than uniformly protective [11]. In Pakistan, population-based research has shown that IPV is strongly associated with poorer mental health among married women, highlighting the broader regional importance of violence-related gender norms for women's psychological well-being [35].

### Attitudes Toward Violence

Women with lower empowerment in the "attitudes toward violence" domain—those less likely to reject justifications for IPV—had significantly higher odds of depression, anxiety, and any mental health symptoms, even after adjusting for confounders. Although the observed aORs were modest in magnitude, they may still be important at the population level because even small shifts in common mental health symptoms can translate into substantial public health impacts in a large population. The findings therefore suggest that attitudes toward violence may be a meaningful but not the sole determinant of women's mental health in Bangladesh. This finding is consistent with broader literature showing that IPV and tolerance of violence are closely linked to women's psychological distress [36,37]. In Bangladesh, previous studies have shown that IPV is associated with depression and that women exposed to violence may face substantial barriers to seeking mental health support [38-40]. Studies in South Asia have also demonstrated that women experiencing IPV report poorer psychological well-being, while attitudinal rejection of IPV can promote resilience and access to social support and services [11,26,35].

Less attention has been paid to the role of women's attitudes toward IPV, as distinct from victimization itself, in shaping mental health outcomes. Recent evidence from Nepal found no significant association between the SWPER Global "attitudes toward violence" domain and mental health symptom prevalence [12], in contrast to the protective effects found in this Bangladeshi sample. The observed benefits in Bangladesh may reflect context-specific pathways. One possible explanation is that women who reject IPV may also differ in other unmeasured ways that are linked to better mental health, although the present cross-sectional data cannot establish such pathways. Given that 23.2% of women in Bangladesh have experienced IPV [8], attitudinal rejection may be a critical focus for both empowerment and mental health interventions.

Taken together, these findings suggest that attitudes toward IPV may capture an important dimension of internalized gender norms that is especially relevant to mental health in Bangladesh. Women who reject the acceptability of IPV may be more likely to recognize abuse, seek support, and resist harmful relationship dynamics, whereas acceptance of IPV may reflect deeper social normalization of violence and reduced psychosocial agency. In a setting where IPV remains prevalent, this domain may therefore be particularly salient for understanding women's mental health vulnerability.

### Social Independence

The association between the "social independence" domain and mental health symptoms was not statistically significant after adjustment for confounders, although the unadjusted analyses suggested a modest protective pattern. The absence of a statistically significant association for social independence does not necessarily indicate that no relationship exists. Rather, it may suggest that any effect is small, context-dependent, or not fully captured by the current cross-sectional measures.

This mixed pattern aligns with existing literature reporting both protective and adverse effects of social independence–related empowerment on women's mental health. In Nepal, higher social independence was associated with lower odds of both anxiety and depression [26]. In Bangladesh, related research among female garment workers suggests that empowerment-related resource mobilization may contribute to lower depressive symptoms and better self-esteem [27]. At the same time, evidence from India indicated that women who were more comfortable speaking up in public reported greater mental distress, possibly because of social backlash and increased visibility within conservative communities [11].

These divergent findings underscore the context-dependent and multidimensional nature of social independence as an empowerment construct. Although greater social independence may be associated with improved access to resources, mobility, and support, it may also coincide with increased scrutiny, interpersonal conflict, or other social pressures in more conservative settings. Because this study is cross-sectional, these patterns should be interpreted cautiously and should not be taken to indicate causal pathways. It is also possible that more socially independent women are more likely to recognize or report psychological symptoms, which could influence observed associations. Further longitudinal and qualitative research is needed to clarify how social independence relates to women's mental health across different contexts.

### Decision-Making

This study found no statistically significant association between women's empowerment in the "decision-making" domain and mental health symptoms. The absence of a statistically significant association for decision-making does not necessarily imply that there is no relationship. Instead, it may reflect a small, context-dependent effect or a pattern that is not well captured by the current cross-sectional design and measurement approach. However, this finding is consistent with the broader literature showing that household decision-making does not have a uniform relationship with women's mental health. For example, higher decision-making empowerment has been associated with increased odds of anxiety and depression in Nepal [26], whereas studies from Mozambique [41] and other sub-Saharan African settings [28,42] have reported protective associations. Evidence from India further suggests that greater decision-making

XSL•FO
RenderX

autonomy may be accompanied by psychological strain when women assume nontraditional roles in patriarchal settings where such changes are not fully supported by families or communities [11,26].

The lack of a significant relationship in our study should be interpreted cautiously. Because this study is cross-sectional, it does not allow causal inference. One possible explanation is that decision-making autonomy may be associated with both potential benefits and potential burdens: although it may increase women's control over household matters, it may also coincide with greater responsibility, interpersonal tension, or social and familial resistance. These findings suggest that the relationship between household decision-making and mental health may be context-dependent, and that instrumental forms of empowerment do not necessarily correspond to better psychological well-being in all settings.

### Mental Health and Empowerment Patterns Across Sociodemographic Groups

In our sample, depression affected a smaller proportion of respondents (4.9%) than that reported in both the 2019 National Mental Health Survey in Bangladesh (7.9%) [43] and the 2021 Global Burden of Disease (GBD) estimate for women aged 15 to 49 years (8.3%). In contrast, anxiety prevalence (19.5% in this study) was notably higher than the estimates from both sources (5.4% and 5.5%, respectively) [43].

Several methodological differences may help explain these discrepancies. The National Mental Health Survey used stricter diagnostic procedures, including assessment by trained research psychiatrists, whereas the present study relied on screening instruments included in the BDHS. The GBD estimates may also reflect older underlying data, and differences in instruments, symptom thresholds, and case definitions across studies may further affect prevalence estimates.

### Policy Implications

The present findings have several practical implications for mental health and gender equity programming in Bangladesh. Because the attitudes toward violence domain was the only empowerment dimension consistently associated with depression, anxiety, and overall mental health symptoms, interventions that aim to reduce the social acceptability of IPV may have benefits beyond violence prevention alone. Mental health providers, community health workers, and frontline practitioners could integrate brief screening for violence-related norms, psychological distress, and support needs into routine services for women, particularly in primary care and reproductive health settings. Public health programs may also benefit from combining mental health promotion with community-based efforts to challenge harmful gender norms, strengthen referral pathways, and improve access to psychosocial support for women at risk of both violence and poor mental health.

These findings also suggest several directions for future research and policy. Longitudinal studies are needed to better understand the causal pathways linking different empowerment domains and mental health over time. Further qualitative and mixed methods research could help clarify why attitudes toward violence appear more strongly related to mental health than social independence or decision-making in this setting. At the policy level, integrating women's empowerment indicators into mental health surveillance and embedding gender-transformative approaches within national mental health and violence prevention strategies may help translate these findings into more effective and contextually appropriate interventions.

### Strengths and Limitations

This study has several limitations. First, all data were self-reported, raising the possibility of reporting bias—especially on sensitive topics such as mental health and women's empowerment—due to stigma or gender norms in Bangladesh. Highly empowered women may also be more likely to recognize and disclose mental health symptoms, potentially inflating observed associations. The BDHS used screening instruments rather than clinical diagnostic tools, which may underestimate the true burden of mental health symptoms and limit the scope of assessed conditions. Although the SWPER Global index is a validated tool, it may not fully capture the cultural and contextual nuances of empowerment. Despite adjusting for key sociodemographic factors, unmeasured confounders—including childhood trauma, extended family dynamics, or access to mental health services—may influence results. We included religion, partner employment status, and BMI as contextual covariates to better account for the cultural environment, household economic conditions, and women's physical health, all of which may plausibly influence both empowerment and mental health. Although these were not the primary variables of interest, their inclusion was intended to reduce residual confounding and improve interpretation of the observed associations.

The main strengths of this study include its use of a large, nationally representative BDHS sample, which enhances the generalizability of the findings to Bangladeshi women. The use of the SWPER Global index also allowed separate examination of 3 distinct dimensions of empowerment—attitudes toward violence, social independence, and decision-making—rather than treating empowerment as a single construct, which improves the specificity of the findings. In addition, the study used standardized screening measures for anxiety and depression and adjusted for several relevant sociodemographic and contextual covariates, which strengthens internal validity and supports a more nuanced interpretation of the observed associations. Finally, this research is among the first to systematically explore the association between women's empowerment and mental health symptom prevalence in Bangladesh, addressing an important gap in the literature.

## Conclusions

In this nationally representative study of Bangladeshi women, only the SWPER Global domain of attitudes toward violence was independently associated with lower prevalence of mental health symptoms after adjusting for sociodemographic factors. Women who rejected justifications for IPV reported lower prevalence of depression, anxiety, and overall mental health symptoms. The lack of association for the social independence and decision-making domains, coupled with inconsistencies across the literature, underscores the need for contextually

XSL•FO
RenderX

tailored interventions. These findings highlight the importance of integrating mental health support and targeting attitudes toward the acceptance of IPV and harmful gender norms within women's empowerment initiatives in Bangladesh. In practice, these results support the inclusion of violence-norm screening, community awareness activities, and culturally responsive psychosocial support within women's health and primary care services. Future research should further investigate the mechanisms linking empowerment domains and mental health to guide more targeted interventions for Bangladeshi women.

## Acknowledgments

The authors acknowledge that this study would not have been possible without the public availability of 2022 Bangladesh Demographic and Health Survey data provided by the Demographic and Health Survey Program. The authors declare the use of generative AI (GAI) in the research and writing process. According to the Generative Artificial Intelligence Delegation Taxonomy (2025), the following tasks were delegated to GAI tools under full human supervision: data analysis, proofreading, and editing. The GAI tool used was Perplexity (Perplexity AI Inc). Responsibility for the final manuscript lies entirely with the authors. GAI tools are not listed as authors and do not bear responsibility for the final outcomes.

## Abstract

**Background:** Despite ongoing global changes in analgesic prescribing practices, long-term trends accounting for age, period, and cohort effects remain poorly understood in Asian populations, where opioid and nonopioid prescribing trajectories differ from those observed in Western nations.

**Objective:** This study aimed to examine the long-term prescribing trends of opioids, nonsteroidal anti-inflammatory drugs (NSAIDs), and paracetamol in Taiwan by age, calendar period, and birth cohort using an age-period-cohort (APC) framework.

**Methods:** We conducted a population-based repeated cross-sectional study using Taiwan National Health Insurance claims data (2001 - 2020). The cohort included all insured individuals aged 1 to 85 years, with an annual population size of 22.3 to 23.1 million. Exposure variables were structured for APC modeling, comprising 5-year age groups, four 5-year calendar periods (2001 - 2020), and 5-year birth cohorts (1920 - 1924 to 2015 - 2019).

**Results:** Opioid prescribing prevalence escalated from 123.66 per 100,000 persons in 2001 to 2005 to 706.93 in 2016 to 2020. APC analysis showed a significant positive net drift for opioids (+10.93% per year, 95% CI 10.36%-11.51%; $P$<.001). The estimated magnitude of the opioid prescribing increase was sensitive to the prescription frequency threshold used. In contrast, paracetamol and NSAIDs showed overall declines (net drifts: −2.44%, 95% CI −2.58% to −2.29%, and −0.82%, 95% CI −0.97% to −0.66%, respectively). Notably, local drifts revealed a significant increase in NSAID prescribing only among adolescents aged 11 to 15 years (+0.80% per year, 95% CI 0.34%-1.27%). Generational analysis suggested higher opioid prescribing risk among younger cohorts (rate ratios 3.06 for the 2015 - 2019 cohort), although the increase relative to the 2000 to 2004 reference cohort was not statistically significant.

**Conclusions:** Reimbursed analgesic prescribing in Taiwan has diverged across drug classes, with a consistent increase in opioid prescribing across all ages and a shift toward NSAID prescribing in younger populations. These claims-based trends should be interpreted as reimbursed prescribing rather than total analgesic use. These findings may inform targeted pharmacovigilance and policies to ensure appropriate pain management while mitigating potential opioid-related risks.

## Introduction

Analgesic prescribing is a core component of pain management and a main objective for pharmacovigilance and population health surveillance. Prescribing patterns are shaped by multiple interacting forces, including demographic aging, evolving clinical guidelines, reimbursement policies, health care access, and medication safety concerns [1,2]. Consequently, long-term monitoring of reimbursed analgesic prescribing at the population

XSL•FO
RenderX

level is essential for identifying changes in prescribing practice and potential safety priorities [2-5].

Over the past two decades, rising opioid-related harms in North America and Europe have prompted broad stewardship initiatives, including guideline revisions, prescribing restrictions, and enhanced monitoring systems, with several settings reporting subsequent stabilization or declines in opioid prescribing [2,6-8]. However, trends have not been uniform across regions. In fact, opioid use in parts of Asia has continued to increase rather than decline [9-12], highlighting the need for context-specific surveillance. Nonopioid analgesics also have distinct trade-offs between clinical efficacy and safety profiles. For example, while some studies found that nonsteroidal anti-inflammatory drugs (NSAIDs) may offer more potent and sustained analgesia than paracetamol (acetaminophen) [13,14], NSAID use is also associated with risks of gastrointestinal bleeding, renal injury, and cardiovascular events [15,16]. For paracetamol, although it is often favored for its relative safety, it still carries a risk of dose-related hepatotoxicity [17]. Analgesic needs and clinical approaches also vary significantly across the life course, ranging from pediatric populations to older adults with multimorbidity [18,19], and are increasingly influenced by generational shifts in attitudes toward pain management. These multifaceted influences highlight the need for a comprehensive assessment of both opioid and nonopioid prescribing to fully capture the evolving landscape of analgesic exposure across different demographic and generational subgroups.

Despite growing attention to analgesic prescribing trends, recent studies have shown that opioid and nonopioid prescribing patterns vary across health systems and population groups [1,20]. However, many studies still focus on a single analgesic class or report only aggregate secular trends, potentially obscuring important heterogeneity across age groups and birth cohorts [7,10,20-22]. Analyses that simultaneously account for age, calendar period, and birth cohort, such as age-period-cohort (APC) approaches, are also needed to disentangle these interrelated temporal dimensions and identify specific age groups or cohorts with disproportionate changes in prescribing risk [23-25]. The limited number of studies jointly considering these factors may inflate observed associations by conflating biological aging with period-specific and generational effects [26]. To address these gaps, we used nationwide Taiwan National Health Insurance (NHI) claims data from 2001 to 2020 to characterize and compare long-term prescribing patterns of opioids, NSAIDs, and paracetamol. Using an APC model, we estimated age, period, and cohort effects to determine whether prescribing trajectories diverged across analgesic classes and identify specific age groups or birth cohorts that may warrant intensified monitoring and targeted stewardship.

## Methods

This study followed the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) reporting guidelines for cross-sectional studies. The completed STROBE checklist is provided in Checklist 1.

### Study Design and Data Source

A population-based repeated cross-sectional design was used for the current study, and our data were drawn from 2 national databases in Taiwan. For medical use data, we used the Taiwan National Health Insurance Research Database (NHIRD), which is managed by the National Health Insurance Administration. The NHIRD covers more than 99% of the population and contains comprehensive records of outpatient services, hospitalizations, and prescriptions, providing a robust source for prescribing surveillance. For population data, we drew from the Department of Household Registration, Ministry of the Interior.

### Ethical Considerations

This study was approved by the Research Ethics Committee of the National Health Research Institutes (EC1111106-E-R2). Because this study used secondary claims data and aggregated population data, the requirement for informed consent was waived by the ethics committee. The NHIRD contains deidentified claims records, and all analyses were conducted using anonymized or deidentified data to protect participant privacy and confidentiality. No participants were contacted, recruited, or compensated in this study.

### Study Population and Observation Period

The analytic sample consisted of NHIRD medical claims data from January 1, 2001, to December 31, 2020, providing a continuous 20-year observation period for examining long-term trends in reimbursed analgesic prescribing. Our study included all insured individuals who were aged between 1 and 85 years. The population at risk was estimated using the year-end population counts from the Ministry of the Interior. Depending on the year, the annual study population ranged from 22,266,932 to 23,078,937 from 2001 to 2020. The NHI policy approved equitable access to health care and limits financial incentives related to the choice of prescription drugs. Our study excluded those with missing or unknown gender and birth date data.

### Measures

Our study defined prescribed analgesic drugs as medications with recognized pain-relieving effects based on prior studies, clinical practice, and evidence-based pain management guidelines [20]. Specifically, pain-related medications are commonly categorized as opioids, paracetamol, NSAIDs, and gabapentinoids [20]. Although gabapentinoids are officially classified as antiepileptic agents, they are known to produce analgesic effects in clinical settings; however, their use in Taiwan is limited due to restrictions under the NHI system [27]. Therefore, our study excluded gabapentinoids and focused solely on paracetamol, NSAIDs, and opioids.

Analgesic prescriptions were identified using the Anatomical Therapeutic Chemical classification system. In our analysis, opioids corresponded to code N02A, NSAIDs corresponded to code M01A, and paracetamol corresponded to codes N02BE01 and N02BE51. Repeated analgesic prescribing was defined as receiving at least 3 prescriptions from the same analgesic class within a calendar year [28,29].

XSL•FO
RenderX

We grouped age, period, and cohort into 5-year intervals, resulting in 17 age groups (1 - 5, 6 - 10, ..., and 81 - 85 years), 4 period groups (2001 - 2005, 2006 - 2010, 2011 - 2015, and 2016 - 2020), and 20 birth cohort groups (1920 - 1924, ..., and 2015 - 2019). For each age group within each period, we estimated the prevalence per 100,000 population. In addition, we calculated age-standardized prevalence using the population of 2001 to 2005 as the standard population. To obtain age-standardized prevalence per 100,000 persons, the age-specific prevalence estimates for each period were weighted accordingly.

### Statistical Analysis

To evaluate temporal trends and age-, period-, and cohort-specific patterns in repeated reimbursed analgesic prescribing, we organized the 2001 to 2020 observation period into four 5-year calendar periods for APC analysis. We then used a 2-step analytical approach. We first conducted a model selection process based on the analysis of deviance as proposed by Clayton and Schifflers [23,24]. We fitted a series of nested APC specifications and used deviance-based tests to assess the incremental contribution of age, period, and cohort effects. The model fit statistics are summarized in Table S1 in Multimedia Appendix 1. Next, given the perfect linear dependency among age, period, and cohort (age = period – cohort), which prevents unique estimation in standard linear regression models, we used the estimable function approach described by Rosenberg et al [25] to address this identification problem. This approach provides interpretable APC summary measures that can be estimated despite the linear dependency among age, period, and cohort rather than relying on uniquely estimated absolute age, period, and cohort effects [25]. Using this approach, we summarized temporal dynamics in prescribing prevalence through 4 APC measures: net drift, local drifts, period rate ratios (RRs), and cohort RRs. Net drift was interpreted as the overall annual percentage change in age-adjusted prescribing prevalence over calendar time, summarizing the combined linear period and cohort trend within the APC framework. Local drifts represented age-specific annual percentage changes, indicating whether prescribing trends increased or decreased differently across age groups. Period RRs represented relative prescribing prevalence in each calendar period compared with the 2001 to 2005 reference period adjusted for age and nonlinear cohort effects. Cohort RRs represented relative prescribing prevalence in each birth cohort compared with the reference birth cohort adjusted for age and nonlinear period effects. Additional age-, period-, and cohort-specific estimates supporting these APC measures are provided in Table S2 in Multimedia Appendix 1. In this study, the 2001 to 2005 period category and the age group of 1 to 5 years were used as the reference categories. Because birth cohort is determined by calendar period and age in the APC framework, this reference age-period combination corresponded to the 2000 to 2004 birth cohort, which was therefore used as the reference cohort. Statistical significance was evaluated using the Wald test with 2-tailed hypotheses and an $\alpha$ value of .05. To assess the influence of the prescription frequency threshold on the APC estimates, we conducted a sensitivity analysis using a broader definition of at least one prescription from the same analgesic class within a calendar year. The results of this sensitivity analysis can be found in Table S3 in Multimedia Appendix 1. All statistical analyses were conducted using SAS (version 9.4; SAS Institute) and R (version 4.3.2; R Foundation for Statistical Computing).

## Results

### Characteristics and APC Model

Age-specific 5-year period prevalence rates of analgesic prescribing are shown in Table 1. Throughout the study period, NSAIDs and paracetamol were the predominant choice for analgesic prescribing. In the initial period (2001 - 2005), their prevalence rates were substantially higher than those of opioids, ranging from 13,052.95 to 51,952.64 for NSAIDs and from 20,397.55 to 54,805.04 for paracetamol per 100,000 persons across age groups. However, the prescribing patterns shifted distinctively over time across drug classes. Both NSAIDs and paracetamol analgesics showed downward patterns by 2016 to 2020, with NSAIDs dropping to between 12,287.48 and 42,051.40 per 100,000 persons and paracetamol dropping to between 13,722.56 and 47,693.16 per 100,000 persons, respectively. Opioid use escalated substantially across all age groups, with prevalence rates rising from a range of 0.36 to 807.97 per 100,000 persons in 2001 to 2005 to a range of 1.00 to 9942.95 per 100,000 persons in 2016 to 2020.

| 81 - 85 | 807.9685 | 3143.605 | 7037.366 | 9942.947 |

A similar trend was observed for age-standardized prevalence. Specifically, the rates for NSAIDs showed a slight overall decline from 22,222.19 to 19,200.22 per 100,000 persons, and paracetamol also followed a steady downward trajectory from 27,624.88 to 18,271.32 per 100,000 persons. Conversely, opioids surged dramatically, increasing from 123.66 to 706.93 per 100,000 persons over the study period.

On the basis of goodness-of-fit statistics (Table S1 in Multimedia Appendix 1), the full APC model yielded the lowest deviance values among all 3 drug classes (NSAIDs: 50,744.95; paracetamol: 50,184.21; opioids: 1041.15), indicating a significantly superior fit compared with any reduced specifications. The analysis of deviance revealed that removing any single temporal dimension led to a substantial increase in deviance ($P$<.001 in all cases), suggesting that the reduced models failed to adequately explain the data. This indicates that the observed analgesic prescribing patterns could not be sufficiently characterized by age, period, or cohort alone or by any 2D reduced specification. Therefore, the full APC model was retained to characterize long-term prescribing trends across all 3 temporal dimensions.

## Overall Trends (Net Drifts) and Period Effects

Net drifts are shown in Table 2, and period RRs are shown in Table 3 and Figure 1B. Overall, the annual percentage changes varied significantly by drug class. NSAIDs and paracetamol exhibited decreasing trends, with net drifts estimated at −0.82% per year (95% CI −0.97% to −0.66%) for NSAIDs and −2.44% per year (95% CI −2.58% to −2.29%) for paracetamol. Conversely, opioids showed a substantial increasing trend, with the net drift estimated at 10.93% per year (95% CI 10.36%-11.51%). Over the study period, period RRs for NSAIDs relative to the 2001 to 2005 baseline declined, reaching 0.91 (95% CI 0.88-0.93) in 2006 to 2010, 0.94 (95% CI 0.92-0.96) in 2011 to 2015, and 0.86 (95% CI 0.84-0.88) in 2016 to 2020. Similarly, period RRs for paracetamol compared to baseline showed a progressive decline, falling to 0.87 (95% CI 0.85-0.89) in 2006 to 2010, 0.84 (95% CI 0.82-0.86) in 2011 to 2015, and 0.67 (95% CI 0.65-0.68) in 2016 to 2020. Conversely, period RRs for opioids increased substantially in each subsequent period, rising to 2.50 (95% CI 2.39-2.61) in 2006 to 2010, 4.08 (95% CI 3.85-4.33) in 2011 to 2015, and 4.79 (95% CI 4.42-5.18) in 2016 to 2020. Sensitivity analysis using a broader definition of one or more prescriptions showed that the positive opioid net drift remained evident, although attenuated (+6.76% per year, 95% CI 6.49%-7.03%). This finding supports the directional robustness of the increasing opioid prescribing trend but indicates that the estimated magnitude was threshold sensitive (Table S3 in Multimedia Appendix 1).

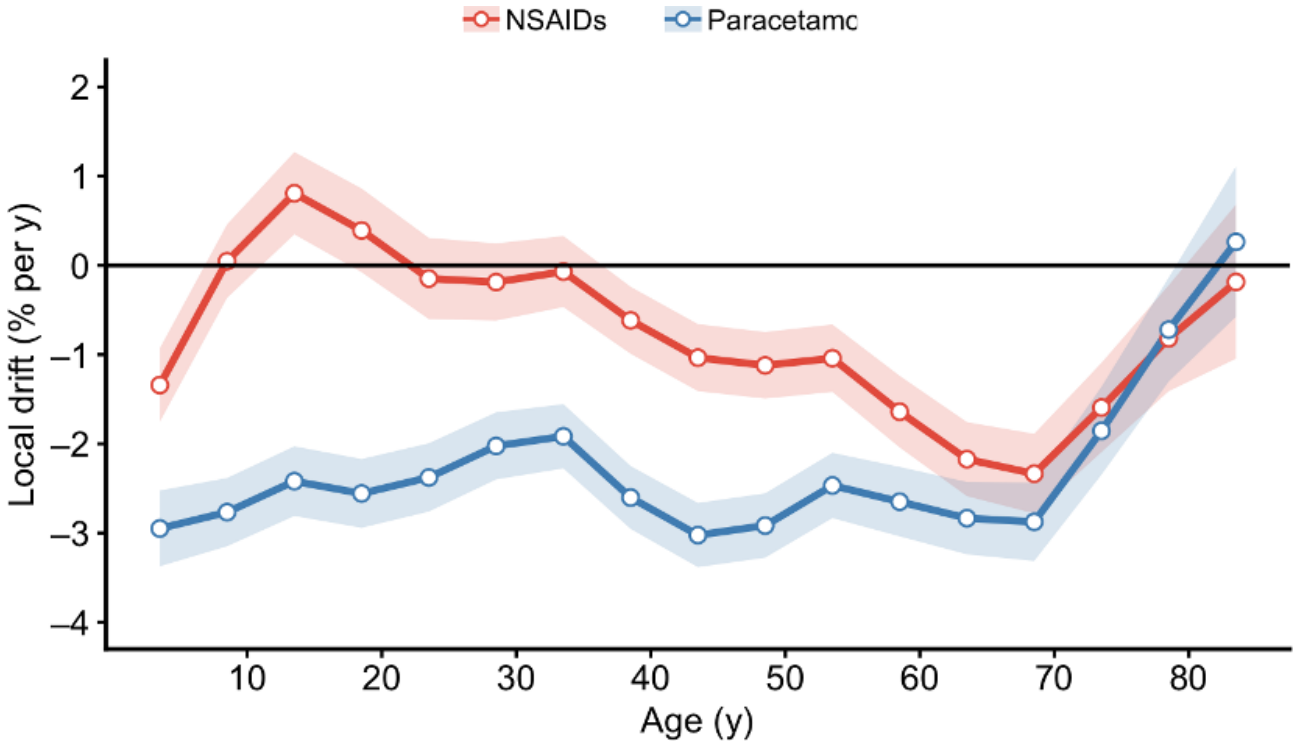
**Figure 1.** Age-, period-, and cohort-specific patterns in repeated opioid prescribing among National Health Insurance beneficiaries aged 1 to 85 years in Taiwan (2001 - 2020). Panel (A) shows age-specific local drifts, expressed as annual percentage changes in opioid prescribing. Panel (B) shows period rate ratios (RRs) relative to the 2001 to 2005 reference period. Panel (C) shows cohort RRs relative to the 2000 to 2004 reference birth cohort. Opioid local drift estimates are displayed separately from those of nonsteroidal anti-inflammatory drugs and paracetamol because their substantially larger magnitude would compress the nonopioid curves and reduce visual readability if plotted on the same scale.



XSL•FO
RenderX

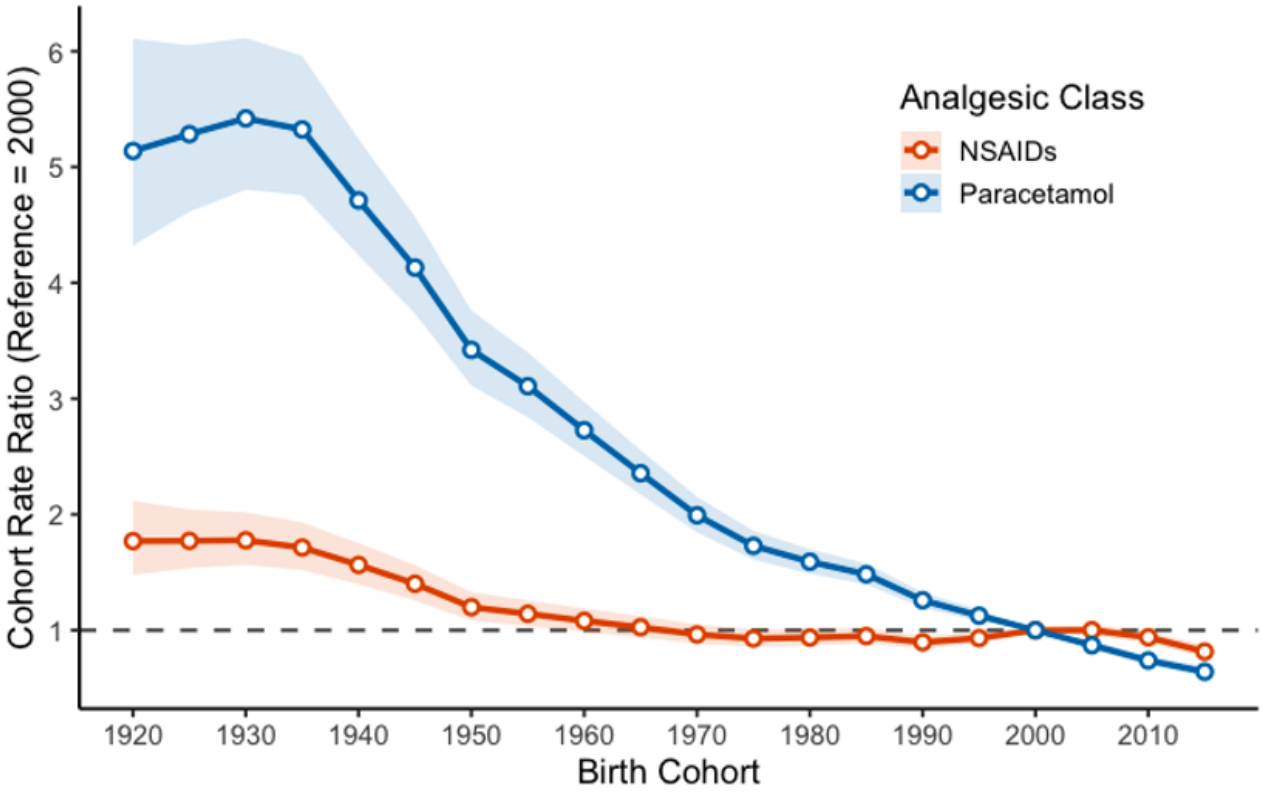
### Age-Specific Divergence (Local Drifts)

Different age-specific local drifts were identified for each analgesic class (Figure 1, Figure 2 and Table 2). Among NSAIDs, trends varied across age groups, with local drifts ranging from −2.33% (95% CI −2.78% to −1.88%) to +0.80% (95% CI 0.34%-1.27%) per year. Children and adolescents generally exhibited positive local drifts across age groups. Specifically, estimates were 0.04% (95% CI −0.36% to 0.46%) for the ages of 6 to 10 years, 0.80% (95% CI 0.34%-1.27%) for the ages of 11 to 15 years, and 0.39% (95% CI −0.07% to 0.86%) for the ages of 16 to 20 years. Notably, only the age group of 11 to 15 years showed a statistically significant increase. In contrast, adult and older populations showed declining local drifts (minimum of −2.33%, 95% CI −2.78% to −1.88%), whereas the oldest age group (81 - 85 years) showed a positive but nonsignificant trend.

**Figure 2.** Age-specific annual percentage changes in repeated nonsteroidal anti-inflammatory drug (NSAID) and paracetamol prescribing among National Health Insurance beneficiaries aged 1 to 85 years in Taiwan (2001 - 2020). The curves represent the estimated local drift (annual percentage change) across age groups for NSAIDs (red) and paracetamol (blue) derived from age-period-cohort models. Shaded ribbons indicate 95% CIs. The solid horizontal black line at 0% marks the threshold of no change; values above this line indicate an increasing trend, whereas values below indicate a decreasing trend.

Paracetamol use showed an overall decline across the life course, with age-specific variation. Specifically, local drifts ranged from −2.94% (95% CI −3.37% to −2.52%) to −2.76% (95% CI −3.14% to −2.38%) among children, from −2.55% (95% CI −2.94% to −2.17%) to −2.41% (95% CI −2.80% to −2.02%) among adolescents, and from −3.02% (95% CI −3.38% to −2.66%) to −1.91% (95% CI −2.27% to −1.55%) among adults aged 31 to 60 years. The magnitude of decline was most pronounced in the age group of 41 to 45 years. Similar to the patterns observed for NSAIDs, the age group of 81 to 85 years exhibited the only positive yet nonsignificant trend.

Opioid use showed an overall increasing trend across the age spectrum, with statistically significant effects in nearly all age groups. The only exception was children aged 1 to 5 years, where the increase was not statistically significant. The magnitude of these annual percentage changes generally trended upward with age, reaching 18.12% (95% CI 17.20%-19.05%) in the oldest age group (81 - 85 years).



### Generational Shifts

Generational analyses, depicted in Figures 1 and 3 and Table S2 in Multimedia Appendix 1, highlight distinct shifts in prescribing risks over time. For paracetamol, a significant downward trend characterized the generational profile. The RRs dropped substantially from the earliest cohorts (1920-1924), decreasing from 5.13 (95% CI 4.32 - 6.10) to 0.64 (95% CI 0.59 - 0.68) for the most recent cohort (2015-2019); notably, the lack of overlap between these CIs underscores the statistical significance of this decline within the model.

XSL•FO
RenderX

**Figure 3.** Estimated cohort rate ratios (RRs) for repeated nonsteroidal anti-inflammatory drug (NSAID) and paracetamol prescribing among National Health Insurance beneficiaries aged 1 to 85 years in Taiwan (2001 - 2020). The birth cohort of 2000 to 2004 was selected as the reference group (RR=1.0). The graph presents cohort RRs for repeated reimbursed prescribing in each birth cohort using the 2000 to 2004 birth cohort as the reference group and accounting for age and period components in the age-period-cohort model.

Trends for NSAIDs generally mirrored this downward trajectory but with distinct nuances. While the RRs declined from 1.76 (95% CI 1.47 - 2.11) in the earliest cohorts to 0.81 (95% CI 0.76 - 0.87) for the most recent group, the trend was not entirely monotonic. The 2005 to 2009 NSAID cohort diverged from the decline, presenting a positive risk that, though not statistically significant, marked a notable interruption in the overall downward trend.

Opioids stood apart with a pervasive upward shift. Among cohorts preceding the reference group (born in 2000 - 2004), the relative risk remained significantly lower than the reference yet displayed a distinct upward trajectory, rising from 0.0001 (95% CI 0.0001 - 0.0001) in the 1920 to 1924 cohort to 0.60 (95% CI 0.46 - 0.77) in the 1995 to 1999 cohort. Following the reference cohort, the point estimates were higher among cohorts born after 2005, reaching 3.06 for the 2015 to 2019 cohort; however, these increases were not statistically significant relative to the 2000 to 2004 reference cohort.

## Discussion

### Principal Findings

To the best of our knowledge, this is the first population-based study using APC analysis to examine the temporal dynamics of analgesic prescribing in Taiwan over a two-decade period. We identified divergent prescribing trends across analgesic classes. While nonopioid analgesics generally exhibited downward trajectories, the decline in NSAID prescribing rate (net drift: −0.82% per year) was notably slower than that of paracetamol (net drift: −2.44% per year), with NSAIDs paradoxically showing increasing trends among children and adolescents. Conversely, opioid prescribing demonstrated a substantial rising trend, with a net drift of 10.93% per year. In addition, our generational analysis revealed a significant overall cohort effect in opioid prescribing, with the cohort RR curve showing an upward pattern across successive birth cohorts. Furthermore, a distinct generational shift was observed in the prescribing of nonopioid analgesics. Among younger generations, prescribing patterns have shifted toward an NSAID-predominant approach; specifically, the likelihood of being prescribed paracetamol has diminished substantially, whereas NSAID prescribing has remained relatively stable or increased.

In contrast to international trends [8,9,21,30], our study identified a continuous and dramatic surge in the likelihood of opioid prescribing in Taiwan. While research using APC to examine opioid prescribing trends across the lifespan remains limited, a study in the United States analyzing individuals aged 16 years and older between 1999 and 2018 identified period effects characterized by an initial increase followed by a subsequent decline [8]. Notably, while the US data indicated a decline in opioid use following its peak around 2015 [8], the likelihood of opioid prescribing in our study continued to escalate without abatement.

Our results align with those of previous Taiwan studies that have identified increasing trends. Specifically, research covering 2002 to 2007 reported an initial rise [31], and a subsequent

XSL•FO
RenderX

study analyzing the 2008 to 2018 period observed a linear increase of less than 20% [10]. However, our results highlighted the importance of applying APC modeling to control for age and cohort effects as the conventional estimates without APC may significantly obscure the true severity of the surge. After controlling for age and cohort effects, the period effect intensified dramatically, with the likelihood of opioid prescribing increasing nearly 5-fold in the most recent period (period RR 4.79) compared to 2001 to 2005.

While prior research indicates that most opioid prescriptions in Taiwan were administered to patients with cancer [10], data from the Taiwan Cancer Registry (2001 - 2020) show that the age-standardized incidence rate of invasive cancer increased by only 21.7% over the study period [32]. This discrepancy suggests that increased prescribing is not solely driven by rising cancer prevalence but likely reflects expanded pain treatment services and evolving standards for noncancer pain management. In addition, although the NHI reimbursement regulations regarding patient eligibility remained largely unchanged between 2001 and 2020, the formulary expanded with the inclusion of 75 new opioid items between 2001 and 2020 [27,33]. That is, the observed increase may not be due to relaxed eligibility criteria but may relate to other factors, such as broader medication options, the expansion of pain management services, high health care accessibility, and a growing emphasis on patient autonomy [10,34,35]. Therefore, continuous surveillance is necessary to ensure reasonable and appropriate opioid prescribing practices [36,37].

Consistent with studies conducted in France and the Netherlands [1,6], our study identified a general decline in nonopioid analgesic prescribing. Notably, this decline differed by drug class, with paracetamol showing a substantially steeper decrease (net drift: −2.44% per year) than NSAIDs (−0.82% per year). Theoretically, these declining trends could be attributed to a reduction in the incidence of diseases requiring analgesia [17,38]. However, this possibility appears unlikely as epidemiological data indicate that the incidence of upper respiratory infections, otitis media, migraine, and tension-type headache remained stable whereas osteoarthritis and low back pain showed an increasing trend in Taiwan throughout the observation period [39]. Another possible explanation lies in the impact of reimbursement policies. According to Article 51 of the National Health Insurance Act, over-the-counter medications are not included in insurance coverage [40]. Following this mandate, the National Health Insurance Administration implemented a policy of gradually phasing out reimbursement for these items since 2005 [41]. Consequently, the decline in nonopioid analgesics likely reflects a shift in acquisition channels.

After controlling for period and cohort effects, our findings indicated that NSAID prescribing showed an increasing trend during adolescence that was statistically significant, specifically in the age group of 11 to 15 years. Specifically, there is mounting evidence suggesting that sleep deficiency is associated with hyperalgesia changes and altered pain processing [42,43]. Given that Taiwanese adolescents have experienced rising rates of sleep problems and inadequate sleep in recent years [44], such chronic sleep deficit among Taiwanese adolescents may facilitate central sensitization, thereby lowering pain thresholds and increasing the demand for analgesia. In addition, obesity and musculoskeletal strain are relatively common among Taiwanese adolescents [45-47], and these conditions may further exacerbate pain sensitivity as obesity-related systemic inflammation can amplify nociceptive responses and increase pain perception [48]. Altogether, the growing use of NSAIDs among younger individuals may reflect their effectiveness in managing inflammation-related pain in the context of increased pain susceptibility.

Furthermore, psychosocial dynamics play a critical role. For adolescents, education demands are high, and falling behind due to absence is a significant concern [49]. Under such pressure, guardians often prioritize antipyretics with superior and prolonged efficacy [50]. This preference aligns with clinical evidence favoring NSAIDs over paracetamol for pediatric pain management [13,14]. Thus, the rising trend in NSAID prescribing may reflect a collective pursuit by adolescents, caregivers, and clinicians for stronger and longer-acting interventions to minimize the disruption of disease on daily routines within a fast-paced, highly competitive society. The proposed mechanisms remain exploratory, and this adolescent-specific NSAID prescribing pattern should be interpreted cautiously given that only the age group of 11 to 15 years reached statistical significance. Nevertheless, this observed rise in NSAID prescribing among adolescents may represent a meaningful deviation warranting continued surveillance.

A central policy implication of applying an APC framework to repeated reimbursed analgesic prescribing is that it helps distinguish broad temporal changes from prescribing patterns concentrated in specific age groups or birth cohorts. In this study, the sustained increase in opioid prescribing, the pronounced increases among older adults, and the adolescent-specific increase in NSAID prescribing indicate where continued surveillance may be particularly relevant within Taiwan's health system. These findings may therefore provide a more targeted basis for future studies using longitudinal NHIRD data to examine clinically meaningful medication-related outcomes, including adverse drug events, opioid-related hospitalizations, and dependence.

## Limitations

This study has several limitations. NHIRD claims lack clinical detail (eg, pain severity, duration, and indications) and do not support dose-based metrics. Therefore, our outcomes should be interpreted as repeated reimbursed prescribing events rather than treatment intensity or indication-specific analgesic use. Because this study analyzed population-level analgesic prescribing trends, it could not determine the relative contributions of cancer-related and non–cancer-related pain management to opioid prescribing trends. In addition, because the primary definition required at least 3 prescriptions from the same analgesic class within a calendar year, short-term or episodic analgesic prescribing, including acute postsurgical opioid prescriptions, may have been underestimated. APC analyses are subject to identification constraints, and 5-year groupings may smooth short-term changes and yield less stable boundary cohort estimates; accordingly, we emphasize long-term

XSL•FO
RenderX

patterns. In addition, our APC models were fitted to aggregated age-by-period data; therefore, results should be interpreted at the population level and do not support individual-level inference. Given the ecological nature of this population-level APC analysis, our study could not directly confirm the underlying causes of the observed analgesic prescribing trends. Although we discussed several potential mechanisms and contextual factors, these explanations may not be exhaustive. Moreover, although younger age groups showed generally positive NSAID local drifts, only the age group of 11 to 15 years reached statistical significance, whereas the adjacent age groups of 6 to 10 years and 16 to 20 years did not. Therefore, population-level interpretations of adolescent-specific NSAID prescribing patterns should be made with particular caution. Finally, analyses were restricted to 3 reimbursed analgesic classes and did not capture over-the-counter or out-of-pocket purchases, so declines in reimbursed nonopioid prescribing may partly reflect channel shifts. As this was a population-based repeated cross-sectional study in a single-payer system, causal inference and generalizability to other health systems are limited.

## Conclusions

In this population-based APC analysis of reimbursed prescribing in Taiwan (2001 - 2020), analgesic prescribing trends diverged markedly across drug classes: opioid prescribing increased substantially, whereas reimbursed prescribing of paracetamol and NSAIDs declined overall, with a steeper reduction in paracetamol. However, the magnitude of the estimated opioid prescribing increase was sensitive to the prescription frequency threshold used. Age- and cohort-specific estimates revealed pronounced heterogeneity, including rising NSAID prescribing in adolescents and a sustained increase in opioid prescribing in older adults, with evidence of higher opioid prescribing risk in more recent birth cohorts. These findings support continued surveillance and stewardship of opioid prescribing and highlight the need for future studies incorporating clinical indications, dose intensity, and nonreimbursed acquisition channels to clarify underlying drivers.

## Abstract

**Background:** The COVID-19 pandemic significantly altered global influenza transmission patterns. Whether the associations among meteorological conditions, visibility, and influenza subtype (A/H1N1, A/H3N2, and B/Victoria) positivity changed after the pandemic remains unclear. We compared these associations before and after the COVID-19 pandemic in northern China.

**Objective:** This study aimed to characterize changes in the associations of meteorological variables and visibility with influenza subtype positivity before and after the COVID-19 pandemic and to identify subtype-specific nonlinear patterns and thresholds.

**Methods:** Using 13 years of influenza surveillance and environmental data, we applied Extreme Gradient Boosting enhanced with Shapley additive explanations (SHAP) to characterize the relative importance and direction of associations between environmental variables and influenza subtype positivity. Generalized additive models (GAMs) were subsequently used to characterize nonlinear association patterns and identify thresholds at which the direction of model-estimated associations changed.

**Results:** Absolute humidity (AH) remained the most influential environmental factor for A/H3N2 and A/H1N1, accounting for 32.2% and 38.5% of relative feature importance, respectively. Visibility increased in importance after the pandemic, rising from being the fourth to the second most influential environmental indicator. GAM analysis identified thresholds corresponding to points where the direction of the associations changed. For A/H3N2, AH below 4 g/m$^3$ was associated with positive SHAP values, whereas higher AH was predominantly associated with negative SHAP values. For A/H1N1, the direction of association changed at an AH threshold of 4.5 g/m$^3$ (95% CI 4.0-4.8) in the postpandemic period. Additionally, relative humidity (RH) demonstrated a complex nonlinear association with A/H3N2 positivity, with transition points at 45.1% (95% CI 43.5%-46.1%) and 69.7% (95% CI 69.2%-70.2%) in the prepandemic period and at 48.7% (95% CI 46.7%-50.4%) and 70.6% (95% CI 66.3%-72.6%) in the postpandemic period. RH values within these ranges were associated with negative SHAP values, whereas values outside these ranges were associated with positive SHAP values. In contrast, visibility showed opposing association patterns for the A/H3N2 and B/Victoria subtypes after the pandemic. Visibility below 17.1 km (95% CI 16.3-17.4) was associated with negative SHAP values for A/H3N2, whereas visibility below 18.4 km (95% CI 18.0-18.9) was associated with positive SHAP values for B/Victoria.

**Conclusions:** AH remained a key environmental determinant of influenza A subtype positivity, while visibility became more important after the pandemic and showed opposing association patterns for A/H3N2 and B/Victoria. The identified nonlinear thresholds highlight subtype-specific environmental associations and may inform influenza surveillance and risk assessment under changing environmental conditions.

## Introduction

Seasonal influenza remains a significant global health concern, causing substantial morbidity and mortality worldwide. The World Health Organization estimates that annual influenza epidemics result in approximately 3 to 5 million cases of severe illness and 290,000 to 650,000 respiratory deaths worldwide [1]. The activity patterns of influenza are influenced by a complex interplay of virological, ecological, and meteorological factors [2,3]. Among these, environmental elements such as temperature, humidity, and air quality play critical roles in modulating viral transmission and survival [4,5]. Traditionally, seasonal influenza has exhibited predictable patterns, with transmission peaks during colder months in temperate regions [6]. However, the COVID-19 pandemic dramatically altered these established patterns of seasonal influenza infection worldwide [7,8]. The implementation of public health and social measures (PHSMs) to combat COVID-19, such as mask wearing, social distancing, and reduced international travel, led to unprecedented changes in influenza transmission dynamics [9,10]. This global disruption presents a unique opportunity to reassess the relationship between environmental factors and influenza transmission in the context of altered human behavior and ecological interactions.

In northern China, the epidemiology of seasonal influenza is characterized by distinct patterns that have undergone significant changes due to the COVID-19 pandemic. Prior to the pandemic, multiple influenza subtypes, including A/H1N1, A/H3N2, and B/Victoria, typically cocirculated during the regular influenza seasons [11,12]. This multisubtype cocirculation pattern was a hallmark of influenza activity in the region. However, with the onset of the COVID-19 pandemic, northern China experienced a dramatic shift in influenza dynamics. Influenza positivity rates plummeted to near-zero levels, ushering in an unprecedented "influenza-free period" that persisted for nearly a year [10,13]. This stark reduction in influenza activity coincided with the implementation of stringent PHSMs to control COVID-19 transmission. As China gradually relaxed its pandemic control measures, a remarkable resurgence of influenza activity was observed. Postpandemic influenza seasons have been characterized by large-scale outbreaks with positivity rates surpassing prepandemic levels [14]. Notably, these postpandemic seasons have predominantly featured single-subtype dominance, a significant departure from the prepandemic multisubtype cocirculation pattern [15]. This shift in influenza epidemiology underscores the need for a deeper understanding of how climatic factors dynamically influence influenza transmission over time, particularly in the context of these altered viral circulation patterns. The region's distinct climate and population density, coupled with these dramatic changes in influenza activity, make northern China an ideal setting for studying the intricate and evolving relationships between meteorological conditions and influenza transmission [16].

This study aimed to address critical gaps in our understanding of how the COVID-19 pandemic has reshaped the relationship between environmental factors and influenza transmission in northern China. Leveraging 13 years of multisubtype influenza surveillance data and high-resolution meteorological records, we used an interpretable machine learning approach to elucidate these complex interactions. Specifically, we sought to (1) quantify the changing impact of key meteorological variables on the transmission of influenza subtypes A/H1N1, A/H3N2, and B/Victoria before and after the COVID-19 pandemic; (2) identify critical environmental thresholds that signify transitions in influenza risk for each subtype; and (3) assess how the relative importance of different environmental factors in influenza transmission has shifted in the postpandemic era, with a particular focus on the temporal dynamics of these influences.

By addressing these objectives, our study aimed to provide a nuanced understanding of the evolving dynamics between environmental conditions and influenza in the wake of a major global health crisis. The insights gained from this research have significant implications for public health planning and disease prevention strategies. Understanding the shifting relationships between environmental factors and influenza transmission can inform more targeted and effective interventions, potentially reducing the burden of seasonal influenza in northern China and beyond. Moreover, this study contributes to the broader scientific discourse on how large-scale disruptions to human behavior and environmental conditions can reshape infectious disease epidemiology, offering valuable lessons for managing future pandemics and adapting to ongoing global climate changes.

## Methods

### Study Design and Setting

This observational study used longitudinal time series data on weekly influenza subtype positivity and environmental conditions in northern China from 2011 to 2024. All available weekly observations within the defined study period were included in the analysis. The study period was split into a prepandemic period (January 1, 2011-December 25, 2019) and a postpandemic period (November 2, 2022-April 30, 2024) [17,18]. The interval from December 26, 2019, to November 1, 2022, was excluded due to the dynamic zero–COVID-19 policy implemented by the Chinese government during the COVID-19 pandemic. This period saw widespread disruptions in influenza transmission as PHSMs significantly altered the usual seasonal influenza patterns. Analyses were conducted at the regional level, with weekly influenza subtype positivity rates and corresponding environmental measures representing northern China as a whole.

### Data Source and Collection

Weekly influenza surveillance data were extracted from the Chinese National Influenza Center and included the number of laboratory-confirmed cases for 3 distinct influenza subtypes: A/H1N1, A/H3N2, and B/Victoria. B/Yamagata was excluded because no cases of B/Yamagata were reported by the Chinese National Influenza Center in the 2021-2023 cycle [19]. Additionally, the number of samples tested each week was collected. To estimate the weekly positive rate, we calculated the ratio of laboratory-confirmed cases for each subtype to the number of test samples [20,21]. Meanwhile, the influenza season was defined as the period from week 40 of one year to week 20

XSL•FO
RenderX

of the following year, consistent with standard epidemiological practices for seasonal influenza surveillance [19].

Meteorological data were sourced from the Visual Crossing data network [22] and spanned the period from January 1, 2011, to April 30, 2024. Data included variables such as cloud cover (percentage), apparent temperature (degrees Celsius), relative humidity (RH; percentage), sea level pressure (SLP; millibars), solar energy (megajoules per squared meter), solar radiation (watts per squared meter), air temperature (degrees Celsius), UV index, wind direction (degrees), and wind speed (kilometers per hour). Visibility (kilometers) was also included as an environmental indicator reflecting atmospheric conditions. Absolute humidity (AH; grams per cubic meter), defined as the weight of water vapor per unit volume of air, was calculated from air temperature and RH based on known formulas [23]. The diurnal temperature range (DTR; degrees Celsius) was computed as the difference between daily maximum and minimum temperatures. Meteorological data for all northern Chinese cities were aggregated into weekly averages to match the temporal resolution of influenza surveillance data reported by the Chinese National Influenza Center. This generated a unified regional time series that reflected the mean environmental conditions across northern China.

To prepare the influenza and environmental data for analysis, time series preprocessing involved checking for missing values, outlier detection and removal, and normalization to ensure data quality and consistency. Before model construction, Spearman correlation analysis was performed to examine associations between environmental variables and positivity rates of A/H1N1, A/H3N2, and B/Victoria. The correlation coefficients were visualized using heat maps, facilitating the identification of potential relationships between environmental conditions and influenza activity.

### Machine Learning Modeling and Feature Interpretation

We used a machine learning approach with Extreme Gradient Boosting (XGBoost) to model the relationship between environmental variables and the positivity rates of the influenza subtypes. Model performance was assessed using metrics including the coefficient of determination ($R^2$), root mean squared error, mean squared error, and mean absolute error, with the results provided in Table S1 in Multimedia Appendix 1 [24].

To interpret the model, we used Shapley additive explanations (SHAP), a unified framework that quantifies the contribution of each environmental variable to model predictions [25]. SHAP values for each predictor were calculated, indicating whether each feature made a positive or negative contribution to the model prediction. This allows for a granular, observation-level interpretation of the influence of environmental factors. The SHAP values were derived using the following linear equation:

$$f(x)=\phi 0+\sum i=1M\phi i$$

In this equation, $f(x)$ represents the prediction for a given input $x$, $\phi_0$ is the model's average prediction, and $\phi_i$ represents the contribution of feature $i$ to the difference between the actual prediction and the baseline. The total prediction is thus broken down into the sum of the baseline and the contributions from all individual features $\phi_i$, where $M$ is the total number of features. SHAP values ($\phi_i$) can either be positive or negative, reflecting how much each feature increases or decreases the predicted outcome. These results were visualized through SHAP summary plots and further stratified by pre- and postpandemic periods to highlight differences in climatic influences.

In addition, generalized additive models (GAMs) were fitted separately for each environmental variable and its corresponding SHAP values to characterize nonlinear patterns in the variable-specific contribution to the XGBoost model output. Model fitting was conducted using the *mgcv* package, which automatically selected the optimal smoothing parameters through generalized cross-validation or restricted maximum likelihood. Nonlinear associations between environmental variables and their SHAP values were described using GAMs. Threshold points were defined as the points at which the fitted GAM curves crossed zero SHAP values, indicating a change in the direction of the model-estimated association between environmental variables and influenza positivity rates. These points were identified using root-finding algorithms. Bootstrap resampling (1000 iterations) was performed to estimate the uncertainty of threshold locations, and the corresponding 95% CIs were calculated.

### Statistical Analysis

All statistical analyses were performed using R (version 4.3.3; R Foundation for Statistical Computing) and Python (version 3.9.0; Python Software Foundation). Continuous variables were summarized as means and IQRs, and differences between 2 groups were evaluated using either the 2-tailed *t* test or Mann-Whitney *U* test as appropriate. The significance level was set at $P<.05$.

### Ethical Considerations

This study used anonymized, aggregated influenza surveillance data provided by the Chinese National Influenza Center. The dataset contained no personally identifiable information and was analyzed in aggregate only. As this study involved secondary analysis of deidentified surveillance data and did not involve direct contact with human participants, ethical review and informed consent were waived because the study involved only secondary analysis of anonymized surveillance data without access to identifiable personal information, in accordance with applicable institutional and national regulations.

All data were deidentified before analysis, and no information that could identify individual participants was available to the investigators. The study findings are reported only at the aggregate level to ensure the protection of participant privacy and confidentiality.

No participant compensation was applicable because no participants were directly recruited for or involved in this study.

## Results

### Overview of Influenza Activity and Meteorological Conditions

During the pre–COVID-19 pandemic period (2011-2019), influenza A subtypes (H3N2 and H1N1) exhibited distinct seasonal patterns with pronounced activity spikes from December to April annually, often cocirculating in most seasons (eg, the winter seasons of 2013, 2017, and 2019). A/H3N2 maintained minor activity even off-season, while A/H1N1 and B/Victoria were primarily confined to the traditional influenza season. B/Victoria showed lower overall positivity rates and less pronounced annual peaks. At the onset of the COVID-19 pandemic (week 10, 2020, to week 1, 2022), influenza activity decreased substantially across all subtypes, with A/H3N2 and A/H1N1 rates dropping to near zero (Figures 1A and 1B). Notably, B/Victoria exhibited unexpected activity during this period, peaking at 32.19% positivity in 2022 (Figure 1C). After the COVID-19 pandemic, particularly after transitioning to routine pandemic management, influenza seasons were characterized by single-subtype predominance with higher intensity than prepandemic levels. From 2022 to 2024, A/H3N2 and A/H1N1 activity rebounded sharply, with postpandemic peaks reaching 33.06% and 32.68%, respectively, significantly higher than pandemic levels ($P$<.001 and $P$=.002, respectively; Figures 1D and 1E). A/H3N2 surpassed prepandemic levels (mean positive rate: 6.30%, SD 9.00% vs 3.54%, SD 5.77%; $P$=.009), while A/H1N1 returned to comparable prepandemic rates. B/Victoria showed significant differences between prepandemic and postpandemic periods (mean positive rate: 1.01%, SD 3.83% vs 3.33%, SD 6.57%; $P$=.003), although pandemic and postpandemic levels did not differ significantly ($P$=.62; Figure 1F).

In addition to changes in influenza activity, we observed variations in environmental factors before and after the pandemic (Table 1). During the prepandemic period, AH, DTR, and RH were recorded at slightly higher levels (mean 7.64%, SD 5.20%; mean 11.38, SD 1.69 °C; and mean 61.16%, SD 8.85%, respectively) than in the postpandemic period (mean 6.22%, SD 4.77%; mean 10.82, SD 1.38 °C; and mean 56.01, SD 8.96%, respectively). Conversely, wind speed and visibility showed the opposite pattern, with higher values in the postpandemic period (mean 20.02, SD 3.09 km/h and mean 18.46, SD 1.03 km, respectively) than in the prepandemic period (mean 18.94, SD 2.88 km/h and mean 11.54, SD 1.76 km, respectively). However, certain climate factors, including cloud cover, apparent temperature, solar energy, solar radiation, temperature, UV index, and wind direction, did not show statistically significant differences across the examined periods, as indicated by the $t$ test ($P$≥.05 in all cases).

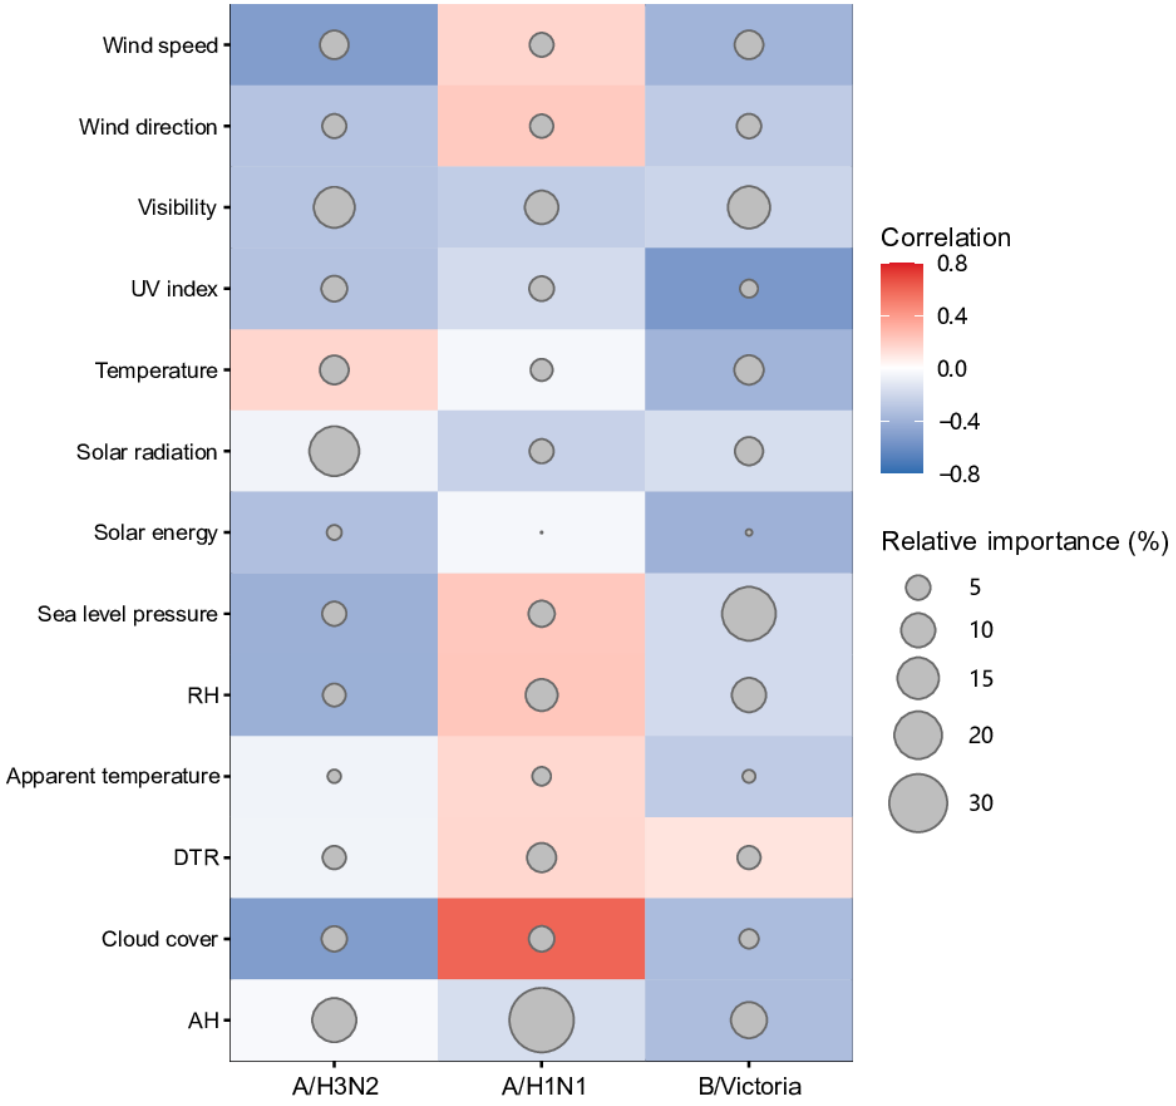
## Environmental Determinants of Influenza Subtype Activity



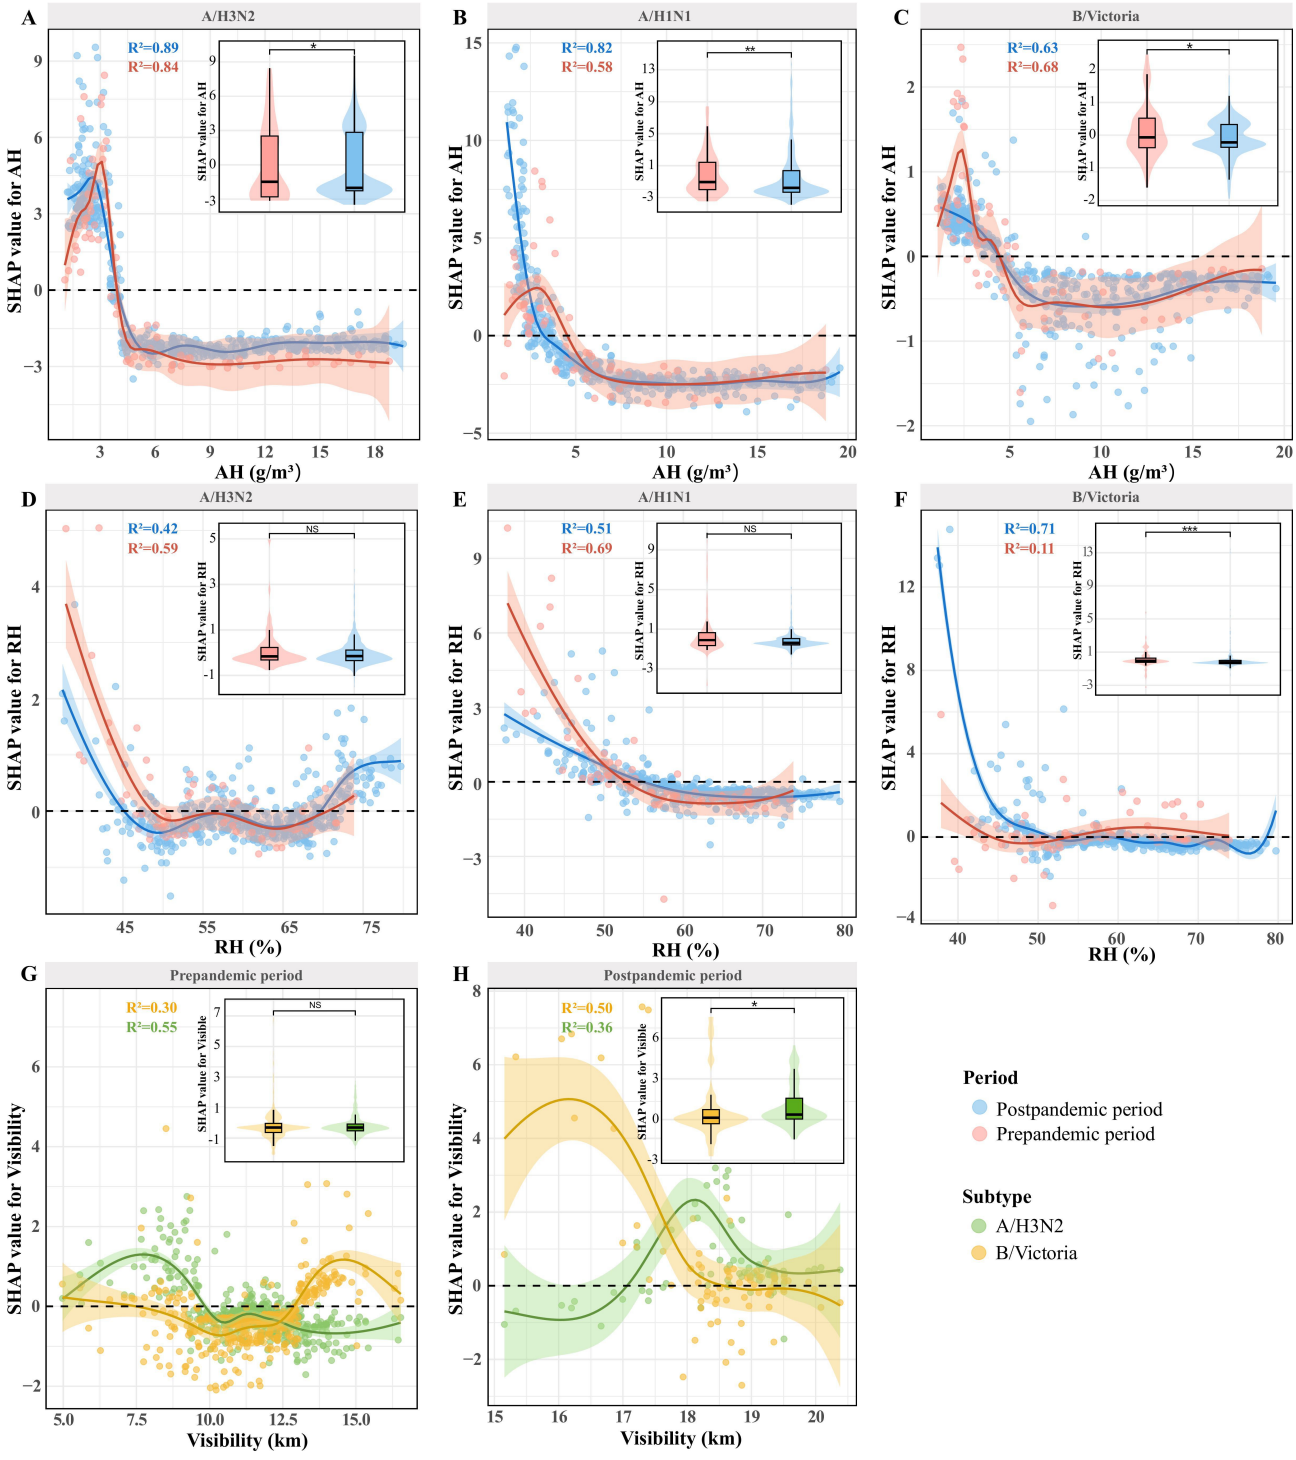
We used XGBoost classification models to investigate the associations between environmental variables and influenza positivity rates for A/H3N2, A/H1N1, and B/Victoria subtypes in northern China. Detailed model results are summarized in Table S1 in Multimedia Appendix 1. To quantify the contribution and influence of each environmental feature on model predictions, we used the SHAP algorithm. Figure 2 illustrates the relative importance of 13 environmental factors for different influenza subtypes derived from SHAP values, with colors representing the Spearman correlation between influenza subtypes and climatic variables. The corresponding relative importance values and Spearman correlation coefficients are provided in Table S2 (Multimedia Appendix 1).

Our analysis revealed distinct patterns of climatic influence across the 3 influenza subtypes. Notably, AH emerged as the most important environmental factor associated with A/H3N2 and A/H1N1 activity, with SHAP contributions of 32.2% and 38.5%, respectively. In contrast, SLP showed the highest SHAP contribution (21.0%) for B/Victoria, followed closely by visibility (Figure S1 in Multimedia Appendix 1). To elucidate the dynamic variation in influenza positivity rates across pre- and postpandemic periods, we stratified the SHAP results into 2 phases (Figure S2 in Multimedia Appendix 1). This stratification revealed that AH remained an important environmental factor across all influenza subtypes, consistently ranking first in importance for both A/H3N2 and A/H1N1 before and after the pandemic. Interestingly, visibility and temperature assumed greater significance in the postpandemic period, particularly for A/H3N2 and A/H1N1. For A/H3N2, the importance of visibility increased significantly (rank: fourth before the pandemic vs second after the pandemic), showing a predominantly positive association with influenza positivity rates (Figure S2A in Multimedia Appendix 1). Similarly, for A/H1N1, the importance of visibility rose substantially (rank: fourth before the pandemic vs second after the pandemic), emphasizing its growing impact in the postpandemic phase (Figure S2B in Multimedia Appendix 1).

XSL•FO
RenderX

**Figure 2.** Correlation and relative importance of environmental factors for A/H3N2, A/H1N1, and B/Victoria. Associations between environmental factors and influenza subtype positivity rates were evaluated using Spearman correlation analysis and Extreme Gradient Boosting (XGBoost) models. Circle size represents the relative importance of each variable in the XGBoost model, and color represents the corresponding Spearman correlation coefficient. AH: absolute humidity; DTR: diurnal temperature range; RH: relative humidity.

We observed that several climatic variables, including wind speed, wind direction, SLP, RH, DTR, and cloud cover, exhibited opposing trends between A/H3N2 and A/H1N1. Notably, the importance of RH was lower than that of AH for A/H3N2 and A/H1N1 (4.9% and 10.7%, respectively) but higher for B/Victoria (12.4%). These findings suggest that AH showed a stronger association with influenza A subtypes, while RH appears more relevant for B/Victoria. SLP and visibility were among the most important environmental factors associated with the B/Victoria subtype before the pandemic, with the role of visibility becoming more pronounced after the pandemic (rank: second before the pandemic vs first after the pandemic). The increase in SHAP values for visibility after the pandemic suggests that visibility became a more influential environmental indicator associated with influenza activity (Figure S2C in Multimedia Appendix 1). Importantly, we noted that the medians of the visibility SHAP values shifted from negative to positive across all subtypes, indicating that the primary impact of visibility on influenza gradually transitioned from suppression to enhancement. We noted differential effects of DTR on subtype transmission. For A/H3N2, DTR was associated with reduced transmission (Spearman coefficient=−0.13), suggesting that stable temperatures might aid in controlling outbreaks of this subtype. Conversely, A/H1N1 and B/Victoria showed positive associations with DTR (Spearman coefficients=0.19 and 0.10, respectively). Temperature also exhibited subtype-specific effects, enhancing the spread of A/H3N2 while showing an opposite interaction with B/Victoria. These nuanced relationships underscore the complex interplay between environmental factors and influenza subtype dynamics in



XSL•FO
RenderX

northern China, particularly in the context of pre- and postpandemic periods.

## Environmental Thresholds Governing Influenza Subtype Risk Transitions

The identified key environmental factors likely exert specific influences on the outbreak risk of multiple seasonal influenza subtypes. To elucidate these relationships and determine critical threshold points at which pandemic risk transitions occur across different phases (before and after the COVID-19 pandemic), we used GAMs to evaluate the effect relationships between these crucial climatic factors and influenza subtype positivity rates (Figure 3).

**Figure 3.** Relationships between Shapley additive explanations (SHAP) values and key environmental factors for A/H3N2, A/H1N1, and B/Victoria. (A-C) SHAP values for absolute humidity (AH) for A/H3N2, A/H1N1, and B/Victoria, respectively. (D-F) SHAP values for relative humidity (RH) for A/H3N2, A/H1N1, and B/Victoria, respectively. (G and H) SHAP values for visibility during the pre- and postpandemic periods, respectively. *$P$<.05; **$P$<.01; ***$P$<.001. NS: not significant.

Our GAM analysis revealed complex, nonlinear associations between key environmental variables and subtype-specific influenza positivity rates, identifying thresholds at which the direction of the model-estimated associations changed across

XSL•FO
RenderX

different influenza strains. For A/H3N2, AH levels below 4 g/m$^3$ were associated with positive SHAP values, indicating a positive association between low humidity conditions and positivity rates (Figure 3A). Above this threshold, SHAP values became negative, suggesting an inverse association between higher AH levels and A/H3N2 positivity. RH exhibited a complex nonlinear association with A/H3N2 positivity rates (Figure 3D). The GAM-estimated response pattern showed 2 thresholds where the direction of association changed: 45.1% (95% CI 43.5%-46.1%) and 69.7% (95% CI 69.2%-70.2%) in the prepandemic period and 48.7% (95% CI 46.7%-50.4%) and 70.6% (95% CI 66.3%-72.6%) in the postpandemic period. Between these thresholds, RH was predominantly associated with negative SHAP values, whereas RH levels outside this interval showed positive SHAP values, indicating a reversal in the direction of association. A/H1N1 positivity rates exhibited an L-shaped response to AH fluctuations, with the GAM curve crossing zero SHAP values at an AH threshold of 4.5 g/m$^3$ (95% CI 4.0-4.8) during the postpandemic period (Figure 3B). For B/Victoria, a similar shift occurred at an AH threshold of 4.5 g/m$^3$ (95% CI 4.0-4.8), with SHAP values showing an increasing trend at higher AH levels, particularly beyond approximately 12.5 g/m$^3$ (Figure 3C). Conversely, A/H1N1 showed consistent declines in SHAP values in response to RH, with prepandemic cutoff points at 54.9% (95% CI 54.0%-55.6%) and postpandemic cutoff points at 52.8% (95% CI 52.0%-54.7%; Figure 3E). For B/Victoria, an RH level below 44.2% (95% CI 41.8%-71.5%) was associated with positive SHAP values during the prepandemic period, indicating a positive contribution to influenza positivity rates (Figure 3F).

Visibility exhibited distinct relationships with influenza subtypes, varying between pre- and postpandemic phases. In the prepandemic period, A/H3N2 showed an inverse curve relationship, initially rising then declining, with a shift from negative to positive impacts at a threshold of 9.69 km (Figure 3G). B/Victoria's trend decreased initially and then gradually increased, surpassing zero at 12.9 km, peaking around 14 km before declining. After the pandemic, significant differences emerged; A/H3N2 exhibited a bell-shaped response, showing a negative association when visibility was below 17.1 km (95% CI 16.3-17.4), then gradually increasing to approximately 18.0 km before declining again (Figure 3H). For B/Victoria, the most pronounced positive influence on influenza positivity occurred in the visibility range of 15 to 17 km, diminishing and turning negative at 18.4 km (95% CI 18.0-18.9). These findings underscore the complex, subtype-specific interactions between environmental factors and influenza transmission dynamics, highlighting potential shifts in these relationships following the COVID-19 pandemic.

## Discussion

### Principal Findings

In this study, we used an interpretable machine learning framework to investigate the associations between environmental factors and influenza subtype activity during the pre- and postpandemic periods in northern China. This approach enabled us to characterize subtype-specific nonlinear association patterns, identify changes in the relative importance of environmental factors, and quantify SHAP-based turning points where the direction of associations changed across different environmental conditions.

Our analysis identified a notable shift in influenza dynamics, particularly with an increase in the activity of the B/Victoria subtype following the COVID-19 pandemic. The COVID-19 pandemic itself had profound effects on influenza epidemiology, leading to a shortened influenza season and decreased viral activity, as corroborated by previous studies [10,14,26]. PHSMs implemented to control COVID-19, such as enhanced use of personal protective equipment, reduced indoor gatherings, and strict physical distancing, likely contributed to these changes [7,10,27]. Our study particularly highlights the persistence of B/Victoria activity during and after the pandemic, in contrast to the fluctuations observed in influenza A subtypes. This could be attributed to differences in the affected populations: while influenza A subtypes are more prevalent among adults and older individuals—demographics also more susceptible to COVID-19—B/Victoria mainly affects children, who experienced less disruption from PHSMs and, therefore, continued to sustain transmission [28,29]. Thus, this may be the reason why this subtype accounted for most influenza cases (97.7%) during the COVID-19 pandemic in northern China [13]. Notably, upon the lifting of pandemic-related restrictions, A/H3N2 activity not only rebounded but exceeded prepandemic levels ($P$<.01), illustrating the dynamic nature of influenza transmission in response to changing public health measures. Additionally, we found that several environmental factors that are important to influenza transmission, such as AH and RH, also differed between the pre- and postpandemic periods. These alterations highlight the necessity of further investigation into the complex interplay between climatic factors and influenza transmission across different stages of the pandemic. Although SLP showed a relatively high contribution for B/Victoria in our model, this association should be interpreted cautiously. SLP is unlikely to represent a direct biological mechanism affecting viral characteristics; instead, it may reflect broader atmospheric conditions or correlated environmental factors that were not directly measured in this study.

Beyond the immediate effects of PHSMs, our study demonstrates that the influence of environmental factors on influenza transmission varies significantly by subtype and period. During the postpandemic period, while AH remained a significant determinant for influenza A subtypes (A/H3N2 and A/H1N1), its overall impact appeared reduced compared to the prepandemic phase, with SHAP values indicating a decrease in influence. This observation suggests that environmental changes following the pandemic may have altered the relative importance of different environmental determinants of influenza transmission. Interestingly, visibility, an indicator related to ambient air quality rather than a conventional meteorological variable, emerged as an important factor affecting all three influenza subtypes, particularly in the postpandemic period. Reduced visibility often reflects increased concentrations of airborne particulate matter and other pollutants, which may influence influenza transmission through effects on respiratory defense mechanisms and host susceptibility [30-32]. A previous

XSL•FO
RenderX

study has also suggested that reduced visibility is associated with the risk of influenza infection, which is consistent with the findings of our study [33]. The increased importance of visibility after the pandemic may reflect broader environmental changes or shifts in population behavior and mobility, warranting further investigation into its role in influenza epidemiology.

We used GAMs to further investigate the complex, nonlinear relationships between environmental factors and influenza transmissibility, revealing variations across subtypes and periods. For example, the L-shaped relationship between AH and SHAP values for A/H3N2, A/H1N1, and B/Victoria suggests that influenza transmission is enhanced at lower AH levels but diminishes as AH increases, stabilizing beyond a certain threshold. Notably, the inflection points of the fitting curves at SHAP=0 consistently fell within the range of 3 to 5 $g/m^3$, aligning with previous studies that indicated the onset of influenza seasons in temperate climates when AH drops below 5 $g/m^3$ [34]. Higher AH levels have been shown to lead to the surface inactivation of lipid-containing viruses, potentially inhibiting the spread of influenza [35]. Similarly, the fitting curves for RH revealed that lower RH levels promote influenza transmission, but its influence diminishes and eventually transitions to a suppressive role at higher RH levels, particularly for A/H1N1. These findings underscore the importance of considering subtype-specific responses to environmental factors when developing predictive models for influenza transmission. Furthermore, our analysis of visibility revealed distinctive patterns for A/H3N2 and B/Victoria, with opposite S-shaped relationships observed between SHAP values and visibility levels. During the prepandemic period, low visibility initially promoted A/H3N2 transmission, while higher visibility had a suppressive effect. For B/Victoria, the relationship was more complex, with visibility initially suppressing and then promoting transmission as it increased. The postpandemic period saw an intensification of these effects, suggesting that changes in visibility, possibly linked to environmental or behavioral shifts, played a more prominent role in influenza transmission. The reasons for these subtype-specific responses to visibility are not entirely clear, but they may involve differences in viral sensitivity to environmental conditions or competition between subtypes [30,32,36]. Previous studies have highlighted the role of air pollutants, such as $PM_{2.5}$ and $PM_{10}$, in increasing the risk of influenza, particularly for influenza A subtypes, further supporting the need for a deeper exploration of visibility's impact on influenza epidemiology [37].

## Limitations

Despite the valuable insights provided by this study, several limitations should be acknowledged. First, this study relied on passive surveillance data, which may be subject to measurement errors and inconsistencies in case reporting. Variability in surveillance practices, laboratory confirmation processes, and health care–seeking behaviors can introduce biases that may potentially affect the accuracy of our findings. Additionally, our analysis did not explore the potential interactions among different climatic factors, which could offer a more comprehensive understanding of how these variables collectively influence influenza transmission. Future studies should aim to investigate these interactions to provide a deeper insight into the complex dynamics involved. Moreover, the complex relationships between environmental variables and influenza activity necessitate more detailed spatial and temporal analyses. In this study, influenza surveillance data were aggregated across northern China, limiting our ability to evaluate spatial heterogeneity arising from differences in climatic conditions, demographic characteristics, and urbanization levels. In addition, meteorological factors may affect influenza activity with delayed effects due to viral survival, transmission processes, incubation periods, and health care–seeking behaviors; however, this study primarily focused on concurrent associations between environmental variables and influenza activity. Factors such as regional climatic zones, demographic characteristics, tourism activities, changes in population immunity, viral evolution, and PHSM implementation may create varied baseline transmission potentials [10,38,39]. These factors may influence the observed associations between environmental conditions and influenza activity in ways that are not fully captured by our study. Consequently, the observed differences between the pre- and postpandemic periods should not be interpreted as reflecting changes in the intrinsic effects of environmental factors alone. Therefore, further research is needed to disentangle these complex dynamics and assess how different environmental and behavioral factors contribute to influenza transmission across diverse geographic settings.

## Conclusions

This study provides a comprehensive analysis of the associations between environmental factors and influenza subtype activity in northern China during the pre- and postpandemic periods. We identified significant shifts in the relative importance of different environmental factors, with visibility emerging as a critical determinant of influenza transmission following the COVID-19 pandemic. AH remained an important environmental factor influencing influenza activity both before and after the pandemic, with its importance being the highest for influenza A and RH having a greater influence for the B/Victoria subtype. These findings underscore the importance of developing adaptive public health strategies that consider the changing environmental influences on influenza transmission, particularly as the world continues to face the long-term impacts of the COVID-19 pandemic. By integrating environmental data into public health planning, the effectiveness of influenza control measures can be enhanced, ultimately reducing the burden of seasonal and pandemic influenza on global health.

## Acknowledgments

The authors extend their deepest gratitude to the numerous staff members of the Center for Disease Control and Prevention, the devoted health care workers, and the diligent data scientists. These individuals tirelessly gather and generously disseminate data,

## Abstract

**Background:** Testing arriving international travelers for COVID-19 paired with whole-genome sequencing (WGS) may identify new introductions of SARS-CoV-2 variants of concern in California, enabling a timely public health response. Traveler genomic surveillance may be a way to improve gaps in worldwide disease genomic surveillance.

**Objective:** This paper aimed to describe a pilot surveillance program to identify SARS-CoV-2 variants in arriving international travelers at San Francisco International Airport (SFO).

**Methods:** The California Department of Public Health implemented a pilot program at SFO to voluntarily test arriving international travelers for COVID-19 from June 2021 to November 2021 to identify SARS-CoV-2 variants. Arriving international travelers were offered self-collect COVID-19 antigen tests upon arrival at SFO. Travelers with positive COVID-19 antigen tests or with COVID-19 symptoms were recommended to self-collect and mail an additional specimen for diagnostic molecular testing. WGS of SARS-CoV-2 was performed on RNA extracts from positive tests to identify variants.

**Results:** In total, 2.1% (19,008/892,558) of all arriving international travelers at SFO from 133 different countries of departure enrolled in the program. The COVID-19 test positivity among this group was 0.7% (33/5038), and the weekly test positivity range, 0% to 1.5%, was lower than the weekly test positivity across the state of California during the same time frame. Arriving international travelers departing from Turkey (3/145, 2.1%), Mexico (7/602, 1.2%), and the United Kingdom (6/626, 1.0%) had the highest test positivity. Of the 14 positive molecular tests, 10 (71.4%) were sequenced, and all were found to belong to the SARS-CoV-2 Delta B.1.617.2 lineage, the most prevalent SARS-CoV-2 variant in California and worldwide at the time.

**Conclusions:** Voluntary testing of arriving international travelers paired with WGS was operationally and logistically feasible. Although the number of sequenced positive COVID-19 specimens in this program was limited, the lessons learned from this pilot informed improvements to subsequent iterations of traveler viral genomic surveillance in California and highlighted the potential value of traveler viral genomic surveillance to support early identification and characterization of emerging infectious diseases entering a region.

## Introduction

Since the beginning of the COVID-19 pandemic, arriving international travelers have posed a risk of introducing new SARS-CoV-2 variants into the United States [1,2]. Many variants of concern that became dominant variants within the United States originated outside of the country [1]. Testing and genomic characterization of SARS-CoV-2 from travelers as they arrive in the United States may identify new variants of concern, enabling a timely and improved public health response.

In June 2021, worldwide rates of vaccination against COVID-19 were low; approximately 5% of the global population had completed an initial COVID-19 vaccine series [3]. At the same time, international travel to the United States was on the rise. The volume of airline passengers arriving in the United States via San Francisco International Airport (SFO) increased from

XSL•FO
RenderX

a low of 2000 passengers per week in April 2020 to 35,000 passengers per week in June 2021 and 46,000 passengers per week in November 2021 [4].

In January 2021, the Centers for Disease Control and Prevention (CDC) mandated that arriving international travelers to the United States test negative for COVID-19 within 3 days of their flight's departure [5]. It was estimated that predeparture testing could miss detection of up to 64% of arriving international travelers who would go on to become infectious with COVID-19 after arrival [6]. The CDC also recommended that arriving international travelers self-test for COVID-19 within 3 to 5 days after arrival, which, when combined with predeparture testing, could identify 70% of infectious days across all arriving international travelers [5,6]. However, lack of COVID-19 test availability, the high cost of tests, and the public's unfamiliarity with self-testing all served as potential barriers for arriving international travelers to follow these guidelines. Furthermore, at the time, there was no system to identify SARS-CoV-2 variant status via whole-genome sequencing (WGS) among arriving international travelers, nor was there a system to understand vaccine uptake among travelers arriving in California. Beginning on October 25, 2021, noncitizens who were nonimmigrants were required to be fully vaccinated against COVID-19 to travel to the United States [7].

In 2021, there were large gaps in SARS-CoV-2 WGS worldwide, and it was minimal in many countries [8]. More than 50% of low- to middle-income countries had less than 0.5% of SARS-CoV-2 cases sequenced, leading to large gaps in genomic surveillance for much of the world [8]. It was not clear whether the lack of diversity in SARS-CoV-2 variants identified at this stage was due to a lack of diversity of variants or a lack of sequencing. There was a need to improve gaps in SARS-CoV-2 genomic surveillance, particularly in California, the site of 2 major international airports where travelers could bring novel variants of concern to California from places with minimal WGS.

We hypothesized that targeted testing and WGS of positive specimens from arriving international travelers would be an efficient strategy to identify emerging SARS-CoV-2 variants and augment the existing viral genomic surveillance system in California. The program could help close gaps in the global SARS-CoV-2 genomic surveillance by identifying SARS-CoV-2 variants in travelers arriving from countries with lower sequencing coverage. Between June 2021 and November 2021, the California Department of Public Health (CDPH) implemented a pilot viral genomic surveillance program at SFO to test arriving international travelers for COVID-19 and identify SARS-CoV-2 variants via WGS. The pilot was also an opportunity to establish a partnership with SFO for ongoing COVID-19 testing and SARS-CoV-2 genomic surveillance. In this paper, we present an evaluation of this pilot program and describe its potential operational and logistical feasibility as a part of California's SARS-CoV-2 surveillance strategy.

# Methods

## Study Design

This was a prospective study evaluating a 2-phased pilot program consisting of COVID-19 diagnostic testing and SARS-CoV-2 genomic sequencing of arriving international travelers implemented at SFO from June 2021 to November 2021.

## Setting

The pilot program took place at the international terminal of SFO, which services routes between 50 international cities and 32 countries. During the pilot period from June 29, 2021, to November 16, 2021, approximately 892,558 passengers deplaned from international flights at SFO [4].

## Ethical Considerations

This surveillance protocol was reviewed by the Committee for the Protection of Human Subjects, California Health and Human Services Agency (project number 2021-180), and determined to not constitute human participant research. Written informed consent for diagnostic COVID-19 testing was obtained from participants at enrollment. Arriving international traveler participation was entirely voluntary, and staff at the airport verbally explained the purpose of this pilot program, its procedures, and the option to decline participation at any point. Participants were informed that their test results and associated data would be used for public health purposes. Participants were not compensated. All data were collected and managed using HIPAA (Health Insurance Portability and Accountability Act)–compliant software and were accessible only to authorized personnel involved in the public health response.

## Participants

### *Pilot Phase 1 Eligibility*

Travelers were eligible to participate in the first phase of the pilot program if they were aged at least 2 years and their country of departure was outside of the United States.

### *Pilot Phase 2 Eligibility*

Travelers were eligible to participate in the second phase of the pilot program if they were aged at least 18 years and their country of departure was outside of the United States.

### *Recruitment*

Participation was voluntary. Announcements were made over the airport public announcement system to inform arriving international travelers of the option to receive free COVID-19 test kits as they exited the international terminal. Signs were placed in the international terminal to inform arriving international travelers about the program as they approached the test site. Trained program staff asked arriving international travelers if they were interested in participating in the pilot program as they passed by the program station, located at the end of the walkway as travelers exit the international arrival area (Figure 1). Recruitment materials were in English.

XSL•FO
RenderX

**Figure 1.** California Department of Public Health COVID-19 testing site at San Francisco International Airport. Arriving international travelers were asked by program staff if they were interested in participating in a voluntary COVID-19 testing program and enrolled as they exited the international terminal from June 29, 2021, to November 16, 2021. The test site operated approximately 8 hours per day and 5 days per week.

### *Enrollment*

Participating arriving international travelers provided informed consent for testing, country of departure, vaccination status, and arrival city within California. Enrollment materials were in 10 languages. “Fully vaccinated” was defined for travelers for the purposes of this pilot as having completed an initial series of an approved World Health Organization vaccine [9]. If a passenger reported that they had not completed the initial vaccination series, they were offered the opportunity to receive a vaccine at the SFO medical clinic.

## Pilot Phase 1 Study Design

Phase 1 took place from June 29, 2021, to October 8, 2021 (approximately 3 months; Table 1). Test site staff offered arriving international travelers 2 free BinaxNOW COVID-19 Antigen Self-Tests (Abbott) and a Color COVID-19 Self-Swab Collection Kit (Color Health, Inc) as they passed by the program table (Figures 1 and 2) [10,11]. The test site operated approximately 8 hours per day and 5 days per week. Participating arriving international travelers were instructed via flyer, email, and SMS text message to get tested at home on the day of arrival using a BinaxNOW COVID-19 Antigen Self-Test following the instructions in the box and report their results online via a web-based reporting software (PrimaryHealth) [11]. Participating arriving international travelers received email and SMS text message reminders to take the second antigen test at home 3 to 5 days after arrival per CDC guidelines [2]. If a participating arriving international traveler tested positive, or if they tested negative but had symptoms of COVID-19, they were recommended to self-collect an anterior nasal sample for molecular testing. Participants packaged the self-collected dry swab specimen and mailed it to the Color Health laboratory. Samples had to be received by the laboratory within 56 hours after collection and were tested at Color Health laboratory via the Color SARS-CoV-2 RT-LAMP Diagnostic Assay (Color Health, Inc) [11,12]. Positive molecular tests were then sequenced by the CDPH Viral and Rickettsial Disease Laboratory to determine the SARS-CoV-2 lineage as part of California COVIDNet [13]. All passengers who tested positive for COVID-19 with an antigen test or a molecular test were recommended to isolate per CDPH guidance [12].

**Table .** Description of the arriving international traveler COVID-19 testing and SARS-CoV-2 variant identification pilot program at San Francisco International Airport (June 29, 2021-November 16, 2021).

| | Phase 1 | Phase 2 |
|---|---|---|
| COVID-19 test | 2 home antigen tests and a home self-collection confirmatory molecular test | Home self-collection molecular test mailed to laboratory |
| Tests, n | 3 | 1 |
| Testing cadence | Day of arrival and 3-5 d after arrival | 3-5 d after arrival or immediately if symptoms presented |
| Test turnaround time | 15-30 min | 1-3 d |
| Symptoms recorded at time of initial test | No | Yes |
| Confirmatory test | Home self-collection molecular test | None |
| Confirmatory test indications | Antigen test positive, or antigen test negative and symptoms present | —[a] |
| All positive molecular tests | Whole-genome sequencing to identify SARS-CoV-2 variant | Whole-genome sequencing to identify SARS-CoV-2 variant |

[a]Not applicable.

**Figure 2.** Flow diagram for the arriving international traveler COVID-19 testing and SARS-CoV-2 variant identification pilot surveillance program.

## Pilot Phase 2 Study Design

Phase 2 took place from October 12, 2021, to November 16, 2021 (Table 1 and Figure 2). As with phase 1, the SFO test site for phase 2 operated for 8 hours a day, 5 days per week, and staff offered arriving international travelers a Color COVID-19 Self-Swab Collection Kit as they passed by the staff table (Figure 1). Participating arriving international travelers were instructed via a flyer to get tested at home 3 to 5 days after arrival using the Color COVID-19 Self-Swab Collection Kit following the instructions provided [10,14]. If the participants had symptoms of COVID-19, they were recommended to self-collect a sample for molecular testing immediately. Self-collected anterior nasal dry swabs were tested at the Color Health laboratory via the Color SARS-CoV-2 RT-LAMP Diagnostic Assay [14], as described above [10,14]. A major difference of phase 2 was that participants self-reported whether they had symptoms of COVID-19 at the time of testing, whereas in phase 1, they did not.

## Sample Processing and WGS

Nucleic acid extraction of molecular specimen swabs was performed at the Color Health laboratory. Nucleic acid extracts frozen at –70 °C were shipped to the CDPH Viral and Rickettsial Disease Laboratory on dry ice for WGS. Specimens were tested using an in-house real-time reverse-transcription polymerase

XSL•FO
RenderX

chain reaction test to determine cycle threshold (Ct) values. Specimens with Ct <33 were sequenced using either the Illumina MiSeq system according to a published protocol or the Clear Dx SARS-CoV-2 test (Clear Labs) on the GridION sequencer (Oxford Nanopore Technologies) [15-17].

### Data Analysis

We provide descriptive analysis of the data collected in the pilot programs. Statewide COVID-19 test positivity and vaccination data were sourced from the CDPH Health and Human Services Agency Open Data Portal [18]. International vaccination data were sourced from Our World in Data [3]. Arriving international traveler data were sourced from public SFO traveler data [4].

## Results

### Participant Demographics

In total, 19,008 arriving international travelers enrolled in the pilot (phase 1: n=15,932, 83.8%; phase 2: n=3076, 16.2%; Table 2 and Figure 2). Arriving international travelers of all ages (median 42.3, IQR 31.5-55.3 years) arrived from 133 different countries of departure (Table 2). We estimate that 2.1% (19,008/892,558) of all international travelers arriving at SFO participated during the pilot period (Table 2). The most frequently listed countries of departure were Mexico, France, Germany, the United Kingdom, and South Korea, which cumulatively accounted for 39.8% (6924/17,418) of the arriving international travelers (Table 2).

[a]Total number of participating arriving international travelers was 19,008.

During the program, 91.6% (17,418/19,008) of the arriving international travelers reported their COVID-19 vaccination status, and 82.3% (14,335/17,418) reported completing an initial COVID-19 vaccination series. Rates of reported complete initial vaccination series increased over the course of the pilot and were generally higher than those for state of California residents (Figure 3 [18]).

**Figure 3.** COVID-19 vaccination status for participating arriving international travelers and the general California population. The graph depicts the percentage of the California population (orange line) and of participating arriving international travelers (blue line) at San Francisco International Airport who reported completing the full initial COVID-19 vaccination series by week from June 29, 2021, to November 16, 2021 [18].

Arriving international traveler–reported initial vaccination series completion rates varied by country of departure. Participants who departed from Japan and Taiwan reported the lowest completion rates (Multimedia Appendix 1). Participants who departed from Switzerland and Croatia reported the highest completion rates (Multimedia Appendix 1). The percentage of participating arriving international travelers who reported completing their initial vaccination series increased over time (Multimedia Appendix 2). The reported initial vaccination series completion rate for participating arriving international travelers was generally higher than the rate for their country of departure (Multimedia Appendix 3) for the countries we examined.

## COVID-19 Test Results

During the pilot, 0.7% (33/5038) of participating arriving international travelers with test results tested positive (Table 2). In phase 1, a total of 0.7% (31/4527) of participating arriving international travelers tested positive. In phase 2, a total of 0.4% (2/511) participating arriving international travelers tested positive. The percentage of positivity of COVID-19 tests among airport program participants ranged from 0% to 1.5% weekly. Test positivity of participating arriving international travelers was lower than the test positivity rate across the state of California during the same time frame, which ranged from 1.8% to 7.2% weekly (Figure 4 [18]). Test positivity varied by country of departure (Figure 5). Participating arriving international travelers departing from Turkey (3/145, 2.1%), Mexico (7/602, 1.2%), and the United Kingdom (6/626, 1.0%) had the highest COVID-19 test positivity during the pilot (Figure 5).

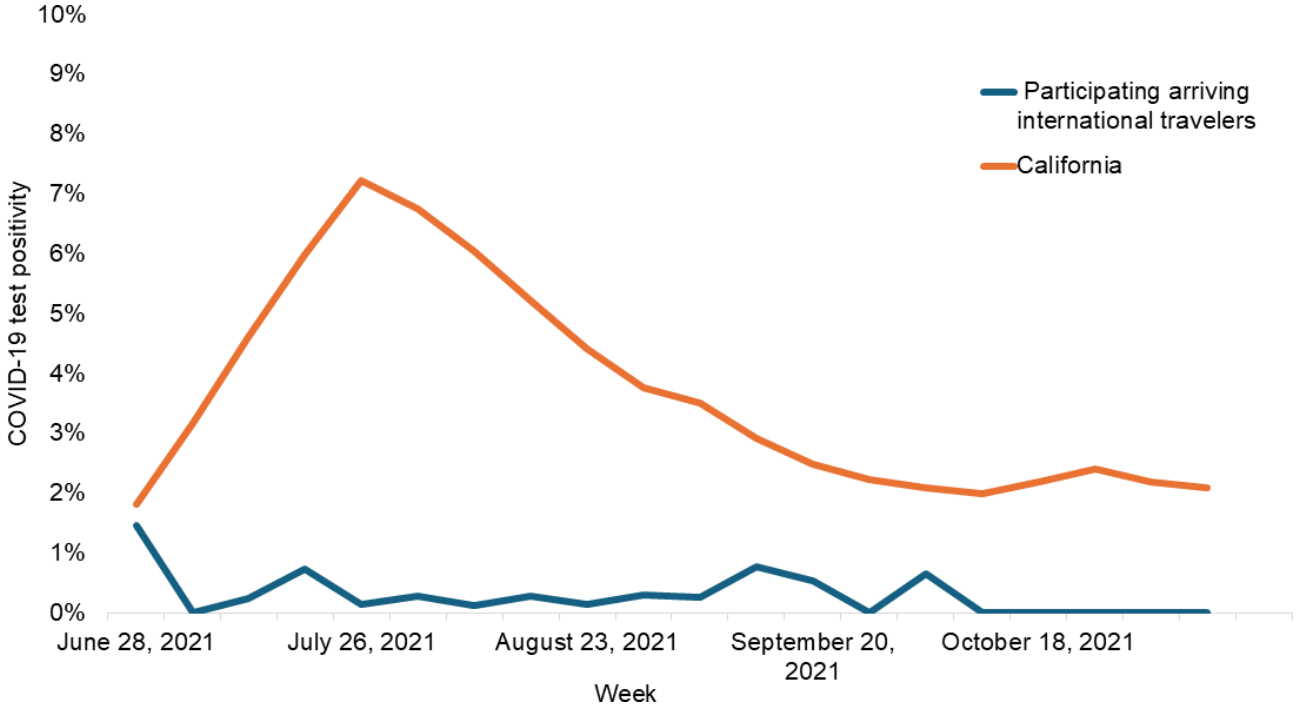
RenderX

**Figure 4.** Participating arriving international travelers and California COVID-19 test positivity by week from June 29, 2021, to November 16, 2021 [18]. Blue line: COVID-19 test positivity for participating international travelers arriving at San Francisco International Airport. Orange line:COVID-19 test positivity for all of California



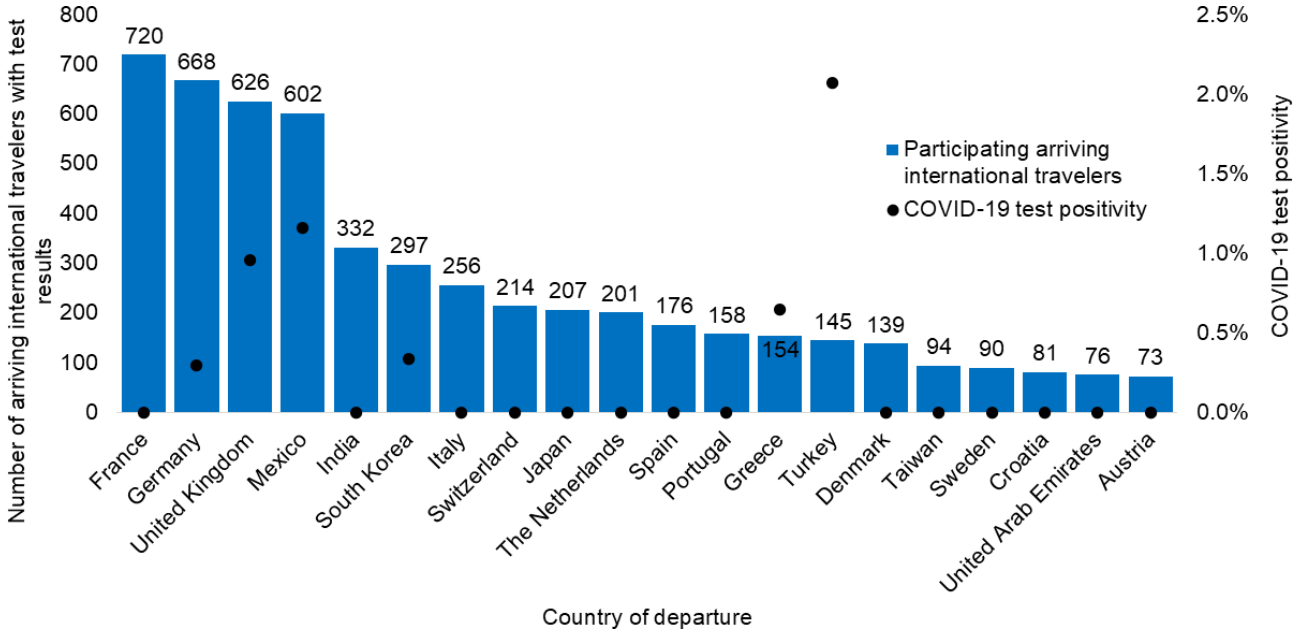


**Figure 5.** COVID-19 test positivity for arriving international traveler participants by country of departure. The blue bars represent the number of participating arriving international travelers to San Francisco International Airport by country of departure from June 29, 2021, to November 16, 2021. The black dots represents the participant COVID-19 test positivity by country of departure. The top 20 countries by number of participating arriving international travelers with test results were included.

During phase 1, a total of 28.6% (4556/15,932) of arriving international travelers reported 1 COVID-19 antigen test result, and 19.3% (3067/15,932) reported 2 antigen test results (Table 2). In total, there were 7499 antigen tests reported, 99.7% (n=7474) had a result, and 0.4% (31/7474) of tests were positive. Among those who tested positive, 67.7% (21/31) tested positive on the first antigen test administered. In phase 1, a total of 106 COVID-19 molecular tests were sent to the laboratory; 89.6% (n=95) had a result, and 12.6% (12/95) were positive. Among arriving international travelers who submitted molecular COVID-19 tests, 75% (72/96) had COVID-19 symptoms. All those who tested positive with a molecular COVID-19 test had symptoms (Table 2).

During phase 2, a total of 17.8% (549/3076) of participants sent molecular test specimens to the laboratory, 93.1% (511/549) of tests produced a result, and 0.4% (2/511) of tests were positive (Table 2). The 2 arriving international travelers who tested positive had symptoms of COVID-19. Among arriving international travelers who were tested, 8.8% (45/511) were

XSL•FO
RenderX

symptomatic at the time of the test; 4.4% (2/45) of symptomatic participants tested positive. Of those who tested negative, 8.4% (43/509) had COVID-19 symptoms (Table 2).

### SARS-CoV-2 Sequencing Results

Of the 14 positive molecular tests during the pilot, 10 (71.4%) were successfully sequenced and assigned a SARS-CoV-2 lineage. All 10 samples were found to belong to the SARS-CoV-2 Delta B.1.617.2 variant, which was the most prevalent SARS-CoV-2 variant in California and worldwide at the time.

## Discussion

### Principal Findings

A two-phased pilot program consisting of diagnostic testing and SARS-CoV-2 genomic sequencing of arriving international travelers was implemented at SFO from June 2021 to November 2021. This pilot program represented the first arriving international traveler COVID-19 testing and SARS-CoV-2 WGS program in the United States and demonstrated that voluntary testing of arriving international travelers for COVID-19 and subsequent SARS-CoV-2 WGS is operationally and logistically feasible. Lessons learned during this pilot informed subsequent iterations of California's testing and genomic surveillance system and strengthened public health partnerships across multiple agencies and private sector collaborators [13,19].

This pilot program showed that an airport-based voluntary traveler diagnostic testing and SARS-CoV-2 genomic surveillance program is feasible. The program voluntarily enrolled 2.1% (19,008/892,558) of all arriving international travelers at SFO. If all travelers who enrolled at the airport completed specimen collection, and assuming a test positivity of 0.7%, the pilot would have collected 133 SARS-CoV-2 sequences, or approximately 30 SARS-CoV-2 sequences per month. At this level of participation, the monthly variant detection threshold in arriving international travelers would be approximately 10% at 95% confidence [20]. This detection threshold from arriving international traveler voluntary testing would likely be useful to detect and characterize emerging new SARS-CoV-2 variants in travelers arriving to California.

The program rapidly built partnerships with federal, state, and local public health agencies; airport and airline authorities; immigration officials; laboratory and informatics vendors; scientific partners; and the media through multiple meetings and outreach efforts. These collaborations enabled timely launch, ongoing refinement based on stakeholder feedback, and integration of SARS-CoV-2 genomic data into California COVIDNet for statewide variant monitoring and provided statewide situational awareness [13]. California COVIDNet facilitated meetings with scientific, health care, and governmental experts across the state on a regular basis to give feedback on SARS-CoV-2 genomic surveillance efforts, including this program [13]. The pilot also developed test reporting mechanisms to enable local public health response if necessary. These mechanisms were developed based on state and local public health official feedback.

Arriving international travelers from 133 countries enrolled in this pilot program, 0.7% (33/5038) tested positive for COVID-19 despite predeparture testing, and 10 SARS-CoV-2 sequences were identified. The pilot program identified the SARS-CoV-2 Delta B.1.617.2 lineage in arriving international travelers, which was the most prevalent SARS-CoV-2 variant in California and worldwide at the time. While this pilot program established that an airport-based traveler testing workflow can be implemented successfully, difficulties with at-home specimen collection and reporting resulted in few positive specimens available for sequencing. As a result, the pilot did not demonstrate effectiveness in detecting emerging or newly introduced SARS-CoV-2 variants. Low testing completion rates of enrolled participants (less than 30% across 2 phases) were largely related to relying on arriving international travelers to complete testing and reporting at home. Low completion of at-home testing and reporting produced few positive specimens for WGS, and two-thirds of arriving international travelers who tested positive with an antigen test (20/30, 66.7%) did not have sequenced specimens. This was likely related to the difficulty of shipping a home-collected specimen to the laboratory, as well as the fact that 7.1% (47/655) of molecular specimens arrived at the laboratory too late to be tested or were inadequate specimens, leading to lost opportunities for sequencing [10,14].

The overwhelming majority of arriving international travelers tested negative for COVID-19, but there were still detections despite predeparture testing, and travelers were likely infectious during travel, highlighting infectious risks for all travelers. Participating arriving international traveler COVID-19 test positivity was lower than the test positivity for the state of California. In a study of arriving international travelers in Qatar, where a similar predeparture testing policy was in place, travelers had a similar COVID-19 test positivity to that in this study [21]. The CDC arriving international traveler predeparture COVID-19 testing requirement likely contributed to the low traveler COVID-19 test positivity [5]. Participating arriving international traveler COVID-19 test positivity varied by country of departure (Figure 5).

From phase 2 of this study, we learned that many travelers (45/511, 8.8% of participating arriving international travelers; Table 2) had symptoms of a respiratory illness during travel. Most people in phase 2 with symptoms consistent with a respiratory illness tested negative for COVID-19 (43/45, 95.6%). This highlights the utility of testing for more than just COVID-19 to determine the epidemiology of respiratory illnesses in arriving international travelers and how infections can spread via international travel.

Participating arriving international traveler vaccination rates were higher than the overall California vaccination rate and generally higher than the overall rate for departure countries during the period of the study [18]. Participant vaccination rates increased over time (Figure 3 [18]). There was variation in arriving international traveler vaccination rates by country of departure that appeared to reflect the overall vaccination rate in each country (Multimedia Appendices 2 and 3). The CDC order requiring noncitizens traveling to the United States for nonimmigration purposes to complete an initial vaccination series against COVID-19 on October 25, 2021, may have

XSL•FO
RenderX

increased vaccination rates among participating arriving international travelers during program operations [7]. Some unvaccinated participating arriving international travelers were interested in getting vaccinated upon arrival at SFO when presented with the opportunity. Determining international traveler vaccination status may enable public health programs to promote vaccination for arriving international travelers and target vaccination to passengers arriving from countries where vaccination rates are lower and disease burden is higher. In future pandemics, vaccine efficacy may vary based on the viral variant.

### Lessons for Future Traveler-Based Pathogen Genomic Surveillance

Multiple operational insights emerged. Completing enrollment and specimen collection at the airport likely would markedly increase testing completion and sequencing yield. Self-collection and self-reporting at home decreased compliance and raised program costs. Integrating diagnostic testing and genomic surveillance into one specimen collection would ease participation by eliminating multiple specimen collections and reducing costs. Providing testing for free likely encouraged arriving international traveler participation. Minimizing the time for arriving international travelers to participate was important to encourage voluntary participation. Testing passengers using a point-of-care test at the airport with results available in 15 to 30 minutes could lead to behavior change that could reduce ongoing transmission from arriving international travelers to residents instead of using a test with a longer turnaround time or a test completed at home. This could be done with a low-cost COVID-19 antigen test, which likely has sufficient sensitivity to COVID-19 (approximately 85% for the BinaxNOW COVID-19 antigen test) [22]. While molecular testing may have higher sensitivity at detecting low levels of the virus, WGS is less likely to be successful with lower concentrations of SARS-CoV-2, and a higher-sensitivity molecular test may not lead to a significant increase in successful sequencing [19]. Using separate laboratories for diagnostic testing and sequencing lengthened turnaround times and complicated logistics as samples needed to be shipped multiple times. WGS from positive point-of-care test specimens may ease logistics as samples would only need to be shipped once from the collection site to the sequencing laboratory, resulting in a shorter turnaround time. These lessons have already informed improvements in California's SARS-CoV-2 genomic surveillance program [19].

### Comparison to Other Traveler Pathogen Genomic Surveillance Programs

This pilot was conducted shortly before the CDC began its traveler genomic surveillance program in 2021 at US airports [23]. The CDC program did not perform diagnostic testing of travelers and focused on global SARS-CoV-2 genomic surveillance using a pooled sequencing strategy. Pooled sequencing does not provide data on arriving international traveler test positivity, does not provide individual participant diagnostic test results, and does not allow for local public health response. In contrast, the pilot program herein described is an example of how diagnostic testing and arriving international traveler vaccination status could be integrated into traveler respiratory virus genomic surveillance, which may have the benefit of increasing voluntary arriving international traveler participation, as well as potentially decreasing ongoing transmission from arriving international travelers and enabling local public health response for individuals who test positive.

### Limitations

There were numerous limitations of this pilot program. Arriving international traveler testing completion rates were low (5038/19,008, 26.5% of enrolled participants), leading to missed opportunities for obtaining SARS-CoV-2 sequences, decreasing program effectiveness in identifying emerging SARS-CoV-2 variants in arriving international travelers. Arriving international traveler participation was also limited due to pilot operating hours not including all flights. Language barriers or difficulty using online user interfaces may have also impacted participation completion. In addition, unsupervised anterior nasal self-swabbing may have resulted in insufficient samples, leading to false-negative tests and missed opportunities for WGS. Self-reported test results in phase 1 may be biased, possibly due to under- or overreporting of positive results relative to the true rate. Participating arriving international travelers' COVID-19 test positivity may not be representative of the COVID-19 test positivity of travelers arriving at SFO during the study period. These factors collectively limited the program's ability to detect emerging SARS-CoV-2 variants.

## Conclusions

This pilot program demonstrated the feasibility of airport-based traveler respiratory virus diagnostic testing and genomic surveillance. The program highlights the strength of state public health department response across multiple disciplines, including infectious diseases, epidemiology, and health communication, to improve situational awareness and public health response in the face of a global pandemic. Because of the high likelihood of future global pandemics, systems are needed to improve global situational awareness, and major international airports allow localities to efficiently access global populations where disease epidemiology, transmissibility, clinical severity, and vaccine and therapeutic effectiveness may be different from local conditions, particularly when large gaps in global surveillance exist. Despite limitations in participant test completion and sequencing yield, the program generated important operational lessons and contributed to California's genomic surveillance infrastructure [19]. Continued advancement of traveler-based surveillance is warranted to strengthen early detection, situational awareness, and pandemic preparedness.

## Acknowledgments

The authors would like to acknowledge the work of the California COVIDNet team; California's COVID-19 Testing Taskforce; Theiagen Genomics; Color Health, Inc; Primary Health; MobileMed; Hallmark Aviation Services; and the San Francisco International Airport team for contributing to this work. The project required coordination among the partners to achieve success, and the authors appreciate the groups' hard work. The authors declare the use of generative AI (GenAI) in the research and writing process. According to the Generative AI Delegation Taxonomy (2025), the following tasks were delegated to GenAI tools under full human supervision: proofreading and editing and checking grammar and punctuation. The GenAI tool used was Microsoft Copilot. Responsibility for the final manuscript lies entirely with the authors. GenAI tools are not listed as authors and do not bear responsibility for the final outcomes.

## Funding

The California COVID-19 Testing Taskforce and the California Department of Public Health and COVIDNet genomic surveillance work were funded by the Centers for Disease Control and Prevention, Epidemiology and Laboratory Capacity for Infectious Diseases Cooperative Agreement (grant number 6 NU50CK000539-02-10). The funder had no role in the design, data collection, data analysis, or reporting of this pilot study.

## Disclaimer

The findings and conclusions in this report are those of the authors and do not necessarily represent the views of the California Department of Public Health or the California Health and Human Services Agency.

## Data Availability

The genomic datasets presented in this paper can be found on the National Center for Biotechnology Information website [24] (bioproject number PRJNA750736).

## Authors' Contributions

EMF, KJ, and DAW conceived this project and guided it to fruition. EMF, ELB, DAW, and KJ performed data analysis and results interpretation and wrote the manuscript. EFB, SG, PA, MS, GG, and CM contributed to pilot management and data acquisition and reviewed and revised the manuscript. All authors contributed to the manuscript and approved the submitted version.

## Abstract

**Background:** The COVID-19 pandemic generated a notable emotional impact on the general population, yet its effects on incarcerated individuals have been far less explored, despite the particular vulnerabilities associated with prison environments.

**Objective:** This study aimed to assess levels of anxiety and fear related to COVID-19 among incarcerated adults in Spain and identify sociodemographic and health-related factors associated with greater emotional distress.

**Methods:** A cross-sectional study was conducted between May 2022 and February 2023 among 711 inmates from 3 Spanish prisons using a nonprobability convenience sampling strategy. Anxiety and fear related to COVID-19 were assessed using the Anxiety and Fear of COVID-19 Assessment Scale (AMICO)–Inmates scale, an adaptation of the original AMICO, developed for the general Spanish population, and subsequently validated for use among prison inmates. Descriptive analyses, bivariate comparisons, and categorical regression (CATREG) were performed to examine factors associated with the total AMICO score.

**Results:** The mean AMICO score was 5.58 (SD 2.55), indicating high levels of anxiety and fear related to COVID-19. In the bivariate analyses, significant differences were observed according to sex, having children, sharing a cell, and the presence of chronic illness. The CATREG model explained 17.4% of the variance in AMICO scores ($R^2$=0.174; $P$<.001). Female sex (β=0.214; $P$<.001), sharing a cell (β=0.112; $P$=.001), and chronic illness (β=0.086; $P$=.01) were independently associated with higher levels of anxiety and fear.

**Conclusions:** Incarcerated individuals experienced high levels of anxiety and fear related to COVID-19. Women, inmates sharing a cell, and those with chronic illnesses appeared particularly vulnerable to emotional distress. These findings highlight the importance of incorporating targeted psychological support and mental health strategies into prison preparedness plans for future public health emergencies.

## Introduction

The psychological impact of infectious disease outbreaks on the general population has been extensively documented over the past decades. Studies following epidemics such as severe acute respiratory syndrome, influenza A and virus subtype H1N1, and Ebola have consistently reported increased mental health morbidity, particularly anxiety and depression, especially

XSL•FO
RenderX

during the early stages of these events [1-3]. When the COVID-19 pandemic emerged, researchers rapidly turned their attention to its psychological effects on emotional well-being and sense of coherence [4-6], identifying high levels of anxiety from the outset and emphasizing the urgent need for targeted mental health interventions. Alongside this, protective factors such as access to adequate health information and the adoption of preventive behaviors were highlighted [7], while evidence further pointed to the central role of information exposure in shaping both anxiety and depression and promoting adaptive protective responses [3,8,9].

Central to understanding these psychological dynamics is the distinction between two closely related but conceptually distinct constructs. Fear is conceptualized as an emotional response to a real or perceived imminent threat, typically associated with immediate defensive reactions and autonomic activation, whereas anxiety refers to a more future-oriented state characterized by anticipation of potential threat, often accompanied by excessive worry and heightened physiological arousal in the absence of immediate danger [10]. In the context of COVID-19, the literature has described a close association among high infection rates, fear, and pandemic-related morbidity and mortality, with elevated fear levels shown to trigger maladaptive behaviors and emotional responses [11].

These effects, while pervasive across the general population, take on particular significance in closed institutional settings such as prisons, where structural conditions and restricted autonomy create heightened psychological vulnerability [12]. The Spanish prison system classifies inmates into three custody grades that fundamentally determine their living conditions. The first grade, or closed regime, involves individual cell confinement with minimal social interaction. The second grade (the most prevalent) corresponds to an ordinary regime in which inmates typically share cells and have daily access to common areas and structured activities. The third grade, a semiopen regime, allows nearly normalized contact with the outside world [13]. The Spanish prison system comprises 65 prisons, 2 psychiatric hospitals, and 13 open facilities, forming a modern and functionally integrated network designed to implement custodial sentences, security measures, and pretrial detention within largely self-contained institutional settings [14]. These differences in confinement levels and social support are critical to understanding how pandemic-related restrictions may have differentially affected anxiety and fear across the incarcerated population [15,16].

During the COVID-19 pandemic, Spanish prisons implemented strict containment measures, including the complete suspension of family visits, prolonged cell confinement amounting to extended solitary isolation, and the cancellation of all group activities such as workshops and outdoor exercise [17]. While these measures were designed to curb transmission, they simultaneously led to the abrupt elimination of social support and daily routine, two cornerstones of emotional stability in custodial settings. It is plausible that such conditions intensified feelings of loneliness, uncertainty, and hopelessness, thereby elevating levels of anxiety and fear in this population. Notably, these strategies differed markedly from those adopted in other countries, where compensatory measures such as video calls or controlled social interactions were frequently maintained [18-21], highlighting the need to contextualize observed psychological outcomes within the specific framework of the Spanish penitentiary system.

The psychological consequences of these conditions have been well documented in the broader prison literature. Social interaction is a fundamental determinant of psychological well-being, and prolonged social isolation has been consistently associated with adverse mental health outcomes, including anxiety, depression, emotional dysregulation, cognitive disturbances, self-harm, and suicide risk [22-28]. These effects may be particularly pronounced in prison settings, where restrictions imposed during the COVID-19 pandemic further limited interpersonal contact and access to social support [19-21]. During this period, fear of infection, the impact of social distancing, the interruption of family visits, and the reduction of mental health services appear to have compounded these preexisting vulnerabilities [19]. Furthermore, poor communication by prison staff regarding pandemic measures has been identified as an additional source of stress and anxiety among inmates [20], while reports indicate that prisoners placed in isolation typically spent between 22.5 and 24 hours per day in their cells, sometimes for months or even years without a defined end point [21]. The high prevalence of preexisting mental health conditions in this population, including mood disorders, substance use disorders, anxiety, depression, and psychosis [29], as well as a family history of mental health problems [30], further renders incarcerated individuals particularly susceptible to the psychological sequelae of pandemic-related restrictions. More broadly, prison environments may amplify the psychological consequences of public health emergencies owing to overcrowding, limited autonomy, reduced access to health care resources, and the concentration of individuals with preexisting vulnerabilities [12,31-33]. Recent research conducted after the acute phase of the pandemic has continued to document substantial psychological distress among incarcerated populations, with persistent symptoms of anxiety, depression, stress, and fear linked to infection risk, restricted social contact, and institutional uncertainty [34,35]. Within this context, fear and anxiety emerged as common psychological responses to perceived threats associated with infection, uncertainty, and concerns about personal and family well-being [36-38].

To assess these psychological responses, validated instruments have been developed and adapted for use in diverse populations. The Fear of COVID-19 Scale has been validated in English [39], Italian [40], and Spanish [11]. Building on this work, Gómez-Salgado et al [41] designed the Anxiety and Fear of COVID-19 Assessment Scale (AMICO, for its acronym in Spanish), beginning with the 10 initial items evaluated by a panel of experts in the study by Ahorsu et al [39] and incorporating 8 additional items to capture COVID-19–specific anxiety alongside the fear construct. The resulting 16-item instrument demonstrated reliability as a screening tool [41] and was subsequently validated in a prison population, where it showed a consistent factor structure and high internal reliability, supporting its use in custodial contexts [42].

XSL•FO
RenderX

Despite this growing body of evidence, studies specifically examining anxiety and fear related to COVID-19 among incarcerated populations remain scarce, particularly in Spain. Given the heightened vulnerability of prison settings during public health emergencies, further research is warranted to better identify these emotional responses in this underserved population. Therefore, the objective of this study was to evaluate the levels of anxiety and fear related to COVID-19 in an adult prison population in Spain following the validation of the AMICO–Inmates through a field study conducted among incarcerated individuals.

## Methods

### Design

A descriptive cross-sectional study was conducted using questionnaire-based data collection. The reporting of this study adhered to the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) (Checklist 1) guidelines for cross-sectional studies [43].

### Participants

The study population consisted of inmates housed in Spanish penitentiary institutions. The total prison population in Spain has been estimated at 49,998 individuals [44]. The sample size was determined using 2 complementary criteria. First, considering the target population, a minimum sample of 450 participants was calculated using a 95% confidence level, 3% precision, and an anticipated attrition rate of 25%. Second, given that the study involved administration of the 16-item AMICO–Inmates, the recommendation of at least 10 participants per item was also considered, resulting in a minimum required sample of approximately 200 participants for stable psychometric and multivariable analyses [45]. The more conservative population-based criterion (n=450) was adopted as the minimum target sample size.

The Spanish prison system comprises 65 prisons. Given the national scope and logistical constraints associated with data collection in correctional environments, a nonprobability convenience sampling strategy was used. Specifically, the selection of the 3 participating institutions (Albolote, Granada; Jaén; and Córdoba) was based on institutional accessibility, administrative authorization, and willingness to participate, which are common constraints in prison-based research.

Inclusion criteria were being aged 18 years or older, being incarcerated in one of the participating institutions during the data collection period, being able to understand and complete the questionnaire, and providing informed consent to participate. No additional exclusion criteria were established other than refusal to participate or inability to provide informed consent. All inmates present in the participating modules on the days of data collection who met the inclusion criteria were invited to participate voluntarily.

A total sample of 711 participants was ultimately obtained, exceeding the minimum sample size required by both calculation approaches. The calculated sample size represented the minimum number of participants required to ensure adequate statistical power. As recruitment continued throughout the study period, all eligible individuals who met the inclusion criteria and agreed to participate were included, resulting in the final sample being larger than the minimum required.

### Variables

The questionnaire collected the following sociodemographic and health-related variables: sex, age, province of residence, marital status, number of children, income, degree of sentence, number of people sharing the cell, perceived health status, presence of chronic disease, and substance use. Scale-based variables were also included, among them the AMICO–Inmates score. Due to feasibility constraints associated with data collection in correctional settings and the need to minimize respondent burden, information regarding previous mental health diagnoses and COVID-19 vaccination status was not collected.

The AMICO–Inmates is a validated instrument designed to assess anxiety and fear specifically related to the COVID-19 pandemic in incarcerated populations [42]. It comprises 16 items grouped into 2 correlated dimensions (anxiety and fear) using a 10-point Likert-type response format ranging from 1 (“strongly disagree”) to 10 (“strongly agree”). Validation in the Spanish prison population demonstrated a robust bifactor structure, adequate unidimensionality (percentage of uncontaminated correlations=0.52; explained common variance=0.64; omega hierarchical=0.82), and excellent reliability (Cronbach $\alpha$=0.95; McDonald $\omega$=0.951), supporting its internal consistency and sensitivity as a screening tool in this context [42]. Although the scale comprises 2 correlated dimensions, previous validation studies have supported the calculation and interpretation of a global score. Therefore, the total AMICO score, obtained as the mean of all item responses, was used as the dependent variable in the present analyses [42].

According to the validation study, interpretation of AMICO–Inmates scores is based on percentile-derived categories established from the distribution of the validation sample: low (0.0 - 3.4 points), moderate (3.5 - 5.5 points), and high (>5.5 points) levels of anxiety and fear related to COVID-19. These categories showed statistically significant differences during the validation process (all Mann-Whitney *U* tests; $P<.001$) and were proposed as interpretative thresholds for the instrument [42].

### Procedure

The necessary permits to conduct the research were obtained from the General Secretariat of Penitentiary Institutions of the Ministry of the Interior, as well as from the management teams of each penitentiary institution.

Access to the centers was facilitated by the medical and/or treatment subdirectorate of each facility, which coordinated communication between the research team and the health care staff, educators, and correctional officers responsible for the modules where data collection took place. The study used a nonprobability convenience sampling approach. Participants were recruited through official and authorized channels, with prison staff assisting in the organization of data collection sessions and the distribution of questionnaires.

XSL•FO
RenderX

Staff were previously instructed by the research team regarding the study aims and procedures. In each module, inmates were gathered in common areas, where members of the research team, assisted by prison staff, administered the paper-based questionnaires and provided standardized instructions while resolving any doubts.

Although the questionnaire was hetero administered by trained prison staff under researcher supervision, strict confidentiality was ensured at all times. Inmates were informed that participation was voluntary, responses were anonymous, and completed questionnaires would be handled exclusively by the research team with no access by prison staff or institutional authorities, thereby minimizing social desirability bias and ensuring privacy in the provision of answers.

Sampling began at the Jaén prison on May 26 and 27 and June 1, 2022. It continued at the Albolote prison (Granada) on September 23, 26, and 29 and October 3 and 5, 2022. The final sampling day was February 23, 2023, in Córdoba.

### Data Analysis

The SPSS Statistics software (version 26; IBM Corp) was used for univariate and bivariate descriptive analysis. Normality of the score distribution was assessed using the Kolmogorov-Smirnov test, which yielded a *P* value of .01, indicating a nonnormal distribution. Accordingly, nonparametric contrast tests were performed, including the Mann-Whitney *U* test and the Kruskal-Wallis test. The Kendall tau-b coefficient was used to examine the correlation between quantitative variables.

To examine the relationship between anxiety and fear levels (total AMICO score) and the remaining variables, a categorical regression analysis (CATREG) was performed given that these variables were qualitative in nature. The CATREG analysis includes key features of classic regression analysis, such as the coefficient of determination ($R^2$), the ANOVA in regression, and the significance of the parameters. For the analysis, the optimal scaling option in SPSS was selected. Categorical regression (CATREG) results are reported using standardized coefficients (β), *F* statistics, and associated *P* values in accordance with the standard output generated by the CATREG procedure in SPSS. Variables were selected for inclusion in the CATREG model solely based on statistical significance in the bivariate analyses ($P<.05$). Variables meeting this criterion were subsequently entered into the model to identify independent predictors of anxiety and fear related to COVID-19.

Prior to analysis, data were screened for completeness. Missing data were minimal and handled using complete-case analysis.

### Ethical Considerations

The updated October 2024 version of the Declaration of Helsinki [46] was taken into consideration for this study, and explicit permission was obtained from participants through informed consent. This ensured the confidential use and processing of data in accordance with Organic Law 3/2018 on the Protection of Personal Data and Guarantee of Digital Rights [47] and Law 14/2007 on Biomedical Research [48]. All data will be duly safeguarded by the research team.

This study forms part of the IMPACTCOVID-19 project, which aims to evaluate the impact of the COVID-19 pandemic on the emotional well-being and psychological adjustment of the general population in Spain. The project was authorized by the Ethics Council and Research Committee of the Regional Government of Andalusia (reference PI 036/20-2)

Authorization to conduct the study was also granted by the Subdirectorate General for Institutional Relations and Territorial Coordination and the General Secretariat of Penitentiary Institutions of the Spanish Ministry of the Interior.

Participation was entirely voluntary. Before completing the questionnaire, all participants received verbal and written information regarding the objectives of the study and were informed that participation was anonymous and confidential and would have no effect on their legal, penitentiary, or health care status. Participants could decline participation or withdraw at any time without consequences. All participants confirmed their voluntary and confidential participation by selecting the corresponding checkbox on the informed consent form. The form additionally informed participants of the possibility of contacting the principal investigator if they required psychological support after completing the questionnaire; for this purpose, participants were invited to provide their full name and email address. Participants received no compensation for taking part.

## Results

### Descriptive Analysis of the Sample

The study sample consisted of 711 incarcerated adults aged 18 years or older from prisons in Spain (Table 1). Of these 711 individuals, 100 (14.1%) were women, and 611 (85.9%) were men. Participants ranged in age from 19 to 82 years, with a mean age of 40.41 (SD 11.67) years. Additionally, 19.3% (n=137) were married, 39.1% (n=278) were single, and 41.6% (n=296) reported another marital status (divorced, separated, widowed, or living with a partner). Furthermore, 67.5% (n=480) had children, while 32.5% (n=231) did not.

**Table .** Sociodemographic characteristics of the study sample and bivariate analysis of anxiety and fear related to COVID-19 among incarcerated adults in 3 Spanish prisons (Spain, 2022 - 2023; N=711).

| Variables | Total sample, n (%) | AMICO[a] score (range 1-10), mean (SD) | Hypothesis testing, *P* value |
|---|---|---|---|
| Sex | | | <.01[b] |
| Female | 100 (14.1) | 6.57 (2.62) | |
| Male | 611 (85.9) | 5.42 (2.50) | |
| Marital status | | | .59[c] |
| Married | 137 (19.3) | 5.52 (2.72) | |
| Divorced | 90 (12.7) | 5.46 (2.63) | |
| Other | 9 (1.3) | 4.48 (2.23) | |
| Single | 278 (39.1) | 5.50 (2.53) | |
| Partnered | 178 (25.0) | 5.85 (2.46) | |
| Widowed | 19 (2.7) | 5.85 (2.23) | |
| Degree of sentence | | | .66[c] |
| First degree (closed regime) | 12 (1.7) | 6.11 (1.83) | |
| Second degree (ordinary regime) | 685 (96.3) | 5.58 (2.55) | |
| Third degree (open regime) | 14 (2.0) | 5.17 (3.28) | |
| Children | | | .03[b] |
| Yes | 480 (67.5) | 5.74 (2.56) | |
| No | 231 (32.5) | 5.06 (2.50) | |
| Receipt of a pension | | | .84[b] |
| Yes | 115 (16.2) | 5.61 (2.56) | |
| No | 596 (83.8) | 5.58 (2.55) | |
| Sharing a cell | | | .05[c] |
| Yes | 508 (71.4) | 5.32 (2.57) | |
| No | 203 (28.6) | 5.19 (2.50) | |
| Chronic illness | | | .002[b] |
| Yes | 241 (33.9) | 6.00 (2.48) | |
| No | 470 (66.1) | 5.37 (2.56) | |
| Substance use | | | .20[c] |
| No substance use | 300 (42.2) | 5.44 (2.62) | |
| Alcohol only | 11 (1.5) | 4.42 (2.42) | |
| Tobacco only | 278 (39.1) | 5.74 (2.47) | |
| Other substance or polysubstance use | 122 (17.2) | 5.68 (2.55) | |

[a]AMICO: Anxiety and Fear of COVID-19 Assessment Scale.

[b]Mann-Whitney *U* test.

[c]Kruskal-Wallis test.

Concerning the degree of sentence classification, 1.7% (12/711) were in the first degree, characterized by more restrictive control and security measures (closed regime); 96.3% (685/711) were in the second degree (ordinary regime); and 2.0% (14/711) were in the third degree (open regime). A total of 16.2% (115/711) received some type of social or noncontributory pension, whereas 83.8% (596/711) did not. The data also indicate that 71.4% (508/711) of respondents shared a cell, while 28.6% (203/711) did not share a cell with anyone. Regarding substance use, 42.2% (300/711) reported no use of any substance, 39.1% (278/711) used tobacco, and 41.4% used other legal or illegal substances.

XSL•FO
RenderX

The mean score obtained on the AMICO was 5.58 (SD 2.55) points, with a range from 1 to 10. The bivariate analysis identified statistically significant differences only in relation to sex, with women presenting a higher mean score (mean 6.57, SD 2.62) than men (mean 5.42, SD 2.50; $P<.01$). For the remaining variables analyzed (marital status, degree of sentence, having children, receipt of a pension, and sharing a cell), no statistically significant differences were observed in the mean AMICO score, with similar values across categories (Table 1).

In relation to the findings derived from the use of the AMICO, Table 2 shows the mean scores and SDs for the 16 items that constitute the instrument. Overall, higher scores were observed for items related to concern about the infection of family members and friends (mean 8.11, SD 2.835), as well as the uncertain duration of the pandemic (mean 7.51, SD 3.130) and the possibility of death from COVID-19 (mean 7.14, SD 3.331).

**Table .** Descriptive statistics of the Anxiety and Fear of COVID-19 Assessment Scale–Inmates items assessing anxiety and fear related to COVID-19 among incarcerated adults in Spanish prisons (2022 - 2023; N=711).

| Items | Score (range 1-10), mean (SD) |
|---|---|
| I am very afraid of COVID-19. | 5.48 (3.325) |
| I feel uneasiness when thinking about COVID-19. | 5.76 (3.391) |
| I am very concerned about getting COVID-19. | 6.29 (3.465) |
| The COVID-19 disease may cause death, and this worries me. | 7.14 (3.331) |
| My hands sweat when I think about COVID-19. | 4.07 (3.466) |
| I feel nervous or uneasy when watching news or stories about COVID-19 in social networks and other media. | 5.53 (3.508) |
| I can't sleep because I am worried about getting COVID-19. | 3.61 (3.239) |
| My pulse races when I think about getting COVID-19. | 3.94 (3.427) |
| Contradictory information about coronavirus in social networks and the media makes me feel anxious. | 4.72 (3.514) |
| I have negative ideas when I hear or read any news related to the disease. | 5.06 (3.470) |
| I am afraid any relative or friend may get COVID-19. | 8.11 (2.835) |
| I am worried about how long the pandemic will last. | 7.51 (3.130) |
| When someone coughs near me or I consider is too close to me, I am afraid of getting infected. | 6.20 (3.429) |
| I am worried about being close to or assisting a person that has or may have COVID-19. | 6.66 (3.464) |
| I feel sad or downcast when I think about the disease and the possibility of getting infected. | 5.32 (3.559) |
| I feel anxious about going out, or considering going out, to fulfill my daily responsibilities (work, family, etc). | 3.90 (3.400) |

In addition, items linked to fear of contracting the disease and physical proximity to others showed elevated scores, as reflected in statements such as "When someone coughs near me or I consider is too close to me, I am afraid of getting infected" (mean 6.20, SD 3.429) and "I am worried about being close to or assisting a person that has or may have COVID-19" (mean 6.66, SD 3.464).

Conversely, the lowest scores were recorded for items associated with physiological anxiety responses, such as "I can't sleep because I am worried about getting COVID-19" (mean 3.61, SD 3.239), "My pulse races when I think about getting COVID-19" (mean 3.94, SD 3.427), and "I feel anxious about going out, or considering going out, to fulfill my daily responsibilities (work, family, etc)" (mean 3.90, SD 3.400).

Taken together, these findings indicate that, within the prison sample, cognitive concern about contagion and the overall impact of the pandemic predominated over physiological symptoms of anxiety (Table 2).

## Regression Analysis

Regarding the association between sociodemographic and health-related variables and AMICO scores, the bivariate analyses revealed statistically significant differences according to sex, having children, sharing a cell, and the presence of chronic illness (Table 1). Women, inmates with children, those sharing a cell, and those reporting a chronic illness showed higher mean levels of anxiety and fear related to COVID-19. No statistically significant differences were observed for marital status, degree of sentence, receipt of a pension, or substance use.

A categorical regression analysis was performed to determine which sociodemographic variables were associated with anxiety and fear scores related to COVID-19 as measured using the AMICO. The resulting model yielded an $R^2$ of 0.174, indicating that the variables included explained approximately 17.4% of the variance in the total score. Although the proportion of the

XSL•FO
RenderX

variance explained was modest, the model was statistically significant ($F_{7,703}$=6.845; $P$<.001), as shown in Table 3.

**Table .** Categorical regression model examining sociodemographic predictors of anxiety and fear related to COVID-19 (Anxiety and Fear of COVID-19 Assessment Scale total score) among incarcerated adults in Spanish prisons (2022 - 2023; N=711).[a]

| Variables | β coefficient | *F* test (*df*) | *P* value |
|---|---|---|---|
| Sex | 0.214 | 16.939 (2, 703) | <.001 |
| Having children | −0.049 | 1.308 (1, 703) | .25 |
| Sharing a cell | 0.112 | 6.918 (2, 703) | .001 |
| Chronic illness | 0.086 | 4.615 (2, 703) | .01 |

[a]Regression model fit: $R^2$=0.174, Fisher $F_{7,703}$=6.845, and $P$<.001.

With respect to the standardized coefficients, 3 variables showed a significant association with the total AMICO score: sex, sharing a cell, and chronic illness. Sex presented the highest β coefficient (β=0.214; $P$<.001), indicating higher levels of anxiety and fear among women than among men. Sharing a cell was also associated with higher AMICO scores (β=0.112; $P$=.001), as was the presence of a chronic illness (β=0.086; $P$=.01). Having children did not remain significant after adjustment in the multivariable model (β=−0.049; $P$=.25).

## Discussion

### Principal Findings

The present study contributes to the growing body of evidence on the psychological consequences of the COVID-19 pandemic by focusing on a population that remains largely underrepresented in the literature: incarcerated individuals. Overall, the findings suggest that the pandemic generated a notable emotional burden among inmates, highlighting the vulnerability of prison populations when confronted with large-scale public health emergencies. These results reinforce previous evidence indicating that restrictive environments, reduced autonomy, uncertainty, and concerns about personal and family well-being can intensify psychological distress during health crises [49].

The findings further suggest that emotional responses to COVID-19 within prisons are not distributed uniformly across individuals. Rather, they appear to be influenced by both personal and contextual factors, supporting ecological and psychosocial models that conceptualize anxiety as the result of interactions between individual characteristics and environmental conditions [20,50,51]. In correctional settings, these dynamics may be particularly relevant given the unique challenges associated with confinement, social isolation, and limited control over daily living conditions [19,52].

From a broader perspective, the study highlights the importance of considering prisons as priority settings for mental health surveillance and intervention during infectious disease outbreaks. The experience of the COVID-19 pandemic demonstrated that concerns related to health risks, uncertainty about the future, and the well-being of significant others may become especially salient among incarcerated populations. These concerns are consistent with theoretical frameworks emphasizing the role of perceived vulnerability, uncertainty, and mortality awareness in the development of anxiety responses during periods of crisis [51-56].

Taken together, the need for prison health policies that incorporate psychological support strategies alongside infection control measures is noticeable. Addressing the emotional consequences of public health emergencies within correctional institutions may contribute not only to the well-being of inmates but also to the overall effectiveness of institutional responses to future crises [12,57].

Our findings are consistent with those of international research documenting intensified emotional distress among individuals deprived of liberty during the pandemic, particularly as a consequence of suspended visits, health-related uncertainty, and perceived risk [58]. Studies conducted in different countries have reported similar patterns, including increased fear of contagion, concern for family members, and perception of institutional vulnerability, factors that have contributed to a widespread rise in symptoms of anxiety, stress, and depression within prison populations [51]. These elements have been identified as especially significant in settings with stringent restrictive measures, where prolonged isolation and reduced external contact act as triggers of emotional vulnerability [59].

The association between chronic illness and higher anxiety and fear scores is also consistent with previous evidence from both prison and community settings. Individuals living with chronic health conditions were repeatedly identified during the COVID-19 pandemic as being at increased risk of severe illness and adverse outcomes, which may have heightened perceptions of vulnerability and uncertainty. Within correctional environments, concerns regarding access to health care, continuity of treatment, and the potential consequences of infection may further amplify these emotional responses. Consequently, inmates with chronic illnesses may represent a particularly vulnerable subgroup requiring additional psychological and health support during public health emergencies [60].

Similarly, the higher levels of anxiety observed among women align with meta-analyses showing a greater prevalence of anxiety disorders in women under adverse circumstances [61]. Within the female prison population specifically, the literature identifies an increased risk of affective and psychological disorders related to factors such as greater exposure to past traumatic experiences, separation from children or other dependents, and the emotional burden associated with caregiving

XSL•FO
RenderX

responsibilities [62]. These factors may have amplified emotional responses during the pandemic, thus helping explain the differences observed.

Elevated concern about infecting family members has also been documented in European and Latin American prison studies, where fear for loved ones' health frequently exceeded fear for one's own physical integrity [63,64]. This pattern is consistent with psychological theories suggesting that perceived threats to significant others can intensify fear due to the activation of attachment and social protection mechanisms [65].

Finally, the findings are in line with evidence from the general nonprison population, which also reported heightened anxiety in the face of uncertainty, risk of infection, and exposure to contradictory information [66,67]. However, in the prison context, these factors appear to be exacerbated by reduced autonomy, limited access to reliable health information, and a perceived lack of control over the environment, which may account for the high scores observed in several AMICO items.

### Contributions, Limitations, and Future Directions

This study makes several contributions to the perception of emotional distress in prison settings. The findings provide evidence on the factors associated with anxiety among incarcerated individuals and highlight the particular vulnerability of women, individuals with chronic illnesses, and those living in shared cells. From a practical and managerial perspective, the results highlight the importance of implementing targeted emotional support interventions, improving staff training in the early detection of anxiety symptoms, and promoting effective communication and organizational practices that support inmates' psychological well-being during health emergencies.

Despite these contributions, several limitations should be acknowledged. First, the study relied on self-reported data, which may be affected by social desirability bias. Second, the cross-sectional design prevents the establishment of causal relationships among the variables examined. Third, a nonprobability convenience sampling approach was used due to the restricted access to correctional settings and the operational constraints inherent to prison research, which may introduce selection bias and limit representativeness. In addition, the absence of prior stratification may have resulted in imbalances across relevant subgroups, such as sex or other custodial characteristics, potentially affecting the precision of the estimates and the stability of the predictive model. Although female sex emerged as the strongest factor associated with anxiety and fear related to COVID-19, women represented a relatively small proportion of the sample. Therefore, the magnitude and generalizability of this association should be interpreted with caution and confirmed in future studies including larger and more balanced samples of female inmates. Accordingly, the findings should not be assumed to be fully representative of all incarcerated populations. Fourth, data were collected between May 2022 and February 2023, a period marked by the progressive easing of COVID-19 restrictions and the transition toward a postpandemic context. Therefore, the level of fear observed in this study may not fully reflect current perceptions of COVID-19–related fear among incarcerated populations. Finally, relevant psychological variables such as perceived stress, coping strategies, and social support were not included. Although the CATREG model explained a meaningful proportion of the variance in anxiety and fear related to COVID-19, the inclusion of these variables could have further improved its explanatory capacity. In addition, the number of inmates who declined participation was not systematically recorded, preventing the calculation of a response rate and limiting the assessment of potential selection bias.

### Conclusions

The findings of this study show that more than half of the evaluated Spanish prison population presented high levels of anxiety and fear related to COVID-19. This prevalence confirms that the pandemic had a substantial emotional impact on a population characterized by structural vulnerability, restrictions on personal autonomy, and limited access to information and social support.

The bivariate analysis and the categorical regression model identified clear sex differences, with women exhibiting significantly higher scores, as well as notable effects associated with sharing a cell and the presence of chronic illness. These results underline the need to consider differential factors, both structural and personal, when assessing emotional distress in prison environments.

The data obtained provide an up-to-date and valuable overview for prison institutions and public health authorities, offering empirical evidence on the emotional needs of incarcerated individuals during health crises. Consequently, the findings support the importance of developing specific preventive and therapeutic interventions, with particular attention to women, individuals with chronic illnesses, and those living in shared cells.

Finally, the results highlight the relevance of promoting further research that integrates psychological, social, and environmental variables, as well as longitudinal studies that allow for a deeper understanding of the evolution of emotional distress among people deprived of liberty following public health emergencies.

## Abstract

**Background:** The COVID-19 pandemic revealed substantial disparities in health outcomes across US communities. High-resolution mobility data offer new opportunities for real-time surveillance of behavioral responses, yet less is known about how precautionary behavior varied within cities and how these differences were associated with subsequent COVID-19 hospitalization risk.

**Objective:** This study assessed how community-level risk shapes heterogeneity in precautionary mobility behavior within cities and whether these differences are associated with subsequent COVID-19 hospitalization risk.

**Methods:** We analyzed anonymized mobile device data from 623 ZIP codes in the 20 most populous counties in Texas and COVID-19 hospitalization records comprising 65,474 hospital admissions from 620 ZIP codes (February-July 2020). We constructed a ZIP code–level measure of precautionary mobility reduction (PMR) and linked it to a composite community risk score derived from US Centers for Disease Control and Prevention social vulnerability indicators. Generalized additive mixed models estimated associations among community risk, mobility patterns, and weekly hospitalization rates, adjusting for epidemic timing, population size, and spatial clustering.

**Results:** Mobility declined by approximately 73% relative to baseline following statewide stay-at-home orders but varied substantially across ZIP codes. On April 2, 2020, PMR was negatively associated with community risk (slope −0.16, 95% CI −0.19 to −0.13; $P$<.001). At peak divergence, high-risk ZIP codes reduced mobility by 12 to 13 percentage points less than low-risk ZIP codes (95% CI 11 to 15). Greater PMR was associated with lower subsequent hospitalization risk (incidence rate ratio [IRR] 0.41, 95% CI 0.31 to 0.53; $P$<.001), whereas higher community risk was associated with increased hospitalization risk (IRR 3.03, 95% CI 2.57 to 3.58; $P$<.001). The protective association of mobility reduction was attenuated in higher-risk communities (interaction IRR 2.79, 95% CI 2.08 to 3.73; $P$<.001).

**Conclusions:** Mobility data can support real-time surveillance of behavioral responses during epidemics. Within-city differences in mobility reduction were associated with subsequent hospitalization risk, but their protective association was weaker in higher-risk communities. Integrating digital mobility data with community risk metrics may improve targeted and equitable public health responses.

## Introduction

As COVID-19 emerged in early 2020, communities worldwide enacted strict lockdowns to curb transmission and ease pressure on health care systems [1-6]. In the United States, policy responses varied substantially by state. Although federal guidelines promoted social distancing [7-11], mask mandates [12,13], and the closure of nonessential businesses [14,15], states differed widely in their implementation, timing, and enforcement [16]. Texas, for example, issued stay-at-home orders on March 20, 2020 [17,18], later than many states, exempted the construction industry from lockdown [19], and began reopening relatively early (May 1, 2020). Within the state, several major cities imposed their own stay-at-home orders days before statewide action and, in some cases, maintained stricter measures. Later in the pandemic, statewide policies,

XSL•FO
RenderX

such as limits on elective procedures and business activities, were adaptively implemented based on local hospital and intensive care unit capacity [20].

Across the country, these uneven and evolving policies meant that communities faced different rules and risks depending on where they lived. Yet even where restrictions were strict, not all populations could adhere to them equally [21-33]. Economic instability, job insecurity, and high employment in essential industries limited many individuals' ability to stay home [19,20,34]. Low-wage workers, particularly in construction [19], agriculture, retail, and food services, often continued working in person without paid sick leave, facing difficult trade-offs between protecting their health and maintaining economic stability for themselves and their families [8,19,21,30,33].

Understanding how these social and economic constraints shaped local behaviors is critical for interpreting the uneven impacts of COVID-19 across communities. Individual-level mobility data, made available early in the pandemic by platforms such as SafeGraph [35], Google [36], and Apple [37], provided critical insights into community movement patterns and improved outbreak forecasts [38]. These anonymized datasets track daily time spent at home and visits to key locations, including workplaces, schools, grocery stores, and medical facilities. However, mobility is only a partial proxy for transmission risk: reductions in movement do not necessarily correspond to proportional reductions in contact, since exposure also depends on factors such as workplace contact intensity and household crowding that mobility metrics do not directly capture.

Studies linking mobility with health care data have shown that low-income populations generally experienced higher mobility, more limited access to health care (including testing and vaccines), and greater COVID-19 disease burden [39-45]. However, most prior research has focused on variation across states or counties, even though substantial variation occurs at finer geographic scales.

Here, we leverage high-resolution mobile device data as a form of digital epidemiological surveillance to characterize behavioral responses during the early COVID-19 pandemic at the ZIP code level. Focusing on the 20 most populous counties in Texas, the second most populous US state, characterized by geographic diversity and decentralized policymaking, we analyze mobility patterns across 623 ZIP codes covering 72% of the state's population. Using precautionary mobility reduction (PMR) as a proxy for behavioral response, we assess how community-level risk shapes within-city variation in mobility, examine differences in destination patterns, and evaluate associations between mobility and subsequent COVID-19 hospitalization risk. By integrating digital mobility data with socioeconomic and health outcomes, we also assess the potential of these data streams to support real-time public health surveillance and inform targeted responses during emerging epidemics.

# Methods

## Study Design and Population

We conducted an ecological, longitudinal study of mobility patterns and COVID-19 hospitalizations among residents of ZIP Code Tabulation Areas (ZCTAs) in the 20 most populous counties in Texas during February to July 2020. The primary units of analysis were ZCTAs and ZCTA-weeks. Mobility analyses included 623 ZCTAs, representing approximately 72% of the Texas population. COVID-19 hospitalization analyses included 620 ZCTAs for which weekly hospitalization data were available from the Texas Department of State Health Services (DSHS). The study integrated 3 population-level data sources: anonymized mobile device location data, ZCTA-level community risk measures derived from social vulnerability indicators, and weekly COVID-19 hospitalization records.

## Data Collection

### *Mobility Data*

We obtained anonymized cell phone location data from SafeGraph, a data provider that aggregates device-level visits from census block groups (CBGs) to specific points of interest (POIs) from numerous mobile apps [35]. To protect user privacy, SafeGraph excludes data if fewer than 2 devices from a given CBG visit a POI in a month. The dataset is not randomly sampled, as inclusion depends on device users having at least 1 location-sharing mobile app. Prior validation studies report that SafeGraph data do not systematically overrepresent CBGs by racial composition, income, or educational attainment at the aggregate county level [44,46,47]. However, more granular audits find that Hispanic, lower-income (<US$ 50,000), and less-educated populations are consistently underrepresented relative to White, higher-income (>US$ 100,000), and college-educated populations, with underrepresentation more pronounced in the South and intensifying after March 2020 [48], overlapping with this study's geography and study period. We address the implications of this bias for our findings in the *Limitations*. SafeGraph defines each device's home location as its most frequent nighttime CBG over the preceding 6 weeks.

For our analysis, CBGs were linked to ZCTAs using the Housing and Urban Development-United States Postal Service ZIP Code Crosswalk File [49], which allocates geography based on residential address distributions. ZCTAs were subsequently linked to counties using the corresponding Housing and Urban Development ZIP code–county crosswalk files. Because ZIP codes, ZCTAs, and county boundaries do not perfectly align, minor boundary misclassification is possible; however, the address-based crosswalk approach reduces this risk relative to centroid-based assignments [49]. Hereafter, we refer to ZCTAs as ZIP codes. Visit counts were scaled to account for ZIP codes' 2020 population [50] and the total number of tracked devices, enabling spatial and temporal comparisons. Hereafter, we refer to these scaled visit counts as visits. Our analysis focused on mobility patterns within the 20 most populous counties in Texas from February 3 to May 31, 2020, relative to the average daily visits during a baseline period (January 6 to February 2, 2020). The baseline period began January 6, 2020, the first Monday

XSL•FO
RenderX

after the New Year's holiday and winter school break, so that mobility patterns had returned to typical, nonholiday levels. It spanned 4 complete weeks to align with our weekly aggregation of visits, and the study period began February 3, 2020, the Monday immediately following the baseline period. Mobility is measured as visits from home locations to POIs regardless of their location within the 20 most populous counties in Texas; that is, POIs could be in the home or away ZIP code (Table S1 in Multimedia Appendix 1).

ZCTAs were included in the mobility analysis if a valid PMR was available for more than 320 of the 333 (96%) days spanning the baseline and study periods. This criterion excluded 98 of the 716 (14%) ZCTAs located in the 20 most populous counties, consistent with SafeGraph's device-count suppression threshold, which disproportionately affects low-population areas. Excluded ZCTAs did not differ from included ZCTAs in community risk score or hospitalization risk but had significantly smaller populations (Multimedia Appendix 1, Section 5).

For each day during the study period, we defined the PMR, which is calculated as follows:

PMRi,t=B-i-Vi,tB-i+Vi,t,

where $V_{i,t}$ are the daily visits from home in ZIP code *i* to a POI regardless of the ZIP code of destination (POI can be located in the same or a different ZIP code from the home ZIP code) on day *t*, and B-i is the baseline daily visits from the home ZIP code i to POIs in any ZIP code for the corresponding day of the week, averaged across the baseline period (January 6 to February 2, 2020). PMR is defined in the range [−1 to 1], where if $PMR_{i,t}>0$, ZIP code *i* had B¯i>Vi,t on day *t* (reduction in visits with respect to the baseline); if $PMR_{i,t}>0$, ZIP code *i* had B¯i<Vi,t on day *t* (increase in visits with respect to the baseline); if $PMR_{i,t}>0$, ZIP code *i* had B¯i=Vi,t on day *t* (no change in visits with respect to the baseline). PMR captures aggregate change in visitation. A change in PMR does not necessarily reflect a personal choice to be cautious. It can also result from other constraints, such as whether a job can be done remotely rather than requiring in-person attendance, whether someone must rely on public transit, or whether someone lacks access to delivery services to meet daily needs. We therefore interpret PMR as a proxy for a broad range of behavioral responses to the pandemic, rather than a simple measure of individual risk perception or compliance.

Additionally, we classified POIs by industry using their North American Industry Classification System codes provided by SafeGraph [51]. This classification included 62 general industry categories, covering more than 4 million unique POIs (Table S2 in Multimedia Appendix 1). We collected detailed information on visit origin and destination ZIP codes. To account for changes in visits to POIs, we calculated the $PMR_{i,t,p}$, which is the PMR for POI *p* on day (or week) *t* from home ZIP code *i*. Visits and baseline values were aggregated for each POI separately.

### Community-Level Risk Score

We used the US Centers for Disease Control and Prevention (CDC)'s Social Vulnerability Index (SVI), a composite measure derived from 15 American Community Survey (ACS) variables designed to estimate a community's ability to withstand environmental, biological, and other stressors [52]. SVI values are provided at the census tract and county levels as percentile ranks (range 0.0-1.0). For example, an SVI of 0.8 indicates that a community is more vulnerable than 80% of other communities within the comparison group. We calculated the SVI for each ZIP code in Texas using data from the 2016 to 2020 ACS 5-year estimates [53]. We assigned ZIP codes to counties using the R package zipcodeR [54] and recreated the CDC/Agency for Toxic Substances and Disease Registry SVI methodology [55] at the ZIP code scale [56]. Percentile ranks were calculated within Texas rather than nationally, so that a ZIP code's SVI reflects its relative vulnerability among Texas communities specifically, using all 15 ACS variables underlying the CDC/Agency for Toxic Substances and Disease Registry methodology. To assess sensitivity to the reference population used for ranking, we additionally recalculated the community risk score locally within each of the 20 counties, ranking ZIP codes only against others in the same county rather than statewide; this comparison and its results are reported in *Results*.

SVI could not be computed for 124 of 1935 (6%) Texas ZCTAs, a limitation concentrated in very low-population areas with unstable ACS estimates. Within the 20 most populous counties, this excluded 30 of 716 (4%) ZCTAs from all downstream analyses, since a valid SVI value was required for inclusion in both the mobility and hospitalization datasets (Multimedia Appendix 1, Section 5).

To assess the relationship between social vulnerability and early COVID-19 mobility, measured by the PMR, we calculated the community risk score for each ZIP code. When needed, we grouped ZIP codes into 4 quartiles of equal size—each containing the same number of ZIP codes, from the lowest-risk quartile to the highest-risk quartile—and calculated the mean PMR within each quartile.

### COVID-19 Health Care Data

We analyzed daily COVID-19 inpatient hospitalization data at the ZIP code level obtained from the Texas DSHS inpatient research data file (institutional review board [IRB] number 23-013). We filtered millions of inpatient records for the state to 65,474 hospital admissions among residents of 620 ZCTAs across Texas during February to July 2020. Patients were categorized as having COVID-19 if the *International Classification of Diseases, 10th Revision* code U07.1 was present on admission as the principal diagnosis or listed among the top 3 comorbidities. These counts reflect inpatient hospitalization events, not unique individuals, in which each record corresponds to 1 inpatient stay, and patients hospitalized more than once during the study period are counted once per admission rather than deduplicated to a single individual [57]. Hospitalizations were aggregated by ZCTA of patient residence and epidemiological week. Patient ZIP codes provided by DSHS were translated to ZCTAs using 2022 Census Topologically Integrated Geographic Encoding and Referencing geographic boundaries for ZCTAs and March 2023 boundaries for ZIP codes from the 2024 Health Resources and Services

XSL•FO
RenderX

Administration ZIP Code to ZCTA Crosswalk [58]. Patients originating outside Texas were removed.

These 620 ZCTAs correspond to 620 of the 623 (99.5%) ZCTAs included in the mobility analysis; the remaining 3 (76544, 78234, and 78419) reported no hospitalizations during the study period, 2 of which are predominantly military ZIP codes (Fort Cavazos and Fort Sam Houston), where residents likely receive care through facilities not captured in the DSHS civilian dataset. We also compared hospitalization risk between ZCTAs included in and excluded from the mobility analysis (see *Mobility Data*); the population-normalized hospitalization rate did not differ significantly between the 2 groups (Multimedia Appendix 1, Section 5).

## Statistical Analysis

### *Modeling Longitudinal Mobility Patterns at the ZIP-Code and County-Level*

To examine how PMR changed across Texas ZIP codes and to quantify how its association with community-level risk factors changed over time, we fitted a longitudinal generalized additive mixed model (GAMM) with nested random effects. This approach accommodates repeated daily observations within ZIP codes, allows flexible nonlinear temporal trends, and accounts for hierarchical geographic structure by including both county- and ZIP code–level random intercepts. Because mobility behavior is temporally autocorrelated, residuals were modeled using an autoregressive AR(1) process.

Formally, for each ZIP code *i* in county *j* and day *t*, we modeled the centered 7-day rolling mean of the PMR as *i* in county *j* and day *t*, we modeled the centered 7-day rolling mean of the PMR as

$$PMR_{i,j,t}=\beta 0+f1(t)+f2(t)RiskScore_{i,j}+cj+zi(j)+\epsilon_{i,j,t},$$

where $f_1(t)$ is the smooth statewide temporal trend, $f_2(t)$ is a smooth, time-varying coefficient capturing how the PMR-risk association evolved over time, $cj \sim N(0,\sigma county2)$ is a county-level random intercept, $zi(j) \sim N(0,\sigma ZIP2)$ is a ZIP code-specific random intercept nested within county *j*, and $\epsilon_{i,j,t}$ follows an AR(1) structure, $\epsilon_{i,j,t}=\rho\,\epsilon_{i,j,t-1}+\eta_{i,j,t}$, $\eta_{i,j,t} \sim N(0,\sigma 2)$. Under this formulation $f_2(t)$ represents the time-specific association between community-risk and PMR, with $f_2(t)>0$ indicating greater mobility reductions in high-risk ZIP codes at time *t*, and $f_2(t)>0$ indicating smaller mobility reductions among high-risk ZIP codes. All smoothness penalties and variance components, including the AR(1) correlation parameter, were estimated using restricted maximum likelihood (REML).

### *Modeling Structural and Behavioral Drivers of COVID-19 Hospitalizations*

We modeled weekly ZIP code–level COVID-19 hospitalizations using a GAMM to account for overdispersed count outcomes, nonlinear epidemic dynamics, and hierarchical spatial structure. The unit of analysis was a ZIP code–week during February to July 2020.

Let $Y_{i,c,t}$ denote the number of COVID-19 hospitalizations among residents of ZIP code *i*, located in county *c*, during week *t*. We assumed $Y_{i,c,t}$ denote the number of COVID-19 hospitalizations among residents of ZIP code *i*, located in county *c*, during week *t*. We assumed

$$Yi,c,t \sim NegBin(\mu i,c,t,\theta),$$

where $\mu_{i,c,t}$ is the expected number of hospitalizations and https://saxarona.github.io/mathjax-viewer/?input=%5Ctheta#0 is the dispersion parameter. The conditional mean was modeled on a log scale as

$$log(\mu i,c,t)=log(N_i)+\beta 0+\beta 1RiskScore_i+\beta 2PMR_{t-4}+\beta 3(RiskScore_i \times PMR_{t-4})+f(t)+u_i+v_c,$$

where $N_i$ is the population of ZIP code *i* (included as a logarithmic offset), ensuring inference on hospitalization rates rather than counts. The fixed-effects coefficients are $\beta_0$, the baseline log hospitalization rate for a ZIP code with average characteristics at the reference point; $\beta_1$, quantifies the association between community risk score and hospitalization risk, capturing structural differences in baseline susceptibility across ZIP codes; and $\beta_2$, quantifies the association between 4-week lagged PMR and hospitalization risk to reflect delays between behavioral change, infection, and severe disease. The interaction term $\beta_3$ allows the association between PMR and hospitalization risk to vary as a function of the community risk score, reflecting the hypothesis that the epidemiological benefits of mobility reduction are conditioned by underlying socioeconomic constraints.

The term $f(t)$ is a smooth, nonlinear function of time (weeks since February 10, 2020), modeled using a thin-plate regression spline. This term captures the underlying epidemic trajectory, including rapid early growth and subsequent stabilization, and prevents time-varying epidemic dynamics from being spuriously attributed to PMR or the community risk score.

To account for unobserved spatial heterogeneity, we included random intercepts

$$ui \sim N(0,\sigma ZIP2),\ vc \sim N(0,\sigma county2),$$

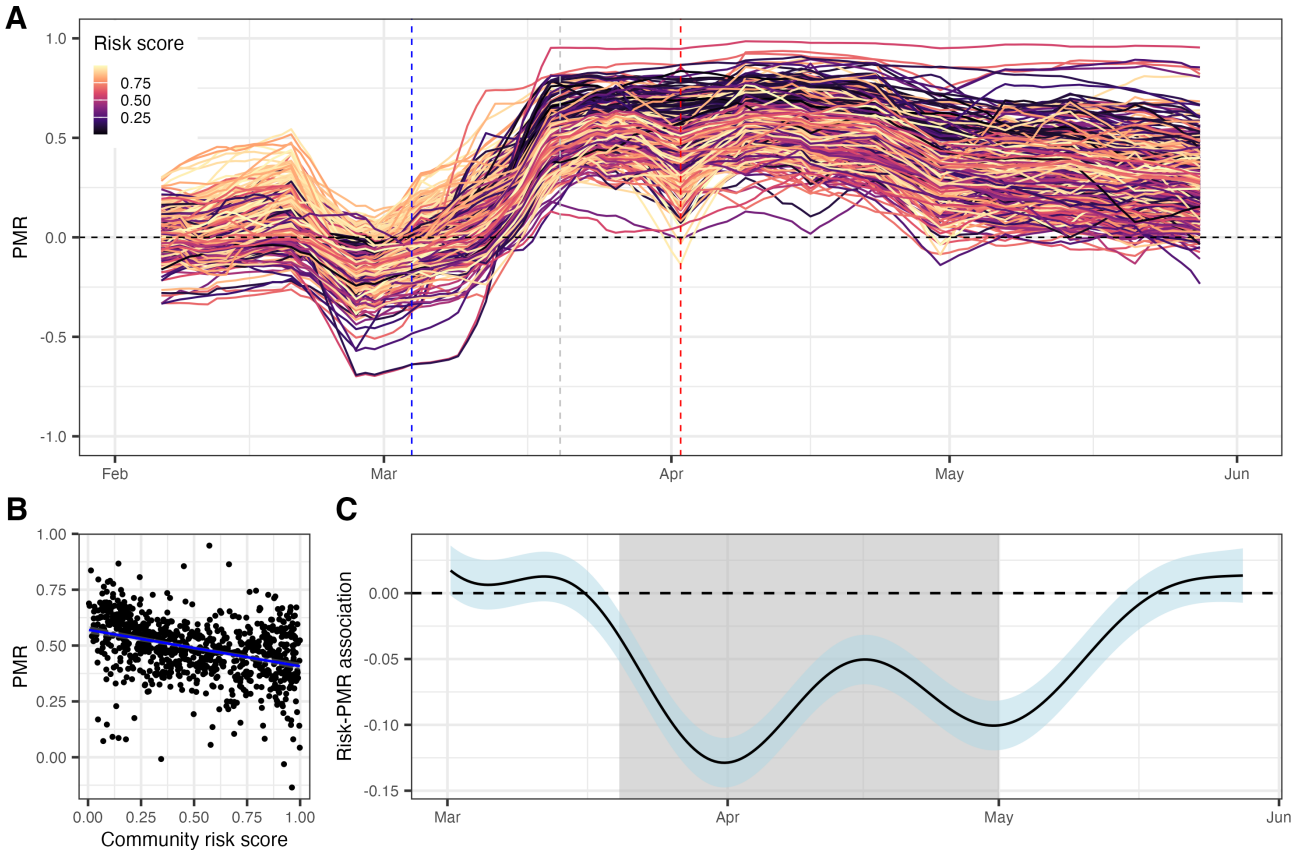
where $u_i$ and $v_c$ capture ZIP code and county-level differences, respectively. Models were estimated using REML with a log link. Exponentiated parametric coefficients are interpreted as incidence rate ratios, representing multiplicative changes in hospitalization rates per unit change in each predictor, conditional on the epidemic trajectory and spatial random effects. For interaction models, marginal effects of PMR were evaluated at representative levels of community risk to facilitate interpretation.

For visualization, marginal model predictions were evaluated at the median study week, averaging over a 3-week window (median ±1 week) to reduce stochastic variation. Observed hospitalization rates were summarized over the same window and, for display only, averaged within quantile-based bins of PMR; binning did not affect model estimation.

All analyses were conducted in R (version 4.5.2; R Foundation for Statistical Computing). GAMMs were fitted using the *mgcv* package (version 1.9-3) with REML for smoothing parameter estimation [59]. Data manipulation and visualization were performed using the tidyverse package (version 2.0.0) [60].

XSL•FO
RenderX

Spatial data processing was conducted using the sf package (version 1.0-21) [61].



### Ethical Considerations

This study was conducted under the Texas DSHS IRB protocol *Spatiotemporal Dynamics of SARS-CoV-2, Influenza, and Influenza-like Illness Across Texas* (DSHS IRB protocol number 23-013). The protocol included a waiver of informed consent because the study involved secondary analysis of existing hospital discharge records and did not involve direct enrollment of participants. COVID-19 hospitalization data were obtained from DSHS under a data use agreement. Mobility data were obtained through Dewey Data (now Advan Patterns), which distributes research versions of the mobility datasets originally produced by SafeGraph. Both datasets were analyzed in aggregated, deidentified form, and no personally identifiable information or individual-level location trajectories were available to the investigators. No attempts were made to identify individual participants. Data were stored and analyzed in secure institutional computing environments in accordance with DSHS data protection requirements and institutional policies. Participants received no compensation.

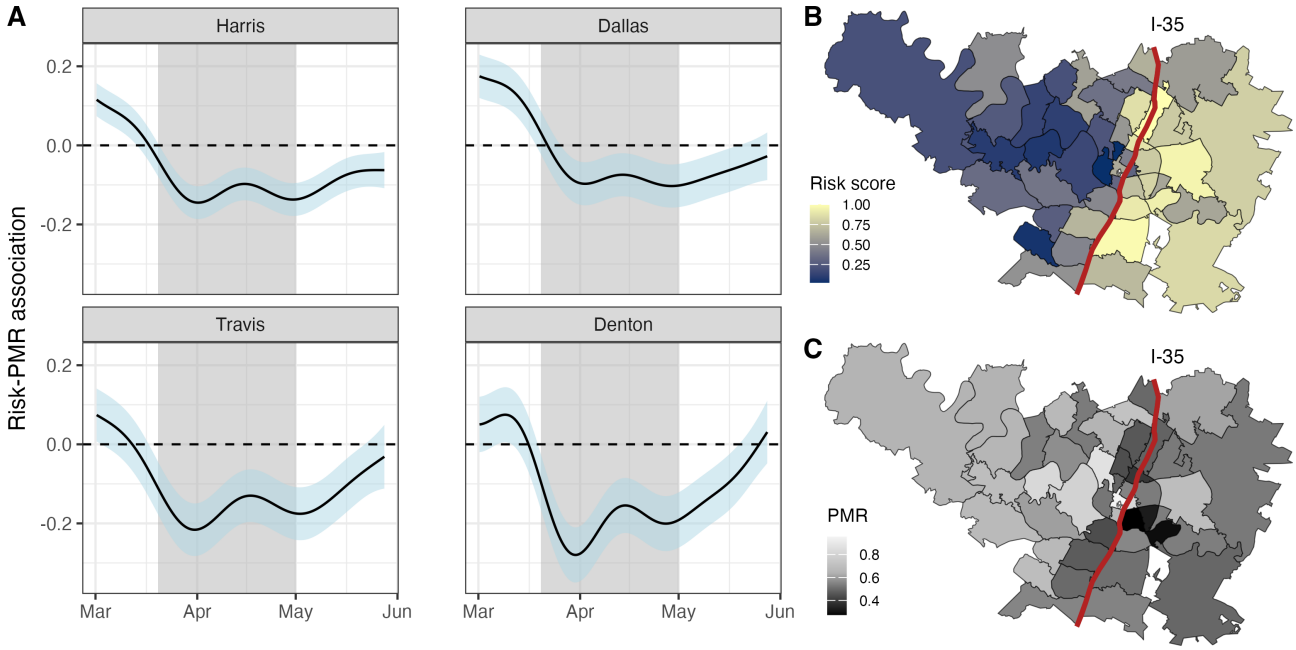
## Results

In Texas, across the 623 ZIP codes within the 20 most populous counties, the mean PMR across counties increased from −0.0035 (SD 0.13) prior to stay-at-home orders (February 3 to March 15, 2020) to 0.57 (SD 0.11) during the first week of April 2020 (April 6-12, 2020), corresponding to approximately a 73% reduction in mobility relative to baseline (Figure 1A). Notably, a marked decline in mobility occurred shortly after the first confirmed COVID-19 cases were reported in Texas (blue dashed line, Figure 1A), well before the statewide stay-at-home order (gray dashed line, Figure 1A).

**Figure 1.** Changes in mobility during the early COVID-19 lockdowns across the 20 most populous counties in Texas. (A) Daily 7-day rolling mean of PMR for 623 ZIP codes from February 5 to May 31, 2020. Lines represent ZIP codes and are colored by community risk score, from lowest risk (dark purple) to highest risk (yellow). The horizontal dashed line indicates PMR=0 (baseline mobility). Vertical dashed lines denote the first reported COVID-19 case in Texas (March 4; blue), the start of the statewide stay-at-home orders (March 20; gray), and April 2, 2020 (red). (B) Association between PMR and community risk score across ZIP codes on April 2, 2020. Points represent ZIP codes; the line shows the fitted linear association (slope −0.16, 95% CI −0.19 to −0.13; $P$<.001). (C) Estimated time-varying association between community risk score and PMR from the longitudinal model. The curve shows the estimated association with a 95% confidence band. The gray shaded region indicates the statewide stay-at-home period (March 20-May 1). PMR: precautionary mobility reduction.

On April 2 (red vertical line, Figure 1A), ZIP codes with lower community risk exhibited larger reductions in mobility than higher-risk ZIP codes ($R^2$=0.13, $P$<2×10$^{-16}$; Figure 1B). Across the full study period, we fitted a GAMM to the 70,329 ZIP code–day observations of the centered 7-day PMR slope, including smooth functions of time and a time-varying community risk effect, as well as random intercepts for counties and ZIP codes with AR(1) residual correlation (Figure 1C). The model achieved excellent fit (adjusted $R^2$=0.898, deviance explained=89.9%). The overall temporal trend in PMR was highly nonlinear (time smooth $f_1$ ($t$): effective degrees of freedom [edf]=9, $F$=2.06×10$^4$, $P$<2×10$^4$, $P$<2×10$^{-16}$) capturing

XSL•FO
RenderX



pronounced changes in mobility during early March followed by a gradual relaxation through May.

Differences in mobility reduction between higher- and lower-risk ZIP codes evolved substantially over time, becoming more pronounced during the early lockdown period (Figure 1C); edf=10, $F$=525, $P<2\times10^{-16}$. Early in the study period (early March), mobility reductions were similar across ZIP codes regardless of community risk $f_2(t)\approx0$. In contrast, during late March through late April, coinciding with the statewide stay-at-home order (March 20-May 1), ZIP codes with lower risk scores began to exhibit significantly greater mobility reductions than higher-risk ZIP codes. At the peak of this disparity in late March, ZIP codes at the 75th percentile of the risk score reduced mobility by approximately 12 to 13 percentage points less than those at the 25th percentile (95% CI 11-15). By late May, differences in mobility reduction by community risk had largely converged. Overall, these patterns indicate a reversal over time in the relationship between social vulnerability and mobility reduction.

County- and ZIP code–level random effects captured substantial residual spatial heterogeneity (county effect $s$ (county): edf=17, $F=4.24\times10^4$, $P<2\times10^{-16}$; ZIP code effect $s$ [ZIP]: edf=593.4, $F$=122, $P$=.04), indicating that meaningful variation in mobility persisted beyond that explained by community-level risk factors and statewide temporal trends. Full model specifications and diagnostics are provided in Multimedia Appendix 1, Section 2.

Across counties, overall mobility reductions were pronounced, but the magnitude and timing of disparities by community risk varied (Figure 2 and Figures S2 and S3 in Multimedia Appendix 1). To evaluate county-level heterogeneity, we recalculated the community risk score locally, scaling ZIP codes within each county so that it reflects relative risk within each county rather than statewide ranking. Several large counties, including Harris, Dallas, Travis, and Denton, exhibited time-varying effects that closely mirrored the statewide pattern (Figure 2A). In these counties, the estimated time-varying effect f2(t) crossed into negative values more abruptly than in the statewide model, indicating earlier and stronger divergence in mobility reductions between higher- and lower-risk ZIP codes. Other counties also showed significant associations, but in many cases, the estimated effects were small or the CIs were wide, indicating weaker or more uncertain differences in mobility (Figure S3 in Multimedia Appendix 1). Among them, Travis County showed the earliest divergences (on March 12, 2020), with higher-risk ZIP codes exhibiting smaller mobility reductions. Spatially, higher-risk ZIP codes east of the I-35 corridor (Figure 2B) corresponded to smaller reductions in mobility during early April (Figure 2C), highlighting marked within-county heterogeneity (additional counties shown in Figure S4 in Multimedia Appendix 1).

**Figure 2.** Temporal and spatial patterns of community risk and mobility reduction during the early COVID-19 pandemic in Texas counties. (A) Estimated time-varying association between the community risk score and 7-day PMR in 4 Texas counties (Harris, Dallas, Travis, and Denton). Lines represent model estimates with 95% CIs. Negative values indicate periods when higher-risk ZIP codes exhibited smaller mobility reductions. The shaded region denotes the statewide stay-at-home order (March 20 to May 1, 2020). (B) Community risk levels in Travis County ZIP codes. (C) Mean PMR by ZIP code in Travis County during the early pandemic period (March 30 to April 5). The I-35 corridor is overlaid in panels B and C to illustrate the east-west spatial gradient in community risk and mobility reduction. PMR: precautionary mobility reduction.

Using a negative binomial GAMM of weekly ZIP code–level COVID-19 hospitalizations (February-July 2020), we found that 4-week lagged PMR was significantly associated with lower subsequent hospitalization rates after adjustment for the community risk score (Table 1). Results were robust to alternative lag specifications (full model specifications and diagnostics are provided in Multimedia Appendix 1, Section 3). The model reproduced the observed temporal trajectories and between-ZIP code variability in hospitalization rates (Figure 3A).

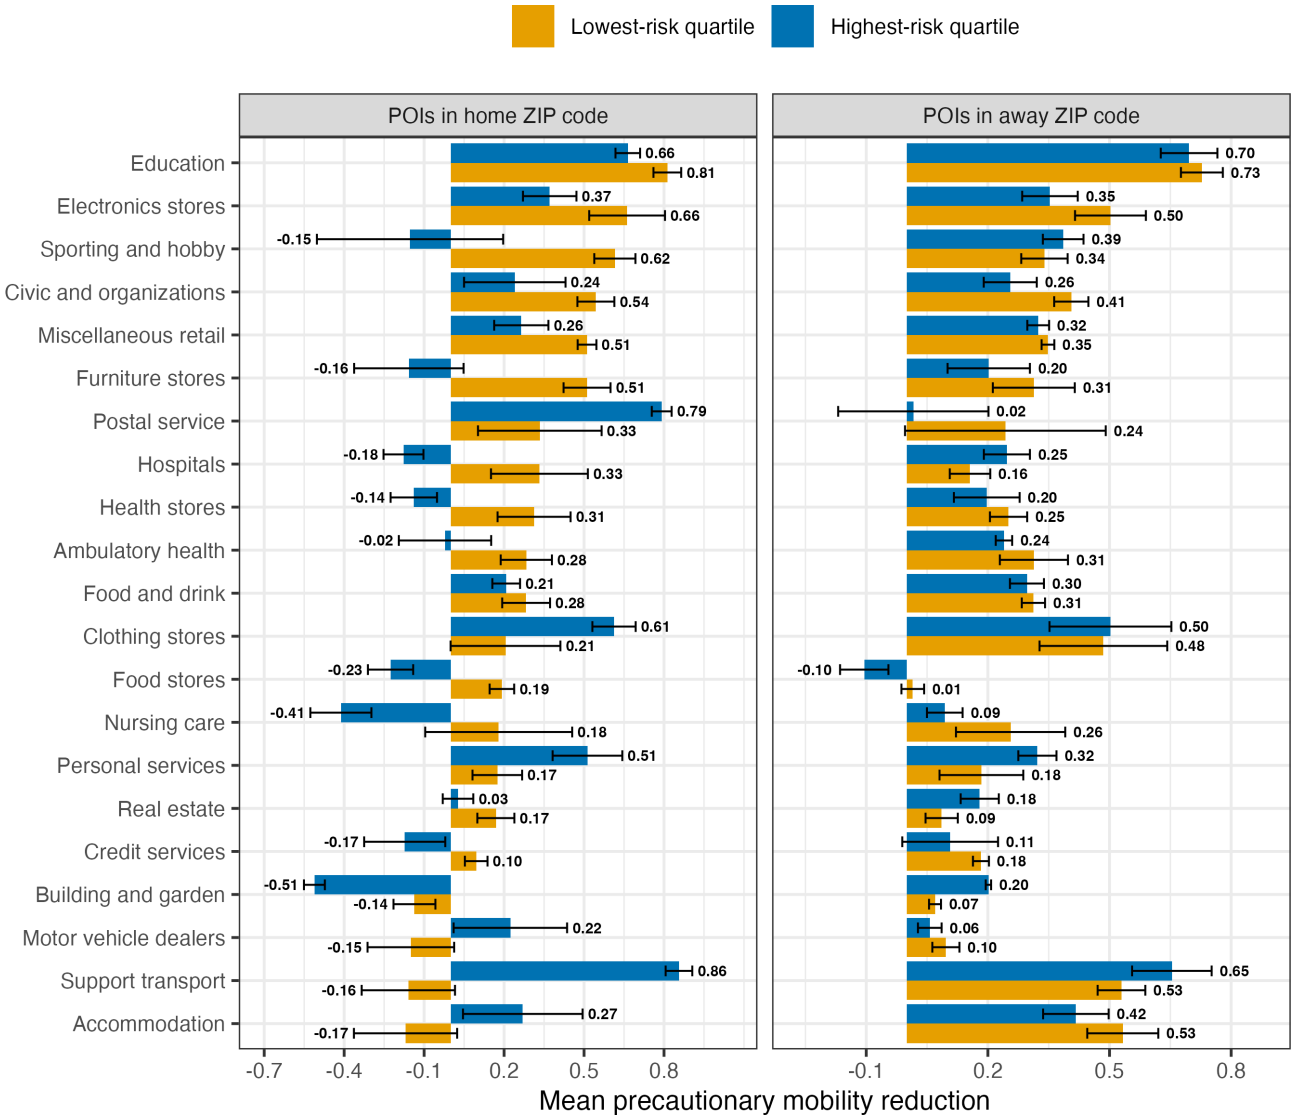
[a]Negative binomial model with a log link and population offset, including PMR (lag 4 wk), community risk score, their interaction, a smooth function of week, and ZIP code– and county-level random intercepts. Model fit: n=10,525 ZIP-weeks; deviance explained=68.3%; θ=5.21; effective degrees of freedom: *s*(WeekIndex)=8.88, ZIP code=415.10, county=17.40. Model diagnostics are provided in Multimedia Appendix 1, Section 3.

[b]PMR: precautionary mobility reduction.

**Figure 3.** Observed and model-estimated COVID-19 hospitalization patterns across Texas ZIP codes. (A) Weekly COVID-19 hospitalization rates per 10,000 people across Texas ZIP codes, February to July 2020. Blue points represent the observed mean across ZIP codes; vertical bars indicate the IQR (thick blue) and 5th to 95th percentiles (thin blue). The red line and shaded ribbon show model-estimated mean hospitalization rates with 95% CIs. (B) Observed (points with 95% CIs) and model-estimated (lines with 95% confidence ribbons) association between 4-week lagged PMR and weekly COVID-19 hospitalization rates per 10,000 people, stratified by ZIP code community risk score quartile. PMR: precautionary mobility reduction.



The model closely reproduced the observed temporal evolution and distribution of hospitalization rates across ZIP codes (Figure 3A), capturing both the statewide epidemic trajectory and the substantial between-ZIP code variability over time. Greater PMR was associated with lower subsequent hospitalization rates overall (*P*<.001), while higher-risk ZIP codes experienced substantially higher hospitalization burdens independent of mobility. The significant PMR × community risk interaction indicated that the protective association of mobility reduction was strongest in lower-risk ZIP codes and attenuated in higher-risk communities (Figure 3B). Thus, although mobility reductions were associated with reduced hospitalization rates, their epidemiological benefits were not evenly distributed across communities. Model comparison analyses indicated that these findings were robust to alternative specifications, including changes in the complexity of the temporal smooth and the inclusion of county-level random effects (ΔAkaike information criterion≤57). In contrast, removing ZIP code–level random effects or the temporal smooth term resulted in substantial deterioration in model fit (ΔAkaike information criterion=1194 and 7933, respectively), underscoring the essential role of fine-scale geographic heterogeneity and temporal dynamics in explaining hospitalization patterns (Multimedia Appendix 1, Section 3).

The types of destinations visited shifted markedly during stay-at-home orders and differed substantially between ZIP codes in the lowest- and highest-risk score quartiles (Figure 4). Of 62 POI categories, 21 showed significant differences in PMR between the 2 groups for visits within residents' home ZIP codes (Figure 4, left; POI definitions in Multimedia Appendix 1, Section 4). In contrast, mobility reductions to POIs located outside the home ZIP code were largely similar across risk levels (Figure 4, right).

XSL•FO
RenderX

**Figure 4.** Mobility reduction by community risk and destination type during the initial COVID-19 lockdown in Texas (March 20 to April 13, 2020). Bars show the mean precautionary mobility reduction across economic sectors, comparing ZIP codes in the lowest (orange) and highest (blue) quartiles of the community risk score. Positive PMR values indicate reduced visits relative to the prepandemic baseline. Panels distinguish visits to points of interest (POIs) located within the home ZIP code (left) versus outside the home ZIP code (right). Error bars indicate 95% CIs. Definitions of POI categories are provided in Multimedia Appendix 1, Section 4. Figure S7 shows analogous patterns for February 2020, prior to the implementation of COVID-19 restrictions.

Across most sectors, lower-risk ZIP codes experienced larger mobility reductions, whereas higher-risk ZIP codes often showed smaller—or, in some cases, negative—PMR values, particularly for health-related destinations such as hospitals, ambulatory care facilities, pharmacies, and nursing facilities. For travel outside the home ZIP code, mobility reductions were generally similar across groups, with the notable exception of food-related venues (eg, supermarkets), where the higher-risk ZIP codes exhibited increased mobility relative to baseline.

# Discussion

## Principal Findings

We integrated high-resolution mobility data, community-level risk measures, and ZIP code–level COVID-19 hospitalization records to examine how behavioral responses and structural conditions shaped early COVID-19 outcomes across Texas communities. We found that higher-risk communities reduced mobility less during the period of greatest restrictions and experienced substantially higher subsequent hospitalization rates. Although greater PMR was associated with lower hospitalization risk overall, this protective association was significantly weaker in higher-risk communities. These findings support the value of high-resolution mobility data for understanding within-city heterogeneity and informing public health surveillance.

## Interpretation of Findings

ZIP code–level analyses revealed marked heterogeneity within counties, with neighboring communities exhibiting divergent mobility patterns and hospitalization rates. Such fine-scale variation is largely obscured in county- or state-level analyses and highlights the value of high-resolution data for public health surveillance. Reliance on coarser geographic indicators may therefore limit the ability to identify vulnerable populations and to target interventions effectively within metropolitan areas.

XSL•FO
RenderX

Mobility reductions during the early pandemic were strongly shaped by community constraints. While mobility declined rapidly following the implementation of statewide stay-at-home orders, higher-risk ZIP codes experienced smaller and less sustained reductions during the period of greatest restrictions, and in subgroups directly engaged in newly surged essential-service demand, such as delivery and grocery workers, mobility may have increased rather than merely declined less, consistent with the persistently elevated food-related mobility we observed in these ZIP codes (Figure 4). This divergence likely reflects structural constraints—including essential employment, limited access to remote work, crowded housing, and caregiving responsibilities—rather than differences in awareness, risk perception, or willingness to comply with public health guidance. Consistent with prior research, our findings suggest that the impact of behavior-based interventions depends on underlying socioeconomic conditions and that framing mobility reductions as individual "compliance" risks overlooking the material constraints that shape exposure and mobility [40-43,45,62,63].

Community risk remained a dominant determinant of hospitalization rates throughout the study period. After adjusting for epidemic timing, population size, spatial clustering, and mobility behavior, higher-risk ZIP codes experienced persistently elevated hospitalization rates. Although mobility reduction was associated with lower subsequent hospitalization rates overall, its protective association was attenuated in higher-risk communities, suggesting that similar behavioral changes may yield unequal epidemiological benefits depending on underlying conditions. Mobility reductions alone were insufficient to offset elevated hospitalization risks in high-risk ZIP codes. Sector-specific analyses further highlight the limits of mobility restriction policies. Higher-risk ZIP codes maintained greater mobility to essential destinations, including food, health care, and service-related locations, highlighting the limits of mobility-based interventions in the absence of broader social protections [34,40-42,62,64,65]. As a result, population-wide restrictions may reduce transmission on average while leaving higher-risk communities disproportionately exposed to severe disease outcomes [19,33,40,44,66,67].

From a public health perspective, these findings highlight the importance of context-sensitive epidemic control strategies [68]. Interventions that rely primarily on behavioral modification may inadvertently reinforce disparities if differential capacity to comply is not addressed [67-70]. Integrating community risk metrics with real-time mobility and surveillance data could help identify communities that require targeted support, including paid sick leave, workplace protections, access to testing, and timely health care services. Such measures may help ensure that mitigation strategies are both effective overall and more equitable in their impact across communities.

## Limitations

This study has several strengths, including its fine spatial resolution, integration of multiple data sources, and use of flexible modeling approaches to capture nonlinear epidemic dynamics and hierarchical geographic structure. Nonetheless, limitations should be acknowledged. Mobility data are not derived from a random sample. While aggregate validation studies report no systematic overrepresentation by race, income, or education at the CBG level [44,46,47], finer-grained audits find that low-income, Hispanic, and less-educated individuals are underrepresented relative to their higher-income, White, and college-educated counterparts, and that this gap widens in the South and after March 2020 [48]. This raises the possibility that our mobility measures do not fully capture behavior in the most vulnerable ZIP codes in our sample. Mobility metrics capture movement patterns but not other protective behaviors, such as mask use or physical distancing, nor activity redistributed to the home, such as remote work, telehealth, or grocery and food delivery replacing in-person shopping. Even after accounting for these unmeasured behaviors, mobility reduction is not equivalent to contact or transmission-risk reduction. Two ZIP codes with identical PMR values can carry different exposure risks if, for example, one has more in-person, close-contact jobs or more crowded housing. Associations between PMR and hospitalization risk should therefore be read as reflecting these unmeasured behavioral and structural differences across communities, not as a claim that reduced mobility directly causes fewer hospitalizations by itself. Hospitalization data may reflect differences in health care access, admission, and reporting practices, or underlying health status across communities.

County-level random intercepts in our statistical model partially absorb systematic differences in reporting and admission practices that operate at the county level, though residual ZIP code–level heterogeneity in health care access could not be directly modeled with the data available. For these factors to fully account for the observed association between community risk and hospitalization rates, they would need to vary systematically with community risk itself; while we cannot rule out such a pattern, we are not aware of data supporting it. Future work incorporating direct measures of health care access, such as hospital bed capacity, insurance coverage, or testing rates, could test this formally through sensitivity analyses. Although our models include ZIP code– and county-level random intercepts, these capture hierarchical grouping rather than explicit spatial correlation, and neighboring ZIP codes are not statistically independent given cross-boundary commuting, shared workplaces, and shared health care facilities. We tested this directly: Moran $I$ on ZIP code–level residuals from the mobility model showed significant positive spatial autocorrelation ($I$=0.19, $P$<.001; Multimedia Appendix 1, Section 2). Because community risk itself follows a known geographic gradient, this residual spatial structure means that standard errors assuming independent observations likely understate true uncertainty, and we cannot rule out that it is partly correlated with community risk itself.

In addition, because our analyses were conducted at the ZIP code level, associations observed at the community level may not reflect individual-level relationships. Finally, the analyses were restricted to the early phase of the COVID-19 pandemic in Texas, and associations may differ under later variants, vaccination campaigns, evolving testing practices, or changing public health policies.

## Conclusions

High-resolution mobility data provide a valuable complement to traditional surveillance systems by capturing population-level behavioral responses in near real time. However, our findings indicate that behavioral indicators should be interpreted alongside measures of underlying community vulnerability because identical behavioral changes may not translate into equivalent health benefits across populations. Integrating mobility data with community risk metrics may therefore improve the targeting of interventions during future epidemics while helping public health agencies identify communities requiring additional structural support.

## Generative AI Use

ChatGPT (GPT-5.6 Sol; OpenAI) was used exclusively for proofreading and language editing under full human supervision. The authors reviewed and approved all revisions and assume full responsibility for the final manuscript.

## Funding

The work was supported by the US Centers for Disease Control and Prevention (CDC grants U01IP001136, NU38FT000008, CDC-RFA-FT-23‐0069, and 75D30122C15411) and the US National Science Foundation (NSF grant 2230125). The contents are solely the responsibility of the authors and do not necessarily represent the official views of the CDC and NSF.

## Data Availability

The COVID-19 hospitalization data used in this study were obtained from the Texas Department of State Health Services (DSHS) Inpatient Research Data File under a data use agreement and cannot be publicly redistributed by the authors. Access to these data is governed by DSHS data access and confidentiality requirements. The mobility data used in this study are licensed, proprietary data obtained through Dewey Data (now Advan Patterns) and cannot be publicly redistributed. Researchers seeking access to the underlying mobility data should request access directly through Dewey Data. The American Community Survey 2016‐2020 5-year estimates used to construct the ZIP code–level community risk score are publicly available from the US Census Bureau and were accessed through the Census Bureau API using the R package tidycensus.

## Abstract

**Background:** The reemergence of the Zika virus, the novel coronavirus, and new influenza strains highlighted the urgent need for an organized forum to access specimens to advance research, diagnostics, and vaccine development. During the COVID-19 pandemic, gaps in supply chains, communication, and standards between local (federated) and centralized systems cost time and lives. The FAIR-VBS (Federated, Accessible, Inclusive, and Responsive Virtual Biorepository) was proposed to connect communities with samples, address specimen-sharing challenges, and promote inclusion and equity.

**Objective:** This study aims to enable equitable contribution, sharing, and access to specimens while addressing the complexities involved. The objective is to build stakeholder consensus on prioritized actions, tools, and responsibilities to establish a functional and practical FAIR-VBS.

**Methods:** A Delphi process was conducted online to gather stakeholder input and develop a prioritized action plan for the FAIR-VBS. Respondents were recruited using snowball sampling, and questions were informed by participatory workshops, feedback, outreach efforts, and discussions to identify gaps and best practices. The Delphi process consisted of 2 rounds: an initial ranking informed by stakeholder input and a second round to refine priorities based on the panel feedback. Items were evaluated using a standardized 5-point Likert scale and retained if prioritized by at least 70% of respondents rating an item 4 or higher and no more than 15% rating an item below 2, with descriptive statistics applied. Advisory board discussions supplemented the virtual process to capture nuances, while qualitative data were analyzed using participatory action research methods.

**Results:** The Delphi process evaluated 34 cumulative items across 2 rounds to identify critical gaps and priorities in biorepository systems. In the first round, 22 out of 30 initial items successfully reached consensus. Panelists organically proposed 4 additional items during the first round; upon evaluation in the second round, 2 of these newly proposed items reached consensus, addressing benefit-sharing challenges (11/15, 73%) and the prioritization of whole blood, plasma, and serum samples (40/42, 95%). Culturally, peripheral blood mononuclear cells were supported as a secondary priority (13/18, 72%). In total, 24 items achieved consensus across both rounds, while 10 items overall did not. Respondents overwhelmingly supported the hybrid FAIR-VBS, which combines federated and centralized systems, offering local convenience with virtual oversight (34/41, 83%). Cost recovery for services was supported by all respondents (43/43, 100%), with a preference for a sliding fee scale to subsidize capacity building in low- and middle-income countries (40/42, 95%).

**Conclusions:** Respondents strongly supported the FAIR-VBS to enable equitable access to specimens, services, and benefits. They emphasized the need for clarity on benefit-sharing, regulatory, and ethical frameworks to ensure effective implementation and global inclusivity. A fair and equivalent system to enhance participation and operational continuity is being discussed.

## Introduction

Access to high-quality, well-characterized specimens that reflect global diversity, including populations from low- and middle-income countries, is critical for advancing research, diagnostics, and vaccine development [1]. Despite the evident need during outbreaks such as Zika (2016) and COVID-19 (2019), and concerns around evolving pathogen threats, a sustainable and trusted global resource for these samples has yet to be realized. While the concept is not new, progress has been hindered by challenges in regulatory and ethical implementation, as well as concerns over tangible benefits and long-term sustainability, which have discouraged partners from advancing these efforts [1]. Disparities in diagnostic kit performance across high- and low-income settings underscore the importance of globally representative specimens [2,3]. The COVID-19 pandemic, in particular, exposed delays in accessing essential samples and hampered timely research and development [4].

Historically, international collections for infectious diseases have been centralized within large, well-funded institutions and biorepositories, often excluding local contributors and geographically diverse populations [5]. The pandemic amplified inequities in diversity, equity, and inclusion within these systems [2,3]. To address these challenges, we propose a virtual biorepository that connects local repository hubs for efficient, equitable, and accessible sample sharing [1].

The FAIR-VBS (Federated, Accessible, Inclusive, and Responsive Virtual Biorepository) is designed to be agile and inclusive, combining the strengths of grassroots initiatives with sensitivity to local contexts as "an additional repository type" to the standard centralized systems. By reducing the need for a centralized multinational facility, the FAIR-VBS reduces overhead but could be limited by the types and uses of its specimens, so we needed to find consensus on how to advance equity while defining the types of accessible samples with simple storage needs that would allow a global partner with limited resources to join the effort. Importantly, our work will complement other major international biobanking initiatives such as the WHO BioHub, H3Africa, and the Global Biobank Alliance; multiple individuals from these groups and others are mentioned in our *Acknowledgments*.

This study uses an international online Delphi process to achieve consensus and solve challenges collaboratively [6,7]. The Delphi method offers several advantages: it (1) empowers underresourced populations by fostering inclusion and reimagining global biorepository systems, (2) amplifies local voices to define the benefits and sustainability of the FAIR-VBS, (3) creates a roadmap for addressing end-user priorities, (4) reduces power imbalances through anonymous contributions, and (5) accommodates cultural and geographic diversity among respondents.

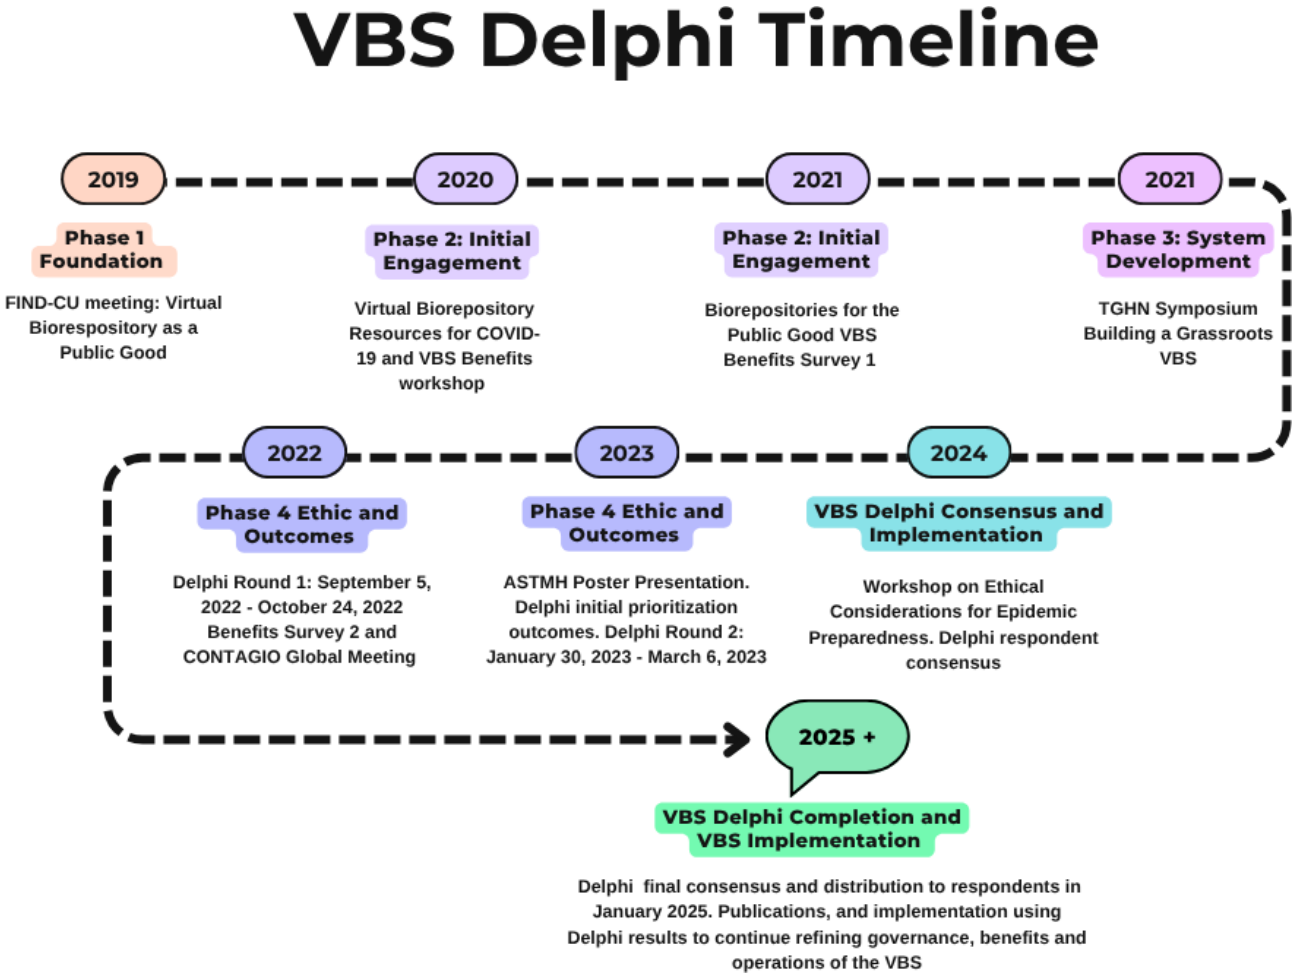
The need for a systematic, inclusive approach to specimen access is urgent, particularly as global health threats like Zika, emerging coronaviruses, and influenza variants resurface [5,8]. Biorepositories are essential for providing qualified, annotated samples that advance diagnostics, disease prediction, and prevention efforts [1,4].

Our aim is to develop actionable recommendations for building and maintaining a virtual biorepository while fostering ongoing consensus as the initiative evolves. This grassroots effort aims to facilitate scientific exchange, equitable specimen sharing, and global collaboration as a public good. By aligning with successful international partnerships, the FAIR-VBS seeks to be an inclusive, additive, and sustainable model for a multinational community. Using the Delphi method, we plan to identify practices that promote biorepository availability, good governance, and long-term sustainability [9]. Our protocol and supplementary materials are available on the Open Science Framework [10] and in Multimedia Appendix 1.

## Methods

### Aims and Objectives

We aimed to identify prioritized actions, tools, and responsibilities necessary to establish a functional and FAIR-VBS. Specifically, our objectives were to develop actionable, consensus-based recommendations for building and maintaining an inclusive, diverse, and equity-driven FAIR-VBS and to generate ongoing findings as the project evolves to ensure continued alignment with stakeholder needs and global priorities.



### Preparation Work

The research team collected information from professional contacts and organizations; conducted surveys and interviews [1]; held workshops; searched the literature; set up websites; and connected with others in the field, including biorepository experts, public health practitioners, policymakers, industry leaders, funders, students, and members of the public. The research team conducted internal audits to systematically evaluate the effectiveness and alignment of its activities with the project's goals. These audits reviewed the outcomes of workshops and stakeholder engagements, assessed gaps in the literature and expert input, and identified actionable next steps [1]. Through this reflective process, we deliberated and concluded that an online Delphi process could offer a practical approach to bridge cultural, linguistic, and geographical divides; foster autonomous local consensus [11]; and ensure cost-effectiveness [12]. Figure 1 shows the timeline for FAIR-VBS and the steps we used to prepare for the Delphi process.

## The Delphi Process

The Delphi method is a structured, iterative communication tool designed to facilitate consensus-building, forecasting, or shared decision-making. Through a series of rounds, whether delivered onsite or by using virtual survey software, respondents evaluate and prioritize presented questions, typically participating in at least 2 rounds [9]. The Delphi method was offered online through a secure interface. After each round, participants received an anonymous summary of the group's input, enabling them to refine and prioritize their previous responses based on others' feedback. This iterative process narrows the range of variation until common ground is reached. The underlying principle is that structured group input yields more accurate and actionable results than unstructured discussions [6].

## Study Design

### *The Mixed Methods Qualitative Bridge*

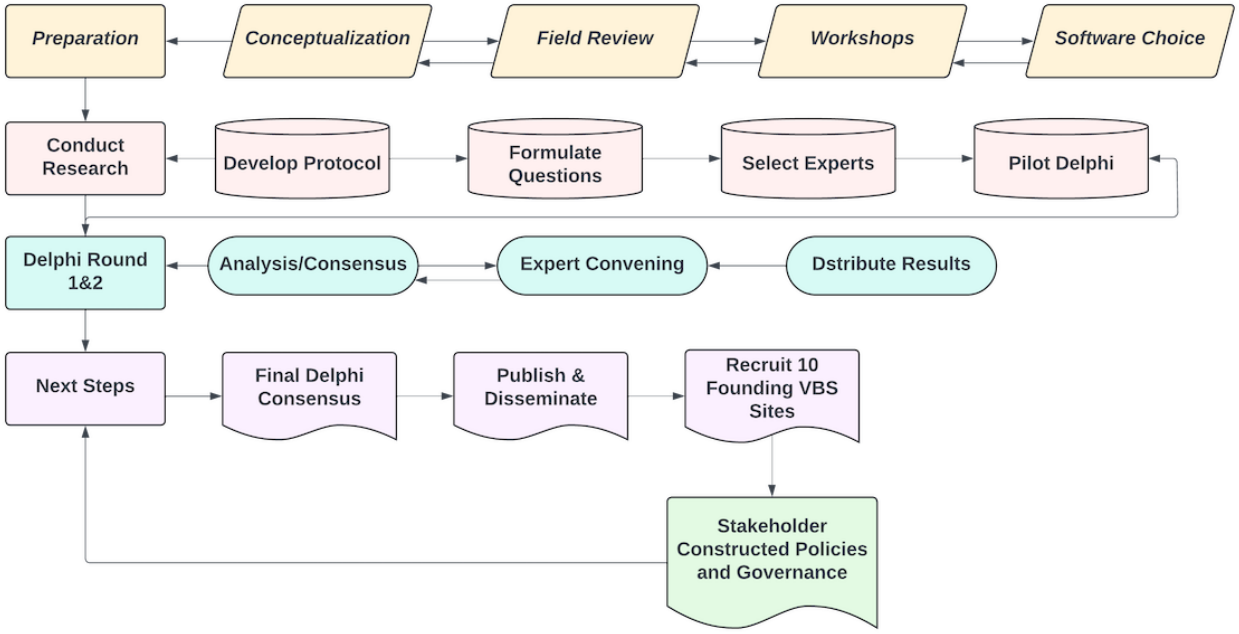
While a traditional Delphi process is fundamentally a quantitative mechanism designed to measure consensus on predetermined metrics, it lacks an inherent qualitative capacity to explore the underlying reasons behind item failure or to capture organic, participant-driven innovations. To bridge this structural limitation, this study used a sequential mixed methods participatory action research design that embedded a formal qualitative content analysis engine between the quantitative survey rounds.

Open-ended comment text fields were appended to every quantitative item. When an item failed to meet the strict quantitative consensus threshold in round 1, the 5-member coding team systematically analyzed the qualitative text fields using a unified coding framework to uncover hidden semantic ambiguities, structural anxieties, and cross-cultural friction points. This qualitative bridge allowed the steering group to actively coproduce and rephrase items based directly on stakeholder insights. Additionally, this bridge provided the mechanism to capture and code the 4 entirely new items proposed organically by the panel in round 1, moving them into the quantitative voting pipeline for round 2. By embedding this qualitative bridge, the study evolved from a passive tracking survey into an agile, iterative, and truly participant-driven consensus process. All participant comments are included in Multimedia Appendix 1.

### *FAIR-VBS Online Delphi Process*

The FAIR-VBS initiative was informed by global webinars, workshops, and feedback sessions involving participants from Africa, Latin America, Southeast Asia, and Europe. Contributors

XSL•FO
RenderX



included biobank experts, blood bank consultants, public health specialists, researchers, and diagnostics manufacturers.

To shape grassroots, equitable approaches for specimen sharing, we used a mixed methods, sequential participatory action research design [13] centered on a multiple round online Delphi. This process was built on insights from workshops, ongoing sample collection efforts, and stakeholder discussions to frame the Delphi questions. We piloted the questions based on key needs identified from feedback from stakeholders and consultative workshops [1], which highlighted three target areas:

1. Types of specimens to share: Identifying priority specimens for global research and diagnostics
2. Solutions to barriers: Addressing logistical, regulatory, and ethical practices and cultural challenges in specimen sharing
3. Benefits and sustainability: Articulating the value and long-term viability of equitable specimen-sharing practices

The Delphi process engaged all stakeholders to rank, refine, and reach a consensus on these critical issues. Figure 2 provides a visual representation of the Delphi methodology and process.

**Figure 2.** Virtual biorepository online Delphi process.

## Advisory Group and Steering Group

The Delphi development was guided by an advisory group specializing in infectious diseases, diagnostic manufacturing, and research methodology. The advisory group provided strategic oversight for the study design and its implementation. The advisory group and the researchers, together, formed the steering group to make decisions for the process. To ensure clarity, the Delphi questions were also reviewed by graduate students and advocates.

## Recruitment

Fifty-seven respondents were recruited using snowball sampling to ensure a diverse and inclusive panel. Stakeholders included public health experts, researchers, clinicians, community members, policymakers, regulators, and industry representatives, as well as respondents from 6 continents.

## Online Delphi Rounds

The Delphi process comprised 2 rounds, with each round serving a distinct purpose in the development and evaluation of the items:

1. Round 1 (exploratory phase): Respondents scored and commented on 30 initial items and were invited to propose additional questions. Items (n=40) were added by respondents, then reviewed and coded by 2 research team members to ensure relevance.
2. Round 2 (evaluative phase): Respondents reviewed results, including advisory group comments from round 1, and voted again on unresolved items. Respondents scored the 4 additional items proposed during round 1.

A consensus was reached after 2 rounds, and the results were reviewed and accepted by the advisory group. All results, including respondent comments with identifiers removed, were compiled and shared with participants. Consensus was defined as at least 70% of responses rating an item 4 or higher and no more than 15% rating an item below 2 on a 1 to 5 scale.

## Delphi Response Preparation

The responses were scored and prioritized using a Likert scale, with a 5-point format [14]. Respondents rated their level of agreement with each statement, with higher scores reflecting stronger agreement. This approach enabled a nuanced understanding of consensus among experts participating in the Delphi process. To further enrich the findings, qualitative content analysis was conducted. Five researchers (AP, LA, MC, JG, and JP) independently reviewed and categorized the textual responses provided by respondents, identifying themes, key concepts, and recurring opinions [6,12]. They reached a consensus on these interpretations, and the deidentified

XSL•FO
RenderX

comments and analysis were presented to the steering group and then to the respondents. This contextual guidance informed the development of round 2 [15].

This method proved valuable in assessing how consensus evolves by considering levels of agreement or disagreement expressed in the comments alongside quantitative data, such as mean ratings or consensus thresholds. The analysis and all deidentified feedback were shared with respondents after the first and second rounds, fostering transparency and enabling a reflective and shared understanding of the group's perspectives. All respondents and the steering group were presented with round 2 results. Following the Delphi rounds, a consensus conference was held via videoconferencing with the advisory group to finalize recommendations and define key next steps.

### Ethical Considerations

Ethical approval was obtained from the University of Oxford Central University Research Ethics Committee (CUREC; application reference number R58550/RE001 [16]). Informed consent was secured from all participants through a secure digital informed consent process. Contributors to the research, at their discretion, could be named as coauthors in the publication while maintaining the confidentiality of their data. To maximize transparency while maintaining participant privacy, all quantitative metrics and descriptive textual feedback were completely deidentified and anonymized prior to steering group appraisal and round-to-round dissemination. No participant compensation or financial incentives were provided for completion of the Delphi survey panels. Authors disclosed competing interests in accordance with ICMJE (International Committee of Medical Journal Editors) guidelines [17]. All data were securely stored online with restricted access limited to project-dedicated personnel.

### Data Collection and Research Reporting

Invitation letters, recruiting materials, forms, and Delphi questions were piloted by volunteers internally and externally. The CHERRIES (Checklist for Reporting Results of Internet E-Surveys [18]) guideline was used to structure and report the survey aspects of the study. The ACCORD (Accurate Consensus Reporting Document) was used to guide our methods for reporting the Delphi process [15].

### Patient and Public Involvement

The respondents and the authorship team spanned multiple continents and brought diverse perspectives to the study. This included partners and stakeholders with an interest in the FAIR-VBS, some of whom had personal experiences during the COVID-19 pandemic. Additionally, the study engaged research, public health, and medical students, as well as members of the public, all of whom actively contributed to the study design, protocol development, Delphi question testing, data analysis, and manuscript coauthorship.

### Dissemination

The FAIR-VBS research will be shared with repository groups; policymaking agencies; regional, national, and international conferences; government agency briefing sessions; the WHO BioHub; social media sites; and on the institutional websites of coauthors and members of our advisory group. Results will be open access and publicly available with a DOI. They will be shared with all respondents ahead of publication.

## Results

### Delphi Consensus Results

The Delphi process evaluated a cumulative total of 34 unique items across 2 operational rounds to identify critical gaps and priorities in biorepository systems. Over the entire life cycle of the study, a final system consensus was achieved for 24 out of 34 items, while 10 items overall did not meet the consensus criteria.

In round 1, the questionnaire evaluated 30 initial items, with 22 successfully meeting the consensus threshold. During this exploratory first round, panel participants organically proposed 4 additional items. These 4 new items were refined and presented to the cohort in round 2, where 2 achieved full consensus. These late-consensus items explicitly addressed institutional benefit-sharing challenges (11/15, 73% agreement) and the prioritization of whole blood, plasma, and serum samples (40/42, 95% agreement; Tables 1 and 2; Figure 3).

XSL•FO
RenderX

**Table .** The FAIR-VBS (Federated, Accessible, Inclusive, and Responsive Virtual Biorepository) Delphi results, round 1.

| Main theme | Question | Answers or additional descriptions | Number of respondents in agreement above threshold[a]/total number of respondents replied to the question (% in agreement) |
|---|---|---|---|
| A. Questions assessing general interest | Overall, how interested are you in access to specimens? | Not applicable | 42/47 (89%) |
| | Overall, how interested are you in biorepository operations? | Not applicable | 40/47 (85%) |
| | Overall, do you think a grassroots effort is supportive of other concurrent efforts? | Not applicable | 38/47 (81%) |
| | Rank support for combined federal and centralized systems | Combination of centralized and federated | 37/47 (78%) |
| B. Questions about specimens | What types of specimens should be prioritized for accrual, storage, and sharing? | Whole blood, plasma, serum[b] | 42/44 (95%) |
| | How should samples be prioritized for accrual, storage, and sharing? | Longitudinal: serial samples from confirmed cases | 40/44 (91%) |
| | | Prevaccination and 2 weeks postvaccination | 37/44 (84%) |
| | | Regionally with known endemic disease | 36/44 (82%) |
| | How important is the availability of high volumes (>10 ml) of specimens for the following uses? | Important for reference or calibration use | 34/34 (100%) |
| | Should there be minimal quality specimen standards and criteria for inclusion in the FAIR-VBS? | Yes | 41/44 (93%) |
| | Which data elements are the highest priority for inclusion as a minimum to accompany specimens? | Specimen description, source and type, primary, or derivative, etc | 41/41 (100%) |
| | | Collection and handling conditions | 41/45 (91%) |
| | | Storage temperature and freeze-thaw cycles | 38/45 (84%) |
| | Would you agree to a ranked system of specimens based on use, specimen quality, and data? | Yes | 41/42 (98%) |
| | Which of the following criteria are most important to determining the tier of a specimen? | Accessibility (can be shipped from country) | 36/42 (86%) |
| | | Completeness of clinical data | 33/42 (79%) |
| | | Tests performed to characterize specimen | 32/42 (76%) |
| | Which of the following criteria are most important to determining the tier of a specimen? | Handling and storage conditions | 32/42 (76%) |

XSL•FO
RenderX

| Main theme | Question | Answers or additional descriptions | Number of respondents in agreement above threshold[a]/total number of respondents replied to the question (% in agreement) |
|---|---|---|---|
| C. Questions about common barriers | If you maintain specimens, does the ability to ship samples impact your ability to share? | Yes | 39/43 (91%) |
| | Would you be able to share specimens designated for immune-based diagnostics or vaccine development? | Yes | 35/38 (92%) |
| | Would you be willing to participate in defining policies for access and use of specimens? | Yes | 33/39 (84%) |
| | Interest in FAIR-VBS generic templates for material transfer agreement (MTA) and material transfer data agreements (MTDAs) | Yes | 36/40 (90%) |
| | Which of the following are important to include in such generic templates? | Ensure specimens are used for approved or designated purpose | 40/42 (95%) |
| | | Ensure specimens are transferred to other collaborators (third parties) by approval | 38/42 (90%) |
| | | Acknowledging the owners of specimens in publications and presentations | 35/42 (83%) |
| | | As a provider, you reserve the decision to share or not with the requesting party | 30/42 (71%) |
| | | Provision for tracking specimens (chain of custody) and their use | 30/42 (71%) |
| D. Questions about benefits | No consensus, move to second Delphi round for additional information | Ask for clarification in round 2[b] | Not applicable |
| E. Questions about services | Would you support a cost recovery plan for services? | Yes | 43/43 (100%) |
| | The following are some of the services we are considering. Rank each from highly desirable to least desirable | Reference panels (for calibration, proficiency, etc) | 34/43 (79%) |
| | | Protocols and templates (collection, storage, best practices, etc) | 33/43 (77%) |
| | | Infrastructure logistics (shipping, cold chain, equipment, etc) | 33/43 (77%) |
| | Would you recommend academic, commercial, LMIC[c], or other sliding fee scales for services? | Yes | 40/42 (95%) |
| | Please rank again, of the following models for biorepositories, central, federated, or combined (repeat from general interest) | Combination of centralized and federated | 34/41 (83%) |

[a]Threshold for analysis: items were included if prioritization reached more than 70% agreement and discarded if fewer than 15% of respondents provided a response.

[b]Move to round 2 for further decision and consensus.

[c]LMIC: low- and middle-income country.

**Table .** The FAIR-VBS (Federated, Accessible, Inclusive, and Responsive Virtual Biorepository) Delphi results, round 2.

| Main theme (from Table 1) | The 2 questions that did not receive consensus in the first round now posed to the second round for clarification | Answers to the questions or additional descriptions | Number of respondents in agreement above threshold[a]/total number of respondents replied to the question (% in agreement) |
|---|---|---|---|
| B. Specimens | Aside from whole blood, plasma and serum as first choice, what is the next ranked specimen for FAIR-VBS to collect? | Peripheral mononuclear blood cells | 13/18 (72%) |
| D. Benefits | What is the single most important benefit to you? | Capacity building (39%) with networking and SOPs[b] (28% each) | None reached threshold |
| | Are there challenges to receiving benefits you selected? | Yes | 11/15 (73%) |

[a]Threshold for analysis: items were included if prioritization reached more than 70% agreement and discarded if fewer than 15% of respondents provided a response.

[b]SOPs: standard operating procedures.

**Figure 3.** FAIR-VBS (Federated, Accessible, Inclusive, and Responsive Virtual Biorepository) mapping global consensus for virtual biorepositories (credit to Gemini and Google Notebook). PBMC: peripheral blood mononuclear cell.

We analyzed and summarized comments for both rounds in our qualitative analysis. For both rounds, we presented respondents with the quantitative responses and the comments from respondents. The items below are those that reached consensus by percentage. All detailed results including all deidentified, comments numbers or percentages, and items that did not reach consensus, are available in Multimedia Appendix 1.

## Participant Flow and Item Completeness

Panel participation followed a fluid, noninterfering sequential format. A total of 57 experts were enrolled in the initial snowball cohort. While overall survey round retention was tracked via secure login tokens, individual item denominators naturally varied across the 2 tables (ranging from n=15 to n=47). Because participants completed the panels autonomously, they frequently skipped highly technical or localized subquestions where they felt they lacked specific institutional or geographic expertise. Rather than introducing arbitrary data noise, this organic respondent flow ensures that the final consensus statistics strictly reflect the uncoerced input of qualified domain experts. Pairwise deletion was used to handle missing variables, maintaining data precision for each discrete question (Tables 1 and 2).

## Descriptive Analysis

### *General Interest and Biorepository Models*

The FAIR-VBS initiative generated a high level of interest among stakeholders, with 89% (42/47) of respondents expressing either “very interested” or “extremely interested” in accessing biorepository specimens. Additionally, 85% (40/47) demonstrated strong enthusiasm for involvement in biorepository operations. When asked about preferred governance models, the combined model that integrates federated standards with local governance was favored, receiving support from 78% (37/47) of respondents. These results underscore the importance of balancing standardization with the flexibility required for diverse operational contexts.

XSL•FO
RenderX

### *Specimen Prioritization and Metadata*

Blood specimens (whole blood, plasma, and serum) were overwhelmingly prioritized for collection and sharing, with 95% (40/42) of respondents ranking them as a high or very high need. The question wording related to prioritized peripheral blood mononuclear cells was clarified for the round, during which it was supported by 72% (13/18) of the respondents (Table 2). Longitudinal collections were emphasized, with 91% (40/44) supporting serial samples from confirmed cases and 84% (37/44) prioritizing prevaccination and postvaccination specimens. Additionally, 82% (36/44) highlighted the importance of sourcing specimens from endemic regions to ensure geographical diversity. Metadata accompanying specimens was deemed critical. All respondents (41/41, 100%) prioritized specimen descriptions (eg, source and type), while 91% (41/45) emphasized collection and handling conditions. Storage parameters, such as temperature and freeze-thaw cycles, were highlighted by 84% (38/45).

### *Governance and Specimen Sharing*

A ranking system for specimens, based on quality and metadata, was supported by 98% (41/42) of respondents. Key ranking criteria included accessibility (36/42, 86%), completeness of clinical data (33/42, 79%), and storage and handling conditions (32/42, 76%). Barriers to specimen sharing were significant, with 77% (33/43) citing international shipping challenges.

### *Sample Quality and Metadata*

Standardized quality metrics were broadly supported, with 93% (41/44) of respondents emphasizing the need for minimum quality standards. Metadata priorities included specimen descriptions (41/41, 100%) and handling conditions (41/45, 91%), reflecting the importance of robust data to support research integrity.

### *Sustainability and Services*

Sustainability emerged as a pivotal concern, with unanimous support (43/43, 100%) for a cost-recovery model. A sliding fee scale, adjusted based on the type of organization (eg, academic institutions, commercial enterprises, or low- and middle-income countries), was supported by 95% (40/42) of respondents. Regarding services, 79% (34/43) prioritized reference panels for calibration and proficiency testing, while 77% (33/43) emphasized the need for protocols and templates for specimen collection and storage. Infrastructure support, such as cold chain equipment and shipping logistics, was highlighted as essential.

### *Consent and Ethics*

Ethical concerns were evident in the Delphi rounds, with only 35% (13/37) affirming that broad consent, as defined by the Common Rule in 2018 [18], could be adopted within their institutions or nations for future specimen use. However, 92% (35/38) supported sharing specimens for immune-based diagnostics or vaccine development. Additionally, 84% (33/39) expressed interest in participating in policy development, reflecting a strong desire for transparency and collaboration in governance.

### *Institutional and Personal Benefits*

Individual and institutional benefits did not reach consensus in round 1 or round 2. It is important to note that although 73% (11/15) acknowledged challenges with specimen-sharing benefits in round 2, no single barrier reached consensus. A lack of consensus does not necessarily indicate opposition to a particular concept. It may instead suggest that the concept is new, or poorly understood, or that respondents come from varied disciplines and cultures [19]. These variances show areas where difficult conversations may be needed with clarifications and understanding to build a FAIR-VBS that effectively meets the needs of our stakeholders [20].

### *Round 2: Refining Priorities*

In round 2, full consensus was successfully achieved for 2 rephrased items that met the prespecified protocol criteria:

1. Specimen prioritization: Following panel feedback from the initial phase, respondents explicitly prioritized peripheral blood mononuclear cells as the secondary tier for biorepository accrual, reaching 72% consensus (13/18).
2. Barriers and benefit-sharing: Respondents strongly confirmed the systemic friction points surrounding resource equity, with 73% (11/15) reaching consensus that clear institutional challenges exist to effectively receive specimen-sharing benefits.

Consensus was not reached concerning the responsibility of the VBS for preserving SARS-CoV-2 specific pathogens. Detailed tracking of all items that failed to reach consensus is archived transparently within Multimedia Appendix 1.

## Delphi Participant Comment Inclusion

To ensure thematic integrity, a collaborative, multicoder qualitative content analysis was integrated into the iterative Delphi rounds. Textual data from the open-comment fields were evaluated independently by a core coding team of 5 researchers (AP, LA, MC, JG, and JP). The team used a consensus-driven coding framework centered on our 3 target domains: specimen prioritization, structural barriers, and resource sustainability. All researchers had current ethics training and practice and received further instruction on Delphi method coding in compliance with ACCORD guidelines.

To prevent steering group bias or top-down paternalism, discrepancies in theme categorization were resolved through a formal reconciliation process where a team agreement threshold of 100% was required before a code was finalized. This qualitative engine served a strict procedural purpose between rounds: when an item failed to achieve quantitative consensus in round 1, its associated open-text codes were systematically used to uncover semantic ambiguities. The steering group then used these exact participant insights to structurally rephrase the items for clear evaluation in round 2, guaranteeing that the subsequent consensus rounds strictly reflected uncoerced, organic stakeholder intent. All comments were deidentified and shared with all participants in the form in which they were written to reduce unintentional bias. Please note that these comments may contain perceptions that are not representative

XSL•FO
RenderX

of consensus. This is common in emergent fields and is helpful in finding unintentional pain points, biases, and errors.

### Open Comments Summary

#### *Specimen Prioritization*

Respondents reinforced the prioritization of blood specimens (whole blood, plasma, and serum) for collection, storage, and sharing. Other suggestions included cerebrospinal fluid, tissue, and breast milk. Feedback emphasized that specimen prioritization should adapt to specific pathogens, with strong support for longitudinal sampling.

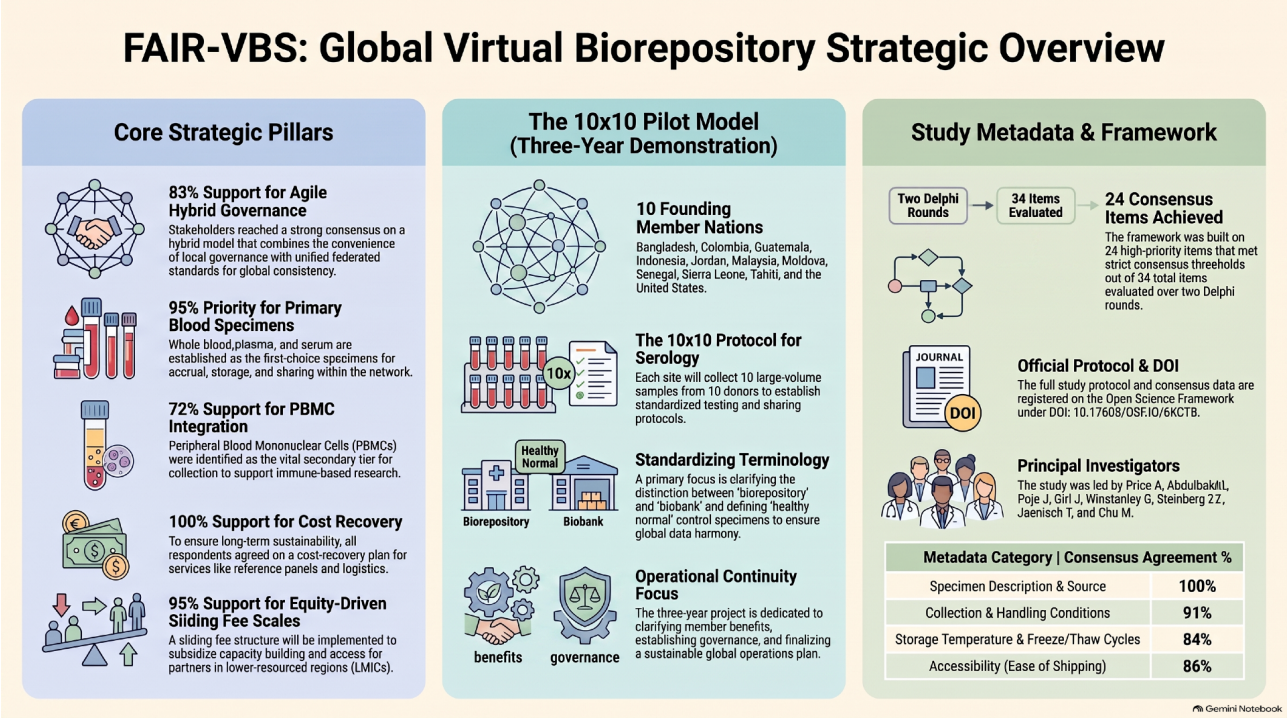
#### *Barriers to Specimen Sharing*

Shipping challenges were the most frequently cited obstacle (11/15, 73%), compounded by infrastructure limitations, especially in regions with inadequate cold-chain capacity. Regulatory complexities, such as the Nagoya Protocol [21], were also noted as a barrier to international sample sharing.

#### *Governance: Federated Standards With Local Adaptation*

The combined governance model, integrating federated standards with local oversight, emerged as the most effective approach. Respondents highlighted the advantages of local governance in enabling rapid responses, particularly during pandemics, while federated standards ensure consistency across regions.

#### *Ethical and Policy Considerations*



Local and national regulations posed obstacles, as identified by multiple respondents. This highlights the need for streamlined logistics and regulatory frameworks to facilitate international collaboration.

#### *Sustainability and Recommendations*

Funding was identified as a major challenge, with respondents stressing the need for long-term coordination and infrastructure development. Recommendations included establishing training programs to build equity in lower-resourced settings and incorporating standard operating procedures. Notably, participants suggested engaging more stakeholders from regions that are underrepresented in the current survey, particularly Africa.

The Delphi survey results emphasize the importance of a flexible yet standardized approach to biorepository governance, robust quality standards, and inclusive stakeholder collaboration. These findings will guide the next stages of developing the FAIR-VBS, ensuring it is equitable, sustainable, and responsive to global research needs (Figure 4).

**Figure 4.** FAIR-VBS (Federated, Accessible, Inclusive, and Responsive Virtual Biorepository) building consensus and priority needs (credit to Gemini and Google Notebook).

## Discussion

### Principal Findings

The Delphi method revealed a rich tapestry of insights about the potential of a FAIR-VBS. The enthusiasm among respondents not only highlighted the transformative possibilities but also brought to light critical areas that must be addressed to ensure its success. One of the most striking benefits of the FAIR-VBS lies in its ability to foster international collaboration. Respondents expressed optimism about how the system could break down traditional barriers in sample sharing, facilitate meaningful cross-border partnerships, and provide opportunities for training and capacity building. This is particularly exciting for underresourced regions, where the FAIR-VBS could play a pivotal role in reducing disparities and promoting equity in global health research [1].

XSL•FO
RenderX

A key strength of the system lies in its ability to connect users with biorepository expertise. By aligning operations with international standards and developing standard operating procedures with quality requirements [22], the FAIR-VBS can elevate the reliability of biospecimen management for infectious disease research worldwide. Respondents envisioned a future with the FAIR-VBS as a cornerstone for consistent, high-quality international research.

Nevertheless, this vision comes with its challenges. A notable emergent theme was the regulatory knowledge gap across countries, highlighting the need for codeveloped resources to align understanding of local and national regulations. This is particularly relevant to the application of benefits under the Nagoya Protocol, as outlined in the Convention on Biological Diversity, which specifies explicit requirements for signatory countries [21]. While this lack of shared knowledge could hinder cross-border collaborations, it also offers an opportunity to develop a system that addresses these gaps through accessible guidance and coproduced documentation.

Concerns about infrastructure and resource limitations were prominent in the discussions. Stable power supplies, reliable storage solutions, and contingency plans for system failures are essential for maintaining sample integrity [22]. Sustainable funding models were another area of concern, as respondents noted the challenges of securing long-term financial support for infrastructure, supplies, and personnel. These issues underline the importance of a robust operational foundation to support the FAIR-VBS's goals.

Logistics posed another layer of complexity, particularly considering past experiences during outbreaks. Shipping delays, high costs, and cumbersome regulations were frequently cited as barriers that needed to be addressed. Respondents called for innovative solutions to streamline these processes, ensuring that the movement of specimens is both timely and cost-effective.

The discussions also explored the unique difficulties of operating in conflict zones or disaster-stricken areas. Strategies to improve access in such environments, such as establishing proxy centers, were proposed as potential solutions to ensure inclusivity and equity.

Ethical considerations emerged as a critical theme, with respondents advocating for careful negotiation of broad consent frameworks [23]. The balance between enabling research and respecting participants' rights was a shared priority, with consensus around the need to limit consent to intended uses and avoid misuse by third parties [23]. Another area of concern was the power dynamics inherent in global collaborations. Smaller biorepositories often face challenges in negotiating on equal terms with larger entities, highlighting the need for governance structures that prioritize fairness and inclusion. Similarly, the importance of equitable benefit-sharing was universally acknowledged, though the variability in challenges across regions pointed to the complexity of designing solutions that work for everyone.

Finally, questions about data and sample quality underscored the importance of consistency and rigor. Ensuring accurate clinical data, maintaining high diagnostic standards, managing samples effectively, and providing timely reference materials were seen as vital to the FAIR-VBS's success [24]. These discussions point to a powerful vision for the FAIR-VBS, one that could transform global health research by promoting collaboration, equity, and innovation. Innovations in safe and secure storage materials that are free of expensive ultralow cold storage could alleviate costs for power, equipment, and shipping. Yet, the path forward requires thoughtful, inclusive strategies to address the challenges and ensure the system's benefits are accessible to all. By fostering transparency, sustainability, and shared ownership, the FAIR-VBS has the potential to become a model for how global health infrastructure can evolve to meet the needs of an interconnected world.

## Challenges and Limitations

The first Delphi round found broad support for a combined biorepository model, incorporating federated standards with local governance to optimize standardization and agility. This approach can address administrative delays inherent in federated systems while allowing for the rapid mobilization of resources necessary for public health emergencies. Consensus was reached on specimen types and quality standards, although defining the normal sample, along with education about why this is critical for research and practice, will be a priority for the FAIR-VBS. Normal control or reference samples may bring the fewest legislative hurdles and could be an appropriate foundation for testing intercountry sharing of specimens, as they are not subject to the same restrictions as infected samples. These samples can also serve as a testing ground for defining terms and differences. Although 1 participant expressed concerns that people living in Africa and working in laboratories were expatriates rather than native, locally educated African individuals, we acted on this assumption by ensuring that native, locally educated people would lead or colead the repositories, thus ensuring local country representation and protection for the laboratories should evacuation or government unrest, or conflict occur. One of the goals of the FAIR-VBS is to ensure strong, trained, and local representation in each country.

The Delphi process allowed us to further query our stakeholders concerning institutional and personal benefits. We found that differing national policies, localized terminology barriers, and ambiguities regarding exactly who would benefit (eg, local collection sites, national governments, or the centralized FAIR-VBS infrastructure) were prominent friction points. Rather than forcing an artificial consensus by shifting our predetermined analytical standards, which would compromise scientific precision, we used our iterative multicoder qualitative framework to map these underlying anxieties.

Recognizing these structural barriers, our ongoing implementation project explicitly codeveloped localized solutions. Specifically, FAIR-VBS sites requested a low operational entry bar featuring an equitable, sliding fee scale tailored for underresourced centers unable to absorb additional costs. Furthermore, stakeholders required a binding assurance that all protocol features remain entirely compatible with their unique national regulatory standards and be mutually agreed upon by all global partners. This participant-driven approach

XSL•FO
RenderX

ensures complete data sovereignty while building international trust in emergent biobanking architectures.

While snowball sampling was highly practical for rapidly engaging a specialized global network, it can introduce inherent network bias. This methodology may limit the overall generalizability of the final consensus due to the potential overrepresentation of specific professional networks, which inherently shapes the demographic and professional diversity of respondents. Language barriers were discussed. We learned that other language respondents were comfortable in filling out the Delphi in English; however, respondents shared that language barriers are more challenging to overcome in oral discussions. Ongoing discussions are needed to address these logistical and ethical challenges. Benefits sharing will require investigation and collaboration locally and within the federated system. Round 2 highlighted the need for reaching people native to the countries, rather than only expatriates assigned to the regions. Respondents expressed anticipated hesitation concerning the FAIR-VBS role and structure, and these findings will guide future discussions as we continue to refine the FAIR-VBS model. As this is an exploratory and participatory Delphi study, we do not pretend to be representative of biorepositories at large and generalizability is limited. For the same reasons, we are not equipped to discuss international rulings or the benefits or barriers of the Nagoya Protocol. Our purpose in asking these questions was to query how this protocol impacted this international sample. We are unpacking nonconsensus items; however, this information is not yet ripe for publication.

### Future Directions

Guided by the Delphi findings, we have launched a 3-year demonstration project involving representatives from 10 countries (Bangladesh, Colombia, Guatemala, Indonesia, Jordan, Malaysia, Moldova, Senegal, Sierra Leone, and Tahiti) and the United States (as the founding and currently facilitating country). This initiative, built around the "10 × 10" model—10 large-volume samples from 10 donors per site for serology testing, focuses on governance, member benefits, and a sustainable operations plan. Early efforts prioritize standardizing terminology, such as clarifying "biorepository" vs "biobank," [25,26] and defining "healthy normal" to ensure consistency across sites.

Reflecting respondents' preferences, the project emphasizes ethical sharing, sustainable access, and locally guided sample collection, supported by a buddy system to expand membership. Contingency plans include sharing calibrated test kits and harmonized standards across sites when specimen sharing proves impractical. During the period between manuscript review and acceptance, our team acted on the Delphi findings. These coordinated efforts aim to advance the FAIR-VBS as a global platform for equitable, ethical, and collaborative specimen sharing.

### Conclusions

These findings highlight the transformative potential of the FAIR-VBS to address critical gaps in international biorepository efforts and the significant challenges that remain to be navigated for implementation. The enthusiasm for enhanced collaboration and capacity building aligns with the FAIR-VBS's mission to promote inclusion and equity in specimen sharing. At the same time, the complexities of infrastructure, regulations, and logistics underscore the need for a strategic and comprehensive approach. Concerns about power dynamics and data quality call for robust and respectful cocreated governance frameworks and agreed-upon quality-control measures. Future efforts will focus on practical solutions, including regulatory harmonization, infrastructure development in resource-limited settings, and equitable governance structures. Pilot work will provide actionable insights into overcoming these challenges. The FAIR-VBS global equity slideshow is presented in Multimedia Appendix 1.

## Acknowledgments

The authors would like to acknowledge the organizations that have worked with us on the Reconciliation of Cohort Data in Infectious Diseases (ReCoDID), the Centers for Research in Emerging Infectious Diseases (CREID), the Global Health Network (TGHN), and our named Delphi respondents: Dr John Spencer, Dr Daniel Olson, Dr Matthias Strobl, Dr Katherine Loens, Dr Kevin Messacar, Dr Oyewale Tomori, Dr. Jane Cardosa, Dr Ute Stöher, Dr Jorge Munoz, Dr Sarah Bethencourt, and Dr Nicole Wolter.

The authors attest that generative AI, large language models, or automated language-generation tools were not used in the conceptualization, execution, data analysis, or writing of this manuscript. Google Notebook and Gemini were used to cocreate Figures 3 and 4.

We acknowledge Dr Geoffrey Winstanley for his contributions to translation of survey questions and reviewing manuscript drafts. The remaining authors and the journal have made every good-faith effort to contact Dr Geoffrey Winstanley for final manuscript approval but were unable to establish communication prior to publication.

## Funding

This work is supported by the European Union's Horizon 2020 Research and Innovation Programme under grant agreement number 825746 (Reconciliation of Cohort Data in Infectious Diseases [ReCoDID]) and 101137283 (CONTAGIO), as well as by the Canadian Institutes of Health Research, Institute of Genetics (CIHR-IG), under grant agreement number 01886-000.

## Abstract

**Background:** The COVID-19 pandemic demonstrated the potential role of digital health tools in enhancing pandemic preparedness and response. These tools became essential, supporting not only health care delivery but also decision-making, communication, case identification, contact tracing, surveillance, vaccination rollout, and intervention evaluation. The interest in applying digital health tools to pandemic preparedness and response motivated conversations about digital epidemiology—a field of study that aims to provide insight into health and disease determinants by leveraging diverse digital data sources. In a globalized world, effective preparedness and response to pandemics require coordinated global action.

**Objective:** This study investigates experts' opinions on strategies for improving global health security through the effective use of digital epidemiology, considering the current landscape of digital determinants of health.

**Methods:** Epidemiologists, public health specialists, data scientists, and professionals with expertise in various components of digital health were recruited through convenience and snowball sampling methods. Their opinions were elicited using an electronic questionnaire developed by the authors in Research Electronic Data Capture (REDCap; Vanderbilt University). To ensure a global perspective, participants were recruited from Africa, North America, Oceania, and Europe. Thematic analysis and the strengths, weaknesses, opportunities, and threats (SWOT) analysis framework were used to analyze participants' responses.

**Results:** Most participants were familiar with the concept of digital epidemiology and expressed positive sentiments about its potential in strengthening global health security. Privacy and security, along with ethical and legal considerations, were ranked by most experts as high priority areas that decision-makers and implementers must consider to ensure sustainable integration of digital epidemiology tools in future pandemic preparedness and response. A SWOT analysis of participants' views on the promise of digital epidemiology revealed fewer strengths and more weaknesses compared to other components of the analysis framework.

**Conclusions:** This study highlights the growing recognition of digital epidemiology as a critical tool for enhancing global health security, particularly using nontraditional data sources and emerging technologies, including artificial intelligence. The study affirms the need for a globally coordinated approach to governance, regulation, and investment in digital health infrastructure to ensure the responsible and effective application of digital innovations in epidemiological practice.

## Introduction

The COVID-19 pandemic underscored the critical role of digital health tools in enhancing pandemic preparedness and response. It is estimated that the COVID-19 pandemic caused more than 2 million deaths worldwide [1]. A report of the Independent Panel for Pandemic Preparedness and Response concluded that the alert system was too slow, the World Health Organization (WHO) was underresourced, and global political leadership was absent [2]. The study by de Souza et al [3] identified 5 critical areas associated with the global failure in facing the pandemic: deficiency in the global alert system and the fragility of the international health regulations, problems of the international response to the pandemic related to global health governance, the dispersed global adoption of the elimination strategy (zero-COVID), fragile control of the disease with a narrow reading of the associated problems, and finally, global setbacks in achieving the sustainable development goals. The need for coordinated global efforts and effective early detection and timely surveillance for a robust pandemic and epidemic early warning and preparedness has been widely discussed amid the COVID-19 pandemic [4].

Digital health tools became a necessity and their popularity increased during the pandemic not only for the provision of health care services but also to support decision-making, communication and information, case identification, contact tracing, surveillance and monitoring, and rolling out of vaccination programs, as well as evaluation of interventions [5-7]. Digital health technologies illustrated the potential to support diverse needs and approaches for early warning and forecasting of epidemics [8]. Nevertheless, in their report, Al Knawy et al [9] acknowledge that COVID-19 highlighted widespread chronic underinvestment in digital health that hampered public health responses to the pandemic. The often ad hoc adoption and use of digital health during the pandemic further illuminated its potential to transform future pandemic preparedness and response efforts [10].

The discussion on applying digital health tools toward future pandemic preparedness and response has motivated frequent conversations around digital epidemiology. Digital epidemiology has been defined as a field of study that aims to provide insight into health and disease determinants in human populations by building on diverse digital data sources [11]. Furthermore, the study by Tarkoma et al [11] posits that digital epidemiology is envisaged as having the potential to contribute toward global health security through inputs, such as syndromic surveillance, public health surveillance, and early pandemic detection.

In the era of globalization, efficient preparedness and response to future pandemics requires a united global action [12,13]. However, realizing the full potential of digital epidemiology as part of such global efforts becomes elusive due to persistent geopolitical tensions as well as the global digital divide and digital access gap [14]. This study aims to investigate experts' opinions on possible means of improving global health security through the effective use of digital epidemiology within the context of the current global landscape of digital determinants of health.

## Methods

### Sampling and Recruitment of Study Participants

Epidemiologists, public health specialists, data scientists, and professionals with expertise in the various components of digital health were recruited using convenience sampling. To gather a global perspective, potential study participants were recruited from Africa, North America, Oceania, and Europe.

For recruitment of potential participants from Africa, an initial email was sent to the general membership of the pan-African health informatics association called Health Informatics in Africa. For the United States, initial recruitment of study participants involved sending an email to members of the American Medical Informatics Association. Snowball sampling method was also used. The initial email to potential study participants described the study objectives and the role of a potential study participant. Study data were collected and managed using the Research Electronic Data Capture (REDCap; Vanderbilt University) tool hosted at the Children's Hospital of Philadelphia [15]. The email package also included a link to an electronic questionnaire developed using the REDCap platform. The electronic questionnaire included a consent form that a potential study participant had to agree to before proceeding to answer the questionnaire.

Recruitment of potential study participants was also done at the Medical Informatics Europe 2023 conference held in Göteborg, Sweden. Paper flyers about the study were placed at convenient places throughout the conference venue. In addition to containing details about the study objectives and participant's role, the paper flyers also included a QR code with a link to the electronic questionnaire developed using REDCap.

Recruitment of study participants continued until data saturation was reached, defined for this study as the point at which additional data no longer generated new insights. As an electronic questionnaire was used for this study, the authors aimed to comply with the Checklist for Reporting Results of Internet E-Surveys [16]. The consolidated criteria for reporting qualitative research were followed for reporting of this study. The completed checklist is provided in Multimedia Appendix 1.

### Study Questionnaire Design and Development

The initial draft of the study questionnaire was designed based on a review of relevant literature. Following an iterative process, the authors developed a study questionnaire aimed at capturing participants' opinions on effective approaches to improving global health security using digital epidemiology within the

XSL•FO
RenderX

context of the current global landscape of digital determinants of health.

A panel consisting of 5 staff members from the Department of Biomedical and Health Informatics at the Children's Hospital of Philadelphia and the Perelman School of Medicine at the University of Pennsylvania was consulted to ensure content validity of the study questionnaire. The panel received the initial draft questionnaire via email and could make suggestions for improvement where needed. Their suggestions were discussed and agreed upon among the authors and final updates were made on the questionnaire. The structured questionnaire included both closed-ended (Likert-scale responses) and open-ended questions, allowing for analysis of trends as well as insights into experts' recommendations. This approach facilitated a comprehensive evaluation of participants' responses.

### Data Analysis

Thematic analysis was used to analyze the qualitative responses from the questionnaire, following an iterative process [17]. All textual data were imported into NVivo software (version 12; Lumivero) to facilitate systematic coding and theme identification. Initial codes were generated based on both predefined study objectives and emerging patterns from the data. Through repeated review and refinement by all authors, broader themes and subthemes were developed to capture key insights. Consensus on the final themes was reached through discussion among all authors.

Descriptive statistics were computed to summarize responses. Participants' responses were analyzed by applying the strengths, weaknesses, opportunities, and threats (SWOT) analysis framework [18] to the digital epidemiology approach. The responses were independently reviewed by 2 coauthors (KLM and BM) and assigned to one of the SWOT categories. Any disagreements or discrepancies in the assignment of responses to SWOT categories were discussed, and consensus on the final categorization of each response was reached by the authors.

### Ethical Considerations

This study involved seeking experts' opinion through the use of an electronic questionnaire—what is commonly classified as a minimal risk study, in which the probability and magnitude of harm or discomfort arising from participation were not greater, in and of themselves, than those ordinarily encountered in daily life or during the performance of routine physical or psychological examination or tests. Nevertheless, ethics approval for the study was obtained from the institutional review board at the Children's Hospital of Philadelphia (institutional review board protocol number: 22-020667). Participants received the survey electronically using REDCap, and consent to participate was obtained from all participants through a consent form embedded in the electronic questionnaire (REDCap). Only participants who provided consent were able to proceed and complete the questionnaire. Participants' privacy and confidentiality were ensured throughout the study. REDCap is a secure, web-based platform designed to support electronic data capture for research and operational projects, and it is compliant with the Health Insurance Portability and Accountability Act and the General Data Protection Regulation. The study did not collect any personally identifiable information. All data collected were anonymized and reported in aggregate form only. Participants did not receive any compensation for taking part in the study.

## Results

Following the data collection phase (February 2023-February 2024), a total of 22 fully completed questionnaires were retained for analysis, while incomplete responses were excluded. Questionnaires were deemed incomplete if participants failed to respond to any of the mandatory sections or to questions measuring key outcome variables. The study participants represented diverse geographical regions, including Africa (7/22, 32%), the Americas (7/22, 32%), Europe (6/22, 27%), and Oceania (2/22, 9%). A detailed breakdown of this distribution is presented in Table 1.

XSL•FO
RenderX

**Table 1.** Characteristics of study participants (N=22) and countries represented in a global expert survey on digital epidemiology conducted from February 2023 to February 2024.

| Region, subregion, and country | Participants, n (%) |
|---|---|
| **Africa (n=7)** | |
| **Eastern Africa** | |
| Rwanda | 1 (4.5) |
| Uganda | 2 (9.1) |
| Malawi | 1 (4.5) |
| **Western Africa** | |
| Ghana | 1 (4.5) |
| **Central Africa** | |
| Cameroon | 1 (4.5) |
| **Southern Africa** | |
| South Africa | 1 (4.5) |
| **Americas (n=7)** | |
| **North America** | |
| United States | 6 (27.3) |
| Canada | 1 (4.5) |
| **Europe (n=6)** | |
| **Western Europe** | |
| Switzerland | 3 (13.6) |
| France | 1 (4.5) |
| Netherlands | 1 (4.5) |
| **Southern Europe** | |
| Greece | 1 (4.5) |
| **Oceania (n=2)** | |
| **Australia and New Zealand** | |
| Australia | 2 (9.1) |

The study participants represented diverse professional backgrounds, with 14 (62%) participants identifying as informaticians, 4 (19%) participants as public health specialists, 3 (14%) participants as medical doctors, and 1 (5%) as a philosopher (Table 2). Participants were required to identify with only 1 mutually exclusive professional category.

**Table 2.** Occupation distribution of study participants (N=22) in a global expert survey on digital epidemiology conducted from February 2023 to February 2024.

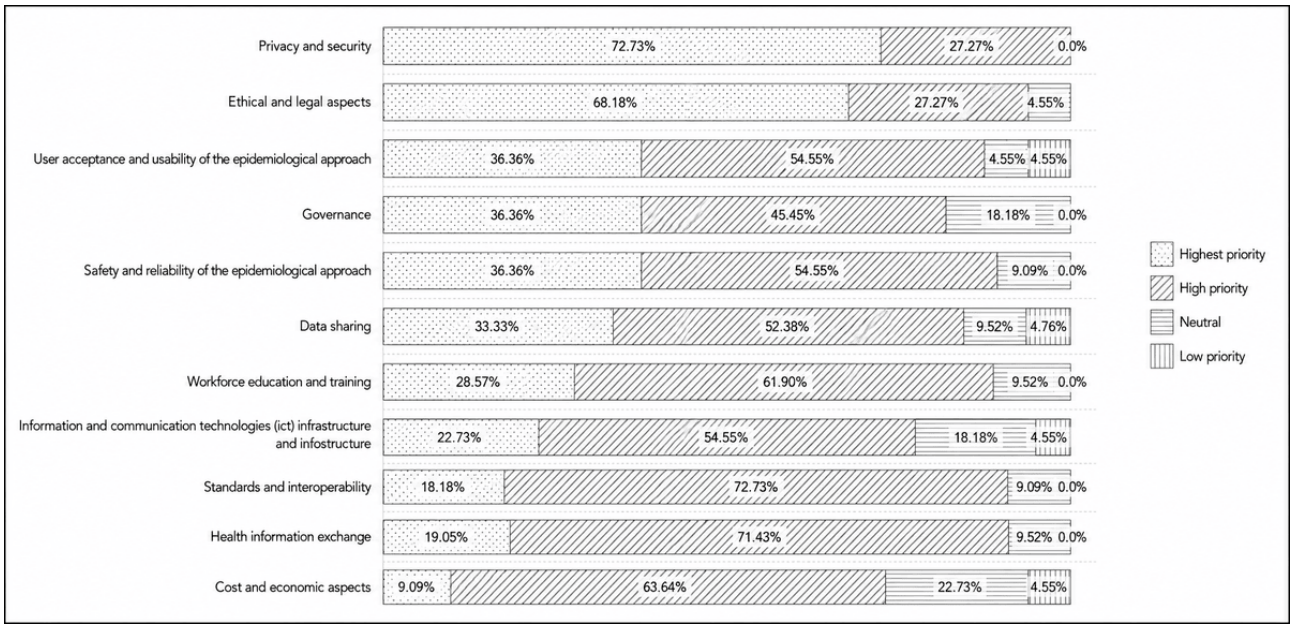
| Occupation | Participants, n (%) |
|---|---|
| Public health | 4 (19) |
| Medical doctor | 3 (14) |
| Informatician | 14 (62) |
| Philosopher | 1 (5) |

This study aimed to explore experts' opinions on what they would consider as optimal conditions necessary for the use of digital epidemiology to enhance future pandemic preparedness and response. Accordingly, it was essential to assess participants' awareness of the concept of digital epidemiology, as this could influence the study's findings and interpretations. As illustrated in Table 3, most study participants were aware of the concept of digital epidemiology, with more than half of the participants either strongly agreeing or agreeing that they were familiar with digital epidemiology.

XSL•FO
RenderX

**Table 3.** Awareness of the concept of digital epidemiology among study participants (N=22) in a global expert survey conducted from February 2023 to February 2024.

| Response category | Participants, n (%) |
|---|---|
| Strongly agree | 11 (50) |
| Agree | 8 (35) |
| Neutral | 1 (5) |
| Disagree | 1 (5) |
| Strongly disagree | 1 (5) |



Participants who either strongly agreed or agreed (n=19 participants) that they were aware of the concept of digital epidemiology (Table 3), generally expressed positive sentiments regarding its potential impact and effectiveness in improving global health security (Table 4).

**Table 4.** Study participants' sentiments regarding the potential impact and effectiveness of digital epidemiology (n=19) in a global expert survey conducted from February 2023 to February 2024.

| Statement | Strongly agree, n (%) | Agree, n (%) | Neutral, n (%) | Disagree, n (%) | Strongly disagree, n (%) |
|---|---|---|---|---|---|
| Digital data can enhance epidemiology purposes | 13 (68) | 4 (21) | 2 (11) | 0 (0) | 0 (0) |
| Digital epidemiology can be effectively applied at a global level toward a coordinated global health surveillance | 11 (57) | 6 (32) | 2 (11) | 0 (0) | 0 (0) |
| Digital epidemiology is reliable | 4 (21) | 12 (63) | 2 (11) | 1 (5) | 0 (0) |

Effective integration of digital epidemiology as part of a united global action toward future pandemic preparedness and response would require a certain level of readiness from the global community [7,18]. Key readiness indicators for decision-makers and implementers to consider are outlined in Figure 1. Study participants ranked these indicators based on their perceived importance and priority. In order of importance and priority, from highest to lowest, the indicators were ranked as follows: privacy and security, ethical and legal aspects, user acceptance and usability of the epidemiological approach, governance, safety and reliability of the epidemiological approach, data sharing, workforce education and training, information and communications technology infrastructure and infostructure, standards and interoperability, health information exchange, and costs and economic aspects (Figure 1). Participants also identified associated strengths, weaknesses, opportunities, and threats. It is noteworthy that fewer strengths and more weaknesses were identified relative to the other components of the SWOT analysis (Table 5).

**Figure 1.** Priority ranking of key readiness indicators for effective integration of digital epidemiology in pandemic preparedness and response, as reported by study participants (n=19) in a global expert survey conducted from February 2023 to February 2024.

XSL•FO
RenderX

**Table 5.** Strengths, weaknesses, opportunities, and threats (SWOT) analysis of opinions on the effective integration of digital epidemiology in pandemic preparedness and response (n=19) in a global survey of experts conducted from February 2023 to February 2024.

| SWOT analysis categories | Themes emerging from participants' responses |
|---|---|
| Strengths | • Increasing investments in digital technologies by countries<br>• Existence of digital health strategies by countries |
| Weaknesses | • Limited competent workforce<br>• Weak digital health infrastructure<br>• Digital divide<br>• Poor data quality<br>• Limited data sharing<br>• Digital illiteracy<br>• Limited use of artificial intelligence or machine learning<br>• Weak ethical and legal considerations<br>• Disconnect between public health departments and hospitals |
| Opportunities | • Global open standards that promote data exchange<br>• Global design<br>• International coordination on ethical considerations<br>• Inclusion of the nonhealth sector |
| Threats | • Data security<br>• Global economic challenges<br>• Patient acceptance<br>• Ethics<br>• Political interference<br>• Political unawareness |

## Discussion

### Principal Findings

This qualitative study gathered insights from 22 experts (Table 1). Although the sample size may be considered relatively small, it is appropriate for the exploratory nature of the research and emphasizes achieving information power [19]. This approach provides a rich, in-depth, context-specific preliminary evidence rather than statistical generalization. In qualitative research designed to identify patterns across data, recruitment of between 15 and 30 participants has been commonly found to be adequate [20].

Digital epidemiology is a relatively new field that has grown rapidly in recent years, with its humble beginnings traced back to when researchers began mining the increasing amount of internet data for epidemiological purposes [21]. The growth of the field, and thus increased awareness, has been fueled by the growing utility of new data sources and artificial intelligence (AI) in epidemiology [22]. The ad hoc use of digital epidemiology methodologies and techniques during the COVID-19 pandemic likely contributed to the heightened awareness of the field [23]. This may explain why most study participants, especially in light of their professional backgrounds, reported being aware of the concept of digital epidemiology (Table 2). However, it is important to note that the attitude of stakeholders, rather than their awareness, may play a more crucial role in driving sustainable use of digital epidemiology. The technology acceptance model features prominently among the methodologies used to measure attitudes toward technology adoption [24,25]. According to the technology acceptance model, perceived usefulness (PU) is characterized by an individual's belief that using technology improves their job performance, while perceived ease of use (PEOU) refers to their belief that using technology requires minimal effort [24]. Both PU and PEOU are primary drivers that influence attitudes toward using technology [25]. Most study participants agreed that digital data can enhance epidemiological purposes (PU), that digital epidemiology can be effectively applied at a global level toward coordinated global health surveillance (PU), and that digital epidemiology is reliable (PU+PEOU). This is illustrated in Table 4 and reflects participants' positive attitudes toward digital epidemiology, particularly regarding its potential impact and effectiveness in improving global health security.

The Riyadh Declaration on digital health is a global call to action promoting the development of infrastructure and best practices necessary for sharing high-quality, real-time data both locally and globally in the fight against pandemics. Its goal is to enable health systems to access actionable information that can inform timely responses to public health threats [26]. Similarly, the US Centers for Disease Control and Prevention launched the Data Modernization Initiative to enhance the quality, availability, and use of data related to pandemics and public health emergencies [27]. Together, these frameworks serve to guide the integration of digital innovations into national and global health systems as part of coordinated efforts to strengthen preparedness and response to future pandemics. A shared theme emphasized across these frameworks is that leveraging digital epidemiology to address global health threats requires a more robust and integrated global health architecture that is capable of better preparing local, national, regional, and global public health partners to predict, prevent, detect, assess, and respond effectively to emerging threats. This calls for intentional efforts by governments and public health authorities

XSL•FO
RenderX

to mitigate digital exclusion at all levels (global, regional, national, and local) and to address data governance and interoperability challenges inherent in using and sharing diverse data sources [28].

Privacy and security, along with ethical and legal considerations, were ranked by most experts as high priority areas that must be considered by decision-makers and implementers to ensure sustainable integration of digital epidemiology tools in preparedness and response to future pandemics (Figure 1). Digital epidemiology, as previously explained, makes effective use of data not originally intended for epidemiological purposes. Examples of such data include internet searches, social media posts, webpage access logs, mobile phone network data, mobile health apps, wearable devices, sensor generated data, call center records, health and patient registries, and environmental monitoring data [21,23]. As some of these data are generated outside traditional public health systems and those involved in generating such data may not have consented to or even be aware of their use for epidemiological purposes, indeed this raises legitimate concerns related to potential data privacy breaches, security vulnerabilities, and ethico-legal issues. The pertinent literature suggests that data on one's health status have the potential to be reused by third parties to discriminate and restrict individual rights, and that institutional and government access to personal data (eg, geospatial data) could inhibit the exercise of basic freedoms, if individuals feel watched as to what they do or with whom they spend time [29]. In the context of the existing global digital divide and digital access gap, reliance on digital epidemiology to drive pandemic preparedness and response strategies may inadvertently perpetuate existing health disparities, benefiting overrepresented populations in the data, while not providing gains to and even possibly harming populations whose data are underrepresented [30]. In light of the current fragmented regulatory landscape and in the absence of a common set of principles on data privacy, security, and ethics, a global coordinated approach is required to establish frameworks that will ensure safe and responsible use of digital epidemiology as part of a unified global effort toward future pandemic preparedness and response [31]. Findings from a study based on the unified theory of acceptance and use of technology framework indicated that cost did not moderate behavioral intention to adopt the technology [32]. This may help explain why, in this study, experts ranked cost and economic aspects lower among the key readiness factors for the adoption of digital epidemiology (Figure 1).

The WHO's Global Strategy on Digital Health 2020 to 2025 provides a structured road map to guide member states in systematically integrating digital health technologies into their national health systems. According to WHO, the vision of the global strategy is to improve health for everyone, everywhere by accelerating the development and adoption of appropriate, accessible, affordable, scalable, and sustainable person-centric digital health solutions to prevent, detect, and respond to epidemics and pandemics [33]. Existence of such a document is indeed a strength in creating an enabling environment for the use of digital epidemiology in future pandemic preparedness and response. Increasing investments in digital technologies by countries and existence of digital health strategies by countries (Table 5) are part of the strategic objectives advanced by the document. The 4 strategic objectives outlined in the Global Strategy on Digital Health are as follows: (1) promote global collaboration and advance the transfer of knowledge on digital health, (2) advance the implementation of national digital health strategies, (3) strengthen governance for digital health at global, regional, and national levels, and (4) advocate people-centered health systems that are enabled by digital health [32]. These strategic objectives align with concerns highlighted as weaknesses by experts in Table 5. In addition to data privacy, security, and ethics already discussed, experts identified sociopolitical challenges and economic constraints as potential threats to a global approach to digital epidemiology (Table 5). This aligns with the study by Davis [34], which discusses the political determinants of digital health, defining them as the intersecting areas of national and international law and policy, local and global governance, civic engagement, and the influence of transnational commercial interests. The author explains that these factors collectively shape access to, uptake of, and the design of digital health systems [34]. As a case point, global geopolitical tensions and varying digital health maturity levels of nations can significantly impact data sharing in public health, resulting in lapses in global health security.

The full potential of digital epidemiology in achieving coordinated pandemic preparedness and response can indeed be leveraged through advancements in global design and international collaborations on digital health–related issues (Table 5). Opportunities exist in open health data standards [35], which promote interoperability and enable effective data sharing across diverse settings. The WHO's extension of the Global Strategy on Digital Health 2025 to 2027 endeavors to provide critical guidance on AI in health, including the ethics and governance of AI for health, and aims to support member states through global workshops on ethical AI implementation [36] and the code of ethics for health information professionals of the International Medical Informatics Association [37], are but examples of opportunities that offer a pathway toward safe and responsible use of digital epidemiology as part of a unified global effort for future pandemic preparedness and response. As previously explained, digital epidemiology uses data sources beyond the traditional health sector to gain insight into disease patterns and trends. As such, a significant opportunity exists in the continued efforts by global health actors to engage representation from nonhealth sectors in plans for future pandemic preparedness and response (Table 5). These sentiments are emphasized in the WHO Pandemic Agreement which sets out principles, approaches, and tools for better international coordination across a range of areas to strengthen the global health architecture for pandemic prevention, preparedness, and response [38]. The WHO Pandemic Agreement perhaps holds great promise toward significantly contributing to the creation of an enabling environment for the effective role of digital epidemiology in future pandemic preparedness and response efforts.

## Limitations

This study is subject to limitations inherent in its design. The use of convenience and purposive sampling methods limits the generalizability of the findings. The sample may have excluded

XSL•FO
RenderX

critical perspectives from underrepresented geographic regions or professional backgrounds. For instance, within the North American region, participants from the United States were heavily overrepresented, with only 1 participant from Canada, thereby excluding perspectives from other countries in the region. The composition of professional backgrounds represented in the sample may have influenced participant responses, potentially skewing perceptions toward more favorable views of digital epidemiology. These notable imbalances may have constrained the diversity and balance of expert opinions captured.

### Conclusions

This study explored experts' perspectives on the potential, readiness factors, and challenges associated with integrating digital epidemiology into global pandemic preparedness and response strategies. The findings underscore a growing recognition of digital epidemiology as a critical tool for enhancing global health security, particularly using nontraditional data sources and emerging technologies such as AI. Participants demonstrated high awareness and positive attitudes toward the utility and applicability of digital epidemiology, especially in advancing coordinated global health surveillance. However, the study also identified key barriers that must be addressed to ensure sustainable integration of digital epidemiology into health systems. These barriers include concerns related to data privacy, security, ethics, sociopolitical influences, and digital inequities across and within countries. The study affirms the need for a globally coordinated approach to governance, regulation, and investment in digital health infrastructure. By highlighting the complex interplay between technological, institutional, political, and social determinants of digital epidemiology, this research contributes important insights into how global health actors can leverage digital innovations responsibly and effectively for epidemiological purposes. Future research directions should focus on developing and validating context-specific frameworks that offer clear guidance for the responsible and sustainable integration of digital epidemiology into existing health systems, to support preparedness for and response to future pandemics.

### Acknowledgments

This research was supported by the US Fulbright Scholar Program and the Children's Hospital of Philadelphia, Global Health Informatics Program. The authors would like to acknowledge the valuable insights and support from faculty at the Perelman School of Medicine, University of Pennsylvania. OpenAI's GPT-5.2 was used by 1 coauthor for grammar and spelling checks in portions of the manuscript. All text was reviewed and finalized by all authors, who retain full responsibility for its accuracy.

### Data Availability

The data used and analyzed during this study are available from the corresponding author upon reasonable request.

### Funding

This research was funded by the US Fulbright Scholar Program and the Children's Hospital of Philadelphia's Global Health Informatics Program. Apart from providing financial assistance for research-related activities, the funders had no influence in the study design, data collection, analysis, interpretation, or the writing of the manuscript.

### Authors' Contributions

KLM contributed to the study concept and design, as well as data collection. KLM, JHH, AL, and BM contributed to data analysis and interpretation of the results. All authors participated in manuscript preparation, critically reviewed the article, and approved the final version of the manuscript.

## Abstract

**Background:** Mobile exposure notification apps (ENAs) can play a significant role in future pandemics. Identifying lessons learned and areas for improvement from such apps, particularly within specific social and cultural contexts, is therefore crucial.

**Objective:** This study aimed to evaluate the Finnish ENA "Koronavilkku," according to chosen key performance indicators to assess the ENA's use and performance during the COVID-19 pandemic in Finland, and to identify strengths and improvement areas.

**Methods:** Using available data on Finland's ENA, we defined metrics for four key performance indicators: ENA use extent, enablers and barriers to use, the ENA's influence on user behavior, and overall acceptability. We performed an evaluation study combining system data and data from a survey of 4061 respondents conducted in April 2022. A sentiment analysis was performed on open-ended responses.

**Results:** Koronavilkku ENA peak coverage reached approximately 53% of active smartphone users shortly after launch. Use declined over time, particularly among individuals diagnosed with COVID-19. User engagement remained high—among ENA users who received a token, the proportion that entered their token into the ENA was more than 50% during the whole study period. Males, individuals older than 34 years, and those living alone were less likely to use the ENA, while those with higher education and households with children were more likely to be ENA users. Almost 70% (64,642/94,280) of SARS-CoV-2–positive users reported not receiving a token from health authorities. Users reported higher adherence to pandemic guidance than nonusers, with prevalence ratios ranging from 1.24 (95% CI 1.19 - 1.29) to 1.65 (95% CI 1.45 - 1.91). Descriptive analyses suggested higher reported adherence among partially compliant users after exposure notifications, whereas little change was observed among noncompliant individuals. Overall acceptability was relatively high, with 68% of respondents using it at least once. However, 49% of those users eventually discontinued use. Our sentiment analysis of open-ended feedback suggests that users expressed more positive attitudes toward the ENA compared to nonusers. However, a substantial portion of the feedback reflected neutral or negative sentiments.

**Conclusions:** Based on observed ENA use trends, we recommend maintaining long-term public interest and engagement in ENAs during prolonged emergencies. Tailored communication should be developed encouraging uptake among demographic groups with lower adoption rates. Initial studies during app rollout could inform these strategies. A major barrier to the ENA's performance was token issuance; earlier and more systematic automation of token distribution in Finland could have enabled more timely exposure notifications and reduced bottlenecks. Future ENAs should define evaluation criteria during development, with periodic assessments measuring effectiveness and informing improvements. A deeper analysis of open-ended feedback provided for the Koronavilkku ENA using advanced language models could provide additional insights into user perceptions and concerns. By addressing these areas, future digital contact tracing tools may improve uptake, acceptability, and integration into pandemic response efforts.

## Introduction

Finland reported its first imported case of COVID-19 in late January 2020, and by mid-March the number of confirmed cases had risen to over 400. In response, on March 16 the government declared a state of emergency, introducing wide-ranging measures including the closure of schools and public facilities, restrictions on public gatherings, and limitations on cross-border travel. Some of these measures were gradually eased by May 2020, although restrictions were reintroduced in autumn as case numbers increased again. Finland began its vaccination campaign in late December 2020, and by November 2021, approximately 80% of the population aged 12 years and older had been vaccinated. As vaccination coverage expanded and the epidemiological situation improved, restrictions were progressively lifted, with all major measures ending by the end of June 2022 [1-3].

Mobile exposure notification apps (ENAs) using digital proximity tracing were introduced during the COVID-19 pandemic in many countries worldwide. In Finland, the national ENA "Koronavilkku" was launched on August 31, 2020, and discontinued on June 1, 2022. The aim of the Finnish ENA was intended to supplement conventional contact tracing and serve as an early warning system for the individual user in case of potential exposure to a SARS-CoV-2–positive person in order to provide them with behavioral guidance mitigating the chance of further transmission [4]. ENA use was voluntary and free of charge.

The ENA was developed using a decentralized approach. Finnish legislation and the European architecture and protocols used for ENAs placed strong emphasis on privacy, data security, and data safety. Due to these constraints, very limited performance information was gathered through the ENA to describe its potential effectiveness under the stated aims [4]. In addition to the ENA, a dedicated system was provided to all health care provider organizations in Finland to enable token issuance for infected app users, which allowed users to activate exposure notifications to potential contacts. The organizations, in turn, granted system access to health professionals who sent tokens to ENA users.

Several studies have evaluated the uptake, acceptability, and potential impact of ENAs during the COVID-19 pandemic, with mixed findings. Modeling and empirical studies suggest that even moderate uptake may contribute to reducing transmission, although effectiveness depends on multiple factors, including user engagement and timeliness of notifications [5-10]. More recent research has emphasized variability in how effectiveness is defined and measured, as well as the importance of contextual factors in determining impact [11]. Research across European countries has also highlighted variability in adoption and acceptability, with sociodemographic factors, trust, and perceived usefulness influencing uptake [12-15]. Implementation challenges, such as delays in notification processes and integration with public health systems, can limit the overall performance of these tools [16,17]. However, comprehensive evaluations combining system-level performance indicators with user-reported experiences remain limited. Our aim was to evaluate the Finnish ENA according to chosen key performance indicators (KPIs) to gain insight into the ENA's use and performance during the COVID-19 pandemic in Finland, as well as to identify strengths and areas for improvement.

## Methods

### Overview

We evaluated the ENA during its period of use (August 31, 2020-June 1, 2022) based on the following set of KPIs:

1. extent of ENA use,
2. enablers and barriers to ENA use,
3. influence of the ENA on user behavior, and
4. general acceptability of the ENA.

### Operational Definitions

Active ENA use: the device has the ENA installed, is operational, and communicates at least once every 24 hours with the backend server to retrieve keys (see "key-matching process").

Keys: randomly generated, encrypted identifiers exchanged through Bluetooth Low Energy between participating devices that are near one another, according to defined distance and duration criteria. These keys provided the basis for anonymous "matching" of devices and the subsequent triggering of exposure notifications.

Key-matching process: phones regularly downloaded keys from users who had received a positive SARS-CoV-2 result and entered their token into the ENA from the backend server and checked them against their own history of contacts for matches. If a match was found, it triggered the exposure notification mechanism based on the calculated exposure risk value (ERV).

Token: one-time code issued by the system used by health care providers upon receiving a positive COVID-19 diagnosis. The token was issued manually to ENA users by health care professionals, although automatic issuance was introduced in some parts of Finland from June 2021. When entered into the ENA by the user, the user's keys were sent to the backend server. Entering a token locked the ENA and it no longer tracked exposures.

Exposure notification: a message issued by the ENA alerting the user that they had recently been in proximity to an individual who has received a positive SARS-CoV-2 finding and has shared their result via the app.

### Data Collection

We accessed system activity data from the ENA provider and the ENA's backend. In Finland, the ENA providers were the Social Insurance Institution (Kela) and the Finnish Institute for Health and Welfare (THL). Variables retrieved included: number of downloads (data available for August 31, 2020-February 8, 2021), number of active users (data available for December 7, 2020-April 24, 2022), number of tokens issued (data available for September 7, 2020-May 29, 2022), and number of tokens used (data available for September 7, 2020-May 29, 2022).

XSL•FO
RenderX

Furthermore, we used data from the cross-sectional online survey conducted from April 13 to April 22, 2022, by a Finnish polling company among respondents aged 15 - 79 years, based on a convenience sample of the company's and its subcontractors' panelists. The survey included 4061 respondents, corresponding to approximately 0.07% of the Finnish population (~5.5 million). Weights were assigned to all respondents based on the distribution of the Finnish population with regard to sex, age, and geographic area (data from Statistics Finland – population by sex and age and major regions in mainland Finland as of December 31, 2020).

Variables from the survey included respondents' sociodemographic characteristics, ENA use, ENA removal, reasons for nonactivation, reasons for removal, receipt of exposure notifications, token receipt, speed of token delivery, use of tokens, adherence to recommendations after notification, reasons for discontinuation of adherence to recommendations, consulting a health care provider after exposure notification, general behavior during the pandemic, COVID-19 diagnosis, and overall feedback on the ENA.

We used data on population size by sex, age, region, and year during 2020 - 2022 from Statistics Finland. We retrieved the daily number of COVID-19 cases reported to the National Infectious Diseases Register (NIDR) from August 31, 2020, to June 1, 2022 [18].

### Koronavilkku Survey Variables

We created the following terms based on variables from the Koronavilkku survey:

- ENA user or nonuser: we divided respondents into two main groups: ENA users and nonusers based on the question "Have you downloaded the Koronavilkku application on your phone?" ENA users were further classified as reporting current or previous use of the ENA. Nonusers were classified as reporting never using the ENA or downloading the ENA but never activating it.
- Exposure notification guidance*:* along with the exposure notification, the ENA gave guidance that was in line with general national pandemic guidelines (Figure 1). Based on the guidance, we used the following terms: self-observation of well-being, avoiding social interactions, hand hygiene, wearing a mask, avoiding errands, cough hygiene, working from home.

XSL•FO
RenderX

**Figure 1.** Guidance shown to users of the Finnish exposure notification app upon receipt of an exposure notification from March 4, 2021, to June 16, 2021. The instructions were updated in line with the national guidelines [4].

XSL•FO
RenderX

The survey included two questions about adherence to the above-mentioned exposure notification guidance: general behavior during the pandemic and after receiving an exposure notification. Respondents were able to mark their adherence to each of the seven points on a scale of "never, part-time, entire time, don't recall/unsure."

### Data Analysis

We assessed each of the four KPIs (extent of ENA use, enablers and barriers to ENA use, ENA influencing user behavior, and general acceptability) according to a set of predefined metrics specified in Multimedia Appendix 1. The analysis was performed using R software (version 4.2.1; R Foundation for Statistical Computing) in RStudio (Posit Software, PBC). *P* values less than .05 were considered significant.

This study used two main data sources for analysis: (1) ENA backend data, used to describe the extent of ENA use; and (2) data from the Koronavilkku survey, used to assess enablers and barriers to ENA use, ENA influence on user behavior, and general acceptability. The data sources for each metric are specified in Multimedia Appendix 1.

Survey weights based on age, sex, and region were applied to descriptive analyses of survey data (excluding sentiment analysis) to improve representativeness of the Finnish population. Prevalence ratios (PRs) were estimated using log-binomial regression models fitted to unweighted data. A large language model (LLM) was used for sentiment analysis of open-ended feedback in the survey. The sentiment analysis was performed using Python 3 (version 3.10.12, Python Software Foundation) and the Llama model version 3.1 70B (model identifier: llama3.1:70b-instruct-q4_K_M; Meta). Finnish input texts were analyzed natively without translation. The response was classified using a prompt that asked for feedback to be in one of four categories: positive, neutral, negative, and not understandable feedback. Prompt rules asked it to return only one of these categories and never to output the original clause or anything other than the classes.

### Sentiment Analysis Validation

To compare Llama classifications to human classifications, we randomly sampled 100 feedback responses, and one reviewer added manual annotations about human-evaluated sentiment. Overall agreement was 63% (Cohen κ=0.486) and considered "moderate." The main pattern found was that Llama classified positives and negatives well but misclassified many human-labeled neutrals as "not understandable feedback." These were mostly policy or feature suggestions without clear opinion on the current version or just statements that the users did not have anything to say.

The validation results can be found in Table S1 in Multimedia Appendix 2.

### Generative AI

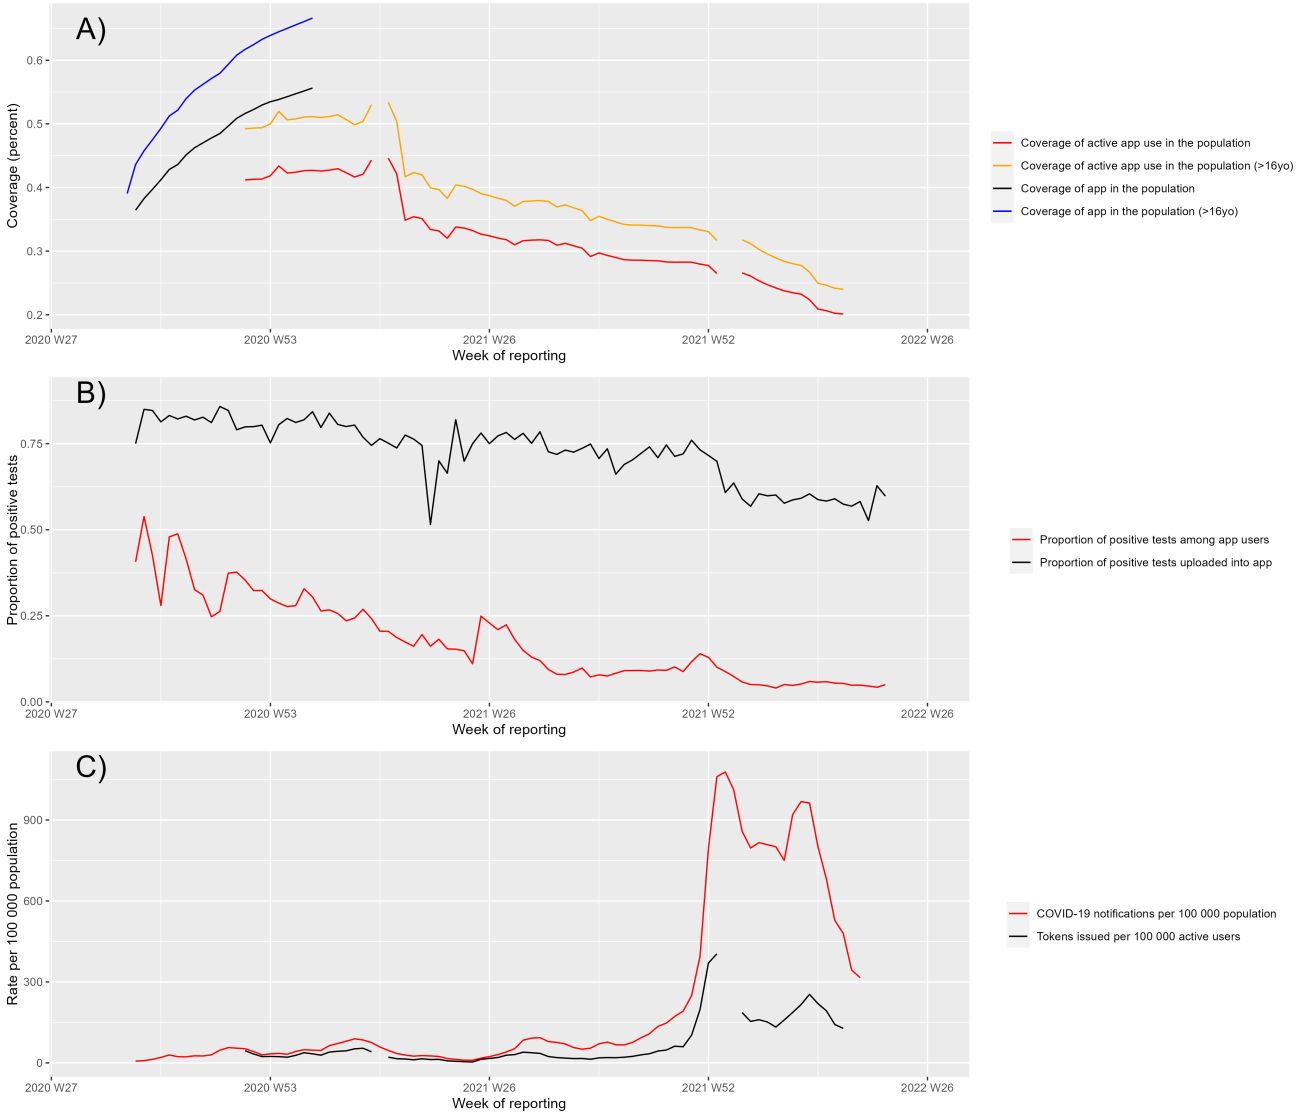
Generative AI was used solely as an analytic tool for sentiment classification (LLM) and was not used to draft or edit the paper.

### Ethical Considerations

The app user data were collected and analyzed as part of THL's mandate; therefore, no ethical approval was required for this study. Upon being recruited to the survey study, participants gave their informed consent. The participants did not receive remuneration for their participation; the polling company had a monthly lottery, where participants were eligible to win prizes, such as gift cards. All analysis was performed on anonymized data; no personal identifying data was used. The legal basis for the ENA and THL's role related to it is detailed in the Communicable Diseases Act 1227/2016 HE 101/2020.

## Results

### Extent of ENA Use



The extent of ENA use was assessed based on backend ENA data.

We used the number of downloads as a proxy for active ENA use at the introduction of the app, after which we switched to monitoring active ENA use. In late 2020, the ENA was actively used by around 40% - 50% of the Finnish population. In 2021, the active coverage peaked around weeks 12 - 14 at 53% among the Finnish population older than 16 years old (45% in the general population), after which it declined to less than 30% in early 2022 (Figure 2A).

XSL•FO
RenderX

**Figure 2.** (A) Proportion of the population that have downloaded and actively use the exposure notification app in Finland August 31, 2020, to April 24, 2022. Results shown for the whole population of Finland and for the population of Finland >16 years old. (B) Proportion of positive SARS-CoV-2 tests among ENA users among all SARS-CoV-2 positive tests in Finland August 31, 2020, to April 24, 2022; proportion of positive SARS-CoV-2 tests uploaded into the ENA (used tokens) among all ENA users that received a token (issued tokens) in Finland August 31, 2020, to April 24, 2022. (C) Rate of SARS-CoV-2 notifications per 100,000 population and rate of tokens issued per 100,000 active users.

At all times during the pandemic, fewer than 50% of all people who tested positive for COVID-19 both used the ENA and entered their tokens. The proportion was highest at the launch of the ENA but declined to less than 30% before the start of 2021. In total, 94,280 tokens were issued during the ENA's lifetime, of which 69% (64,642/94,280) were entered into the ENA (Figure 2B).

The weekly proportion of ENA users who received a token and entered it into the ENA to alert other users of potential exposure reached 86% (586/683) in late 2020 and did not dip below 50% at any point. During the period of ENA use, the mean was 73% (SD 9%) and the median 75% (IQR 67%-80%), indicating high user engagement (Figure 2B).

The rate of positive tests among ENA users relative to the rate of positive tests reported in the general population was similar at the beginning, when the COVID-19 notification rate was relatively low. The rate of tokens issued did not scale in the same way as the notification rate during its highest peaks (Figure 2C).

## Enablers and Barriers to ENA Use

Enablers and barriers to ENA use were assessed based on data from the Koronavilkku survey.

### *Sociodemographic Characteristics of ENA Users vs. Non-ENA Users*

The prevalence of ENA nonusers was higher among males than females (PR 0.93, 95% CI 0.89 - 0.97) and in the age groups above 34 years. There were no significant regional differences between ENA users and nonusers (Table 1).

XSL•FO
RenderX

**Table .** Sociodemographic characteristics of exposure notification app users vs non-exposure notification app users based on a survey conducted in Finland from April 13 to 22, 2022 (n=4061, weighted n=4334). Results weighted according to age, sex, and regional distribution of the Finnish population.

| Characteristics | Non-ENA[a] users, (N=1321), n (%) | Non-ENA users, Weighted (n=1407)[b] | ENA users, (N=2740), n (%) | ENA users, Weighted (n=2927)[b] | PR[c] | 95% CI | *P* value |

[a]ENA: exposure notification app.

[b]weighted % (95% CI).

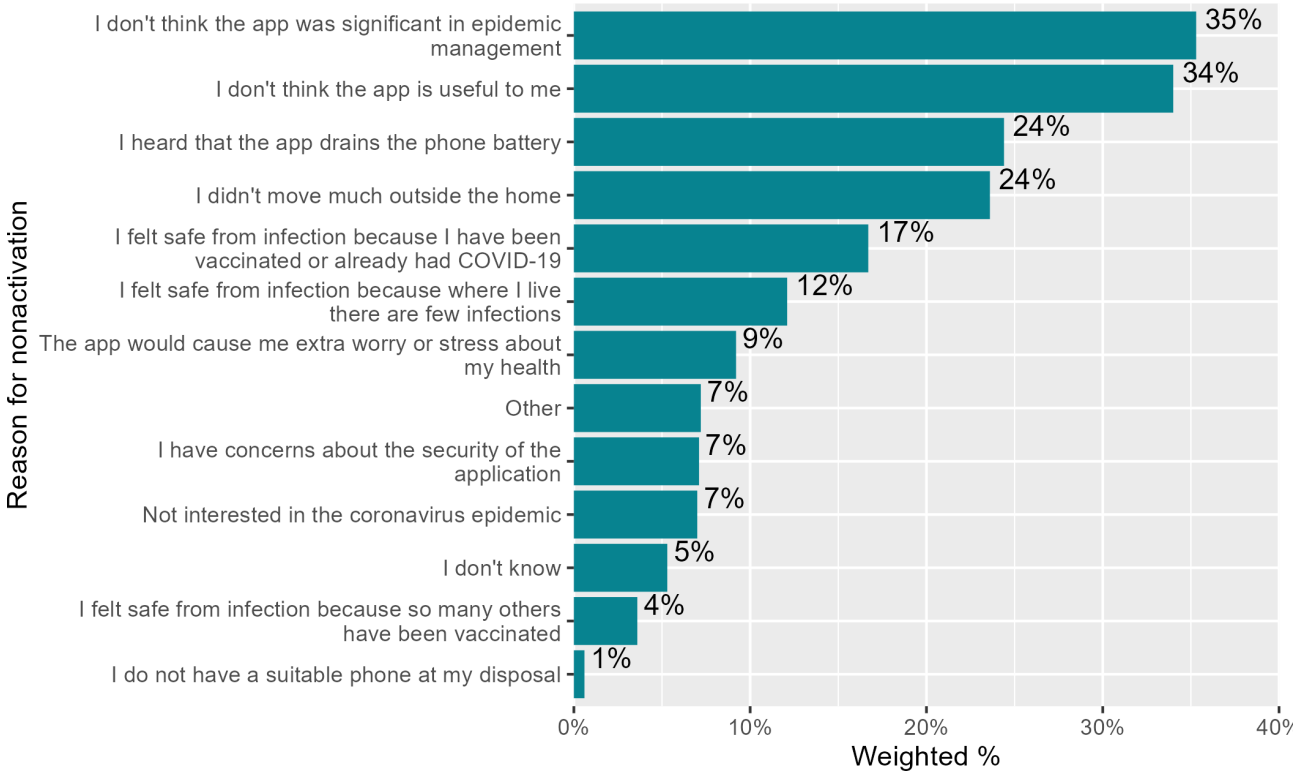
[c]PR: prevalence ratio.

[d]N/A: not applicable.

ENA users had a higher level of education more often than nonusers. Compared to those that had primary or national school-level education, ENA use was more prevalent among those that finished high school (PR 1.22, 95% CI 1.12 - 1.34), a university of applied sciences (PR 1.25, 95% CI 1.14 - 1.37), college (PR 1.26, 95% CI 1.14 - 1.38), or university or college (PR 1.33, 95% CI 1.22 - 1.45; Table 1).

Compared to employees, ENA use was more prevalent among those holding functionary, higher functionary, and leadership positions as well as among students. Nonusers were more often unemployed (PR 0.75, 95% CI 0.67 - 0.84; Table 1).

ENA users were more often couples (PR 1.10, 95% CI 1.04 - 1.16) or living in households with children (PR 1.15, 95% CI 1.09 - 1.21; Table 1).



### *Reasons for Nonactivation of the ENA*

The most frequent reasons for not activating the ENA after download were perceived lack of usefulness of the ENA for pandemic control (35%) or for oneself (34%). Around 24% of respondents indicated phone battery life and staying at home as reasons for nonactivation (Figure 3).

XSL•FO
RenderX

**Figure 3.** Weighted frequency distribution of reasons for not activating the exposure notification app (n=149, weighted n=163). Data from survey conducted in Finland from April 13 - 22, 2022. Results weighted according to age, sex, and regional distribution of the Finnish population. Exact estimates with 95% CIs are provided in Table S2 in Multimedia Appendix 2.

### *General Behavior During Pandemic of ENA Users vs Non-ENA Users*

ENA users reported at least part-time adherence to general pandemic guidance more often than nonusers, ranging from avoiding errands (PR 1.24, 95% CI 1.19 - 1.29) to wearing a mask (PR 1.65, 95% CI 1.45 - 1.91; Table 2). However, these associations may reflect self-selection and cannot be interpreted as causal.

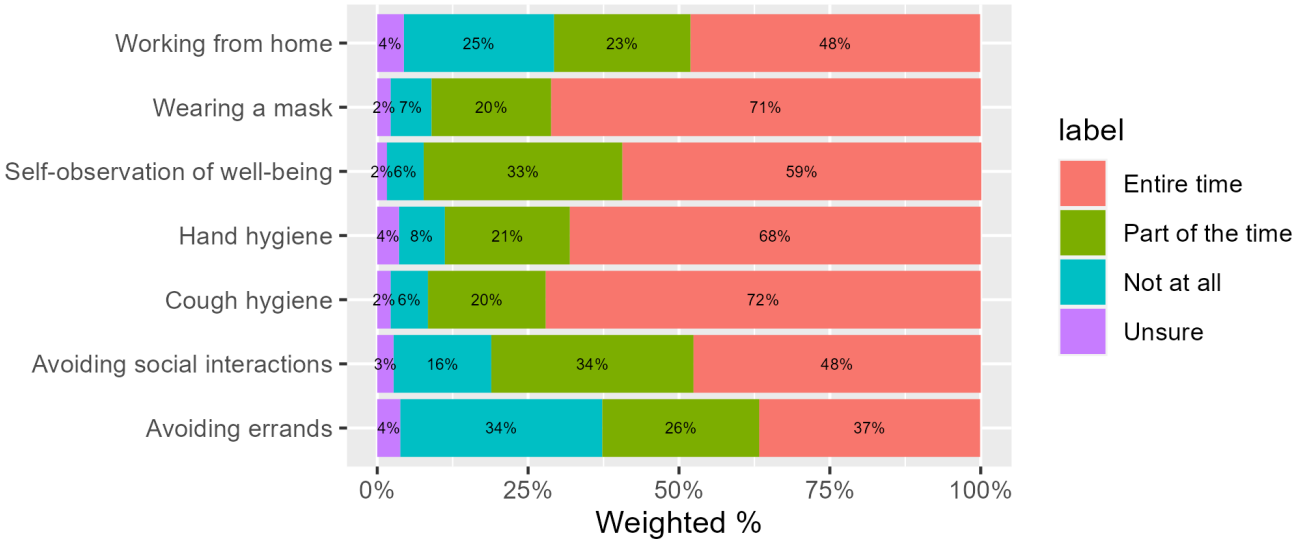
### *Token Use*

Based on survey data, of those ENA users reporting a positive SARS-CoV-2 result (n=881, weighted n=904), close to 70% did not receive a token and 1% reported being diagnosed abroad. Of the 30% receiving a token (n=259, weighted n=269), most (79%) reported entering it into the ENA. For approximately 72% of users, tokens were delivered in under 48 hours from diagnosis, and of those, 51% were received within 24 hours. However, delay in token delivery by 3 - 4 days was reported by 17%, 5 - 7 days by 3%, and over 7 days by 2%. Six percent did not recall the speed of token delivery.

These survey-based token-use estimates are not directly comparable with token use proportions calculated based on ENA backend data, as the backend metrics reflect all eligible users over the full study period, whereas survey metrics reflect self-reported experiences in a cross-sectional respondent sample.

### *Influence of ENA on User Behavior*

Influence of ENA on user behavior was assessed based on data from the Koronavilkku survey.



### *Adherence to Recommendations After Notification*

The majority of ENA users who received a notification of potential exposure adhered at least part-time to all guidance provided in the ENA. The least adhered to recommendations were “to avoid running errands” (34% reported no adherence), “work from home” (25% no adherence), and “avoid social interactions” (16% no adherence; Figure 4).

XSL•FO
RenderX

**Figure 4.** Weighted frequency distribution of adherence to pandemic behavioral recommendations after receiving an exposure notification in the exposure notification app (n=644, weighted n=670). Data from survey conducted in Finland from April 13 to 22, 2022. Results weighted according to age, sex, and regional distribution of the Finnish population. Exact estimates with 95% CIs are provided in Table S3 in Multimedia Appendix 2.

### *Change in Adherence to Recommendations in General During Pandemic vs After Notification*

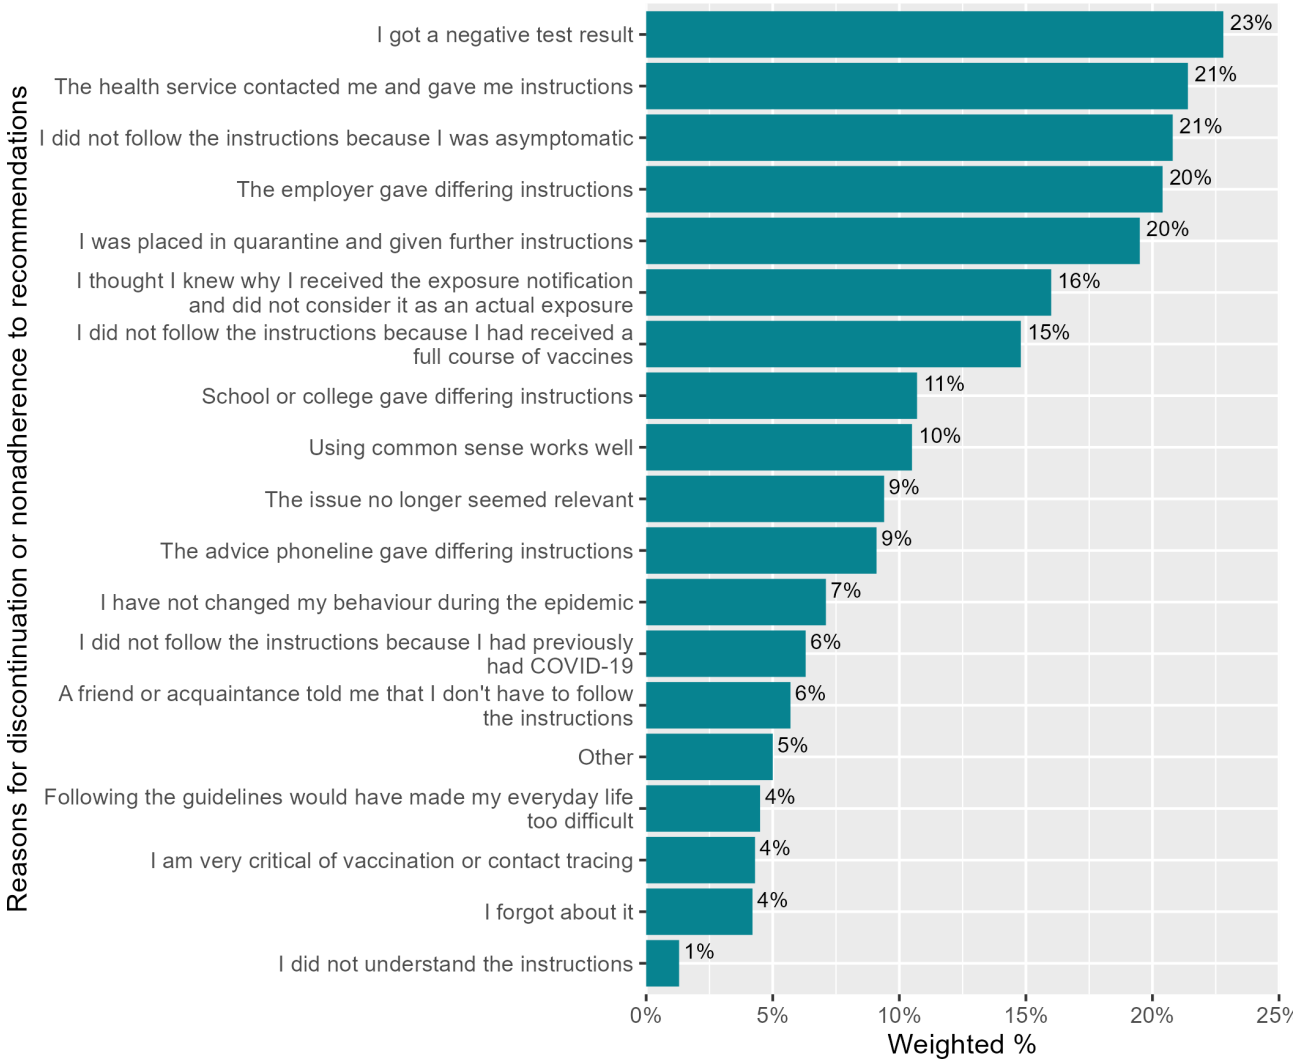
Looking at ENA users (n=2740, weighted n=2927), Bowker's test of symmetry showed significant differences between general adherence to pandemic recommendations versus after receiving an exposure notification for working from home ($\chi^2_3$=75.5; *P*<.001), self-observation of well-being ($\chi^2_3$=18.3; *P*<.001), avoiding social interactions ($\chi^2_3$=114.6; *P*<.001), wearing a mask ($\chi^2_3$=26.9; *P*<.001), and avoiding errands ($\chi^2_3$=74.4; *P*<.001).

Adherence to hand hygiene ($\chi^2_3$=0.6; *P*=.90) and cough hygiene ($\chi^2_3$=0.6; *P*=.90) guidelines showed no differences.

Further analysis of transition patterns in adherence to pandemic recommendations suggested the following:

1. More transitions from none to full-time adherence for "avoiding errands" (odds ratio [OR] 6.08).
2. Transitions from part-time to full-time adherence were more frequent than the reverse for "working from home" (OR 3.53), "self-observation" (OR 2.07), "avoiding social interactions" (OR 6.05), "wearing a mask" (OR 2.5), "avoiding errands" (OR 4.04).
3. Transitions from part-time to no adherence were observed for "working from home" (OR 5.61), "avoiding social interactions" (OR 2.19).

These transition ORs are descriptive and should not be interpreted as inferential tests of specific pairwise changes.



### *Reasons for Discontinuation of Adherence to Recommendations*

A negative test was the most stated reason for not adhering, partly adhering, or discontinuing adherence to exposure notification guidance (23%). Other commonly reported reasons included receiving instructions from health care (21%), being asymptomatic (21%), receiving instructions from employer (20%), or being put in mandatory quarantine as defined by the Communicable Diseases Act (20%; Figure 5).

XSL•FO
RenderX

**Figure 5.** Weighted frequency distribution of reasons for discontinuation or nonadherence to pandemic behavioral recommendations after receiving an exposure notification in the exposure notification app (n=534, weighted n=556). Data from survey conducted in Finland from April 13 to 22, 2022. Results weighted according to age, sex, and regional distribution of the Finnish population. Exact estimates with 95% CIs are provided in Table S4 in Multimedia Appendix 2.

### *Contacting Health Care Provider*

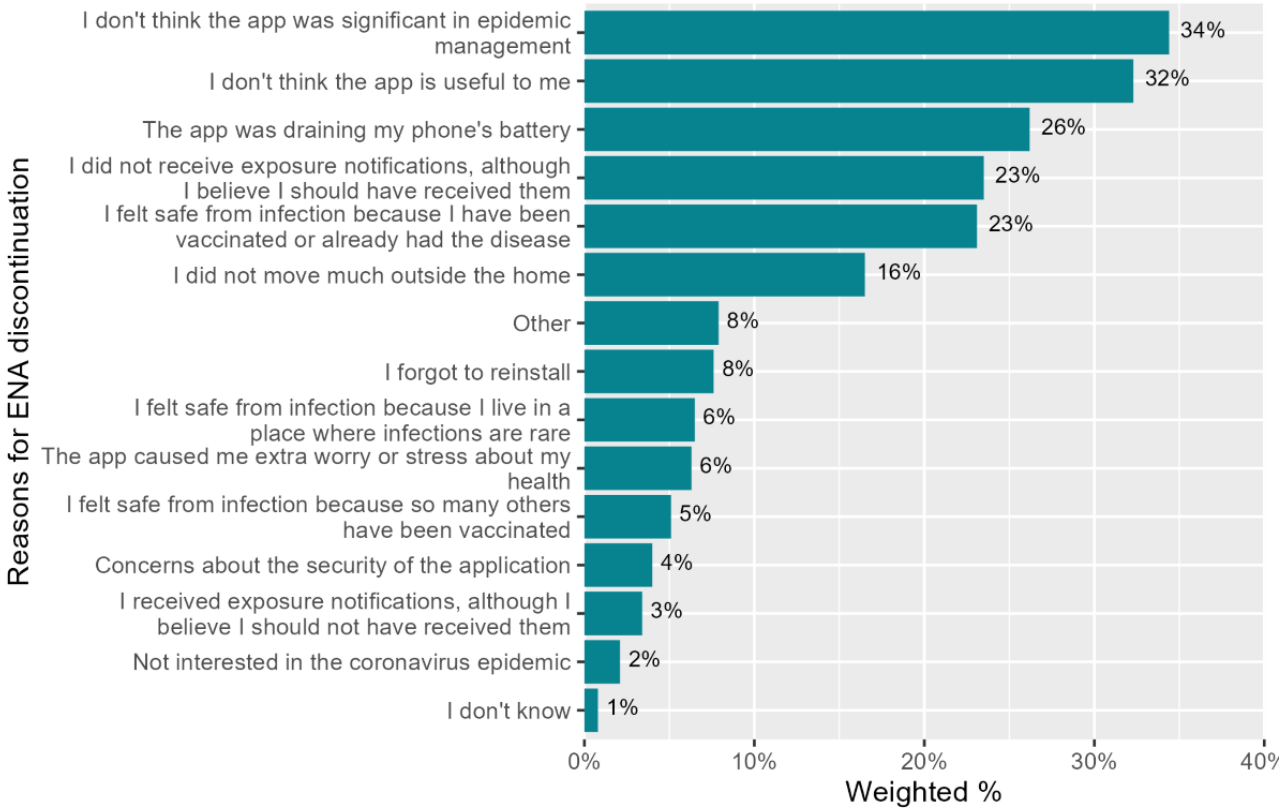
Among ENA users receiving an exposure notification (n=644, weighted n=670), more than 50% contacted health care afterwards either by phone (25%) or through the Finnish electronic service platform providing symptom checks and guidance called “Omaolo” (DigiFinland Oy; 27%). Around 45% did not report contacting health care and the remaining 3% were unsure.

### *Acceptability of the ENA*

The ENA’s acceptability was assessed based on data from the Koronavilkku survey.

### *ENA Use*

Among 4061 respondents (weighted n=4334), 33% never downloaded or activated the ENA. Another 34% downloaded and actively used it at the time of the survey, while 33% downloaded the ENA but later removed it or did not activate it again on a new mobile phone.

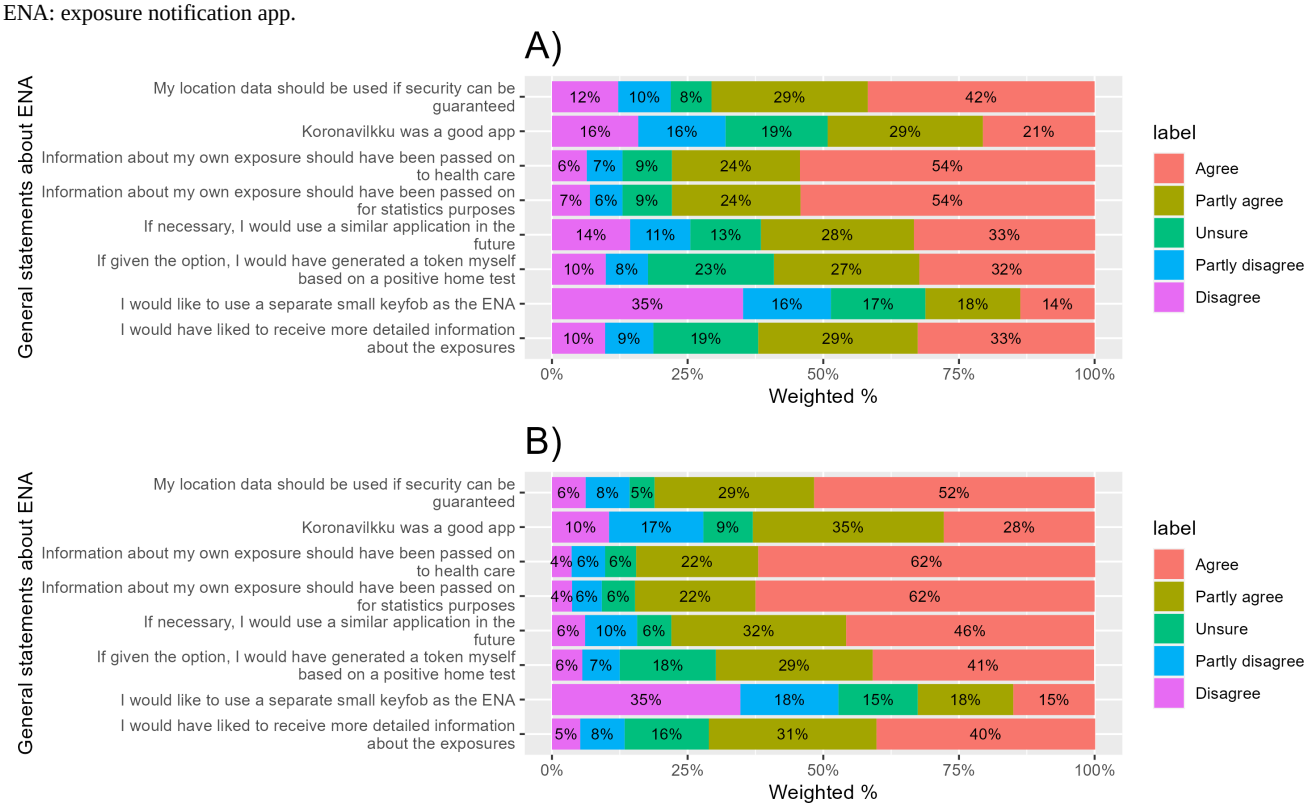


### *Reasons for Removal*

Among former ENA users, the most common reasons for discontinuation of ENA use included not seeing any use for pandemic control (34%) or to oneself (32%). Negative effect on battery life was the third most common reason (26%; Figure 6).

XSL•FO
RenderX

**Figure 6.** Weighted frequency distribution of reasons for discontinuation of ENA use (n=1370, weighted n=1444). Data from Koronavilkku survey conducted in Finland from April 13 - 22, 2022. Results weighted according to age, sex, and regional distribution of the Finnish population. Exact estimates with 95% CIs are provided in Table S5 in Multimedia Appendix 2. ENA: exposure notification app.



### *Overall Feedback*

Opinions on the quality of the ENA were divided. Almost half (49%) of the respondents at least partly agreed with the statement “Koronavilkku was a good application.” Almost two-thirds of respondents (62%) at least partly agreed that they would use the ENA if it was relaunched (Figure 7A).

XSL•FO
RenderX

**Figure 7.** Weighted frequency distribution of attitude toward general statements about the ENA among (A) all respondents (n=4061, weighted n=4334); (B) among ENA users (n=2740, weighted n=2927). Data from Koronavilkku survey conducted in Finland from April 13 - 22, 2022. Results weighted according to age, sex, and regional distribution of the Finnish population. Exact estimates with 95% CIs are provided in Table S6 in Multimedia Appendix 2. ENA: exposure notification app.

Among ENA users, this percentage was higher: 63% at least partly agreed that it was a good ENA, and 78% stated that they would use it again (Figure 7B).

Between 62% - 78% of respondents stated they would have accepted more data (such as additional information about exposure or localization data) being collected by the ENA or being sent to notify health authorities and for situation monitoring or statistical analyses (Figure 7A). The percentage of respondents who at least partly agreed with all statements was higher among ENA users (Figure 7B).

### *Sentiment Analysis*

Sentiment analysis using an LLM was performed for open-ended feedback provided by 813 respondents, 557 (69%) of whom were ENA users.

In comparison to the survey respondents, open-ended feedback was provided more often by males, aged 15 - 24 years, and persons living in Helsinki-Uusimaa and Western Finland regions (Table 3).

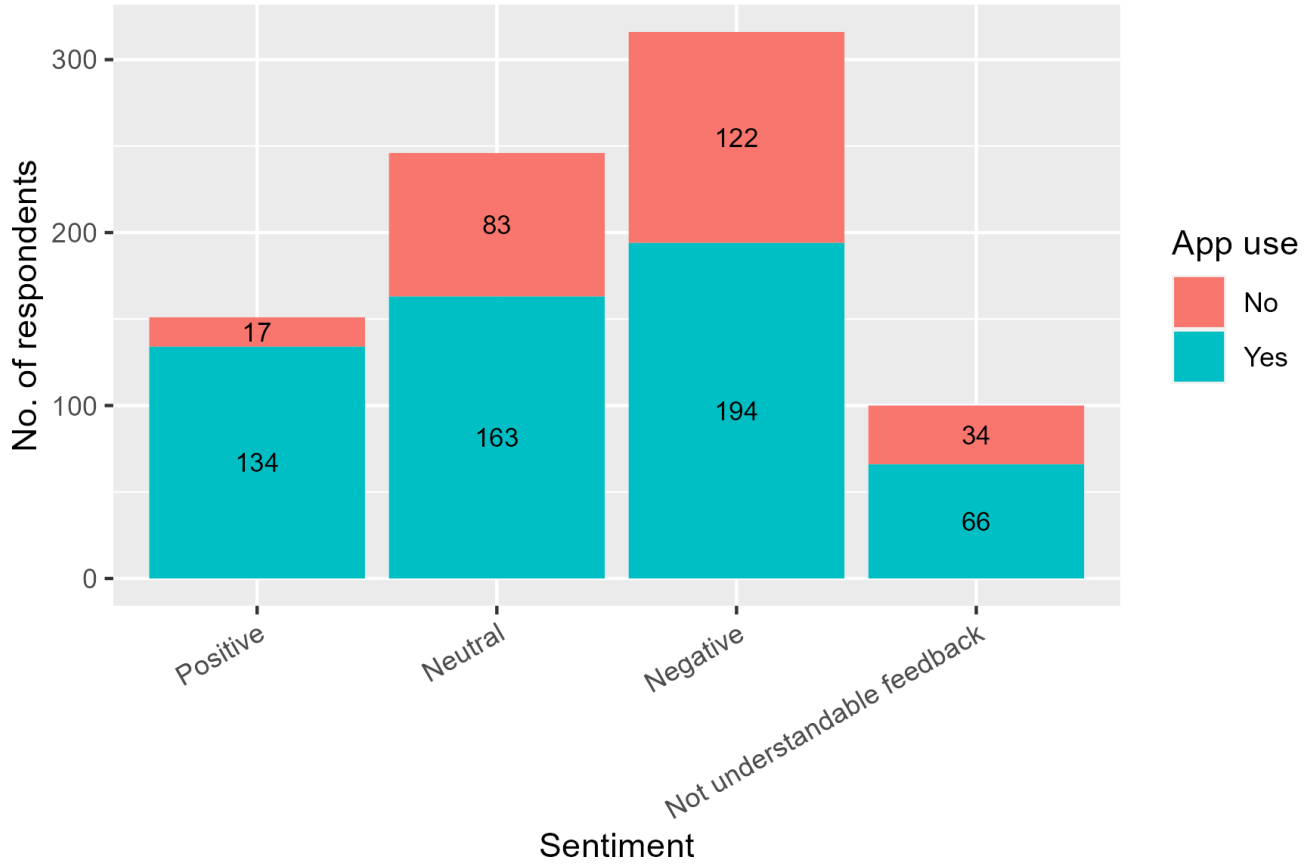
XSL•FO
RenderX

**Table .** Characteristics of respondents giving open feedback vs those responding to survey overall.

| Characteristics | Open feedback respondents (n=813), n (%) | Survey respondents (N=4061), n (%) | *P* value[a] |
|---|---|---|---|
| ENA[b] use | 557 (69) | 2740 (67) | .51 |
| Sex | | | <.001 |
| Female | 341 (42) | 2058 (51) | |
| Male | 472 (58) | 2003 (49) | |
| Age group (years) | | | <.001 |
| 15 - 24 | 148 (18) | 537 (13) | |
| 25 - 34 | 139 (17) | 684 (17) | |
| 35 - 49 | 224 (28) | 1135 (28) | |
| 50 - 64 | 183 (23) | 993 (24) | |
| 65 - 79 | 119 (15) | 712 (18) | |
| Region | | | <.001 |
| Southern Finland | 162 (20) | 886 (22) | |
| Helsinki-Uusimaa | 300 (37) | 1295 (32) | |
| Western Finland | 207 (25) | 991 (24) | |
| Northern and Eastern Finland | 144 (18) | 889 (22) | |

[a]Pearson chi-squared test with simulated *P* value (based on 2000 replicates).

[b]ENA: exposure notification app.



Sentiment analysis determining the emotional tone of the open-ended feedback shows that most provided feedback had a negative sentiment (316/813, 39%), while positive-oriented feedback was provided by 19% (151/813) of respondents. Overall, 12% (100/813) of the provided feedback was not understandable by the model.

A higher percentage of positive responses were provided by ENA users than non-ENA users (24%, 134/557 vs 6.6%, 17/256). Nonuser comments more often expressed negative or neutral sentiments (48%, 122/256 and 32%, 83/256, respectively) than ENA user comments (35%, 194/557, and 29%, 163/557, respectively; Figure 8).

XSL•FO
RenderX

**Figure 8.** General sentiment analysis of open-ended feedback according to four categories (positive, neutral, negative, and not understandable feedback; n=813).

## Discussion

### Principal Findings

This study evaluated the Finnish ENA Koronavilkku using predefined KPIs related to uptake, user characteristics, behavioral influence, and acceptability. We found that the ENA achieved high initial uptake but declined over time, with relatively high engagement among users who received tokens. Survey results indicated differences in ENA use across demographic groups and higher self-reported adherence to guidance among ENA users compared to nonusers. While exposure notifications were associated with changes in adherence among some users, barriers such as token issuance and declining engagement over time limited overall system performance.

### Comparison With Prior Work

#### *Extent of ENA Use*

The Koronavilkku ENA saw widespread adoption during its initial months, with peak active coverage reaching approximately 53% of smartphone users and 45% of the general population. However, as the pandemic progressed, token use declined, especially among people diagnosed with COVID-19, a key target group, with fewer than half of notified COVID-19 cases registered in the ENA, and this proportion fell over time. This trend may reflect reduced app use, reduced token issuance, or a combination of both. Despite this, overall user engagement remained relatively high throughout the ENA's operational period.

ENA effectiveness is closely tied to its level of adoption. Studies indicate that even modest uptake (15% - 30%) can reduce infections [5,6], while others provide more conservative estimates, indicating that 70% - 80% coverage among smartphone users (56% in the general population) is required to control the pandemic effectively [7,8]. Achieving 80% ENA coverage has been linked to a reduction in COVID-19 mortality by up to 85% [9]. Despite these varying results, one could extrapolate that ENA effectiveness is complex and influenced by multiple factors, with partial benefits seen already at lower coverage rates of around 20% [10]. Notably, Koronavilkku achieved the highest active ENA user coverage among European Union and European Economic Area countries [19].

#### *Barriers and Enablers to ENA Use*

Our findings identified demographic disparities in ENA use. Males, individuals 35 or older, and those living alone were less likely to use the ENA, while females, those with higher education, and households with children were more likely to be ENA users. However, studies from other European countries revealed differing and sometimes contradictory results. A French study found no significant link between sociodemographic factors and ENA use, except for financial deprivation [12], while a German study reported that males and those 65 years and older were more likely to use the national ENA [13]. Results from the latter study associating higher education levels with increased ENA use were in line with our findings [13]. On the other hand, a different German study indicated that those who were more unwilling to install the national ENA and use it correctly were men and those aged between 30 and 59 years

XSL•FO
RenderX

old [14]. These differences suggest that country-specific cultural and contextual differences also play a significant role in ENA use.

A major barrier to the ENA's performance was token issuance. Over two-thirds of COVID-19-positive users did not receive a token in connection with contact tracing by health care professionals. However, among those who did, most entered their token into the ENA, suggesting strong user motivation when the system functioned properly. Initially, tokens were issued manually by health care contact tracing teams, but high workloads likely caused delays. Recognizing this, Finland implemented partial automation of token issuance in some regions between June and October 2021 [4]. Despite this, issuing exposure tokens remained a significant challenge, particularly during high-incidence periods such as the Omicron wave in late 2021-early 2022. Wider automation of token issuance based on positive results from local systems or a national patient data repository instead of providing a separate system to health care providers would have likely increased the number of issued tokens and shortened token delivery times. However, these possibilities were constrained by a lack of readily available system integrations, risks of not getting complete and reliable result data from the national repository, and short validity periods of tokens. The process for automated token issuance has been described in detail elsewhere [4].

Timely exposure notifications are crucial for effective mitigation. Ferretti et al [20] found that reducing quarantine delays from three to two days significantly curtailed SARS-CoV-2 spread, provided a large portion of the population used the national ENA. Similarly, a Swiss study showed that ENA users quarantined earlier than those not warned by the ENA, though delays in token issuance, linked to manual contact tracing bottlenecks, remained a challenge [16]. A study from Singapore demonstrated that automating public health responses expedited the issuance of quarantine orders compared to manual contact tracing [17].

Our study also explored reasons for nonactivation of the ENA. Consistent with findings from other studies, the most commonly cited reason for not using or uninstalling the ENA was a perceived lack of usefulness [15,21]. Additionally, concerns about battery drain were mentioned as a reason for removing the ENA [21]. These barriers emphasize the need for improved communication around the ENA's intended benefits and for technical solutions to mitigate the effect on battery life.

### *ENA Influence on User Behavior*

Most users who received exposure notifications followed at least some pandemic guidelines recommended by the ENA. ENA users reported adherence at least part-time to general pandemic guidance more often than nonusers, which may reflect self-selection, with ENA users being more health-conscious in general compared to those who did not download the ENA.

Notifications were associated with higher reported adherence among partially compliant users but showed little association among noncompliant individuals. A UK study similarly found high self-reported compliance with self-isolation recommendations following exposure notifications [22].

The only recommendation with declining adherence was "working from home." This likely reflects job constraints (remote work was not feasible for all occupations) or legal arrangements under which official isolation or quarantine was treated as sick leave, with no obligation to work remotely, even though it was highly recommended by the government [23,24]. Over half of notified users sought health care guidance, which may indicate the ENA played a role in prompting further preventive actions. However, about 20% cited a negative COVID-19 test result as their reason for not fully adhering to guidelines.

### *General Acceptability of the ENA*

The ENA's general acceptability was relatively high, with 68% of respondents using it at least once. However, nearly half eventually stopped using it, particularly as the pandemic prolonged. Similarly, users from other countries also reported their ENAs as trustworthy, reliable, and user-friendly [25]. Nevertheless, a study in Belgium found that features focused on informing citizens or facilitating test appointments were viewed more favorably than those related to access and control [15]. In addition, ENA acceptability has been linked to trust in government, scientists, and health care professionals [12].

A substantial proportion of users expressed interest in enhanced features such as automated exposure notifications to health care providers and improved data tracking. However, it is crucial to balance these functionalities with user privacy concerns that can also evolve over time. In the development of the Finnish ENA, addressing such concerns was a priority. At no point did the ENA process or have access to the identities of users or of persons they encountered, irrespective of infection status. Furthermore, location data from encounters were neither collected nor used, despite the technical feasibility of doing so. Notably, a German study found that public acceptance of privacy-invading technologies, such as tracking, was higher at the beginning of the pandemic, but this acceptance waned as the pandemic continued [26].

Our sentiment analysis of open-ended feedback suggests that users generally expressed more positive attitudes toward the ENA compared to nonusers. While a considerable portion of the feedback reflected neutral or negative sentiments, this should be interpreted with caution. Research on response bias suggests that people are more likely to provide open-ended feedback when they have strong opinions or concerns (either very positive or very negative), whereas users with more moderate views may be less inclined to respond without specific prompting [27-29]. As a result, the overall sentiment of the user base may be more positive than the open-ended responses alone suggest. Additionally, there appear to be differences between those who chose to provide open feedback and the broader survey respondents, suggesting that certain demographics were more inclined to share their views. In contrast, a study conducted in Ireland found that the overall perception of their COVID-19 ENA was mostly positive (90%), although they conducted their sentiment analysis manually [30].

RenderX

### Limitations

Several limitations should be acknowledged and considered when interpreting the observed results. First, the survey was conducted late in the pandemic, when at-home testing with over-the-counter SARS-CoV-2 diagnostic tests had become more common [31,32]. At that time, laboratory testing was limited [31,32], and few exposure tokens were being issued due to the requirement for a laboratory-confirmed result. Additionally, the ENA was discontinued on June 1, 2022, but many users had already uninstalled it in the preceding months, which may have introduced recall bias. Furthermore, we were only able to analyze prevalence in this cross-sectional study, not infer causal relationships. Although the survey sample represents a small proportion of the Finnish population, weighting was applied based on age, sex, and region to improve representativeness. However, as participation was voluntary, the sample may overrepresent individuals with higher interest in health or digital tools, potentially limiting generalizability. Social desirability bias could have influenced responses to seem more positive, particularly regarding adherence to pandemic guidelines. Despite this, similar patterns of ENA adoption and user behavior have been reported in other European countries, including Germany and the United Kingdom, where uptake and use were associated with sociodemographic factors, trust in public health systems, and user perceptions [13,22].

The LLM used for sentiment analysis has its own drawbacks. First, the model was unable to categorize all responses, with some classified as “not understandable feedback.” Second, each response was assigned a single sentiment category, even though some answers may have contained a mix of sentiments. Third, it faced challenges in accurately interpreting tone and complex language structures. Furthermore, while recent advancements have significantly improved the model’s performance with the Finnish language, translation and interpretation issues can still occur.

The survey did not collect information on the reasons for not using the ENA, only reasons for not activating it after downloading. This additional information could have been useful to identify potential problem areas and opportunities for improvement.

Finally, questions about adherence to health guidelines after receiving an exposure notification referred only to the most recent notification, limiting our ability to assess changes over time. Our analysis relied on a proxy, comparing general behavior during the pandemic to behavior following an exposure notification, but this approach does not provide a comprehensive picture of behavioral shifts.

### Conclusions and Recommendations

This study provides insights into the implementation and performance of a national ENA during a prolonged public health emergency.

Based on observed ENA use trends, regular information campaigns are recommended to maintain long-term public interest and engagement in ENAs during prolonged emergencies.

Furthermore, tailored communication should be developed to encourage uptake among demographic groups with lower adoption rates. Initial studies during ENA rollout could inform these strategies.

Earlier and more systematic automation of token distribution across all regions is critical to enable timely exposure notifications and reduce manual bottlenecks. This should be facilitated by ensuring integrated availability of high-quality laboratory results data from systems using open standard interfaces instead of having to create such mechanisms during the crisis.

Future ENAs should define evaluation criteria during development, with periodic assessments to measure effectiveness and inform improvements. Collecting data on reasons for not downloading the ENA, as well as the timing of installations and removals, could offer valuable insights into retention patterns. Surveys should include questions on factors that would encourage installation, reinstallation, and positive feedback to identify best practices.

From a hardware perspective, nonphone-based contact tracing solutions, such as wearable devices or hardware tokens, could help address battery-life limitations and potentially improve uptake. A deeper analysis of open-ended feedback provided for the Koronavilkku ENA using more advanced language models could provide additional insights into user perceptions and concerns.

Overall, these findings highlight that the success of digital contact tracing tools depends not only on technological functionality, but also on system integration, public trust, and sustained user engagement. Addressing these factors will be essential to support their effective use in future pandemic preparedness and response efforts.

### Acknowledgments

We thank all the respondents who generously dedicated their time and effort to respond to our questionnaires.

We extend gratitude to the ECDC EPIET/EUPHEM Fellowship frontline coordinator Barbara Schimmer (based at the National Institute for Public Health and the Environment – RIVM in the Netherlands) for her guidance, input, and continuous support and encouragement.

### Funding

The ENA project was funded by the Finnish Government (LTAE III/2020) and a European Union (EU) grant (FINLAND-LC-01590941). Funders had no role in writing or approving this manuscript. WK has been a fellow of the ECDC

Institute for Global Health Sciences, University of California, San Francisco, 550, 16th St, 3406, Floor 3, San Francisco, CA, United States

## Abstract

**Background:** During the COVID-19 pandemic, over 100 countries successfully deployed smartphone-based exposure notification (EN) apps alongside conventional contact tracing to mitigate the transmission of SARS-CoV-2. These systems enabled millions of COVID-19–positive individuals to anonymously alert community members of a potential exposure. Although evidence on EN program implementation is limited, leveraging expertise from public health professionals, academics, and global implementers from various disciplines can contribute to addressing this research gap.

**Objective:** This study aimed to explore barriers and facilitators to adoption, identify optimal use cases for these tools, and understand how advancements in technology and policy might maximize EN utility for mitigating other infectious outbreaks.

**Methods:** We used the Delphi method to develop a comprehensive online survey comprising closed-ended and open-ended questions. We considered consensus was reached when at least 75% of respondents selected “agree” or “strongly agree” for an item or statement. More than 30 global EN experts known to the investigators were invited to participate in the survey, and those who participated were asked to nominate or recruit others deemed eligible via a peer-to-peer method. We used descriptive and content analyses to summarize key findings from the survey. We invited the same experts to attend virtual focus groups to further probe their insights into the survey findings.

**Results:** Twenty-two experts from 6 countries, including 10 experts from the United States, representing 3 continents, participated. Respondents were involved in the implementation of various EN technologies that encompassed varying levels of integration with existing public health agencies’ infrastructure. Consensus was reached concerning the development of additional functionalities of the system, such as the ability for users to self-report a positive result from a SARS-CoV-2 at-home test, receive additional public health information from the app (ie, information on testing and social services), and receive general venue-based notifications concerning superspreader events. Other items that reached consensus included how the tool could be used for additional epidemiological purposes, such as expanding the technology to other airborne diseases, and the need for integration with surveillance data streams to augment analytics and forecasting.

**Conclusions:** Global EN systems have the potential to be optimized for public health emergencies beyond COVID-19 and can be used as epidemiological surveillance tools in future disease outbreaks. Decision-makers and experts should revise existing protocols and seek to incorporate new functionality to alleviate the disease burden on both users and public health agencies.

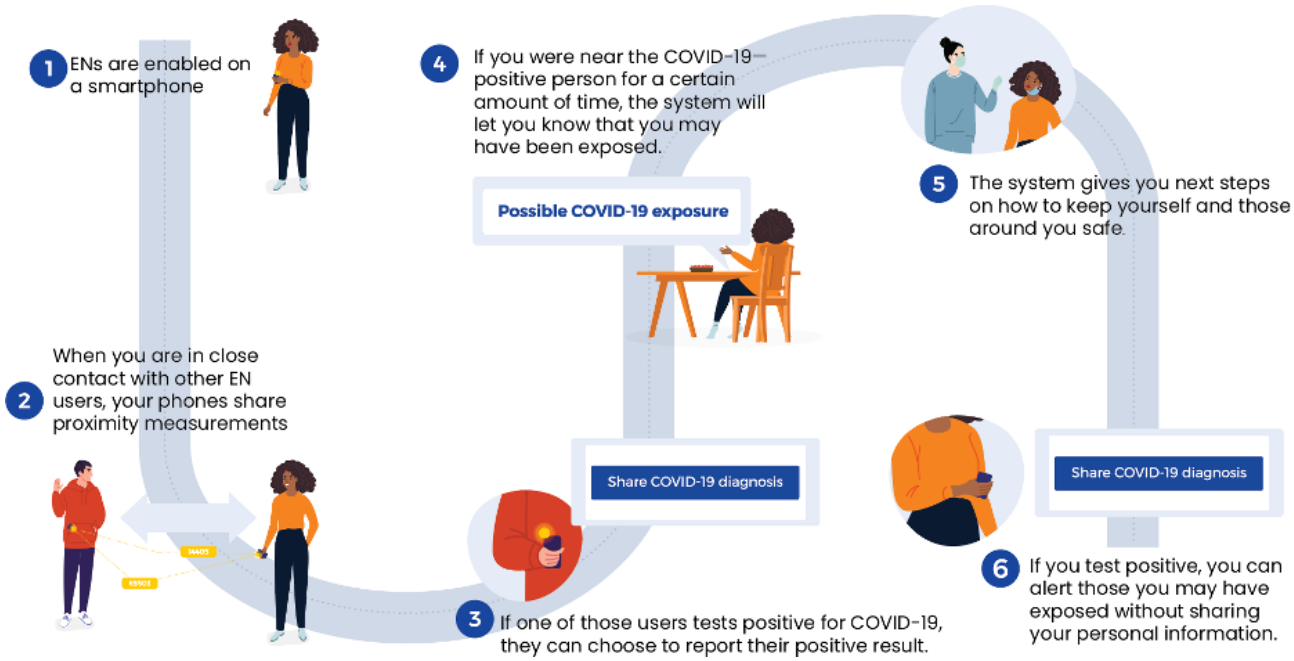
## Introduction

### Background

The COVID-19 pandemic placed unprecedented demands on the public health workforce. In response, digital contact tracing (DCT) and exposure notification (EN) tools were developed to enhance the efficiency of public health outbreak control, particularly during large case surges [1,2]. While some DCT systems were based on direct reporting, a new generation of more automated, scalable EN systems leveraged smart devices to alert individuals of a potential exposure to the SARS-CoV-2 virus, even without direct contact or relationship with the case. Implementation and evaluation of these EN systems within different jurisdictions were shaped by diverse system

XSL•FO
RenderX



architectures, deployment strategies, and communication protocols, each influenced by political, social, and financial contexts. These tools also varied in their approach to privacy; some collected personal identifiers while others were completely anonymous and privacy-preserving [3].

## Proximity Detection Technologies

EN systems work by measuring distances between individuals, using various technologies, such as GPS and Bluetooth Low Energy, to determine if a user was in close contact of a person with a confirmed COVID-19 diagnosis [4]. GPS was used in multiple systems—including those in South Korea and China—because it can capture specific user information [5,6]. However, standard GPS is considered unreliable in determining the exact position of a person and requires a significant amount of battery power.

On the other hand, Bluetooth-based systems could not record an individual's specific location and therefore were unable to identify where a person was exposed; however, they could assess the proximity between 2 individuals and provide greater privacy protection [7,8]. These systems relied on the generation of random digital codes; when 2 devices came close together, the codes were exchanged. By relying on 2 servers, a key server that stored keys from devices whose users reported positive tests and a verification server that checked for genuine positive tests, devices routinely searched for matches among stored codes. If a match occurred, the app alerted the user about a potential exposure, without disclosing who, when, and where the exposure took place [9,10]. Examples of Bluetooth-based EN systems include Singapore's BlueTrace protocol—which was used in Singapore's TraceTogether app and Australia's COVIDSafe app—and Google and Apple's jointly developed EN protocol, Google and Apple Exposure Notification (GAEN) system, which became the most widely adopted EN system during the pandemic. GAEN apps used Bluetooth Low-Energy signal exchanges between EN-enabled smartphones to estimate exposure risk based on duration and proximity to an individual's smartphone who voluntarily disclosed a positive COVID-19 test result (Figure 1) [3,7,11,12].

**Figure 1.** Overview of mobile exposure notification (EN) apps using the Google and Apple Exposure Notification (GAEN) System. Adapted from the California Department of Public Health and Aronoff-Spencer et al [13].

Other proximity detection technologies used Wi-Fi or ultra-wideband systems, while others deployed a QR-based system or a combination of multiple approaches [8]. Some apps also used a combination of different technologies, such as India's "Aarogya Setu" app, which used both GPS and Bluetooth [14].

## Centralized vs Decentralized Data Systems

Global EN systems also differed in whether they used centralized or decentralized protocols. Centralized protocols stored user interactions on a central server, which allowed for more meticulous epidemiologic tracking and analysis. These protocols enabled public health agencies (PHAs) to track second-order contacts and super-spreader events. Singapore's BlueTrace system used a centralized system, as did China's and South Korea's apps [6]. However, centralized protocols were often considered controversial, given that they potentially enabled governments to access personal health data and therefore raised many user privacy concerns. Conversely, decentralized protocols determine and save proximity data and exposure risk entirely on a user's mobile phone to preserve user privacy. While decentralized protocols made epidemiologic analysis difficult, they allowed for greater privacy of user data [7]. Apps created on the GAEN system prioritized user privacy over disease surveillance, using a decentralized protocol, while allowing PHAs to set risk parameters and public health messaging by jurisdiction, at the national or subnational level [13,15].

## The Future of EN

Most EN systems relied on government-sponsored servers to enhance cross-jurisdictional interoperability while preserving

XSL•FO
RenderX

user privacy. However, PHAs varied in how they assessed exposure thresholds, further complicating comparisons across implementations [16,17]. While GAEN's privacy-preserving model limited targeted public health messaging and robust impact assessments, modeling studies in settings with meaningful adoption rates—such as the United Kingdom and the states of Washington and California in the United States—suggest that digital EN systems averted significant numbers of new cases [11,12,16-28]. By contrast, non-GAEN systems, which collected identifiable data and location information, offered potential advantages in precision and public health follow-up. These systems could provide more tailored guidance to users and enable PHAs to assess the broader impact of exposures on public health. However, these systems often raised privacy concerns and faced barriers to adoption [2].

As the COVID-19 public health emergency concluded, scientists, policymakers, and public health leaders began to discuss both future and alternative uses of EN systems. Proponents highlighted the unprecedented collaboration between major technology companies and government institutions, resulting in the global deployment of EN systems, with over 300 million users worldwide [20,29-31]. Critics noted that while some countries and states deployed EN systems successfully, many regions either did not adopt the technology or failed to achieve meaningful user uptake. Despite variations in adoption and evaluation, EN systems demonstrated significant potential to augment infectious disease response and a remarkable ability to scale to large numbers of users and link jurisdictions, all while preserving privacy. As health systems prepare for future outbreaks, it is crucial to address gaps in EN design, deployment, and adoption to maximize the impact of these tools. It is also critical to understand the barriers and facilitators to their use to guide the development of policies and technologies that strengthen national and global health capacities.

We developed a modified Delphi study and engaged experts to explore barriers and facilitators to adoption, identify optimal use cases for these tools, and understand how advancements in technology and policy might maximize EN utility for mitigating other infectious disease outbreaks. By learning from the successes and limitations of EN systems during the COVID-19 pandemic, we seek to inform the design and implementation of more effective outbreak response tools for future use.

## Methods

### Study Design Overview

We used a modified Delphi Type 3 approach to gather expert knowledge on EN systems, using a comprehensive survey designed to capture both quantitative and qualitative data [32]. Appendix A in Multimedia Appendix 1 summarizes the study characteristics [33,34].

### Curation of Ideas to Inform Survey Development

We curated initial ideas based on the authors' direct experiences implementing an EN system in California, as well as insights gathered from meetings of the Digital Notification Alliance (DNA), a US-based community of EN practitioners active during the COVID-19 pandemic, with participation from representatives of 16 states. To further develop our framework, we conducted a targeted literature search in PubMed and Google Scholar for relevant peer-reviewed articles and white papers during March-April 2023. The search focused on studies describing the implementation, evaluation, or adoption of EN systems and, when contextually relevant, other DCT tools during the COVID-19 pandemic. We used combinations of keywords such as "exposure notification," "digital contact tracing," "implementation," "barriers," "facilitators," "COVID-19," and "evaluation." We searched for papers published between 2020 and 2023 in English. Publications were included if they discussed real-world implementation experiences, adoption barriers, or lessons learned from EN systems. The references identified through this process—together with relevant white papers and reports from our professional networks—were used to structure survey items and domains [3,5,9-11,17,20-22,24,26,28,29,35]. Additionally, we contacted our network of EN implementers across the United States and internationally to inquire about relevant publications and gray literature.

### Survey Development

Based on curated inputs, we developed a Delphi survey to collect expert insights on best practices, implementation challenges, and future directions for EN systems, with a focus on those using the GAEN protocol during the COVID-19 pandemic. The survey comprised six major sections: (1) participant consent and survey introduction; (2) expert demographics and professional background; (3) perceived successes, barriers, and facilitators of EN deployment; (4) perspectives on key system functionalities, disease applicability, macro-level governance, and considerations around privacy, equity, and communication; (5) opinions on potential uses of EN technologies beyond infectious disease outbreaks; and (6) participant demographics and peer referrals.

The final survey included approximately 100 questions, incorporating multiple-choice (including Likert-scale and rank-order items) and open-ended formats. Likert-scale items assessed the perceived importance or level of agreement on various implementation dimensions, while open-ended items allowed for elaboration and identification of additional considerations. The survey was administered via Qualtrics [36]. The instrument is available in Appendix B in Multimedia Appendix 1.

### Participant Recruitment

Using a combination of convenience and peer-referral methods, we recruited participants from our extensive network of US-based and international EN experts with whom we had collaborated and exchanged scientific ideas throughout the pandemic. We initially identified participants through the DNA network group to share lessons learned and best practices in EN implementation. Through the DNA network, we distributed invitations via its membership listserv, solicited referrals (snowball sampling), and leveraged its endorsement to broaden participation beyond our immediate collaborators. We also invited key authors of published papers on EN prior to the inception of our study. In total, 56 eligible experts representing PHAs, academia, and the technology industry were invited to

XSL•FO
RenderX

participate. Eligibility criteria included being at least 18 years of age and having experience in the development, implementation, or evaluation of EN systems during the COVID-19 pandemic. Of the 56 identified experts, a total of 30 initially expressed interest in participating.

### Pilot Testing and Data Collection

Using QualtricsXM, we conducted a pilot test with 4 individuals to evaluate the survey's logistics, length, content, and flow [36]. Based on feedback, we made minor revisions and then distributed the survey via email to 30 experts who had previously expressed interest in participating. The survey was launched in fall 2024, with up to 3 reminder emails sent at 7- to 10-day intervals. All responses were anonymous and untraceable after the pilot phase. Data from the pilot were included in the final data analysis.

### Data Analysis

We conducted descriptive analysis of the quantitative data using Microsoft Excel. For Likert-scale questions, we adopted the 75% agreement threshold that was suggested in the systematic review of reporting Delphi studies to establish a working definition of "large majority" for our study [34]. This threshold was used to identify items that were deemed more important or to represent a higher level of agreement among experts, but it should not be seen as a consensus threshold. For items or statements that required ranking, we used a weighted score to determine the order based on the number of responses for each question:

Weighted score=[(number of first place votes)×1.0]+[(number of second place votes)×0.5] +[(number of third place votes)×0.33]+[(number of fourth place votes)×0.25] +[(number of fifth place votes)×0.2]+[(number of sixth place votes)×0.16] +[(number of seventh place votes)×0.14]+[(number of eighth place votes)×0.12] +[(number of ninth place votes)×0.11]

For the qualitative data, 2 researchers conducted a thematic analysis to identify recurring themes, which were used to supplement our analysis of the quantitative data. This allowed us to further elaborate on expert experiences and opinions, from which we could infer major key points and generate actionable recommendations. Examples are shown in Table 1.

**Table .** Thematic analysis of open-ended question responses[a].

| Themes and questions | Responses | Subtheme |
|---|---|---|
| Lessons from the COVID-19 pandemic | | |
| Do you think your EN[b] program achieved goals and objectives? | "It did so by complementing conventional contact tracing; compared to the latter, it led to an estimated 5% - 10% increase in the number of cases detected." | Public health |
| The next EN application | | |
| Would you consider continuing EN programs if COVID-19 resources were available? | "EN systems should ideally run continuously, even when there is no immediate need. That way, it can be ready to scale up quickly when needed." | Public health |
| Do you have suggestions as to what governance principles and procedures should be in place prior to the next implementation of EN systems? | "International coordination between public health agencies and tech companies is necessary to iron out interests and articulate norms that can guide decisions." | Public policy |
| Are there ways to improve the opt-in sharing of information? | "There should be levels of information sharing for the comfortability of opting into the system..., but there should be no requirement for it." | Technical features |

[a]The themes included in the survey are shown in the first column. Based on question types and responses, 3 subthemes emerged: technical features of EN applications, public health, and public policy issues.

[b]EN: exposure notification.

### Expert Review and Validation of Findings and Final Recommendations

Following the initial round of data analysis, all expert participants were invited to a live, 2-hour virtual presentation to review findings and provide additional insights. Two sessions were conducted, and discussions were recorded with participants' permission. One researcher took detailed notes from the sessions and analyzed participant feedback. Comments and suggestions from these sessions were integrated into the final interpretation of results. The final recommendations were developed through a multistep process. Topics and ideas that were deemed important or reached a high level of agreement in the quantitative survey were prioritized. These were further enriched by qualitative feedback provided by participants and subsequently validated through the live expert reviews and discussions.

### Ethical Considerations

Our study protocol was reviewed and approved by the Committee on Human Research at the University of California, San Francisco (UCSF), through an expedited review process (IRB number: 23-39886; reference number: 398640). The study did not include personal or sensitive questions and focused instead on gathering expert opinions about a digital health product. All data were stored securely within UCSF's protected

XSL•FO
RenderX

data systems and reported only in aggregate form to safeguard participant privacy. Participants could choose to share their general geographic location for national-level analysis. Those who provided informed consent were invited to complete the survey and received a US $50 gift card for participating in at least 1 round of data collection. Individuals who also took part in the live discussion received an additional US $100 gift card.

## Results

### Demographics

A total of 22 individuals from 3 World Health Organization (WHO) Regions (Americas, Europe, and Western Pacific), representing 6 countries, participated in our Delphi. We asked participants to select their involvement with EN systems during the pandemic, as all had carried out more than one specific activity (Table 2). The most common roles included data analysis (n=19, 86.3%), coordination with public and private partners (n=17, 77.2%), and elaborating policies and guidelines for decision-makers (n=14, 63.6%; Table 3).

## Lessons From EN System Implementation During the COVID-19 Pandemic

### *Overview*

When inquired about specific barriers to EN program implementation, the large majority of participants (15/20, 75% of respondents) identified "community mistrust in the government" as a major barrier (Figure 2). Items voted by at least half of the participants as barriers to implementation included the following: the lack of political support from policymakers (11/20, 55%) and community mistrust in EN systems (11/21, 52.4%). Other items voted by less than 50% of respondents as barriers included, but were not limited to, the following: community mistrust in technology companies (10/21, 47.6%), lack of staff workforce within PHAs *(*7/19, 36.8%*)*, and lack of departmental technical knowledge (6/19, 31.6%).

**Figure 2.** Barriers to exposure notification (EN) program implementation during COVID-19. Response statements have been shortened for practical reasons. Agreement and disagreement percentages are aggregates of "agree," "strongly agree," "disagree," and "strongly disagree," respectively. Statements are ranked from the highest to the lowest percentage of agreement.

XSL•FO
RenderX

### *Implementation Barriers*

Respondents pointed out a combination of factors such as "lack of awareness, privacy concerns, government mistrust, and lack of understanding of how the app worked" as barriers to PHA implementation. For others, a bigger budget could have translated into "continuous development, better privacy features, and relevant data analysis." In the case of the United States, the lack of a centralized system caused a "significant burden on jurisdictions." In addition, we inquired about ideal resources (framed as a "Wishlist") for better programmatic and health outcomes. Respondents indicated a desire for higher budgets for increasing user engagement, stronger analytical resources for tracking relevant metrics, access to testing without symptoms, full support from decision-makers, an opt-out modality, central collection of outcome data (eg, test results for notified contacts), better integration between testing and treatment resources (as well as with other agencies), more app promotion, and a "multilateral dialogue on EN system design principles with tech giants with a deference to public health."

### *Program Goals*

When inquired whether participants thought their EN programs achieved proposed goals and objectives, some stressed that they did so by "alerting hundreds of thousands of people of exposures," while others expressed that the system notified "far more contacts per exposure than traditional contact tracing." Conversely, some believed they did not achieve their goals and objectives because they faced little adoption, late integration into their health authorities' processes, and "lack of public communication about the processes of the app."

## Epidemiological and Clinical Considerations for Future EN Systems

With respect to the applicability of proximity-based EN apps for infectious diseases, the large majority of respondents labeled airborne diseases as "very applicable" (17/21, 80.9%), while fomite-transmitted diseases were considered "very applicable" by less than half (9/20, 45%). On the other hand, blood-borne diseases and sexually transmitted infections were predominantly considered as "not very applicable" by 80% (16/20) and 65% (13/20) of respondents, respectively. Concerning the incorporation of diseases into future EN apps, the large majority of participants considered COVID-19 (20/22, 90.9%) and measles (17/22, 77.3%). Other diseases that were considered by at least half of the respondents were influenza (15/22, 68.2%) and tuberculosis (13/22, 59.1%). Additional pathogens that were suggested in the written comments by participants included respiratory syncytial virus, meningococcal meningitis, Disease X, HIV, hepatitis A, Mpox, and other sexually transmitted infections.

Finally, we asked participants to rank key epidemiological and clinical characteristics of pathogens that should be considered for future app developments, which resulted in the following order of priorities: (1) transmissibility of the pathogen (incubation period, infectiousness, etc; 82 points); (2) available protective actions (75 points); (3) disease burden (71 points); (4) level of community immunity (67 points); and (5) economic availability (or feasibility) to take protective actions (65 points).

## Public Health and Implementation Considerations for Future EN Systems

### *EN Value for the Future*

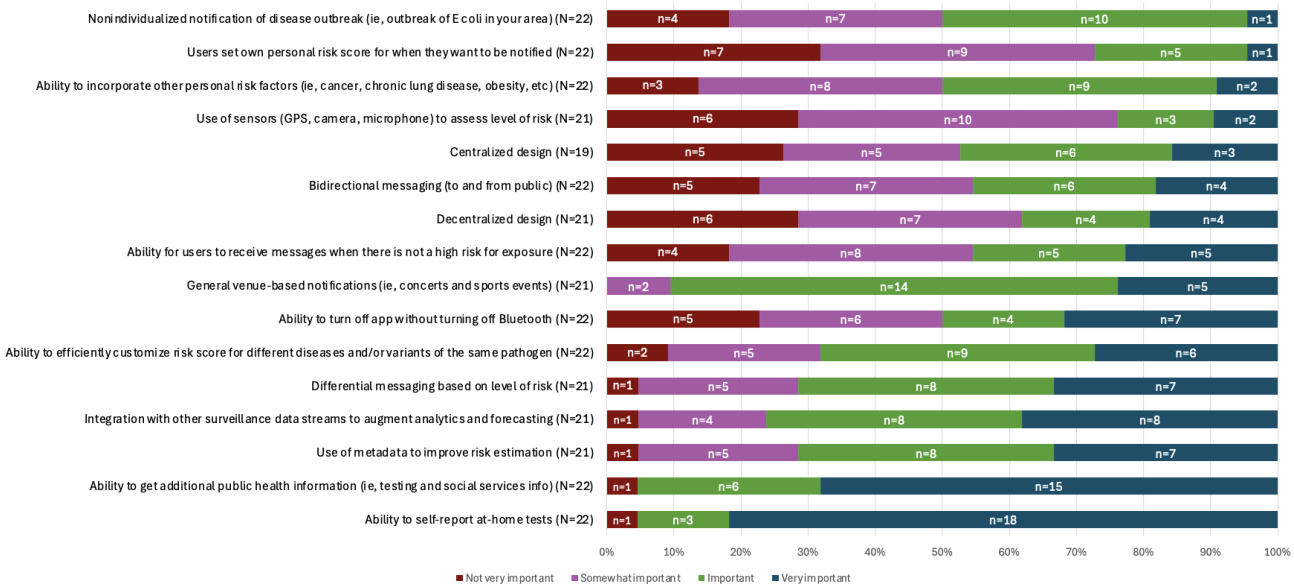
When asked if there was any value in continuing EN programs after the end of the COVID-19 pandemic as a public emergency of international concern, respondents agreed that there is a need to be ready: "waiting for an emergency will always be too late...even modest benefit with ongoing use is worthwhile." Pandemic preparedness and response require a set of continuous actions, and for EN systems, "ideally they should run continuously...ready to scale up quickly when needed." A challenge highlighted was the need to demonstrate its value to secure the necessary resources and political support, with one participant noting, "we need to demonstrate value to enable resource allocation and political support."

### *Strategies to Improve EN Adoption*

Clear communication—such as the benefits for the individual and community, goals, and privacy issues—is key, as is open communication about any uncertainties (ie, "letting the wider public know what we don't know"). On communicating with users about their exposure, messages need to be accurate and readable. As shared by the group, "information has to be credible and accessible." Another suggested strategy was to include venue-based exposure alerts. On how to best leverage experience from implementors, a shared answer was to create standardized guides for PHA EN deployment, covering design, development, implementation, evaluation, and other aspects encompassing a public health intervention.

### *Communication Campaign*

When participants were asked to select topics that should be considered for public-facing communication campaigns, topics deemed "very important" by the large majority were as follows: reminders to use the system when testing positive (18/22, 81.8%) and that users should directly benefit from using the system (17/22, 77.2%). Items that were selected by more than 50% but were below the large majority threshold included how to use the system (15/22, 68.1%), community benefits from using the system (13/22, 59.1%), and user privacy protection (13/22, 59.1%). Marketing strategies for EN technologies through public agencies included using social media and communicating to the broader public while advertising the app as "a tool for citizen science" to strengthen societal preparedness. About reducing technological disparities, "using free standalone devices" that can provide text-based notifications and inform of actions that communities can take was identified as the most common approach. Finally, when inquired about the utility and importance of a comprehensive and multifunctional EN app for future public health threats, participants stated that "it may lose focus on what the main priority...and users may become overwhelmed," while a participant suggested that EN apps should be limited to infectious disease monitoring and control.



XSL•FO
RenderX

## Technical Features Considerations for Future EN Systems

### *General Technical Features for Future App Development*

Participants were asked to label the importance of functionalities and characteristics for future EN systems. The ability to self-report at-home tests was the only item that was considered "very important" by the large majority (18/22, 81.8%) of respondents, while the ability to get additional public health information was considered "very important" by 68.2% (15/22). Also, the venue-based notifications feature was labeled as "important" by more than half (14/21, 66.7%) of participants. Features like the use of sensors to assess the level of risk and the ability to set a personal risk score for notifications were categorized as "somewhat important" by almost half of the participants. No feature was deemed "not very important" by one-third or more of respondents. The level of importance of all functionalities is shown below (Figure 3).

**Figure 3.** System functionalities and characteristics for the next exposure notification (EN) app are shown together by their level of importance on a 4-point Likert scale. Items are ranked based on the percentages obtained for "very important" from respondents (n=22).

### *Specific Technology for Proximity Detection*

Half of the participants considered mixed EN signaling technologies to be the best solution for future developments, followed by only Bluetooth Low Energy (5/22, 22.7%) and ultra-wideband (2/22, 9.1%). Mixed EN technology examples included combining Bluetooth Low Energy with other methods (ie, GPS or venue-based alerts), and participants commonly wrote down "Bluetooth plus Ultra-wideband system" as another option. Nearly 20% (4/22) of respondents did not offer a specific opinion.

When participants were asked to rank strategies to ease user burden, the order is as follows: (1) easier methods for activation (97 points), (2) increased access to other public health resources (86 points), (3) more accessible language (85 points), (4) different user workflows (73 points), (5) new methods for direct user communication (50 points), and (6) new EN hardware (29 points). Furthermore, the group was divided on whether the use of custom hardware or devices should (10/21, 47.7%) or should not (11/21, 52.3%) be incorporated. Further insight on this revealed that it has the potential "to be quickly deployed in outbreaks in populations without smartphones" but made no sense in settings where mobile phone coverage is high, as "it seems unnecessary to ask them to carry another device."

### *Privacy*

Out of 4 options (accuracy of EN, perceived risk by users and their willingness to adopt, scalability tradeoff, and system evaluation capabilities), we asked participants to identify the option that is more important to consider for future EN development in relation to the level of privacy. Privacy was the only characteristic deemed as "more important" by the large majority against the perceived risk by users and their willingness to adopt (18/22, 81.8%). Privacy was voted as "less important" by more than half of participants and less than the large majority for the following: accuracy of EN (13/22, 59.1%) and system evaluation capabilities (12/21, 57.1%). Finally, privacy was neither more nor less important for the scalability tradeoff (50% vs 50%; N=20). The use of technology with a Bluetooth-based protocol that does not require information about the location of the user was considered advantageous, as "it preserved privacy while not creating a huge burden on user batteries—unlike GPS—...with the downside of not fully understanding the location of cases." Concerning how users should share information, participants felt that "there should not be a requirement for data sharing" and that users should be provided with layers or levels of data sharing that users can choose to opt into, allowing users to exercise autonomy.

## Institutional and Governance Considerations for the Future EN Systems

Concerning where to place EN programs in organizational structures, more than half opted for a hybrid model (eg, sharing responsibilities between emergency response and data informatics; 13/22, 59.1%), leaving out emergency response (5/22, 22.7%), data systems-information (2/22, 9.1%), and contact tracing programs (2/22, 9.1%) as potential sites. Other

XSL•FO
RenderX

proposed locations included disease surveillance and biosecurity within the military structure. Another response suggested a more restrained approach: "discussing the benefits and challenges with agencies, as it requires an interdisciplinary approach."

On governance for EN programs, some acknowledge that it should be on a country level and that "a regulatory framework should be in place before the next public health emergency." A considerable proportion of participants (13/21, 61.9%) expressed that implementation levels should be nationwide, with an option for states to customize.

International and national institutions that should be reached out to for future collaborations include the WHO (14/34, 41.2%), National Institutes of Health (9/34, 26.4%), and Federal Emergency Management Agency (8/34, 23.5%), as well as other agencies such as Centers for Disease Control and Prevention, Homeland Security, Food and Drug Administration, European Center for Disease Prevention and Control, and central hubs from around the world. When asked to rank institutions that should be tasked with building trust, the following order emerged: (1) public health departments (79 points), (2) EN system-technologies (66 points), (3) state government (64 points), (4) technology companies (54 points), and (5) federal governments (52 points). With respect to organizing working groups (such as DNA in the United States), respondents expressed that these groups should continue to meet and plan for the next steps, as "it fosters relationships with private and public partners." The most effective way to use these groups is to leverage their expertise in designing next-generation tools.

The importance of working with smartphone manufacturers was emphasized by the large majority of the group (17/22, 77.2%), as some pointed out that in addition to tapping into their technical expertise, "it helps build relationships and improve operations that benefit actors." When examining the possibility of working with other companies aside from Google and Apple, participants expressed that mobile phone and app companies should be included, though "many settings are regulated by these two companies...both need to open up their ecosystem and infrastructure that allows others to work," highlighting the support from big tech companies.

## Discussion

### Summary of Key Findings

To our knowledge, this is the first study to systematically capture insights from experts on the future of EN systems. Although others convened group discussions for similar purposes, those attempts were not as comprehensive as ours, were not peer-reviewed, and were convened or led by industry personnel [35]. Our study suggests that during the COVID-19 pandemic, the main barriers to EN program implementation included community mistrust in technology companies and mistrust in EN systems, followed by a lack of political support from policymakers. Airborne diseases, such as measles, influenza, respiratory syncytial virus, and tuberculosis, were considered the most appropriate group of diseases to incorporate into EN systems. Additional features to consider for the next app include pathogen transmissibility, protective measures, and the burden of disease in the community. Some of the most important features and system characteristics for future apps were the capacity to self-report at-home tests, access to additional public health information, general venue notifications, and differential messaging based on risk level. Finally, for public policy purposes, the study highlights the need to further discuss the benefits and challenges with involved agencies, as it requires collaboration within and across institutions, and efforts should be made to foster working groups to enhance EN systems.

### Public Health and Policy Implications and Recommendations

This study serves multiple purposes. The first is to describe barriers experienced during the COVID-19 pandemic that require action for improving performance and facilitating the implementation of future EN systems. The second is to provide a landscape of improvements to be considered for the next batch of EN systems. These improvements build upon the experience participants shared and make a call for intersectoral collaboration across public health professionals, the technology industry, and policymakers with key roles in advancing preparedness and response against infectious diseases across all government levels, civil society, and academia. Third, it advocates the preservation of current technologies to enhance public health functions by expanding its scope of work to other infectious diseases and by promoting working groups to leverage expertise (regardless of geographical dimensions), develop guidelines, and foster networks across sectors. Finally, it lays out recommendations for decision-makers, public health professionals, and the technology industry for enhancing the next generation of EN systems as follows:

First, efforts to strengthen EN systems should address key implementation and adoption barriers. Legal barriers should be identified and resolved first to facilitate timely technological development and deployment. At the same time, community trust should be built via close partnership with public health authorities at local, state, and national levels. Furthermore, close collaboration with technology companies is critical to develop strategic work plans aimed at strengthening user trust and increasing app adoption.

Second, to enhance the functionality and effectiveness of EN apps, participants recommended incorporating several core epidemiological and clinical features. These include information about the transmissibility and natural history of the pathogen, clear guidance on protective actions that individuals can take—both pharmacological and nonpharmacological—as well as information about available economic resources to support those actions. Including contextual information about disease burden was also considered important. In addition, experts supported expanding EN systems beyond COVID-19 to other high-burden pathogen groups, including airborne diseases, vaccine-preventable diseases, and sexually transmitted infections.

Third, several system-level and user-level characteristics were identified as priorities for future development. EN systems should enable general venue notifications and provide differential messaging based on individual risk level. The use of metadata to improve risk estimation and the integration of

XSL•FO
RenderX

other surveillance data sources to enhance analytics and forecasting were also recommended. At the user level, functionality should allow individuals to self-report at-home test results, request additional public health information, incorporate individual-level risk factors, and receive notifications that clearly indicate exposure risk level (eg, high or low). Participants also emphasized that users should be able to turn off the app regardless of Bluetooth status. To improve access, EN systems should incorporate easier methods for app activation, expand access to other public health resources, and improve accessibility by offering multiple language options.

Finally, to support sustainable implementation, experts recommended fostering structured working groups that include local and national public health departments and other relevant organizations. These groups should create subcommittees focused on specific topics, use standardized approaches to estimate key performance indicators, organize workshops to equip implementation teams with practical tools, and systematically document and share lessons learned. Finally, planning, implementation, and evaluation of EN systems should involve coordinated engagement with public health departments, EN technology developers, state and local governments, technology companies, and, when appropriate, federal agencies.

### Comparison to Prior Work

Although no prior peer-reviewed study has examined the same breadth of EN implementation barriers, disease applicability, future system functionality, and governance priorities in one place, some studies addressed certain aspects of our findings. For instance, other studies also noted that adoption of EN and DCT apps was influenced by privacy concerns, trust, perceived usefulness, and usability [6,37]. Furthermore, another paper emphasized that EN deployment depended on close collaboration among technology companies, developers, and public health authorities, while fragmented rollout and limited data collection complicated effectiveness assessment [7]. Our findings also reinforce the conclusions from the best-practice guidance and implementation experiences from several European countries: EN apps should rapidly connect users to testing, quarantine guidance, and other public health resources, and risk-stratified messaging and actionable recommendations may improve both engagement and public health utility [8]. Implementation experiences in Finland also suggested that EN systems function best when integrated into broader public health response activities rather than operating as stand-alone notification tools [38]. Our findings on future system characteristics suggest integration with surveillance data—extending prior work that proposed standardized evaluation metrics for EN systems [13] and suggested that EN activity may support short-term outbreak forecasting and surveillance functions [39]. Finally, our recommendation for structured working groups and stronger cross-sector coordination is reinforced by lessons from collaborative work in the United States during the COVID-19 pandemic, such as the MIT Lincoln Laboratory initiatives [35] and DNA [40], which emphasized iterative assessment, governance mechanisms, and sustained collaboration among PHAs, policymakers, and technology partners.

### Caveats and Limitations

Although this study is the first to systematically gather and synthesize data to outline actionable steps for strengthening EN systems, the findings should be interpreted with caution. First, our sampling strategy and modest sample size limit generalizability, particularly because most participants were based in the United States and only about half reported direct implementation experience.

Second, this study employed a type 3 Delphi approach to gather expert perspectives on enhancing EN systems as part of infectious disease response. By design, our modified Delphi approach included only a single round, which constrained our ability to capture a more iterative or comprehensive assessment. Unlike a type 4 Delphi that seeks structured consensus over multiple rounds, our goal was to surface areas of opportunity and identify priorities as health systems prepare for emerging and reemerging infectious disease outbreaks. Additional work is needed to further refine these priorities and inform next steps for advancing EN technologies.

Finally, although our analysis was not explicitly structured around an implementation science framework, the barriers and facilitators identified map closely onto commonly used domains—such as contextual readiness, stakeholder engagement, and system integration—and can guide future research that applies models like the CFIR (Consolidated Framework for Implementation Research) or RE-AIM (Reach, Effectiveness, Adoption, Implementation, and Maintenance) to digital public health interventions.

### Conclusion

EN systems have the potential to play a broader role in supporting ongoing public health responses to outbreaks beyond COVID-19. Our findings suggest that there are opportunities to adapt EN technologies into more flexible tools for future outbreaks. Achieving this mandate will require revisiting existing protocols, improving core functionalities, and addressing practical barriers that limit usability and integration with routine public health activities and cross-sectoral coordination.

Despite its limitations, our study helped identify priorities as a starting point for a roadmap to strengthen EN systems as part of preparedness for emerging and re-emerging infectious diseases. With system improvements, stronger coordination between technology and public health leaders, and continued evaluation, EN technologies can evolve into a more reliable and sustainable component of modern outbreak response.

## Abstract

**Background:** An ecological momentary assessment (EMA) is a methodological framework designed to capture real-time data in a participant's natural environment, yet its feasibility in older adults, particularly in a large, multisite study, remains underexplored.

**Objective:** This study aims to assess the feasibility of implementing automated daily phone surveys in a large, geographically diverse cohort of older adults.

**Methods:** A total of 1283 participants from the Multi-Ethnic Study of Atherosclerosis (MESA) were enrolled across 6 US field sites. Participants were scheduled to receive 1 automated phone survey per day for 7 consecutive days following a clinic visit. Feasibility was assessed through a dual lens of participant engagement (survey adherence, phone survey duration, and cancellations) and administrative implementation (scheduling errors).

**Results:** Of the 1272 participants who received at least 1 of the 7 phone surveys, high adherence was observed, with 81.84% (1041/1272) completing 5 to 7 surveys. Age was the only demographic characteristic significantly associated with completion ($P$=.002), as younger participants demonstrated higher adherence. While the median survey duration was 3 (IQR 2 - 4) minutes, 26.84% (2371/8835) of surveys lasted 5 minutes or longer. However, adherence remained remarkably robust even among participants experiencing these extended durations. Participant-initiated cancellations during the 7-day monitoring period were rare, occurring among 21 of 1272 (1.65%) participants who began monitoring. Administrative scheduling errors were also uncommon, accounting for 37 of the 8835 (0.42%) total scheduled surveys not being delivered.

**Conclusions:** Findings support the feasibility of automated daily phone surveys for collecting repeated real-world data in large, multisite studies of older adults. Future studies should incorporate standardized participant feedback to identify barriers to engagement and support more inclusive, participant-centered adaptations of automated phone-based EMA protocols.

## Introduction

Ecological momentary assessment (EMA) encompasses a diverse methodological framework designed to capture real-time data on thoughts, feelings, and behaviors within the context of a participant's natural environment. By using repeated sampling, EMA offers a more dynamic picture of daily life that effectively minimizes the recall biases often associated with traditional laboratory-based or retrospective methods [1]. EMA exists on a spectrum regarding its procedural flexibility: sampling protocols can be structured as signal-contingent (random prompts), event-contingent (participant-initiated), or interval-contingent (fixed schedules). The frequency and duration of EMA vary significantly across research designs; protocols may range from multiple assessments within a single day to a single assessment over many days, and monitoring periods are similarly variable in length [2-5]. These assessments can also be deployed through a wide variety of interfaces, ranging from mobile apps and wearable sensors to paper diaries and telephone-based systems [1,6-8].

While older adults have been increasingly included in EMA research and recent research suggests that EMA compliance in older adults is generally promising, the broader body of evidence remains mixed and limited [9-18]. A 2023 systematic review

XSL•FO
RenderX

and meta-analysis by Yao et al [17] indicates a combined compliance rate of 86.41%, yet completion rates are significantly influenced by participant-level factors and much of the existing evidence is limited by methodological constraints. Studies are predominantly characterized by small sample sizes, often less than a sample size of 100, and limited multisite recruitment [9-18]. Consequently, while existing research provides a foundational understanding of EMA feasibility, these findings may not fully generalize to the unique complexities of studies involving a larger, geographically diverse sample of older adults.

To address these limitations and accommodate the significant scale and geographic distribution of the Multi-Ethnic Study of Atherosclerosis (MESA), we implemented an EMA framework designed for both participant acceptability and operational sustainability. Specifically, among the diverse sampling strategies categorized under EMA, we used the daily diary approach, which is a fixed-interval method involving a single assessment at a consistent time each day [1]. This method was selected to support large-scale implementation because its fully automated, phone-based interface enabled data collection across a multisite cohort of more than 1000 older adults while minimizing burden on participants and research staff.

To evaluate the feasibility of this approach, we used a dual lens that considered both participant engagement and the administrative requirements of the study. Participant engagement feasibility reflected whether participants completed and continued with the daily phone surveys. Participant engagement was evaluated through descriptive participant characteristics, survey adherence metrics, and participant-initiated cancellation of the phone surveys. These measures allowed us to characterize the stress reactivity ancillary study sample relative to the broader MESA Exam 7 cohort, identify patterns across survey adherence groups, describe the extent to which participants completed the phone surveys and their experience, and assess active requests to stop future phone surveys. Administrative implementation feasibility was assessed by quantifying scheduling errors that disrupted the full delivery of phone surveys during the 7-day monitoring period. Specifically, we tracked the number of participants impacted by at least one scheduling error and the total volume of missed surveys relative to the overall study target. This study aims to assess the feasibility of automated daily phone surveys in a large, multisite study of older adults. Our findings contribute to the growing body of work on EMA use in older adults and offer practical guidance for implementing automated phone-based protocols in large-scale, multisite studies.

## Methods

### Study Population

The MESA is an ongoing, community-based cohort study designed to investigate the prevalence and progression of subclinical cardiovascular disease among adults. The study enrolled 6814 racially and ethnically diverse men and women aged 45 to 84 years who were free of known cardiovascular disease at enrollment. Participants were recruited from 6 field centers across the United States: New York, NY; Baltimore, MD; Forsyth County, NC; St. Paul, MN; Chicago, IL; and Los Angeles County, CA. Baseline (Exam 1) data collection took place from 2000 to 2002, with multiple examinations conducted thereafter among participants from Exam 1: Exam 2 (2002 - 2004), Exam 3 (2004 - 2005), Exam 4 (2005 - 2007), Exam 5 (2010 - 2011), Exam 6 (2016 - 2018), and Exam 7 (2022 - 2024). These participants were followed longitudinally to identify updates on health, interim hospitalizations, cardiovascular events, and mortality. Detailed information on the MESA study and recruitment procedures has been published previously [19] and is available on the study website [20].

Exam 7 consisted of core examination components and 7 ancillary studies. Participants from the original MESA cohort who remained active at follow-up were invited to complete the core Exam 7 visit. All participants completing the core exam were considered for ancillary studies unless they met ancillary-specific exclusion criteria. A total of 2276 MESA participants successfully completed Exam 7 [20]. Of this initial cohort, 1834 individuals were identified as eligible for recruitment into ancillary studies. Among those eligible, 1524 participants provided informed consent to participate in the ancillary studies. Within this consenting group, 1283 individuals agreed to participate and were enrolled specifically in the MESA Stress Reactivity Ancillary Study (ancillary study). Reasons for attrition included ineligibility at the screening phase, declining to participate in ancillary research generally, or declining the specific protocols required for the stress reactivity ancillary study.

This paper primarily focuses on participants and data from the MESA Stress Reactivity Ancillary Study. Participants were eligible if they agreed to wear a continuous ambulatory heart monitor (Cardiac Insight, Inc) and complete daily phone-based surveys over a 7-day monitoring period. Exclusion criteria included allergy to skin adhesives, refusal to shave the upper left chest, and the presence of implanted electronic devices such as pacemakers. The stress reactivity ancillary study component of the Exam 7 visit was estimated to take 30 minutes and included consent, heart monitor application, and participant instructions. Although enrollment in the stress reactivity ancillary study included both heart monitor wear and daily phone surveys, the present analysis focuses specifically on the feasibility of implementing the automated daily phone survey protocol.

### Automated Daily Phone Surveys Protocol

Given the large, multisite structure of MESA and the average age of its participant population (mean 77.3, SD 7.50 years), selecting an EMA method that balanced acceptability, scalability, and staff sustainability was a priority. To gauge possible data collection options, an off-cycle survey covering a variety of topics was administered to MESA participants. Among the 1381 respondents, 39.03% (539/1381) indicated willingness to use a mobile device for data collection. Given the limited interest in using mobile devices for data collection in the larger MESA cohort, an alternative EMA delivery method was needed as opposed to smartphone app-based EMA.

Our study drew on Almeida's daily telephone interview approach [21], in which participants completed brief telephone interviews that took approximately 10 to 15 minutes each

XSL•FO
RenderX

evening for 8 consecutive days. However, for the stress reactivity ancillary study, live interviewer-administered calls were not considered practical considering the number of participants in MESA. Additionally, since the willingness to use mobile devices for data collection was low, an alternative approach that did not depend on mobile device use was needed. This led to the selection of a call-based method that could also accommodate participants who relied on landlines. Collectively, these considerations led to a modified version of the Almeida approach that used a centralized, automated system to deliver the daily phone surveys.

The automated phone-based system was implemented using REDCap, a data collection and management tool developed by Vanderbilt University, together with the third-party voice delivery service Twilio Voice (Twilio Inc). REDCap was used to store participants' phone survey scheduling preferences, daily stress survey questions, and responses, while Twilio served as the platform for generating automated outbound calls. At the clinic visit (day 0), field center staff entered the information needed to schedule the automated daily phone surveys in REDCap, including the date of the first call, the participant's preferred call time, preferred language (English, Spanish, Mandarin, or Cantonese), time zone, and phone number. This 1-time entry triggered the automated survey call sequence for the full 7-day monitoring period, so that the field center staff did not need to manually reschedule calls for each day of the monitoring period. This initial entry was critical because it governed both the first scheduled call and the subsequent daily calls over the 7-day monitoring period. Incorrect entry could therefore disrupt the delivery of the full survey sequence and affect participants' opportunity to receive or complete surveys.

The first call was intended to be scheduled for the day after the clinic visit. Participants selected a preferred call time after 4:00 PM based on their availability, as this time window was intended to increase the likelihood that participants would be at home and available to answer the phone surveys if they indicated to receive the daily phone surveys at their landline. The preferred call time had to be entered into REDCap in military format for the automated calls to go out after 4:00 PM. For instance, if a clinic visit occurred on January 1, 2023, and the participant selected 4:30 PM as their preferred call time, the first call should be entered into REDCap as January 2, 2023, 16:30.

The daily stress survey was programmed in REDCap as a survey instrument, and participants heard the survey questions from this instrument during the automated phone calls delivered through the Twilio Voice integration. Therefore, once the participants' scheduling information was entered, REDCap transmitted both the survey content and call settings to Twilio, which placed the automated call. REDCap rendered each survey question, Twilio delivered the questions by phone, participants entered responses using their phone keypad, and the responses were returned to and stored in REDCap. This process was repeated until all survey questions were completed, after which the call ended [22]. For participants who selected a language other than English, the daily stress survey questions and call script were translated from the English version and delivered in the participant's preferred language: Spanish, Mandarin, or Cantonese. Non-English calls used text-to-speech audio through the same automated workflow using REDCap and Twilio. No additional study-specific modifications were made to the automated system for tonal languages. This approach accommodated participant language and scheduling preferences while reducing staff burden and supporting standardized data collection across multiple sites.

From the participant's perspective, once this 1-time setup was initiated at the clinic visit by the field center staff, participants received 1 phone survey per day for 7 consecutive days, beginning the day after their clinic visit. The daily stress surveys were delivered each day at the participants' preferred time. Participants responded to these phone-based surveys using their phone keypad. Most questions had "Yes" or "No" response options, with responses recorded as "1" for Yes and "0" for No. Some questions included branching logic, where a Yes response triggered follow-up questions answered on a numeric scale, typically ranging from 1 to 4 but extending up to 7. Each survey was expected to be completed within 5 minutes. If a participant missed the initial call, the system automatically initiated a follow-up call 15 minutes later. Up to 2 additional follow-up calls were sent at 15-minute intervals for a maximum of 3 phone calls per day across the 7-day monitoring period. If all 3 attempts were missed, the phone survey was considered incomplete for that day. Surveys were also classified as incomplete if a participant terminated the call early before responding to all survey questions. A survey was considered complete if the participant answered the call and progressed through all the programmed questions. The surveys were not designed to allow partial completion.

## Procedures to Support Survey Delivery and Protocol Adherence

Several procedures were put in place to support accurate protocol implementation and maximize the likelihood that participants received all 7 scheduled phone surveys. Participants using cell phones were encouraged to program the Twilio number into their contacts under "MESA Study" to minimize the risk of calls being missed or marked as spam. For those using landlines, the caller ID displayed "MESA Study." During the initial clinic visit, participants also completed a demo phone survey to familiarize themselves with the automated call system. They were asked to dial a practice number and complete a brief test phone survey using the same response format as the scheduled calls, with field center staff available to answer any questions and provide assistance during this practice session.

To support accurate protocol implementation and ensure quality control, the centralized coordinating team (hereinafter "reading center") for the stress reactivity ancillary study received real-time notifications after the REDCap scheduling forms were completed by the field center staff. Upon receiving the notification, the reading center staff reviewed the entered information for accuracy and completeness. If any discrepancies or missing data were identified, the reading center staff contacted the appropriate field center to request corrections. Once the information was corrected, the call schedule was reprogrammed accordingly via the Twilio platform. Because the first phone survey was scheduled for any time after 4:00 PM the day after the initial clinic visit, field center staff were

XSL•FO
RenderX

expected to complete the scheduling form as close to the clinic visit as possible. This allowed the reading center staff enough time to review the information and request or make corrections before the first scheduled phone survey. All communication between the reading center and field centers was documented in Smartsheet (Smartsheet Inc), a centralized work management platform used to track and coordinate study operations.

Field center staff were also instructed to conduct a check-in call with participants 2 days after the clinic visit and following the first scheduled phone survey to ensure the participant had not encountered any issues with receiving or completing the survey. If the first survey was missed, field center staff were expected to work with the participants to identify the reason and provide support as needed. In parallel, the reading center staff monitored survey completion status in REDCap for each participant daily. If a participant missed 2 consecutive surveys, the reading center staff contacted the corresponding field center staff to coordinate outreach and troubleshoot ongoing issues. Participant feedback, when provided, was documented in Smartsheet. At the conclusion of the 7-day monitoring period, the total number of completed surveys per participant was tracked in REDCap.

## Feasibility

To assess the feasibility of our EMA approach, we considered both the participant experience and the administrative requirements of the study. Participant engagement feasibility was evaluated using three components: (1) descriptive participant characteristics, (2) survey adherence, and (3) participant-initiated cancellation of the phone surveys. Descriptive participant characteristics were examined for 2 purposes. First, we compared participants enrolled in the MESA Stress Reactivity Ancillary Study with MESA Exam 7 participants who were not enrolled in the ancillary study. Second, among ancillary study participants included in the adherence analysis, we examined demographic and socioeconomic characteristics across survey completion groups to explore patterns in participant engagement, with particular attention to participants with high adherence and zero adherence.

Survey adherence was defined as the number of daily phone surveys completed during the 7-day monitoring period. Participants were categorized into 4 completion groups: 0 surveys, 1‐2 surveys, 3‐4 surveys, and 5‐7 surveys. Completion of 5‐7 surveys was considered high adherence because it represented completion of most of the daily phone surveys. This categorization was informed by EMA studies that commonly define high adherence at the participant level as completion of approximately 80% of prompts, although this threshold is not formally established [13]. At the opposite end, participants with zero adherence were defined as participants completing 0 surveys. Means and SDs were reported for continuous variables, and frequencies were reported for categorical variables across the 4 completion groups. These analyses were descriptive in nature, and no formal hypothesis testing was performed. We also characterized participant engagement by analyzing survey duration, defined as the time elapsed from phone survey initiation to completion, to assess the burden and tolerability of the daily phone surveys.

In addition to survey adherence, we also assessed participant-initiated cancellation of the daily phone surveys as another indicator of participant engagement feasibility. Participant-initiated cancellations were defined as participant requests to stop the daily phone survey and were categorized as either premonitoring or during monitoring cancellations. Premonitoring cancellations were defined as requests to opt out of the phone surveys before the start of the 7-day monitoring period. During monitoring, cancellations referred to requests made after the first phone survey went out and at any point during the 7-day monitoring window. Participants could request cancellation by notifying field center staff, including at the clinic visit or after the monitoring period had begun.

Participants who canceled before monitoring began did so before the first scheduled phone survey was delivered and therefore did not receive any daily phone surveys. These premonitoring cancellations were retained as a separate subgroup because they represented participant-initiated requests to stop the phone survey component before survey delivery began, which differs from missed or incomplete surveys due to nonresponse or administrative scheduling errors. Therefore, premonitoring cancellations were not included in the survey adherence analysis. Participants who canceled after the monitoring period began were included in adherence analyses based on the number of surveys completed before cancellation. There was no standardized protocol requiring staff to systematically ask for or record reasons for cancellations. As a result, cancellation reasons were available only in some cases and were not analyzed formally. When available, these reasons were used descriptively to provide context for possible participant burden, lack of interest, or challenges with the automated phone survey system.

Administrative implementation feasibility was defined as the extent to which study staff successfully followed the automated daily phone survey protocol according to study procedures. A scheduling error was defined as any staff entry error that resulted in one or more expected daily phone surveys not being sent as intended. Therefore, to evaluate administrative implementation feasibility, we calculated (1) the number and proportion of participants affected by at least one scheduling error, and (2) the number and proportion of expected daily phone surveys that were not sent because of such errors.

## Ethical Considerations

The Multi-Ethnic Study of Atherosclerosis was approved by the University of Washington institutional review board under STUDY00014523, with reliance agreements from participating institutions. All participants provided written informed consent for both the core and ancillary study components. Participants received US $50 compensation for participation in the stress reactivity ancillary study. Data used in this study were deidentified prior to distribution, with HIPAA (Health Insurance Portability and Accountability Act)–defined identifiers removed [20]. Access was limited to approved investigators and governed by MESA data use requirements, including safeguards against participant reidentification, restrictions on disclosure of potentially identifying information, and prohibitions on further data distribution.

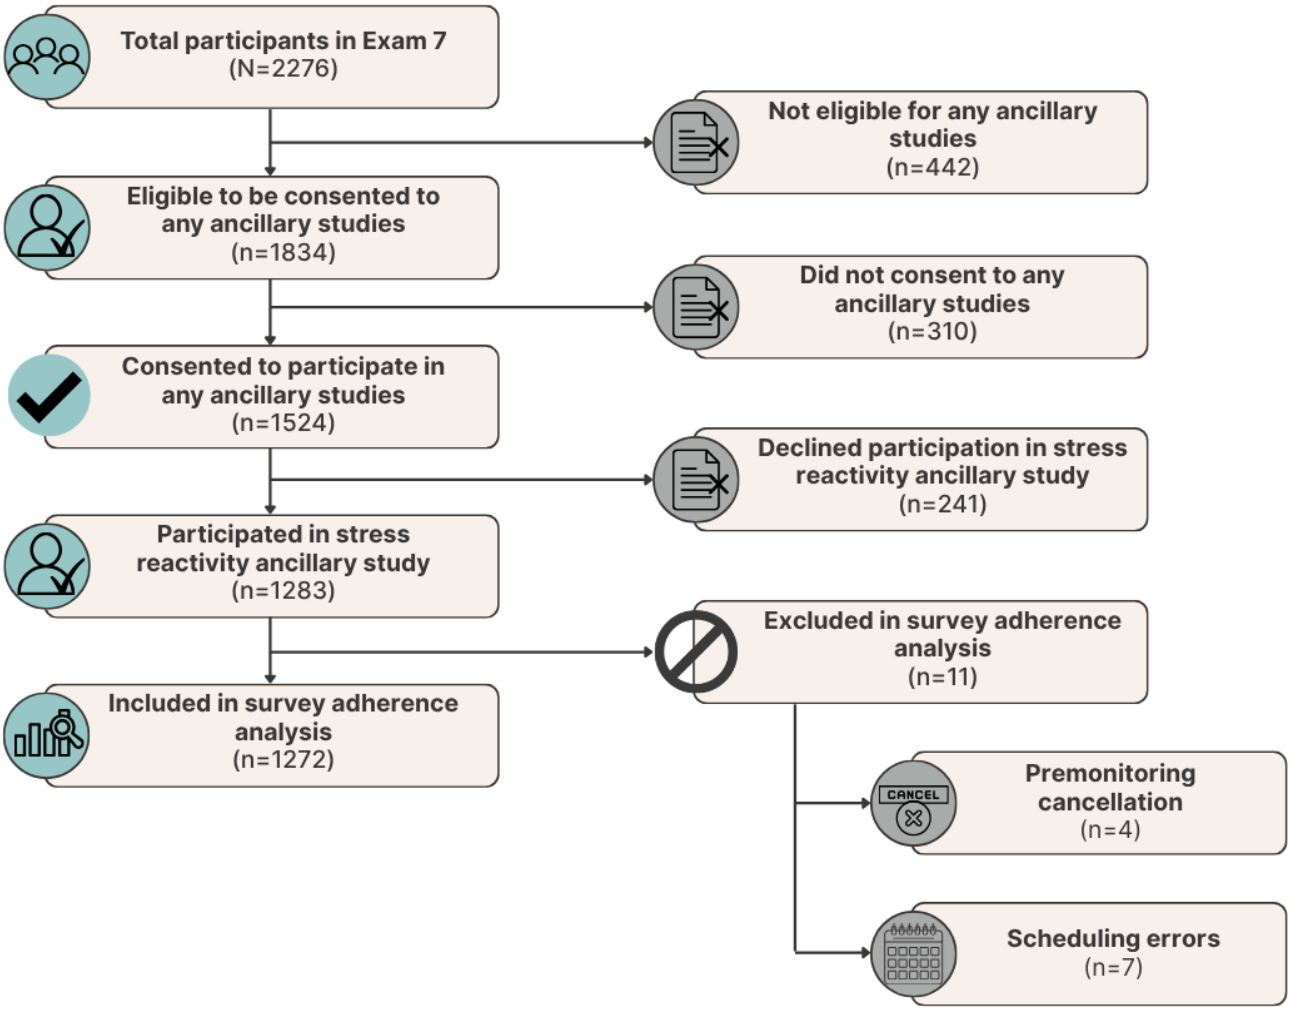
### Statistical Analysis



All analyses were descriptive and aimed at evaluating the feasibility of implementing automated EMA phone surveys in a large cohort of older adults. Descriptive statistics were generated to compare the demographics and socioeconomic characteristics of the MESA Exam 7 participants with those of our stress reactivity ancillary study participants. Frequencies and percentages were used to summarize scheduling errors, survey completion rates, and participant-initiated cancellations. All analyses were conducted using SAS (SAS Institute Inc). Data were compiled from REDCap and Smartsheet, and participant-level survey completion logs were used to calculate all outcome measures.

## Results

### Study Enrollment and Data Volume Summary

A total of 1283 participants were enrolled in the MESA Stress Reactivity Ancillary Study from the primary Exam 7 cohort of 2276 individuals. Participant flow from initial Exam 7 completion to final stress reactivity ancillary study enrollment is summarized in Figure 1. While all 1283 participants were included in initial demographic comparisons, the analysis of survey adherence focused on the 1272 individuals who received at least 1 phone survey. A total of 11 participants were excluded from the adherence analysis: 4 individuals who initiated cancellations prior to the monitoring period and 7 individuals who failed to receive any surveys due to administrative scheduling errors. A total of 8835 phone surveys were scheduled across the stress reactivity ancillary study's enrollment period. This aggregate volume of participants and scheduled surveys serves as the foundation for our evaluation of participant engagement and administrative implementation feasibility.

**Figure 1.** This flowchart illustrates participant recruitment, eligibility, and enrollment from the larger Exam 7 cohort into the stress reactivity ancillary study, and inclusion in the survey adherence analysis.

### Participant Engagement Feasibility: Participant Characteristics and Survey Adherence

A total of 1283 participants were enrolled in the MESA Stress Reactivity Ancillary Study from the larger MESA Exam 7 cohort (N=2276). To evaluate the representativeness of the ancillary study sample, characteristics were compared between enrolled and nonenrolled participants (Table 1). Enrolled participants were significantly younger than those who did not enroll (mean age 75.96, SD 7.07 years vs 79.07, SD 7.75 years; $P$<.001).

XSL•FO
RenderX

Significant differences were also observed regarding socioeconomic status. Participants in the ancillary study had higher levels of educational attainment (*P*<.001) and higher annual household incomes (*P*=.01). Specifically, 27.95% (355/1270) of enrolled participants held a graduate degree compared to 24.67% (240/973) of nonenrolled participants, and a higher proportion of the enrolled group reported an income exceeding US $100K (25.06% vs 23.33%). Despite these differences, the enrolled sample remained demographically representative of the larger Exam 7 cohort in terms of gender (*P*=.23) and racial and ethnic distribution (*P*=.88), with similar proportions of African American (338/1283, 26.34%), Chinese (141/1283, 10.99%), Hispanic (282/1283, 21.98%), and non-Hispanic White (522/1283, 40.69%) participants.

**Table .** Demographic and socioeconomic characteristics of participants in the MESA[a] Exam 7 cohort and the subset of participants enrolled in the MESA Stress Reactivity Ancillary Study across the 6 US field sites.

[a]MESA: Multi-Ethnic Study of Atherosclerosis.

[b]*P* values compare characteristics of the MESA Exam 7 cohort with those enrolled in the stress reactivity ancillary study.

Descriptive analysis of survey completion groups revealed that adherence was largely consistent across demographic and socioeconomic characteristics (Table 2). Age was the only variable significantly associated with survey completion (*P*=.002), with participants in Group 1, the noncompletion group, being significantly older than those in Group 4, the high-adherence group (mean age 79.11 vs 75.74 years). High adherence (5 - 7 surveys) remained consistently above 77% across all racial and ethnic subgroups, with the highest rates observed among African American participants (442/520, 85%). However, variation was noted by language. Participants completing surveys in Mandarin (43/56, 76.79%) or Cantonese (22/31, 70.97%) demonstrated lower high-adherence rates than those using English (874/1058, 82.61%) or Spanish (102/126, 80.95%). Completion rates were similar across socioeconomic tiers, with high adherence rates between 78% and 84% for all education and income levels. Noncompletion was uncommon across all subgroups, generally ranging between 4% and 10%.

[c]Values are presented as n (%). Percentages in Groups 1 - 4 are row percentages.

[d]Significant at the .05 level.

Beyond demographic and socioeconomic trends, we also assessed the practical experience of survey completion. Among the 1272 participants who received at least 1 phone survey during the 7-day monitoring period, the median survey completion time was 3 (IQR 2 - 4) minutes, which was consistent with the anticipated duration. However, we evaluated extended durations as a proxy for participant burden and tolerability. While the phone surveys were designed to be less than 5 minutes, 2371 of the total 8835 (26.84%) surveys lasted 5 minutes or longer. This was a common experience among the participants in the survey adherence analysis, with 73.19% (931/1272) of participants completing at least 1 survey that met this threshold. For these phone surveys, the mean completion time was approximately 7 (SD 5.03) minutes. Despite the increased time commitment, these participants demonstrated high adherence, completing a median of 6 (IQR 3-7) surveys.

XSL•FO
RenderX

More extreme durations were rare but followed a distinct demographic pattern. Surveys lasting 10 minutes or more accounted for 2.60% (230/8835) of total phone surveys and occurred among 15.25% (194/1272) of participants. Phone surveys exceeding 20 minutes were exceptionally infrequent, representing only 0.62% (53/8835) of all surveys. We observed that participants who required more time to complete the phone surveys tended to be older than the average participant, with the mean age increasing incrementally alongside survey duration from 76.09 (SD 7.01) years in the 5-minute or longer category to 77.73 (SD 7.31) years in the 20-minute or longer category. Notably, while participants experiencing these longer durations were more likely to miss at least 1 individual phone survey, they consistently completed most of their scheduled phone surveys across the 7-day monitoring period, maintaining a median of 6 completed surveys across both duration categories (IQR for over 10 minutes: 5-7; IQR for over 20 minutes: 4-7).

### Participant Engagement Feasibility: Cancellations

Participant-initiated cancellations occurred both before and during the monitoring period. Of the 1283 participants enrolled in the stress reactivity ancillary study, premonitoring cancellations only accounted for 0.31% (4/1283) of participants. These early withdrawals were primarily associated with an inability to comply with other broader aspects of the ancillary study rather than issues specific to the automated phone system. During monitoring, cancellations accounted for 1.65% (21/1272) of participants who received at least 1 phone survey. Of these individuals, 23.81% (5/21) had completed at least 1 survey before deciding to discontinue.

### Administrative Implementation Feasibility

To evaluate administrative implementation feasibility, we assessed operational accuracy by identifying scheduling errors that disrupted the intended 7-day survey sequence. Among the 1283 participants enrolled in the stress reactivity ancillary study, only 7 (0.55%) individuals were affected by scheduling errors that prevented their phone surveys from being initiated. As a result, these participants did not receive any of the daily phone surveys during the 7-day monitoring period. An additional 17 (1.33%) participants received fewer than the 7 intended phone surveys because of scheduling errors during the initial scheduling process at the clinic visit. Additionally, only 0.42% (37/8835) were not delivered because of scheduling errors. These findings indicate that scheduling errors affected only a small proportion of participants and expected surveys, supporting the administrative implementation feasibility of the automated phone-based daily surveys across a large, multisite research infrastructure.

## Discussion

### Principal Findings

By evaluating both participant engagement and administrative implementation, this study supports the feasibility of automated daily phone surveys for collecting real-time data in a large, geographically diverse cohort of older adults. Comparing the ancillary study sample with the broader MESA Exam 7 cohort provided important context for interpreting the generalizability of these feasibility findings. The lack of significant differences in gender distribution ($P$=.23) and racial and ethnic composition ($P$=.88) suggests that the ancillary study sample was broadly similar to the Exam 7 cohort across these demographic characteristics. However, participants enrolled in the ancillary study were younger ($P$<.001) and had higher levels of education ($P$<.001) and household income ($P$=.01) than those who were not enrolled. Because age was the only participant characteristic significantly associated with survey completion ($P$=.002), the high adherence rate of 81.84% observed in this study may be higher than what would be expected in older cohorts or in populations with fewer socioeconomic resources. Therefore, while our findings support the feasibility of automated daily phone surveys, additional tailoring may be needed to support consistent engagement among older adults who may face greater barriers to participation.

Participant engagement remained high, with 81.84% (1041/1272) of the participants who received at least 1 survey demonstrating high adherence by completing 5 - 7 surveys. Statistical analysis revealed that age was the only demographic variable significantly associated with survey completion ($P$=.002). Although adherence was consistently high across racial and ethnic groups, descriptive variation was observed by survey language, as Mandarin- and Cantonese-speaking participants showed slightly lower rates of high adherence compared to English- and Spanish-speaking participants. The study used translated scripts but did not implement additional system-level modifications specific to tonal languages. Because formal feedback was not systematically collected from Mandarin- and Cantonese-speaking participants, we cannot determine whether language delivery, automated voice quality, cultural adaptation, or other factors contributed to these differences. These findings suggest that future automated daily phone surveys may benefit from additional usability testing and language-specific tailoring for individuals who speak other languages. At the same time, offering the phone surveys in English, Spanish, Mandarin, and Cantonese according to participant preference may have contributed to the enhanced engagement across this cohort.

This feasibility study also offers insights regarding participant burden and tolerability. While surveys were designed to take no more than 5 minutes, 26.84% (2371/8835) of all phone surveys exceeded this duration. Despite these extended survey durations, adherence remained high: participants who experienced at least 1 survey lasting longer than 5 minutes still completed a median of 6 phone (IQR 3-7) surveys. These findings suggest that the automated phone survey protocol was generally tolerable for older adults, even when individual surveys exceeded the intended duration. The simplified response format, consisting primarily of Yes or No keypad entries and brief numeric scales, may have contributed to the high adherence observed.

A small subset of participants in Group 1 provided feedback on why they did not respond to any or missed the phone surveys: 8 participants reported never receiving the phone surveys, 5 cited hearing difficulties, and 4 mentioned phone-related issues such as a disconnected number or accidentally blocking the study line. These observations suggest that noncompletion

XSL•FO
RenderX

among this subgroup should be explored further to uncover specific barriers to participation and to determine whether additional tailoring in the automated phone-based survey approach could enhance engagement and accessibility.

The use of premonitoring and during monitoring cancellation metrics provided a nuanced view of study attrition. Both forms of participant-initiated cancellation were rare, with 4 premonitoring cancellations and 21 during monitoring cancellations, totaling 25 participants, or 1.95% (25/1283) of the 1283 ancillary study participants. A small subset of participants provided reasons for canceling the phone surveys. Most premonitoring withdrawals were associated with an inability to comply with broader study components rather than the phone surveys themselves, even though participants were encouraged to continue the daily phone surveys regardless of their participation in other study components. Other individuals reported finding the automated calls a nuisance, preferring live interviewer calls for privacy, or feeling stressed while waiting for the scheduled automated phone calls. Despite these instances, the low overall rate of attrition supports the high acceptability of the automated daily phone surveys within an older adult population.

Beyond participant-facing features, the protocol optimized administrative implementation feasibility and staff sustainability by automating the initial scheduling process, which significantly reduced the daily administrative burden on field center staff and provided a notable advantage for large-scale studies where coordination across multiple sites is complex. This reduction in daily tasks allowed staff to prioritize proactive participant follow-up, troubleshoot technical issues, and support overall protocol adherence. Together, these findings help fill an important gap in the EMA literature and support the feasibility of using automated phone surveys in a large, multisite population of older adults.

### Limitations

Despite the promising results, several limitations should be considered. First, although the majority of participants completed most or all of the surveys, a small subset either completed none or requested early cancellation. These individuals may have experienced barriers such as limited comfort with phone technology, hearing impairments, or other unmeasured factors. However, because our protocol did not include a formal process for collecting feedback from participants who were disengaged, we were unable to determine the reasons for noncompletion. Incorporating brief follow-up interviews or satisfaction surveys could provide valuable insights for future research. Additionally, we did not assess participants' perceptions of the survey experience, such as satisfaction or perceived burden. These perspectives are essential for interpreting adherence and for refining EMA protocols to maximize feasibility and acceptability among older adults. Finally, although the delivery of phone surveys was fully automated, the initial scheduling process relied on manual entry by field staff. While errors were rare, this step remains a potential source to further streamline workflows. Future efforts might explore opportunities to automate or standardize scheduling processes, informed by field staff feedback, to further minimize the risk of human error, especially in multisite studies where coordination is complex.

### Conclusion

Our findings suggest that daily EMA surveys by phone can be both practical and scalable for use in large, multisite studies involving older adults. High adherence rates, as well as low cancellation and operational error, suggest this approach is not only feasible but well-tolerated in a real-world research setting. These results provide a promising model for incorporating EMA into aging research. Future studies should explore strategies to improve accessibility among subgroups with lower adherence (eg, due to hearing problems) and evaluate the validity and predictive value of phone-based EMA data. As EMA continues to evolve as a tool for real-time data capture, our findings offer actionable insights for designing and deploying EMA in older adult populations, with implications for broader adoption in multisite health research.

## Acknowledgments

The authors thank the other investigators, the staff, and the participants of the Multi-Ethnic Study of Atherosclerosis (MESA) study for their valuable contributions. A full list of participating MESA investigators and institutions is available on the MESA study website [19]. This paper has been reviewed and approved by the MESA Publications and Presentations Committee. A generative language model (ChatGPT, version 4) was used in a limited capacity to assist with proofreading and clarity editing. Responsibility for the final manuscript rests entirely with the authors.

## Abstract

**Background:** Discrimination toward single-parent families (SPFs) is prevalent at structural and individual levels.

**Objective:** This study examined the association between perceived discrimination toward SPFs and parental depressive symptoms in South Korea.

**Methods:** This study included a nationally representative sample of 3300 single mothers (n=2205, 66.8%) and fathers (n=1095, 33.2%). Single parents' perceptions of discrimination toward SPFs were measured using eight items evaluating the discrimination toward both participants and their children, which were categorized into four groups (lowest, low, high, and highest). Depressive symptoms were evaluated using the 9-item Patient Health Questionnaire. To examine the association between discrimination toward SPFs and depressive symptoms in single mothers and fathers, logistic regression models were used, and adjusted odds ratios and 95% CIs were calculated.

**Results:** Of all participants, 11.7% (n=386) reported depressive symptoms. The prevalence of depressive symptoms was 7.7% (57/744), 6.4% (44/684), 8.2% (54/659), and 21.7% (155/714) among individuals with the lowest, low, high, and highest levels of discrimination, respectively. Compared to those experiencing the lowest level of discrimination, the highest level of discrimination was associated with 5.10-fold (95% CI 3.33 - 7.79) and 6.12-fold (95% CI 2.80 - 13.39) higher odds of depressive symptoms among single mothers and fathers, respectively. Further analyses demonstrated that discrimination directed toward both oneself and one's children was associated with depressive symptoms.

**Conclusions:** Discrimination against SPFs was prevalent in Korea and associated with depressive symptoms in both single mothers and fathers.

## Introduction

In recent decades, sociocultural shifts have increased societal interest in diverse family structures. These family forms, which often include civil partnerships, same-sex parent families, and single-parent families (SPFs), challenge the traditional and often narrowly defined concept of a family as consisting of a heterosexual couple and their biological children [1]. This shift reflects diverse ways in which individuals form meaningful familial relationships. In Korea, approximately 1.5 million households consisted of SPFs in 2023, accounting for 6.9% of total households [2]. In light of the growing interest in SPFs, the Korean government has implemented policies aimed at assisting child-rearing and providing financial resources for SPFs [3,4].

The mental health of SPF members has garnered substantial public health interest, as both single parents and their children are more vulnerable to various risk factors for mental health deterioration, including material deprivation, dual burden of work and childcare, and lack of social support [1,5,6]. For instance, previous studies have demonstrated that various factors, such as socioeconomic status, work-life balance, and social acceptance and support, can be associated with the mental health of single parents [5,7,8]. Indeed, single parents are more likely to have mood disorders and depressive symptoms than couple parents [9,10].

SPFs face various forms of discrimination at the institutional, structural, and individual levels [11]. In South Korea, influenced by Confucianism, which upholds the traditional family structure as the norm [12], cultural acceptance and institutional support

XSL•FO
RenderX

for SPFs have progressed more slowly than in Western societies [13]. Parents of SPFs often experience stigmatization and discrimination in their daily lives, which negatively affects their mental well-being and overall health. For example, single mothers, particularly those who are divorced, face negative perceptions and stigmatization from neighbors and even close acquaintances [5,14]. Moreover, single parents are frequently stigmatized as having a lower socioeconomic status, rendering them more vulnerable to institutional discrimination in public and professional spheres than partnered parents [5,14,15]. Such stigmatization and discrimination can limit access to resources, employment opportunities, and social support systems [13].

Discrimination, irrespective of its nature, is a well-documented risk factor for poor mental health; however, the specific link between discrimination experienced by SPFs and depressive symptoms has been scarcely investigated. Experiencing discrimination can act as a major trigger for depressive symptoms by increasing chronic stress and lowering self-esteem [16]. Furthermore, social isolation and loneliness caused by discrimination can mediate the link between discrimination and depressive symptoms [17].

The existing literature on the mental health of single parents has some limitations. While studies have found that discrimination toward SPFs is linked to poor mental health among parents [7,18,19], most studies have primarily focused on single mothers, leaving important gaps in understanding sex-based differences in discrimination experiences and their association with depressive symptoms among single parents [20]. Therefore, based on a nationwide survey conducted in Korea, the objective of this study was to examine the association between perceived discrimination toward SPFs and the depressive symptoms of both single mothers and fathers by comprehensively assessing everyday discrimination experiences using a multidimensional discrimination measurement instrument. We hypothesized that perceived discrimination toward SPFs would be positively associated with depressive symptoms among single parents.

## Methods

### Study Population

The study sample was collected from the Single-Parent Family Survey, administered by the Korean Women's Development Institute under the Ministry of Gender Equality and Family in Korea. The survey was conducted between August and November 2021. To ascertain a representative sample, the selection process involved probability proportional sampling of 331 administrative districts across South Korea, each containing at least eight single-parent households using the data from the 2019 Population and Housing Census. Systematic sampling was conducted within each district to select 8 to 15 households, and the household heads were surveyed. The survey response rate was 86.5%. If a selected household head refused to participate or remained unavailable despite repeated contact attempts, the household was classified as nonresponsive and replaced with an adjacent reserve household (13.5%). Consequently, 3300 parents of SPFs were included in the survey. In the survey, a single-parent household was defined as one in which the head of the household was divorced, widowed, never married, or separated, and the household included the head and at least one of their children aged 18 years or younger. A standardized survey weight was calculated for each individual to enhance the representativeness of the sample. Data collection involved structured one-on-one household interviews by trained interviewers conducted in compliance with COVID-19 prevention guidelines.

### Discrimination Toward SPFs

The perceived discrimination toward SPFs was evaluated in eight contexts. Specifically, participants were asked, "How often do you and your child experience unfair treatment or discrimination as a single-parent family? Please provide your responses from the perspectives of yourself and your child for each of the following contexts." The first five items measured perceived discrimination toward participants in the following contexts: (1) neighborhood or community, (2) school or childcare facilities, (3) family and relatives, (4) workplace, and (5) public institutions. The remaining three items assessed participants' perceived discrimination against their child in the following contexts: (1) neighborhood or community, (2) school or childcare facilities, and (3) family and relatives. To facilitate the participants' understanding and ensure standardized responses, 2 to 3 examples were provided for each item, as detailed in Table S1 in Multimedia Appendix 1. Each item was rated on a 4-point Likert scale (1 "Never experienced discrimination," 2 "Tended not to experience discrimination," 3 "Tended to experience discrimination," and 4 "Experienced severe discrimination"). Furthermore, participants could specify whether they had disclosed their single-parent status in each context rather than responding on a 4-point Likert scale. In such cases, the corresponding item was considered missing and replaced using multiple imputations. The total discrimination score ranged from 8 to 32, with higher scores indicating greater perceived discrimination toward SPFs. The Cronbach α was 0.93 for the sample. Based on the quartile values of the discrimination scores in the sample, participants were categorized into four groups: lowest (scores 8 - 10), low (scores 11 - 14), high (scores 15 - 17), and highest (scores 18 - 32) levels of discrimination.

### Depressive Symptoms

The Korean version of the 9-item Patient Health Questionnaire, a validated tool comprising nine items that evaluate mood and vitality over the past two weeks, was used to assess depressive symptoms [21,22]. Each item is scored on a scale ranging from 0 to 3, resulting in a total score between 0 and 27. Based on previous literature, a total score of 10 or more was classified as indicative of depressive symptoms [21,23].

### Covariates

The following sociodemographic features of the participants were considered confounders in the analyses: sex (male, female), age (<40 y, 40 - 49 y, ≥50 y), education level (middle school or below, high school, college or above), marital status (divorced, others—separated, widowed, never married), monthly household income (<₩1,000,000, ₩1,000,000 - ₩1,999,999, ₩2,000,000 - ₩2,999,999, and ≥₩3,000,000; an exchange

XSL•FO
RenderX

rate of ₩1000=US $0.67 is applicable), employment status (employed, unemployed), the number of children (one, two, three, or more), and physical activity. Physical activity was assessed using the following question: “How often do you currently engage in regular physical exercise (eg, walking, hiking, gym workouts, soccer, cycling, swimming)?” Participants who reported engaging in regular physical exercise 1 day or more per week were classified as physically active (yes), whereas all others were classified as no.

### Data Analysis

For the descriptive analysis, the sociodemographic characteristics of the study participants were examined according to their perceived discrimination levels. The prevalence of depressive symptoms was explored according to study variables. Moreover, the response frequency for each item was examined to analyze the distribution of discrimination responses for each context.

Multivariate logistic regression models were used to evaluate the association between discrimination of SPFs and depressive symptoms. Subsequently, discrimination was separated into two types: discrimination toward parents and discrimination toward children. Specifically, we assessed how an increase in the summed scores for the five items assessing discrimination toward parents and an increase in the three items assessing discrimination toward their children were associated with depressive symptoms. Adjusted odds ratios (ORs) and 95% CIs were determined. All analyses were not only conducted for the overall sample but also stratified by the sex of the parent to account for potential sex differences. Missing values were handled using multiple imputations, with 20 complete datasets generated through the multiple imputation by chained equations technique. Pooled estimates were calculated and presented. Statistical analyses and visualizations were conducted using R software (version 4.6.2; R Foundation for Statistical Computing). The complex survey design that involves systematic sampling was addressed using the “svydesign” and “svyglm” functions in the R package *survey* [24]. Subsequently, the results were combined using the *mice* package. We also assessed the robustness of our findings by performing a sensitivity analysis of all cases (n=2801). Finally, considering the wide range of scores in the highest category of perceived discrimination, it was further divided into 18 to 24 and 25 to 32 to examine whether a dose-response pattern could be observed.

### Ethical Considerations

This study was a secondary data analysis based on anonymized raw data from the Single-Parent Family Survey, which is publicly available at MicroData Integrated Service [25] without specific permission. To protect participants’ privacy and confidentiality, all data were anonymized and deidentified before the publication of the dataset by the Korean Women’s Development Institute. Therefore, the data provided to the authors were fully anonymized. Informed consent was provided by all participants during the original data collection procedure, and participants received no compensation for completing the survey. The Institutional Review Board (IRB) of the Yonsei Health System approved the study protocol (IRB application 2024-3489-002; IRB granting 4-2024-1607) and waived the requirement for additional informed consent because the study involved secondary analysis of existing data.

## Results

Table 1 shows the characteristics of the 3300 study participants. The sample consisted of 1095 (33.2%) male parents and 2205 (66.8%) female parents. Compared to those who experienced the lowest level of discrimination, individuals who reported higher levels of discrimination were more likely to be younger, have a marital status other than divorced, have lower income levels, be employed, and have only one child. However, no clear difference was noted in the proportions of male and female participants across the levels of perceived discrimination.

Table 2 presents the prevalence of depressive symptoms. Of the 3300 participants, 11.7% (n=386) had depressive symptoms. The prevalence of depressive symptoms was 7.7% (57/744), 6.4% (44/684), 8.2% (54/659), and 21.7% (155/714) among those with the lowest, low, high, and highest levels of discrimination, respectively. Furthermore, the prevalence of depressive symptoms was higher among women, those with low educational levels, those with low income levels, unemployed individuals, and individuals with three or more children.

Table 4 shows the association between perceived discrimination toward SPFs and parental depressive symptoms. Compared with those with the lowest discrimination level, those with the low (adjusted OR 1.64, 95% CI 1.05 - 2.57), high (adjusted OR 1.74, 95% CI 1.12 - 2.69), and highest (adjusted OR 5.33, 95% CI 3.65 - 7.76) levels were more likely to have depressive symptoms. Furthermore, the highest discrimination level was associated with 6.12-fold (95% CI 2.80 - 13.39) and 5.10-fold (95% CI 3.33 - 7.79) increases in the odds of depressive symptoms in men and women, respectively.

**Table .** Association between discrimination toward single-parent families and depressive symptoms of parents. Single-Parent Family Survey, 2021, South Korea (cross-sectional study; n=3300). The models were adjusted for sex (overall model), age, education, marital status, income, employment status, number of children, and physical activity.

Figure 1 shows the associations between domains of perceived discrimination and depressive symptoms among single parents. A 5-point increase in discrimination toward oneself, as measured by the summed score, was associated with a 2.11-fold (95% CI 1.46 - 3.05), 1.95-fold (95% CI 0.82 - 4.61), and 2.12-fold (95% CI 1.41 - 3.19) increase in the odds of depressive symptoms in the overall, male, and female samples, respectively. Similarly, a 3-point increase in discrimination toward one's children, as measured by the summed score, was associated with a 1.55-fold (95% CI 1.06 - 2.25), 1.89-fold (95% CI 0.73 - 4.87), and 1.48-fold (95% CI 0.98 - 2.22) increase in the odds of depressive symptoms in the overall, male, and female samples, respectively.

**Figure 1.** Associations between domains of perceived discrimination and depressive symptoms among single parents. The odds of depressive symptoms were estimated for a 5-point increase in discrimination toward oneself and a 3-point increase in discrimination toward one's children. Single-Parent Family Survey, 2021, South Korea (cross-sectional study).

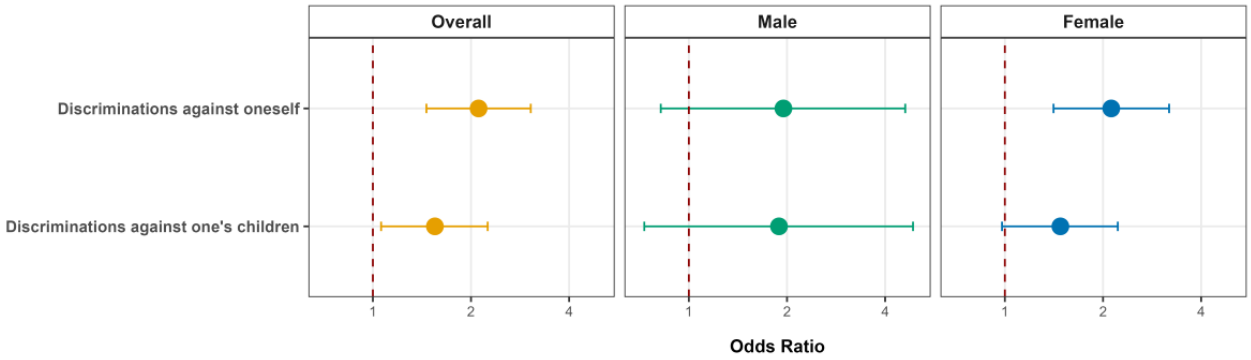

Table S2 in Multimedia Appendix 1 presents the association between discrimination toward SPFs and depressive symptoms in the complete cases. The findings of the sensitivity analysis were consistent with those of the main analysis, showing a similar positive association between discrimination experience and depressive symptoms. The results from the analyses further stratifying the highest category showed that, although the CIs were wide, notably elevated ORs were observed at the highest levels of discrimination, suggesting a dose-response pattern for this exposure category (Table S3 in Multimedia Appendix 1).

## Discussion

This study found an association between perceived discrimination toward SPFs and depressive symptoms in single parents. Single mothers and fathers who experienced the highest levels of discrimination were more likely to report depressive symptoms than those who experienced the lowest levels of discrimination. Furthermore, discrimination directed towards both parents and their children was positively associated with parents' depressive symptoms.

Descriptive analysis revealed that 11.7% (386/3300) of the participants presented with depressive symptoms. This figure is notably higher than the prevalence of depressive symptoms measured by the 9-item Patient Health Questionnaire in nationally representative Korean samples, which ranged from 2.8% to 5.2% [26,27]. Furthermore, while a substantial number of single parents reported experiencing discrimination across various domains, clear sex differences in their levels of discrimination were not evident.

Our findings align with those of the existing literature, showing an association between experiences of discrimination and mental health problems such as depressive symptoms, suicidal behaviors, and anxiety [28,29]. Furthermore, the results of our study are consistent with those of previous research, showing that discrimination toward minority family structures is associated with poor mental health outcomes in affected individuals. For instance, discrimination targeting families with same-sex marriage has been linked to adverse mental health outcomes for themselves and their children [30,31]. Moreover, perceived discrimination negatively correlated with happiness among unmarried mothers [19]. Although various forms of discrimination, including those based on sex and race/ethnicity, have consistently been shown to be associated with mental health problems [28,29], this study adds to the literature by exploring the relationship between discrimination directed toward SPFs and depressive symptoms.

Complex mechanisms may explain the association between perceived discrimination toward SPFs and depressive symptoms of single parents. Multiple pathways may link the experience of discrimination to mental health deterioration, and the existing literature suggests that discrimination can induce psychological, physiological, and behavioral responses that contribute to poor health outcomes [16]. Prolonged exposure to discrimination can lead to chronic psychological distress by inducing anxiety regarding exclusion or by reducing self-esteem [32,33]. The persistence of stress can eventually result in the development of depressive symptoms. Moreover, physiologically, chronic stress arising from the experience of discrimination was linked to the dysregulation of the hypothalamic-pituitary-adrenal axis, which manifests as increased cortisol levels [34,35]. Hypothalamic-pituitary-adrenal axis overactivity plays a key role in the pathophysiology of depressive symptoms [36]. Finally, the discrimination experienced by SPFs may lead to behavioral changes. For instance, experiencing chronic stress may induce individuals to rely on coping mechanisms, such as smoking or alcohol consumption, which can contribute to the deterioration of mental health [37].

This study had certain limitations. First, the causal effects of discrimination toward SPFs on depressive symptoms could not be identified, as the analyses were based on cross-sectional survey data. For instance, the possibility of reverse causality, in which depressive symptoms influence the perception of discrimination [38], could not be ruled out in this cross-sectional study. Therefore, longitudinal studies are needed to examine whether experiences of discrimination can predict the onset of depressive symptoms over time. Second, key variables, including depressive symptoms, were assessed using self-reported measures, which may be subject to measurement errors, such as recall bias. Future studies should consider using medical records or physician diagnoses to verify the association between discrimination and objective clinical diagnoses. Third, certain factors that could influence both discrimination and depressive symptoms, such as psychiatric history, personality, social support, neighborhood income levels, alcohol use, smoking status, and other health behaviors, were not accounted

XSL•FO
RenderX

for due to the lack of available information. We acknowledge that the failure to account for these potential unmeasured confounders may have resulted in an overestimation of the association between discrimination experiences and depressive symptoms. Fourth, our discrimination survey questionnaire aimed to capture experiences of discrimination toward SPFs across various daily contexts. However, as it relies on subjective recall, it may be subject to recall bias. Additionally, the survey responses demonstrated high reliability, the instrument has not undergone formal validation. Because the measure was not externally validated, it may be conceptually limited and may not comprehensively capture discrimination toward SPFs. Additionally, the subjective nature of the measure may introduce systematic bias if individuals with depressive symptoms differentially report higher levels of perceived discrimination in comparison to those without [38]. Therefore, future research should establish a theoretical framework for understanding discrimination experiences among SPFs and develop a validated measurement tool to overcome these limitations. Fifth, although this study addressed missing data using multiple imputation, the assumption of missing at random could not be verified. We acknowledge that missingness may have been influenced by unobserved socioeconomic or health-related factors; therefore, the results derived from multiple imputation may still be subject to bias. Sixth, although this study aimed to explore sex-specific associations between discrimination toward SPFs and depressive symptoms, the relatively small sample size of single fathers resulted in wider CIs and less stable estimates compared with those observed among single mothers. Future epidemiological studies may address this limitation by including a larger sample of single fathers.

Despite these limitations, this study contributes to existing literature in several ways. First, the study sample was selected through systematic sampling, representing a nationally representative population, which enhances the generalizability of the findings. Second, our study provides novel insights by analyzing the scarcely studied association between discrimination toward SPFs and mental health.

This study showed that single parents experience discrimination toward both themselves and their children owing to their single-parent status, which is closely associated with depressive symptoms. An association between perceived discrimination toward SPFs and depressive symptoms was noted in both single mothers and fathers.

## Acknowledgments

This study used data from the 2021 Single-Parent Family Survey, conducted by the Korea Women's Development Institute (KWDI) under the Prime Minister's Office of the Republic of Korea. The authors gratefully acknowledge the researchers at KWDI for providing access to the data and for their efforts in conducting the survey. We also extend our sincere thanks to the anonymous participants of the 2021 Single-Parent Family Survey. During the preparation of this work, the authors used ChatGPT from OpenAI for enhancing grammar and proofreading under full human supervision. Responsibility for the final manuscript lies entirely with the authors.

## Funding

The authors declared that no financial support was received for this work.

## Data Availability

The raw data of the Single-Parent Family Survey, 2021 were anonymized by the researchers at the Korean Women's Development Institute. The raw data are publicly available at the home page of MicroData Integrated Service [25].

## Abstract

**Background:** Despite the vast growth of vaccine studies during the SARS-CoV-2 pandemic, clinical trials failed to adequately represent diverse societal groups, resulting in the underrepresentation of specific populations. Understanding the factors hampering participation in vaccine clinical trials is essential to better identify structural, ethical, and communication barriers and to improve inclusive strategies for broader and more equitable participation in future vaccine research.

**Objective:** This study aimed to identify the perceived barriers to participation in vaccine trials among pregnant and lactating women, children aged younger than 18 years, and adults aged older than 65 years, as reported by professionals with expertise in vaccines or vaccine trials.

**Methods:** An online questionnaire was developed to gather personal information, group-specific barriers to vaccine trial participation, and suggestions to overcome these barriers. Data are presented as absolute (n/N) and relative frequencies (%).

**Results:** A total of 115 respondents, the majority (n=73, 63.5%) of whom were working in the scientific community, completed the online survey. Challenges in recruiting children were identified due to “safety or efficacy concerns,” “difficulties about ethics and regulatory issues,” and “lack of targeted information and communication.” Challenges in recruiting pregnant and lactating women were primarily “ethics and regulatory requirements,” “safety issues,” and “lack of prioritization or interest.” “Lack of information and communication channels adapted to the specific target group,” along with “lack of prioritization,” were the main challenges in recruiting older participants. Provision of health-related incentives, including but not limited to access to new treatments and receiving expert medical care, seems to be the top-rated motivation to participate in vaccine clinical trials.

**Conclusions:** The main challenges in recruiting pregnant and lactating women and children in vaccine trials involve safety and efficacy concerns, as well as lengthy ethical and regulatory processes. For older adults, key issues include poor communication

XSL•FO
RenderX

channels tailored to their needs, limited information, lack of prioritization, funding, infrastructure, and industry interest. Across all underrepresented groups, low awareness of and poor communication about research opportunities were major barriers. Additionally, mobility issues affected older adults, while lack of motivation and incentives affected children, and low health literacy and provider uncertainty impacted pregnant and lactating women. Improving communication infrastructure and enhancing communication strategies with clear, tailored messages to build trust and motivate participation are essential to improve inclusion in vaccine research.

## Introduction

Ensuring a diverse representation of population groups in clinical trials is essential for advancing health equity, as these groups may have different risk factors and variable responses to medical products [1]. Despite the rapid expansion of vaccine studies during the SARS-CoV-2 pandemic, clinical trials failed to adequately represent diverse societal groups, resulting in the underrepresentation of specific populations [2]. Underrepresented groups could include people who have inadequate access to health care for any reason, including unreachable or inadequate vaccination systems, health care provider discrimination, lack of health care provider recommendations, or legal restrictions [3,4]. A cross-sectional study examining trials registered at ClinicalTrials.gov identified that among 230 vaccine trials based in the United States, Black or African American individuals (constituting 10.6% of all participants) and adults aged 65 years or older (constituting 12.1% of the participants) were underrepresented compared with US census data [5]. On the other hand, certain populations with access to health care may still be underrepresented in clinical trials largely because of the exclusion of these population groups right at the initial stage of vaccine trial design. For instance, only 8 (9.5%) clinical trial protocols among the 84 phase II and phase III vaccine clinical trials reporting from 2009 to 2019 explicitly included pregnant people [6]. A semistructured qualitative interview conducted in the United Kingdom showed that although pregnant women acknowledged the importance of vaccine trials to demonstrate the safety and effectiveness of vaccines, they were reluctant about their own involvement in such trials [7].

We cannot underestimate the impact of increasing vaccine hesitancy on the underrepresentation of certain populations in vaccine clinical trials. For instance, Willis et al [8], who surveyed 1205 Arkansas adults in July and August of 2020 to evaluate COVID-19 vaccine hesitancy, showed that among Black or African American populations, 50% of respondents showed hesitancy toward receiving the COVID-19 vaccine, compared to 18.37% of White respondents.

Recently, Daniel et al [9] investigated the enablers and barriers to participation in vaccine trials. Safety concerns, institutional distrust and misinformation, sociocultural and religious norms, and logistical burdens were the most prominent barriers overall. Safety concerns were the predominant barrier among pregnant and pediatric participants. Recruiting children can be particularly challenging and may even lead to early trial termination due to failure to meet recruitment targets [10].

Strategies to better ensure diverse representation in vaccine clinical trials, particularly in preventive vaccine studies, are needed. Understanding the factors hampering participation in vaccine clinical trials for certain population groups may enhance future access to and engagement with a diverse selection of volunteers in clinical trials and facilitate better promotion of tools such as the VACCELERATE Volunteer Registry [11-17]. In addition to pinpointing the most underrepresented population groups, it is also crucial to identify the barriers that prevent professionals from involving these population groups in vaccine trials.

Within the VACCELERATE consortium, a task force was assigned to launch, disseminate, and analyze an extended online survey targeted at professionals with expertise in vaccines or vaccinations, with the aim of identifying barriers to participation in vaccine trials among pregnant and lactating women, children (aged <18 y), and older adults (aged >65 y) in the European region. For this reason, an internal consultation addressed to the National Coordinators was conducted to identify the challenges of vaccine trial participation of the underrepresented population groups [11]. Although the underrepresented populations could be diverse, based on the results of the initial survey, as well as a consultation with experts from the European Centre for Disease Prevention and Control and the World Health Organization, the task force selected (1) children (aged <18 y), (2) pregnant and lactating women, and (3) older adults (aged >65 y) to be the primary focus of the extended survey. Hence, this study focuses specifically on children, pregnant and lactating women, and older adults for the purposes of the analysis.

This study aimed to identify the perceived barriers to participation in vaccine trials among pregnant and lactating women, children aged younger than 18 years, and adults aged older than 65 years, as reported by professionals with expertise in vaccines or vaccine trials.

## Methods

### Study Design and Population

VACCELERATE is a pan-European clinical research network established to accelerate vaccine trials and pandemic preparedness [18]. The project aimed to streamline and harmonize clinical trial efforts across Europe. One of the work packages was dedicated to designing and implementing a European Union–wide, dynamic, harmonized, and sustainable

XSL•FO
RenderX

volunteer registry for phases II and III vaccine clinical trials with an initial focus on the COVID-19 pandemic and for the future expansion to any forthcoming European epidemic or pandemic. Within this work package, the study was designed to identify the causes of underrepresentation of pregnant and lactating women, children aged younger than 18 years, and adults aged older than 65 years as perceived by professionals in the vaccine field. It was not intended to explore the reasons why these population groups are not targeted at the trial design stage or to compare the magnitude of differences and the impact of perceived barriers across the underrepresented groups. Indeed, we did not inquire on the reasons why most of the vaccine trials were excluding these population groups and how we could get sponsors to design trials that are more inclusive and diverse. Instead, we have assumed that trials are open to children, pregnant and lactating women, and older adults.

An online 11-item questionnaire, divided into 3 sections, was developed by the authors. The full questionnaire can be found in Multimedia Appendix 1. The authors were engaged in several rounds of discussion to list the most appropriate response options for each group, as analyzing the results of the open-ended questions in this heterogeneous group of underrepresented populations would have been particularly challenging. Section A consisted of 6 questions, aiming to capture personal information of the survey respondents, such as (1) the capacity in which respondents filled out the survey (expert opinion or organization representative), (2) the underrepresented population groups that the respondents had experience with (children, pregnant and lactating women, and/or older adults), (3) affiliation of the respondent (civil society, funder, industry, and public health agencies), (4) geographical area of expertise, (5) highest level of expertise (spanning from junior to executive), and (6) total years of experience in vaccines and vaccination. Section B aimed to capture group-specific barriers to vaccine trial participation of certain population groups. The questions of section B followed a smart-branching design based on the answers of the respondents in section A. More specifically, in questions 7, 8, and 9 (referring to children, pregnant and lactating women, and older adults, respectively), survey respondents were asked to agree or disagree with statements provided regarding (1) the reasons they are unable to recruit volunteers from the given population group and (2) the main reasons the given population group does not participate in clinical trials as the professionals perceive from their side. Section C was titled “Overcoming Barriers” and involved 2 questions. Question 10 was a free text question, asking professionals for their opinion on what could improve equal access and representation of underrepresented population groups in COVID-19 vaccine research. Finally, question 11 asked on motivators of individuals to participate in a volunteer registry.

The VACCELERATE consortium included National Coordinators from Austria, Belgium, Cyprus, the Czech Republic, Denmark, France, Germany, Greece, Hungary, Ireland, Italy, Lithuania, the Netherlands, Poland, Portugal, Serbia, Slovakia, Spain, Sweden, Israel, Norway, Switzerland, and Turkey. A pilot study was done with the National Coordinators to ensure that the online platform for the survey was working appropriately. As these coordinators were all experts in vaccine research from 23 different countries, this pilot study also ensured that the questions were valid and sound before the survey questionnaire was circulated more widely. No patient or trial participant was targeted either in the pilot phase or in the actual survey.

To reach as many professionals as possible, National Coordinators were asked to list relevant agencies and organizations (ie, public health authorities, academia, nongovernmental organizations, and research development departments) in their network. After mapping down the potential participants, we created an extensive list of possibly eligible professionals. We used this list to disseminate our survey and attract more professionals with opportunity sampling, given that effective communication and collaboration with professionals are key to survey success. Invitation letters (Multimedia Appendix 2) included a statement to point out that the survey targeted professionals with expertise in vaccines or vaccinations to enroll qualified respondents.

### Ethical Considerations

#### *Ethics Approval*

The study was conducted in accordance with the Declaration of Helsinki and approved by the Hacettepe University Ethics Committee (approval 2023/06 - 30; approved on April 4, 2023).

#### *Informed Consent*

Informed consent was obtained from all survey respondents prior to answering the questions of the survey. Respondents could withdraw at any point before submission by simply closing their web browser.

#### *Privacy and Confidentiality*

The survey was hosted by LimeSurvey, a platform fully compliant with the General Data Protection Regulation, and was accessible via the VACCELERATE stakeholder survey link [19]. All collected data were anonymized; no traceable information was collected.

After clicking on submission, there was no way of identifying the respondent or associating their answers with them. As such, the answers could not be revoked once submitted. No identifying information of the participants was collected or published.

#### *Participant Compensation*

Participants did not receive any compensation for participation.

### Statistical Analysis

Data are presented as absolute (n/N) and relative frequencies (%). Statistical analysis was performed using Microsoft Excel. Free-text data are presented as raw answers and categorized.

## Results

### Overview

As a first step, a list was prepared, including contact information of professionals and institutions to serve as the basis of the dissemination process. Afterward, the list was refined to contain 219 email addresses from 26 countries. Invitation letters for the professionals to participate in the online survey were initially

XSL•FO
RenderX

sent on June 8, 2023. The invitation letter and the link to the survey were also distributed through personal communication networks. The initial deadline to reach the targeted number of at least 100 responses was set on September 30, 2023; however, as the target number of responses could not be reached, the deadline was extended 3 times until November 7, 2023.

## Demographics and Expertise Area of Respondents

A total of 115 survey respondents with expertise in the vaccine field in the European region completed the survey. Most respondents (n=91, 79.1%) stated that they answered the survey on their own behalf, while 24 (20.9%) respondents indicated that they responded on behalf of or were appointed by an organization. The distribution of countries where the institution, company, or organization of the survey respondent is based is presented in Table 1.

**Table .** The distribution of countries where the institution, company, or organization of the survey respondent is based.

| Country | European region | Values, n (%) |
|---|---|---|
| Turkey | Southern Europe | 29 (25.2) |
| Sweden | Northern Europe | 16 (13.9) |
| Greece | Southern Europe | 10 (8.7) |
| Spain | Southern Europe | 8 (7) |
| The Netherlands | Western Europe | 6 (5.2) |
| Austria | Western Europe | 5 (4.3) |
| Norway | Northern Europe | 5 (4.3) |
| Cyprus | Southern Europe | 4 (3.5) |
| Germany | Western Europe | 4 (3.5) |
| Switzerland | Western Europe | 4 (3.5) |
| Australia | N/A[a] | 3 (2.6) |
| Belgium | Western Europe | 3 (2.6) |
| Italy | Southern Europe | 3 (2.6) |
| Slovenia | Southern Europe | 3 (2.6) |
| Denmark | Northern Europe | 2 (1.7) |
| France | Western Europe | 2 (1.7) |
| Lithuania | Northern Europe | 2 (1.7) |
| Albania | Southern Europe | 1 (0.9) |
| Canada | N/A | 1 (0.9) |
| Ireland {Republic} | Northern Europe | 1 (0.9) |
| Poland | Eastern or Central Europe | 1 (0.9) |
| Singapore | N/A | 1 (0.9) |
| United States | N/A | 1 (0.9) |

[a]NA: nonapplicable.

Table 2 shows the population groups that the respondents work toward improving the health of, and Table 3 exhibits the study areas or groups that are most relevant to the respondents' areas of expertise.

**Table .** The distribution of the underrepresented groups that the survey respondents had experience with (N=115).

| Groups[a] | Values, n (%) |
|---|---|
| All | 38 (33) |
| Adults aged >65 y | 51 (44.3) |
| Pregnant women | 31 (27) |
| Lactating women | 25 (21.7) |
| Children aged <5 y | 35 (30.4) |
| Children aged 5 - 11 y | 25 (21.7) |
| Children aged 12 - 17 y | 28 (24.3) |

[a]Experience among groups may be overlapping.

**Table .** Distribution of the area of expertise of the survey respondents.

| Area of expertise | Values, n (%) |
|---|---|
| Civil Society (eg, NGOs[a], patient advocacy groups, etc) | 9 (7.8) |
| Funder (providers of nonrepayable funds such as public and other traditional R&D[b] funders) | 1 (0.9) |
| Industry | 11 (9.6) |
| Policy and decision makers | 7 (6.1) |
| Public health agency, including European (HERA[c], ECDC[d], EC[e]) and international (WHO[f]) | 21 (18.3) |
| Regulatory Authority (including EMA[g]) | 1 (0.9) |
| Scientific community (academia, RIs[h] supporting vaccine R&D or other relevant global health fields) | 73 (63.5) |
| Vaccine development alliances (biomedical R&D RIs [National, European, International, PDPs[i], and other major initiatives]) | 5 (4.3) |
| I do not wish to specify | 5 (4.3) |

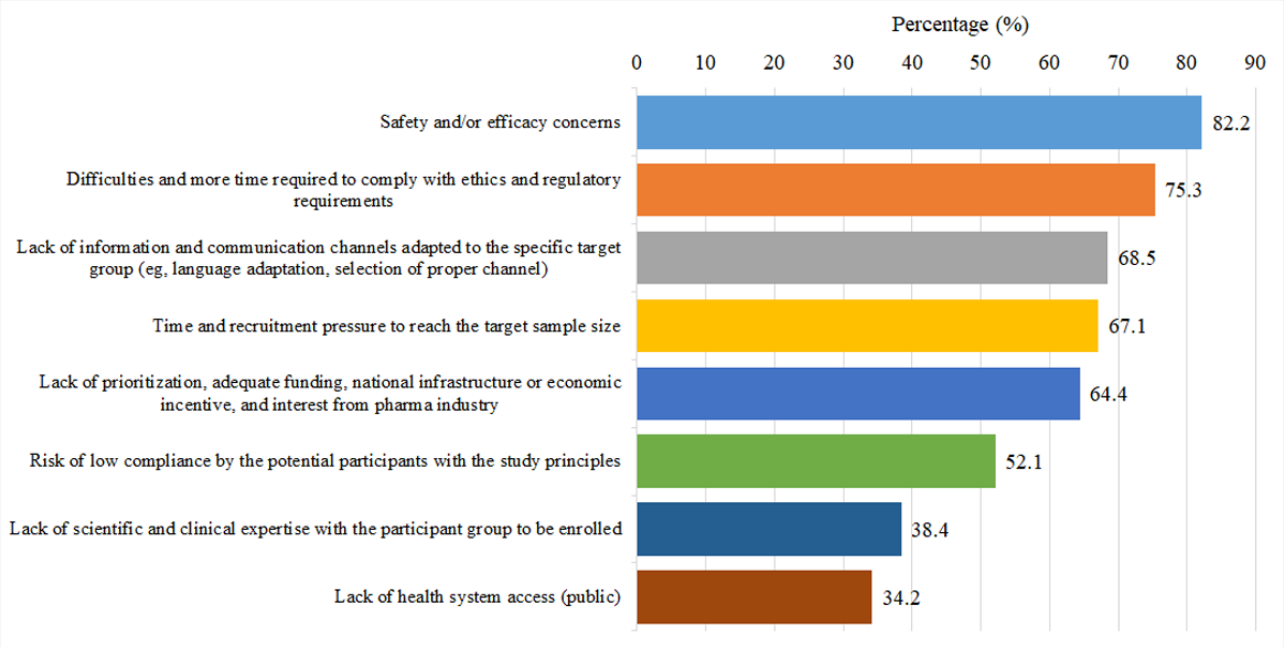
[a]NGO: nongovernment organizations.
[b]R&D: research and development.
[c]HERA: Health Emergency Preparedness and Response Authority.
[d]EDCD: European Centre for Disease Prevention and Control.
[e]EC: European Commission.
[f]WHO: World Health Organization.
[g]EMA: European Medicines Agency.
[h]RI: research infrastructure.
[i]PDP: product development partnership.

The expertise of the respondents was relatively equally divided among the 3 groups, whereas 1 in 3 respondents reported having experience with all groups. While 21.7% (25/115) of the respondents declared expertise at the entry and associate levels (<5 y) in the field of vaccines and vaccination, 39.1% (45/115) had expertise at the midsenior level (≥5 y), 27% (31/115) were at the director level, and 12.2% (14/115) were at executive levels. Overall, 44.3% (51/115) of the respondents had an experience of 15 years or more in the fields of vaccine and vaccination. Most (73/115, 63.5%) of the respondents were working in the scientific community, whereas 18.3% (21/115) and 9.6% (11/115) of them were working in public health agencies and the pharmaceutical industry, respectively. The geographical areas to which the respondents' expertise is most related are presented in Table 4. There was a heterogeneous representation of the Southern Europe or Mediterranean region, followed by Western Europe, which constituted the most represented geographical regions.

XSL•FO
RenderX

**Table .** Distribution of the geographical area where the survey respondents' expertise in vaccines is or are mostly related[a].

| Geographical area | Values, n (%) |
|---|---|
| Western Europe | 39 (33.9) |
| Eastern Europe | 17 (14.8) |
| Central Europe | 11 (9.6) |
| Northern Europe | 19 (16.5) |
| Southern Europe or Mediterranean | 50 (43.5) |



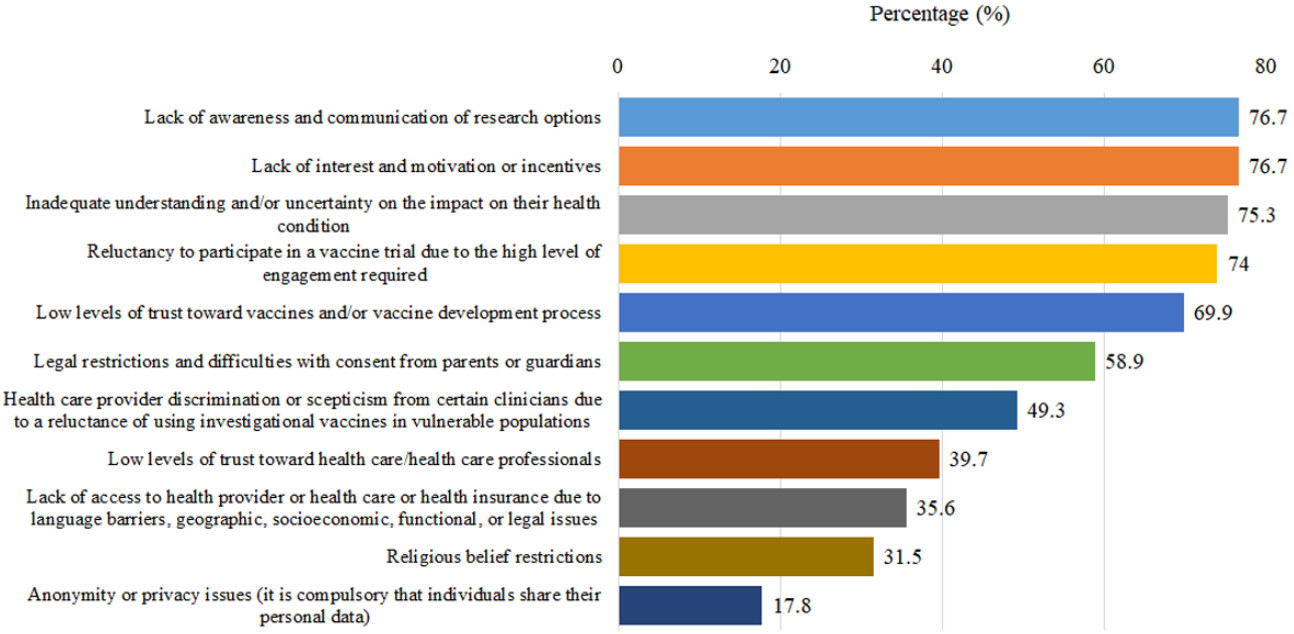
[a]Some respondents reported more than one geographical area.

## Reported Challenges in Recruiting Certain Population Groups in Vaccine Trials

### *Pediatric Population*

Figure 1 shows the challenges in recruiting children as participants; the 3 most pertinent being "safety and/or efficacy concerns" (60/73, 82.2%), "difficulties and more time required to comply with ethics and regulatory requirements" (55/73, 75.3%), and "lack of information and communication channels adapted to the specific target group" (50/73, 68.5%).

**Figure 1.** Distribution of reasons providers are unable to find or not willing to recruit a sufficient number of children participants in vaccine trials from the survey respondents' perspective.



The top 3 reasons why children are not participating in vaccine trials, as perceived by the responding professionals, were emphasized as "lack of awareness and communication of research options" and "lack of interest and motivation or incentives" (56/73, 76.7% for both), "inadequate understanding and/or uncertainty on the impact on their health condition" (55/73, 75.3%) and "reluctancy to participate in a vaccine trial due to the high level of engagement required" (54/73, 74%; Figure 2).

XSL•FO
RenderX

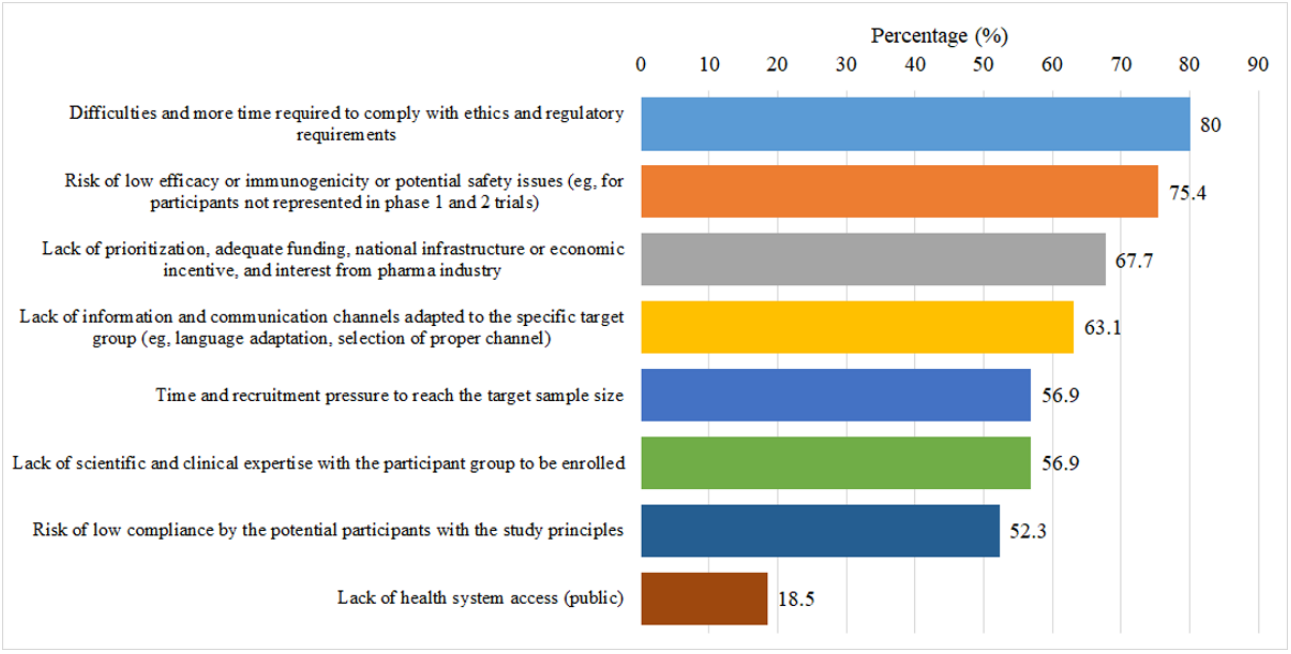


**Figure 2.** Distribution of the main reasons that children are not participating in vaccine trials from the survey respondents' perspective.

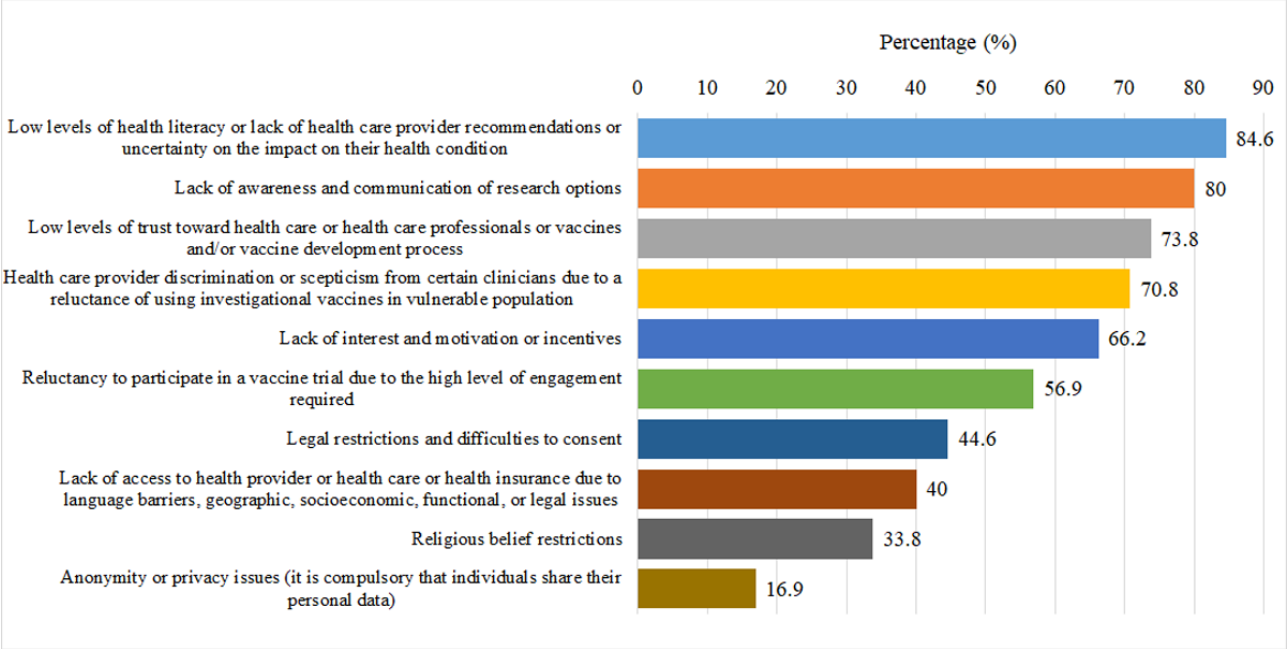
### *Pregnant and Lactating Women*

The main challenges in recruiting pregnant and lactating women in vaccine trials were "difficulties and additional time required to comply with ethics and regulatory requirements" (52/65, 80%), "risk of low efficacy or immunogenicity or potential safety issues (eg, for participants not represented in phase I and II trials)" (49/65, 75.4%), and "lack of prioritization, adequate funding, national infrastructure or economic incentive, and interest from pharma industry" (44/65, 67.7%; Figure 3).

**Figure 3.** Distribution of reasons providers are unable to find or not willing to recruit a sufficient number of pregnant and lactating women participants in vaccine trials from the survey respondents' perspective.



"Low levels of health literacy or lack of health care provider recommendations or uncertainty on the impact on their health condition" (55/65, 84.6%), "lack of awareness and communication of research options" (52/65, 80%), and "low levels of trust toward health care, health care professionals, vaccines and/or vaccine development process" (48/65, 73.8%) were the main reasons why pregnant and lactating women are not participating in vaccine trials (Figure 4).

XSL•FO
RenderX

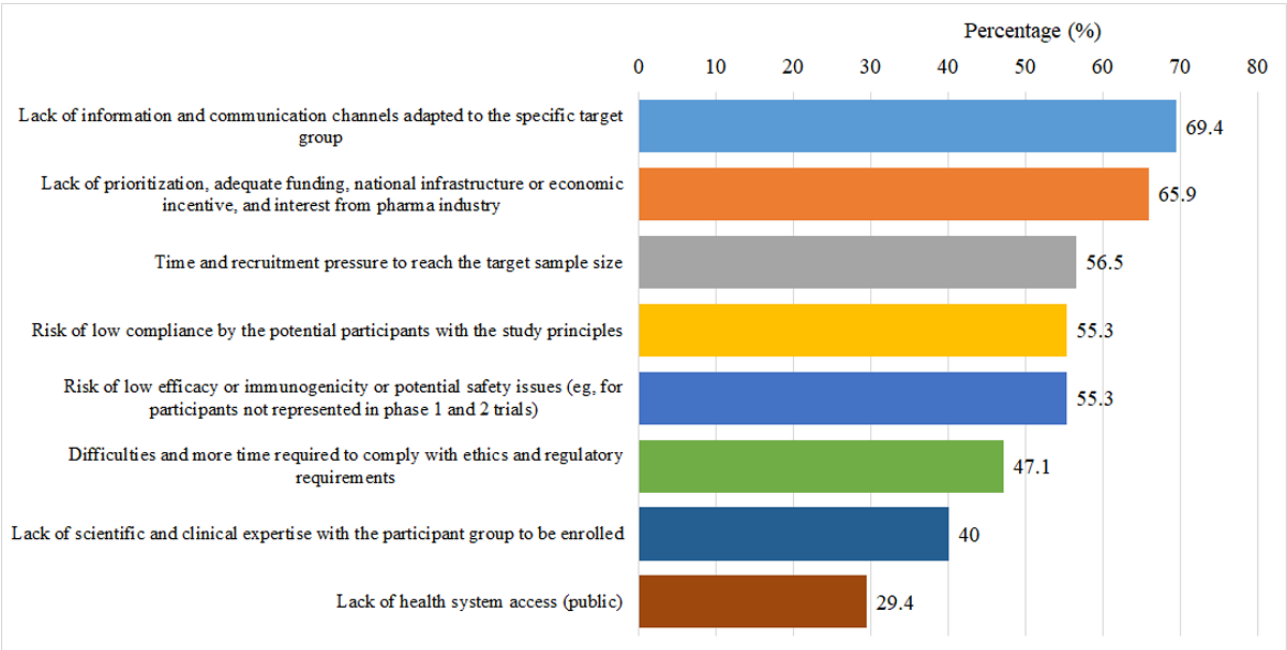


**Figure 4.** Distribution of the main reasons that pregnant and lactating women are not participating in vaccine trials from the survey respondents' perspective.

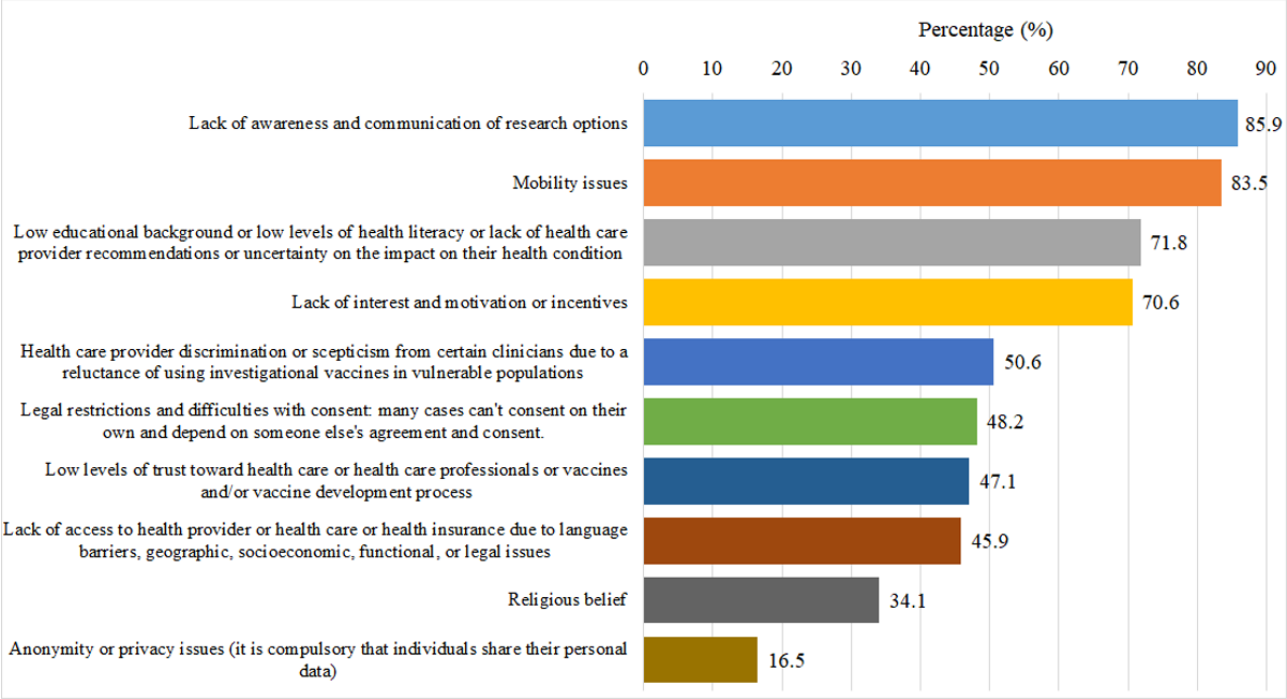
### *Older Population*

Figure 5 depicts the challenges in recruiting older adult participants. The 3 most frequent challenges were "lack of information and communication channels adapted to the specific target group" (59/85, 69.4%), "lack of prioritization, adequate funding, national infrastructure, or economic incentive and interest from pharma industry" (56/85, 65.9%), and "time and recruitment pressure to reach the target sample size" (48/85, 56.5%).

**Figure 5.** Distribution of reasons providers are unable to find or not willing to recruit a sufficient number of older adult participants in vaccine trials from the survey respondents' perspective.



The main barriers for which older adults are not participating in vaccine trials were "lack of awareness and communication of research options" (73/85, 85.9%), "mobility issues" (71/85, 83.5%), and "low educational background, low levels of health literacy, lack of health care provider recommendations or uncertainty on the impact on their health condition" (61/85, 71.8%; Figure 6).

XSL•FO
RenderX

**Figure 6.** Distribution of the main reasons that older adults are not participating in vaccine trials from the survey respondents' perspective.

### *Reported Facilitators in Recruiting Certain Population Groups in Vaccine Trials*

The responses to the free-text question asking about how to improve equal access or improved representation in COVID-19 vaccine trials were mainly segregated into 5 categories: access and participation, collaboration and trust, information and communication, safety and compensation, and others. Factors that would motivate the participation in vaccine trials or studies are presented in Table 5.

**Table .** Distribution of the domains from the perspective of the survey respondents that motivate the participation of volunteers in a volunteer registry for vaccine trials or studies.

| Motivation for participation | Values, n (%) |
|---|---|
| Provision of health-related incentives (including access to new treatments, getting expert medical care) | 82 (71.3) |
| Provision of monetary incentives | 59 (51.3) |
| Rapid access to disease-specific related information (eg, COVID-19 or Monkeypox) | 64 (55.7) |
| Personal empowerment for active participation in the fight against an urgent public health threat | 70 (60.9) |
| Sharing an opinion that influences the design of trials or studies | 43 (37.4) |

## Discussion

The recent COVID-19 pandemic demonstrated that new vaccine development against an emergent pathogen can prevent the loss of millions of people, restore the livelihoods of communities, and ensure safe travel. However, real-life evaluation of vaccine efficacy can be challenging due to the difficulties of recruiting different segments of the population and ensuring representation of the wider community with different sociodemographic characteristics. We have shown from the professionals' perspective that recruitment of children, pregnant and lactating women, and older adults had specific challenges that required tailored approaches.

Unfortunately, there has been limited exploration of these challenges in vaccine trials from the perspective of other professionals to compare with the perspectives of our cohort. This is indeed one of the strengths of this study to provide novel findings where there is a knowledge gap. Studies have either explored the challenges based on race or ethnicity and primary language [20,21] or challenges in therapeutic trials such as cancer trials [22]. Therefore, we can only comment on the findings of other studies that report on the reflections of participants (either themselves or the caregivers of participants).

Recently, Meskell et al [23] published a Cochrane review on the factors that influence an individual's choice to participate in a vaccine trial during a pandemic or epidemic. The trial team emerged as a significant factor, impacting how trial information was conveyed, the design of the trial for participant convenience, the provision of financial incentives, and access to additional support services. Personal considerations also played a role, including concerns regarding vaccine side effects, efficacy, and

XSL•FO
RenderX

potential effects on daily life. Personal incentives encompassed access to vaccines, enhanced health outcomes, improved disease understanding, and the easing of pandemic or epidemic restrictions. Societal benefits included community assistance and contribution to scientific progress, often driven by memories of families and friends lost to the disease. Family and societal influences were also influential in potential participants' decision-making processes. In another study, public information about COVID-19 vaccines and vaccine trials in Europe was compiled from official sources (eg, governments, public agencies, and nongovernment organizations). While information for the public was abundant across Europe, there was a large variation in number, type, and target audiences for the information among countries. Notably, little or no information was found for population groups that are typically underrepresented in vaccine clinical trials [12].

In this study, we surveyed professionals with expertise in vaccines or vaccinations to understand, for each underrepresented group, (1) the reasons why the providers are unable to find or unwilling to recruit participants from the underrepresented groups in vaccine trials and (2) the reasons why the individuals from the underrepresented groups are not participating in vaccine trials. The challenges in recruiting children and pregnant and lactating women were mainly shaped around "safety or efficacy concerns," "difficulties about ethics and regulatory issues," and "lack of targeted information and communication." A rising threat of vaccine hesitancy among parents can be shaped around safety concerns. Caudal et al [24] illustrated that primary concerns revolved around vaccine adjuvants, the potential for short- and long-term adverse effects, and the risk of developing a disease or disability due to vaccination. Detoc et al [25] disclosed from the participant's point of view that having a favorable opinion about vaccines was the only independent factor associated with agreement to enroll in a preventive vaccine trial. Acceptance of participation in vaccine trials was closely linked to a generally positive attitude toward vaccines. Notably, information provided by physicians was pivotal in the decision-making process for 70.2% of those who accepted participation. Similarly, parents whose children participated in the phase III clinical trial of the Oral Cholera Vaccine—Simplified disclosed logistical issues, costs, misinformation, and concerns about trial procedures and potential side effects as the major barriers [26]. Vaccine hesitancy poses a potential obstacle to recruitment in vaccine trials; therefore, enhancing altruism and ensuring the quality of information provided are crucial factors in fostering acceptance of participation in such trials.

Meanwhile, the reasons why children and pregnant and lactating women are not participating were mainly stated around "lack of awareness and communication," "inadequate understanding and uncertainty," and "trust issues." Social capital, defined by Putnam, refers to "features of social organization such as networks, norms, and trust, that facilitate coordination for mutual benefit" [27]. Terraneo et al [28] found an association between social capital and the inclination to participate as volunteers in COVID-19 vaccine trials. These results may also be pertinent in encouraging parents and pregnant women to engage in vaccine trials. At the same time, fine-tuning the ethical and regulatory processes may not only accelerate recruitment but also help the sponsors to design trials that are not excluding these population groups right at the beginning. Interestingly, survey respondents stated "health care provider discrimination or skepticism due to a reluctance of using investigational vaccines" as a challenge in recruiting pregnant and lactating women, which corresponds to a lack of scientific and clinical knowledge not only among underrepresented populations but also among the health care providers. Upskilling the health care providers about vaccines and vaccinology or seeking researchers with expertise in pregnancy would be helpful to motivate the participation of pregnant and lactating women in vaccine trials.

Enrollment of older people has been a challenge during COVID-19 vaccine studies. However, it is crucial to ensure adequate representation of older individuals in clinical trials assessing preventive approaches to gain a comprehensive understanding of both the benefits and risks of interventions across the entire population. "Lack of information and communication channels adapted to the specific target group'' was especially apparent as the main challenge in recruiting older adult participants. A French digital national platform, namely Covireivac, was set up in June 2020 [29]. An analysis of this registry underscored that computer-based recruitment methods might not be suitable for older individuals, despite the presence of a toll-free hotline and third-party registration options on the platform [30]. Conversely, in Germany, following public announcements regarding a planned phase I trial of the vaccine candidate MVA-SARS-2-S against SARS-CoV-2, volunteers successfully reached out to the study team via email. Remarkably, one-third of these volunteers were aged older than 60 years [31]. These data show that effective and culturally tailored combinations of communication strategies can increase the participation of volunteers among older age groups.

Among the main reasons why older adults are not participating in trials from the health care professionals' perspective were also "lack of awareness and communication" and "low levels of health literacy" similar to the previous groups. However, a new challenge, "mobility issues," was added as a challenge specific to this target group. Frailty among the older adults not only impacts mobility but also the ability to engage, and this may pose a significant barrier. Limited mobility and lack of social support for older adults may be one of the most important challenges in their participation in clinical trials but also the easiest challenge to overcome by careful planning and resource allocation. However, among a survey of 400 older adults living in Atlanta, Georgia, two-thirds of the participants admitted that they were willing to participate in vaccine clinical trials; however, one-third had had limitations due to physical, mental, or emotional problems [32]. The need to travel to the clinical research site was also salient as a barrier.

Provision of health-related incentives, including but not limited to access to new treatments and receiving expert medical care, seems to be the top-rated motivation for volunteers to participate in COVID-19 vaccine trials. However, it should also be considered that monetary incentives, in particular, might lead to an overrepresentation of financially disadvantaged groups [33].

XSL•FO
RenderX

Heterogeneous results with regard to the barriers for different underrepresented population groups demonstrate the need for tailored policies for each group. Andrasik et al [34] suggest that all clinical research sites are required to have active community advisory groups with clear lines of communication to clinical research site staff and leadership. To align all the stakeholders in vaccine development and implementation studies on the same agenda, the gap between the scientific community, public health community, and the policymakers should be closed. Hence, to convert the outputs of this task into societal impact, the results will be shared with diverse groups of stakeholders who play a role in vaccine studies. This can help to overcome some of the obstacles to enroll underrepresented population groups in clinical vaccine studies just by fine-tuning the processes such as ethics and regulatory processes.

The first limitation of the study was the narrower assessment of the underrepresented populations, focusing only on children, pregnant and lactating women, and older adults, while omitting other underrepresented groups (eg, socioeconomically disadvantaged populations, ethnic minorities, migrants, or individuals with disabilities). Another limitation was the fact that the extended survey was addressed to a very specific target population, that is, professionals with hands-on experience in vaccines and/or vaccinations. Given the lack of a systematic measurement of these professionals across countries, we could not perform representative sampling. Furthermore, we did not assess the perceptions of the patients or trial participants themselves. Future studies should elaborate on our findings and exhaustively explore means to reach results from more diverse and representative samples. A possible direction toward this goal is communication with national and international professional and expert organizations. Another limitation is that the survey covered responses from 23 countries, although Turkey, Sweden, and Greece (29, 16, and 10 respondents, respectively) constituted 47.8% of the represented countries. Most of the responses reflected the personal, not institutional, views of the respondents. Moreover, 81.7% (94/115) of the respondents were either from the scientific or public health community (73/115, 63.5% and 21/115, 18.3%, respectively), indicating the gap in the countries and the professional groups that could be reached. However, there was relatively good representation in terms of geographical regions and the population groups with which the survey respondents work, although the results cannot be generalized beyond Europe. Finally, we have used different response options instead of string responses for each underrepresented group in the survey for the sake of a quantitative descriptive analysis, but this might have been a potential source of bias as a few of the response options were not identical across groups. The responses should be interpreted as insights from experts in the vaccine field rather than reflections of trial participants. The results can therefore not directly point out the perspectives of participants from underrepresented populations but rather guide the design of future studies to get personal insights from these populations.

In conclusion, the major challenges stated by the providers for recruiting pregnant and lactating women and children were around safety or efficacy concerns and difficulties, and more time required to comply with ethics and regulatory requirements. On the other hand, the major challenges in recruiting participants from the older population were the lack of information and communication channels adapted to the specific target group and lack of prioritization, adequate funding, national infrastructure, or economic incentive and interest from pharma industry. While the lack of awareness and communication of research options was a common major perceived barrier for the participation of all the underrepresented groups, mobility issues emerged as another prominent factor for the older people. Lack of interest and motivation or incentives was another major perceived barrier for the children, while low levels of health literacy or lack of health care provider recommendations or uncertainty on the impact on their health condition were highlighted for the pregnant and lactating women. Improvement in communication infrastructure and channels to convey effective, easy-to-understand, and tailored messages to build trust in vaccines and convey the research options to motivate people to participate in vaccine trials seems to be a crucial step to increase the participation of the underrepresented groups.

## Acknowledgments

This work is presented on behalf of the VACCELERATE consortium [18]. The authors declare that no generative artificial intelligence tools were used in any portion of the manuscript preparation.

## Funding

This work was supported by the European Union Horizon 2020 research and innovation program under grant 101037867 (VACCELERATE). The research leading to these results was conducted as part of the VACCELERATE consortium. For further information, please refer to the official website of the VACCELERATE network (https://vaccelerate.eu/).

## Data Availability

The dataset is available from the authors upon reasonable request.

## Authors' Contributions

Conceptualization: ZDP, DP, GCT, OAC, and IK
Data curation, preparation of stakeholders' list: all authors
Formal analysis: MDT

## Abstract

**Background:** Many patients have been treated by physical therapists after an infection with COVID-19. The policy changes and unique situation of the COVID-19 pandemic necessitate a retrospective analysis.

**Objective:** This study examined physical therapy provision for adult patients recovering from COVID-19 in primary care in the Netherlands over the first 2.5 years of the pandemic. The primary aim was to examine changes in the amount of health care provision and associated factors. Furthermore, we aimed to gain insight into the patient population and changes over time, as well as the use of advised outcome measures in physical therapy after COVID-19.

**Methods:** We conducted a retrospective cohort study using routine health care data from the electronic health records of physical therapy practices in Dutch primary care. In total, 71,152 COVID-19 treatment trajectories initiated between March 1, 2020, and December 18, 2022, were included. Multilevel generalized linear mixed model analyses examined changes over time in the patient population and in the amount of physical therapy within treatment trajectories (ie, duration in weeks and number of consultations). Outcome measures were analyzed using descriptive statistics.

**Results:** Completed treatment trajectories had an overall duration of 24 weeks with 28 consultations, with a decreasing trend in the amount of physical therapy provided over time ($P$<.001). Also, a parabolic effect of age ($P$<.001) was found, showing a maximum number of consultations and duration of the treatment trajectory among older patients aged 60 to 79 years, with smaller quantities for younger and older patients. Treatment trajectories for women were 1.5 weeks longer than those for men (β 1.5, SE 0.12; $P$<.001) but did not include more consultations ($P$=.76). In 83% (59,184/71,152) of treatment trajectories, a baseline score on at least one of the included advised outcome measures was registered. Median (IQR) baseline scores were 420 (340-490) m on the 6-minute walking test (n=27,035); 13 (10-17) seconds on the 5-times sit-to-stand test (n=2337); 5.8 (5 - 6.3) points on the Fatigue Severity Scale (n=995); 8 (7-10) points on the Patient-Specific Functional Scale (PSFS; n=55,074); 10 (9-12) points on the Short Physical Performance Battery (n=4665); and 29 (22-38) and 30 (24-40) kg of grip strength, respectively, on the left (n=12,306) and right (n=12,293) hand. Difference scores could be examined for the 6-minute walking test, grip strength, and the PSFS.

**Conclusions:** This study demonstrates the potential of routinely collected health care data to describe real-world physical therapy provision for COVID-19 in Dutch primary care. Patients showed severe perceived fatigue, reduced functional capacity, and lower-limb strength at the start of physical therapy. The amount of physical therapy declined over the first 2.5 years of the pandemic, differed by age and gender, and was generally lower than the amount reimbursed by the Dutch government through basic health insurance.

## Introduction

Since the start of the SARS-CoV-2 pandemic in early 2020, millions of people have contracted COVID-19 [1]. Patients who were admitted to the hospital could develop acute respiratory distress syndrome, muscle weakness, or post–intensive care syndrome [2-4]. Furthermore, it is estimated that between 3% and 6% of people continue to experience symptoms beyond the acute phase of the infection, known as postacute COVID-19 syndrome [5-8]. Common persistent symptoms include fatigue, dyspnea, memory problems, posttraumatic stress disorder, sleep disorders, anxiety, depression, and joint pain [9-11], substantially impacting general health, activities of daily living, quality of life, and working capacity of patients [9,12-14]. Considering the impact of COVID-19 and postacute COVID-19 syndrome on motor and cognitive functions, many patients have been treated by allied health care providers, mostly by physical and exercise therapists (hereafter, physical therapists) [15]. Physical therapists play an important role in supporting respiratory function, guiding active mobilization, ensuring a good load vs load capacity [16], and providing therapy for impairments in movement-related functioning affecting daily activities or participation [17].

Therefore, a temporary policy change was introduced in the Netherlands during the early months of the pandemic to enhance the accessibility to physical therapy after a COVID-19 infection under certain conditions [18]. Usually, in the Netherlands, physical therapy is included in the obligatory basic health insurance package only for a selection of diagnoses. Physical therapy for other diagnoses is paid out-of-pocket or reimbursed through voluntary supplementary health insurance. As of July 18, 2020, basic health insurance temporarily covered up to 50 physical therapy sessions for patients with COVID-19 over a 6-month period, with the option for a medically justified extension [18]. Furthermore, as COVID-19 was a new condition, treatment guidelines had to be developed based on the experiences of the first patients with COVID-19 and the opinions of experts. Over time, many studies have provided more insight into the biological and clinical aspects of the condition, and several adjustments to treatment guidelines were made [17]. However, it is not known how the policy regarding physical therapy for COVID-19 in primary care and the changing circumstances over time influenced the physical therapy use of patients with COVID-19. With such policy changes and unique circumstances, it is necessary to look back at how this was handled in order to learn from them and increase future pandemic preparedness.

Therefore, the overall aim of this study was to gain insight into the real-world physical therapy provision for adult patients recovering from COVID-19 in Dutch primary care over the first 2.5 years of the pandemic. In the Netherlands, several registries are available that receive routine health care data from the electronic health records (EHRs) of primary care physical therapy practices. Data from these registries can be used to build a retrospective cohort of the patients who sought physical therapy for symptoms of COVID-19, using real-world data. These data therefore offer the opportunity to look back on the period of the COVID-19 pandemic and learn from it. More specifically, the primary aim of this study was to examine the amount of physical therapy provided for patients after a COVID-19 infection over time and to identify which factors (ie, patient characteristics and course of the pandemic) were associated with it. The second aim was to provide insight into changes over time in the patient population starting with physical therapy after COVID-19 and in the clinical profile of these patients. The final aim was to examine the use of outcome measures as recommended in Dutch guidelines concerning physical therapy for COVID-19 [17].

## Methods

### Study Design and Setting

This retrospective cohort study was set up as part of a greater nationwide project in the Netherlands to evaluate the recovery of patients receiving allied health care treatment in primary care practices after a SARS-CoV-2 infection, the ParaCOV study (The Dutch Consortium Allied Healthcare COVID-19) [19]. Routine health care data from EHRs collected in the databases of (1) Nivel, the Netherlands Institute for Health Services Research, Primary Care Database (Nivel-PCD) [20], (2) the Dutch National Data Registry (in Dutch: LDK) of the Dutch Association for Quality in Physical Therapy (in Dutch: SKF), (3) the National Registry Exercise Therapy (in Dutch: LDO), and (4) the National Physical Therapy Database (in Dutch: LDF) of the Royal Dutch Society for Physical Therapy (in Dutch: KNGF) were combined. Together, these databases contain information on approximately 1 million unique patients receiving physical therapy in primary care for a broad range of diagnoses. The data in these registries are structured in the same way, enabling a smooth process of combining the datasets. To avoid duplicates, data from physical therapy practices affiliated with data collection via Nivel (Nivel-PCD, LDK, and LDO), which are all collected via the same route, were used as a starting point and supplemented with data from nonoverlapping practices affiliated with LDF. To define comorbidities (see *Outcomes*), data from approximately 500 general practices collected in Nivel-PCD, covering around 10% of the Dutch population, and the Nivel-PCD physical therapy practices were linked for the subset of patients for whom information was available in both of these databases.

### Ethical Considerations

Data collected for the registries were pseudonymized at the source (within the practices), leaving out direct identifying information such as names and address. This study has been approved in accordance with the governance code of Nivel-PCD under number NZR-00322.046. The use of EHRs for research purposes is allowed under certain conditions. When these conditions are fulfilled, neither obtaining informed consent from patients nor approval by a medical ethics committee is obligatory for this type of observational study containing no directly identifiable data (Art 24 GDPR [General Data Protection Regulation] Implementation Act jo art 9.2 sub j GDPR [21]).

### Cohort

In the EHRs of physical therapists, data on the provided care and accompanying information are registered per patient and

XSL•FO
RenderX

per diagnosis in a so-called treatment trajectory, wherein the diagnosis is registered using the diagnostic code for allied health care professionals (DCSPH-code [22]). Inclusion criteria for the cohort of physical therapy treatment trajectories in this study were (1) DCSPH-code 9363 (ie, COVID-19); (2) starting March 1, 2020, or later; (3) consisting of at least 2 consultations, that is, registered contacts on separate dates (see also *Outcomes*); and (4) adult patients (18 y and older). Physical therapists were only allowed to use this diagnostic code when a patient had a referral from a general practitioner or medical specialist indicating that the patient was in need of physical therapy after a COVID-19 infection. Data were available up to February 20, 2023. However, to reduce the chance of missing treatment trajectories based on not yet available data in the respective databases and to avoid the drop in starting treatment trajectories over the Christmas holidays, only treatment trajectories starting the latest on December 18, 2022, were included in the final cohort.

Additionally, the study period was divided into start weeks, running from Monday to Sunday, with March 1, 2020, falling into start week 1 and the week of December 12 to 18, 2022, being the last start week (start week 147). Each treatment trajectory was assigned to the week in which that treatment trajectory started, based on the date of the first consultation.

The amount of physical therapy provided can only be analyzed on treatment trajectories that have ended. Therefore, for those analyses, a subset of treatment trajectories was defined. A treatment trajectory was defined as being closed when the therapist registered it as such or when there had not been a consultation for more than 60 days. Based on the median duration of closed treatment trajectories in the full dataset, treatment trajectories starting in the last 22 start weeks of the final cohort were excluded to minimize the effect of including only shorter closed treatment trajectories near the end of the data collection. Therefore, this subset consisted of closed treatment trajectories starting the latest in start week 134 (September 18, 2022).

Data are provided per treatment trajectory, and the assumption was made that all treatment trajectories could be assigned to individual patients (as 95.4%, 64,668/67,825 of patients had only 1 registered treatment trajectory over time).

## Outcomes

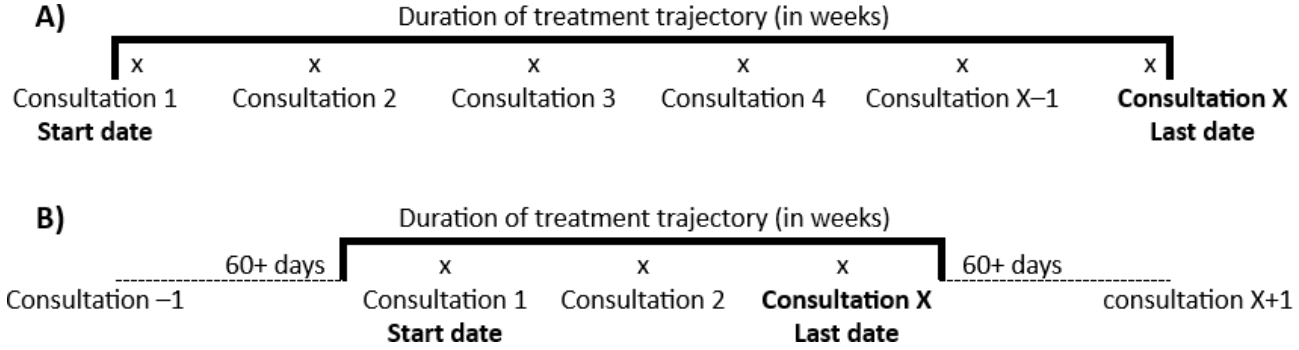
### *Patient Characteristics*

Patient characteristics, such as “age,” “gender,” “duration of symptoms,” and “number of comorbidities,” were collected at the start of treatment. “Duration of symptoms” was registered by the physical therapist at the start of the treatment trajectory and refers to the duration in weeks from the start of the symptoms to the first visit of the patient at the physical therapist in three categories: (1) first visit within 0 to 2 weeks, (2) first visit within 3 to 12 weeks, and (3) first visit more than 12 weeks after the start of the symptoms for which the patient visits the physical therapist. The number of comorbidities (0, 1, or more than 1) was defined for the subset of patients for whom data were available from (1) Nivel-PCD general practices and/or (2) registered outcome measures in the treatment trajectory. Per treatment trajectory, it was determined whether the patient was registered as having diabetes, obesity, heart failure, cardiovascular diseases and hypertension, chronic pulmonary disease, chronic kidney damage, and liver disease, in at least one of the data sources, or none of those comorbidities in either source. See Multimedia Appendix 1 for the definition of the comorbidities.

### *Population Characteristics*

The subtype of the SARS-CoV-2 infection was unknown at the individual patient level but was preassigned to each treatment trajectory based on the most dominant virus subtype at the population level 9 weeks before the treatment start. The most dominant virus subtype was defined as the virus type that had the highest percentage of patients in that week, according to the Dutch National Institute for Public Health and the Environment (in Dutch: RIVM [23]). A delay of 9 weeks before the start of the treatment trajectory was chosen based on the median time between the start of the infection and the start of the physical therapy treatment trajectory, as defined in the data from the national prospective cohort study on allied health care in patients recovering from COVID-19 [19].

### *Amount of Health Care Provision Per Treatment Trajectory*



The provided health care per treatment trajectory is registered as so-called care products. A consultation was defined as a date with a registered care product within the treatment trajectory, irrespective of the number of care products registered within the treatment trajectory on that specific date. For example, when 2 care products (eg, an “intake” and “treatment”) for a patient were registered on the same date in the same treatment trajectory, this counted as one consultation. Based on this, the variables were defined as follows (Figure 1):

- Start date: The first date in the treatment trajectory with a consultation (Figure 1A). An exception was made for treatment trajectories in which there was a gap of more than 60 days between the first and second consultations, while after the second consultation, there were more consultations within less than 60 days. In that case, the second consultation was taken as the start date of the treatment trajectory, assuming that the actual treatment started then (Figure 1B).
- Last date: The last date in the treatment trajectory with a consultation (Figure 1A), unless there was a gap of more than 60 days since the penultimate consultation, while the penultimate consultation was part of a streak of consultations (Figure 1B). Here, the assumption was made that a sole registered care product after 60 days was not part of the actual treatment but had more administrative or aftercare reasons.
- Duration of the treatment trajectory: The number of weeks between the assigned start date and the last date of the treatment trajectory (the bold line in Figure 1).
- Number of consultations: The number of consultations within the determined treatment trajectory. In the final cohort, only treatment trajectories consisting of at least 2 consultations were included.

XSL•FO
RenderX

**Figure 1.** Visualization of determined variables regarding physical treatment trajectories for COVID-19: start date, last date, number of consultations within, and duration in weeks of a treatment trajectory. The treatment trajectory is determined based on the registered consultations. The first consultation defines the start date and the last consultation, the last date of the treatment trajectory (A), in which first and last consultations that are separated by at least 60 days from the respective next and previous consultations are not considered (B). The duration of the treatment trajectory and the number of consultations within it are the number of weeks between the start date and last date (bold line) and the total number of consultations (consultation X).

### *Outcome Measures*

Many different outcome measures can be registered in the EHRs and sent to registries [24]. Therefore, a selection of outcome measures was based on a combination of the position statement provided by the KNGF [17], guidelines for physical therapists provided by the ParaCOV-consortium [19], and data availability in the registries [25]. This concerned 4 functional therapist-assessed outcome measures and 2 patient-reported outcomes. The 5-times sit-to-stand test (5TSTS) was recommended for functional strength. In the 5TSTS, the patient is asked to get up and sit down in a chair 5 times in a row as fast as possible without using their hands [26]. The 6-minute walking test (6MWT) and Short Physical Performance Battery (SPPB) were (optionally) recommended for functional capacity. The 6MWT measures the maximum distance a patient can walk within 6 minutes [27]. The SPPB consists of 3 parts: balance, gait speed, and 5TSTS, on which 0 to 4 points can be scored [28]. The 5TSTS is performed as described above, and the gait speed task consists of walking 4 meters at a normal pace; in both subtasks, the time is recorded and scored. The balance tests include, in this particular order, side-by-side stand, semitandem stand, and tandem stand. Grip strength was recommended to be measured with a hand-held dynamometer as an indicator of overall upper-body strength [29].

Patient-reported outcomes were the Fatigue Severity Scale (FSS) for patient-reported fatigue [30] and the Patient-Specific Functional Scale (PSFS) for functional status [31]. In the PSFS, the patient is asked to rate the extent to which they feel limited in 3 self-selected activities that are most important to them. These activities should, according to the patient, be (1) relevant, (2) limiting performance, and (3) regularly performed (at least weekly). Here, the first one registered was taken as an outcome.

Lastly, the Global Perceived Effect (GPE) was also included as a measure of the perception of the patient regarding recovery and/or satisfaction with the treatment [17,32].

Measurements were considered to reflect baseline data when registered in the period from 2 weeks before the start date, as defined above, until 1 week (for treatment trajectories with a duration of 2 - 4 wk) or 2 weeks (minimum duration of 5 wk) after the start date. Similarly, measurements were considered to reflect the posttest when registered in the period from 1 to 2 weeks, depending on the duration of the treatment trajectory, before the last date of the treatment trajectory until 2 weeks after the last date. Difference scores were calculated for each outcome measure by comparing baseline and posttest values, when at least 1000 treatment trajectories were registered with that outcome measure. The threshold of 1000 treatment trajectories was set arbitrarily to ensure a substantial sample size, given the secondary use of the data over an extended study period. If grip strength of both hands was measured, the difference score on the hand with the greatest difference score was used.

## Analysis

All data preparation and descriptive analyses were conducted in Stata (version 16; StataCorp LLC). Missing values were not imputed, and the significance level was set at 0.01, given the considerable size of the dataset. Descriptives of the total cohort were assessed by providing means and SDs, or frequencies and percentages, as appropriate. Statistical analyses were conducted in MLwiN (Centre for Multilevel Modelling, University of Bristol).

### *Patient Population Starting Physical Therapy for COVID-19 Over Time and Clinical Profile*

Multilevel generalized linear mixed model analysis was conducted to examine the patient population starting physical therapy within the cohort over time (relative incidence). Defined levels were physical therapy practices, patients, and start week.

Relative incidence was determined as the proportion of treatment trajectories starting per age subgroup and gender subgroup in that start week, compared to all starting physical treatment trajectories for COVID-19 in primary health care in the Netherlands in the first 2.5 years of the pandemic. Notably, it does not give the incidence of patients starting physical therapy for COVID-19 in the Dutch population, as there is no underlying population available in the registries for persons who did not attend an associated physical therapy practice. In the multilevel analysis for relative incidence, the dichotomous incidence outcome was analyzed as logistic regression, and all start weeks (weeks 1 to 147 [March 1, 2020, to December 18, 2022]) in the final cohort were included. Gender (man and woman), age (18 - 39, 40 - 59, 60 - 79, and >80 y), and time (centered around the midpoint of the time range) as a polynomial of the

XSL•FO
RenderX

third-order (to capture the nonlinear curve over time) were combined. The combination of gender and age (8 categories in total) estimated a separate time effect for each of the 8 categories. Virus type (ie, original Wuhan, Alpha, Delta, and Omicron) was included as a fixed effect.

To examine the clinical profile of patients at the start of the treatment trajectory, the median and IQR of baseline scores on the selected outcome measures were examined.

### *Changes in Physical Therapy Provision for COVID-19 Over Time*

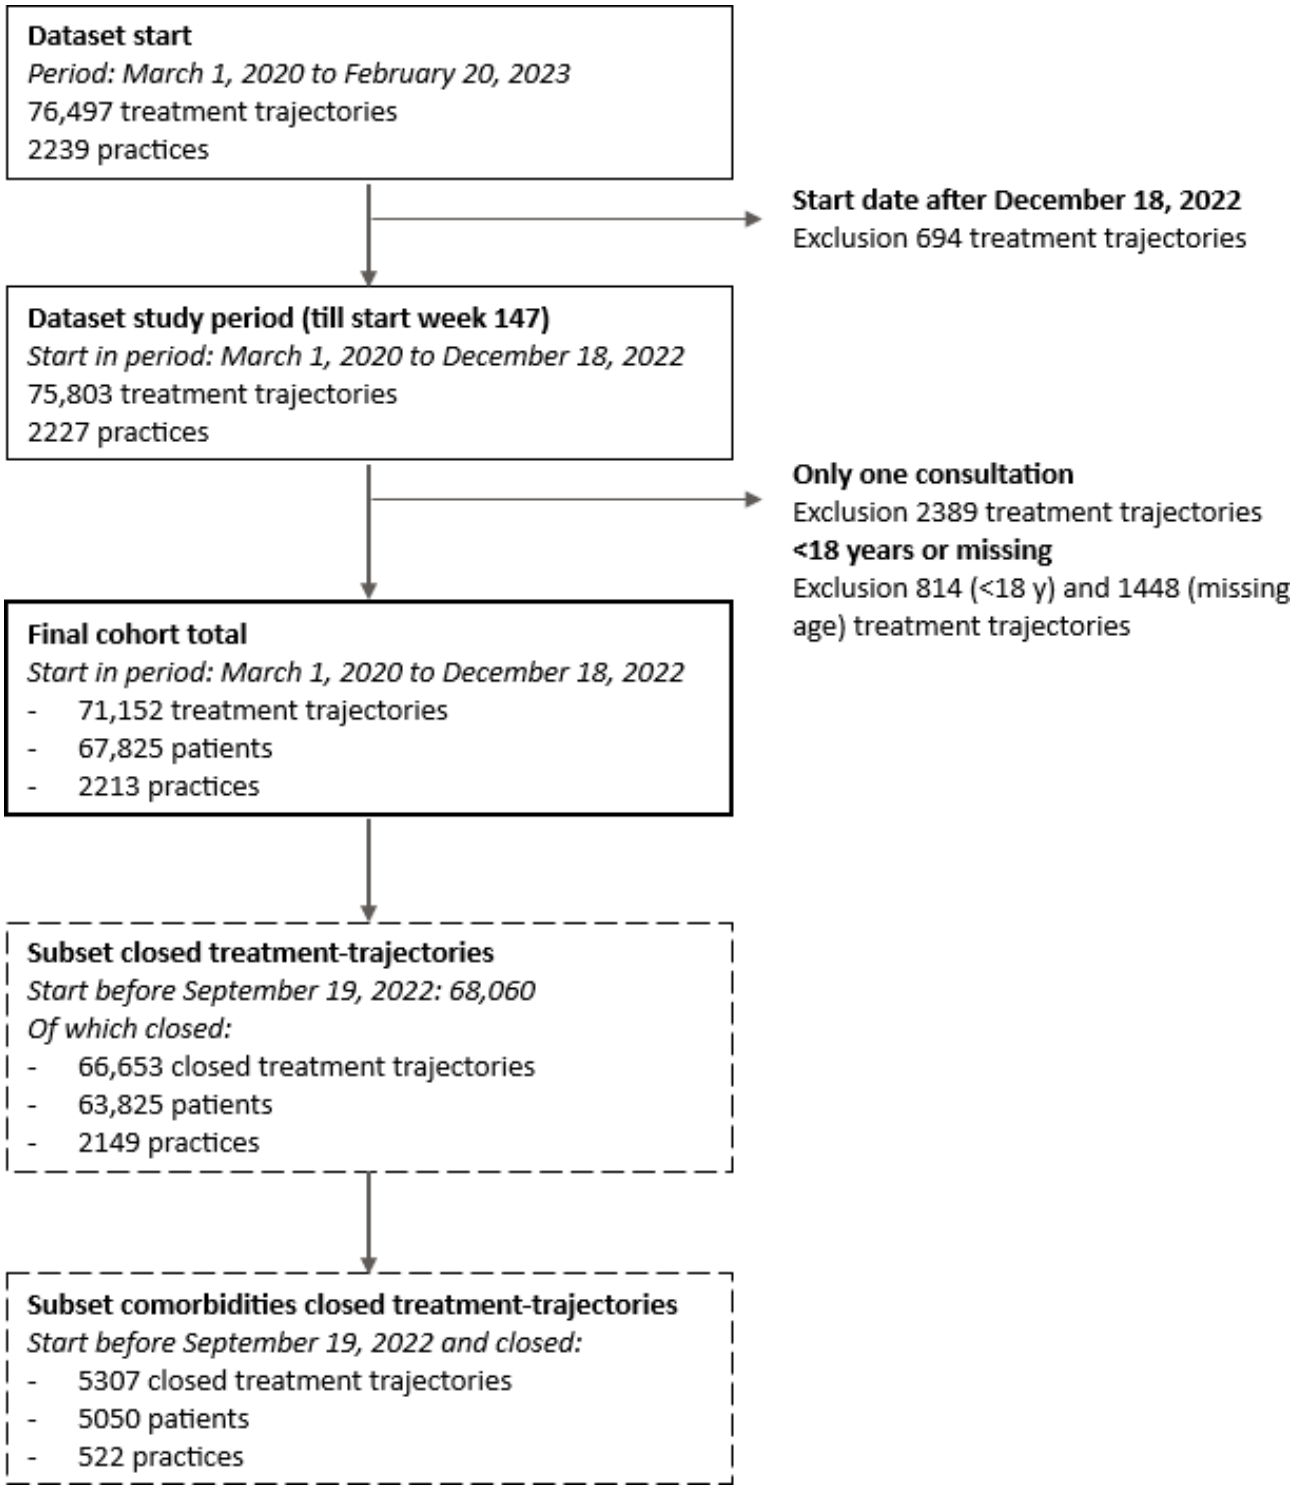
Multilevel generalized linear mixed model analyses were also executed to examine the amount of physical therapy provided over time by (1) the number of consultations within closed treatment trajectories and (2) the duration of closed treatment trajectories in weeks. The defined levels were physical therapy practices, patients, and start week.

The variables for the amount of physical therapy provided, that is, the number of consultations in and the duration in weeks of a treatment trajectory, were analyzed as normal regressions on the subset of closed treatment trajectories. In these multilevel analyses, only closed treatment trajectories with start weeks 1 to 134 (March 1, 2020, to September 18, 2022) were included. In these 2 models, gender, age, and virus type were included as fixed effects. The same multilevel analyses were conducted on the subset of closed treatment trajectories wherein the number of registered comorbidities could be determined, while including the number of comorbidities (0, 1, and >1) as a fixed effect.

### *Use of Recommended Outcome Measures*

Analyses of the use of recommended outcome measures were performed on the subset of closed treatment trajectories. To examine the use of the outcome measure in the closed treatment trajectories, the percentage of treatment trajectories, including the outcome measure as a baseline measure or as both baseline and posttest, was calculated. Furthermore, the median and IQR of the scores at baseline, at posttest, and of the difference score were calculated for each outcome measure. Difference scores less than the 25th percentile minus 1.5 times the IQR or greater than the 75th percentile plus 1.5 times the IQR were treated as outliers.

## Results



### Cohort Description

Figure 2 provides a flowchart of the included treatment trajectories, and Table 1 provides the descriptives of the cohort. In the final cohort, a total of 71,152 new treatment trajectories for COVID-19 were included. Most treatment trajectories started with the original variant as the dominant virus type (n=21,564, 30.3%), followed by Omicron (n=18,611, 26.2%), Delta (n=16,982, 23.9%), and Alpha (n=13,995, 19.7%) variants. In one of the treatment trajectories, the gender of the patient was missing. A total of 66,653 treatment trajectories were considered closed and thus included in the specific analyses of the number of consultations in, and the duration of, closed treatment trajectories (Figure 2). For the subset of closed treatment trajectories of patients for whom comorbidities could be determined (n=5307), 65.3% (n=3466) had no registered comorbidities, 24.0% (n=1275) had one comorbidity, and 10.7% (n=566) had multiple comorbidities.

## Patient Population Receiving Physical Therapy After COVID-19

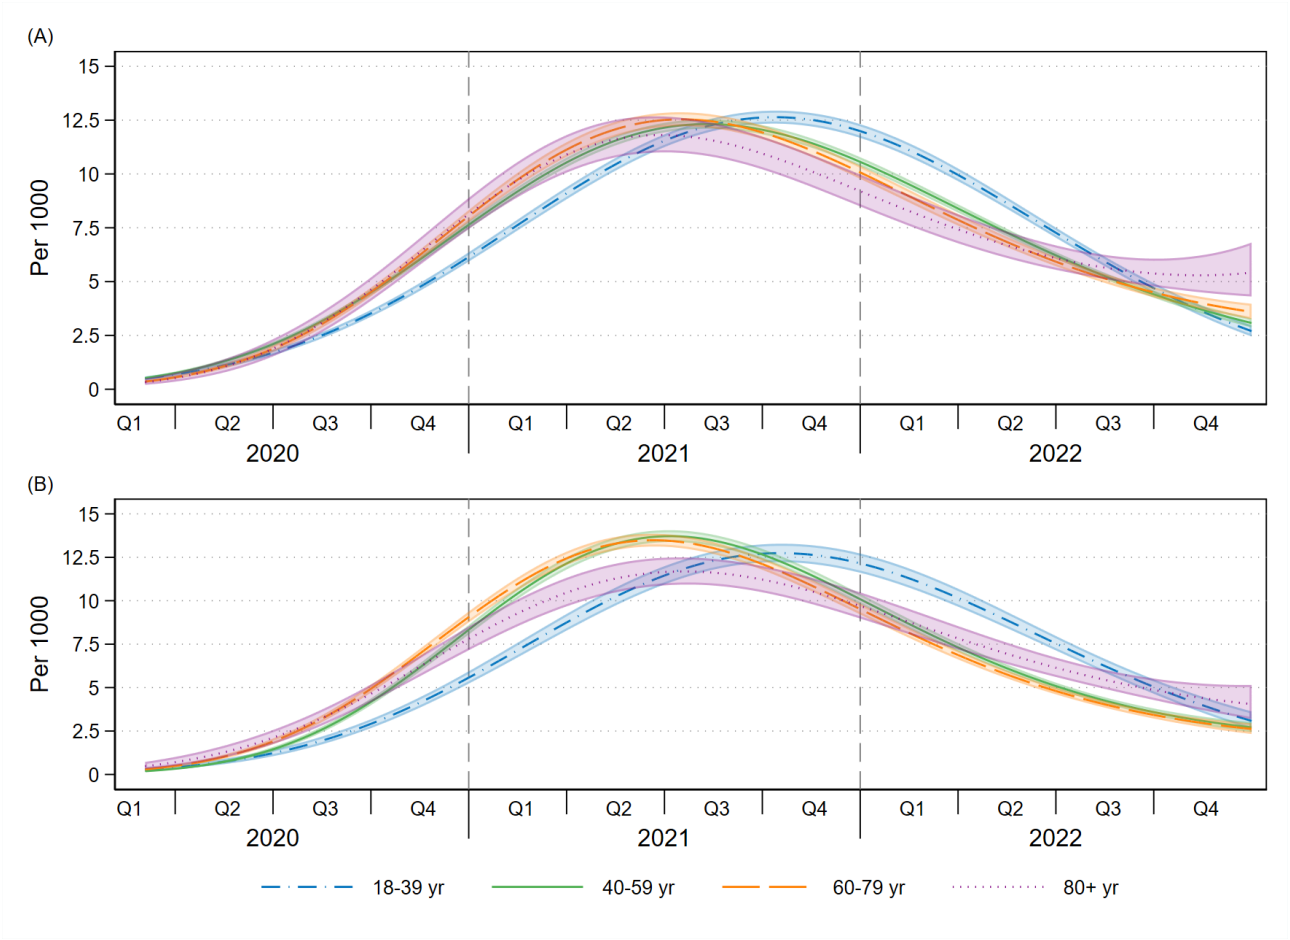

Table 1 presents the baseline scores on the outcome measures registered around the start of the physical therapy treatment trajectories for COVID-19. In 83.2% (59,184/71,152) of the treatment trajectories, at least one measurement with any of the included outcome measures at baseline was registered.

Figure 3 provides a visual representation, for women (3A) and men (3B) separately, of the relative incidence and 95% CIs of the starting treatment trajectories for COVID-19 per start week, relative to all started treatment trajectories for COVID-19 in the cohort per age category, corrected for dominant virus type at the population level (see Multimedia Appendix 2 for the model). It demonstrates a difference between the subgroups in relative incidence of starting a physical therapy treatment trajectory after COVID-19 over the first 2.5 years of the pandemic. For both men and women, the 3 older age groups (40 - 59, 60 - 79, and >80 y) show the greatest relative incidence of starting a physical therapy treatment after COVID-19 in mid-2021. For the younger age group (18 - 39 y), the peak for both women and men is in the beginning of the fourth quartile of 2021. In line with the number of treatment trajectories per subgroup (Table 1), the CIs are widest around the oldest age group (1479 treatment trajectories for women and 1562 for men) and smallest for the age groups of 40 to 59 years (22,064 treatment trajectories for women and 10,994 for men).

XSL•FO
RenderX

**Figure 3.** Relative incidence of the starting physical therapy treatment trajectories for COVID-19 in the Netherlands, included in the retrospective cohort over 2020 to 2022, per age category and per start week for (A) women and (B) men. Q: quartile.

## Amount of Physical Therapy Provided Within Closed Treatment Trajectories

Table 2 shows the models for the duration (in weeks) and number of consultations per closed treatment trajectory. Figure 4 displays these respective models per start week, with the 95% CIs. Overall, the closed treatment trajectories had a duration of 24 weeks with 28 consultations in the first 2.5 years of the pandemic, while correcting for age, gender, and dominant virus type (Table 2). A decreasing trend in duration (in weeks) and in number of consultations within the closed treatment trajectories was shown over time of the start of the treatment trajectories, thus patients who started a physical treatment trajectory for COVID-19 in 2020 generally received more physical therapy sessions than patients who started the treatment trajectory in 2022. For the duration of the treatment trajectory, the model shows a steeper decline at the start of the pandemic (year 2020), which stabilizes over 2021, and shows some decline again in 2022 (Figure 4). The number of consultations per treatment trajectory decreases more linearly over time (Figure 4).

XSL•FO
RenderX

**Figure 4.** The duration (in weeks) and number of consultations in closed physical therapy treatment trajectories for COVID-19 in Dutch primary care, per start week over the period 2020 to 2022, corrected for age, gender, and dominant virus type. Q: quartile.

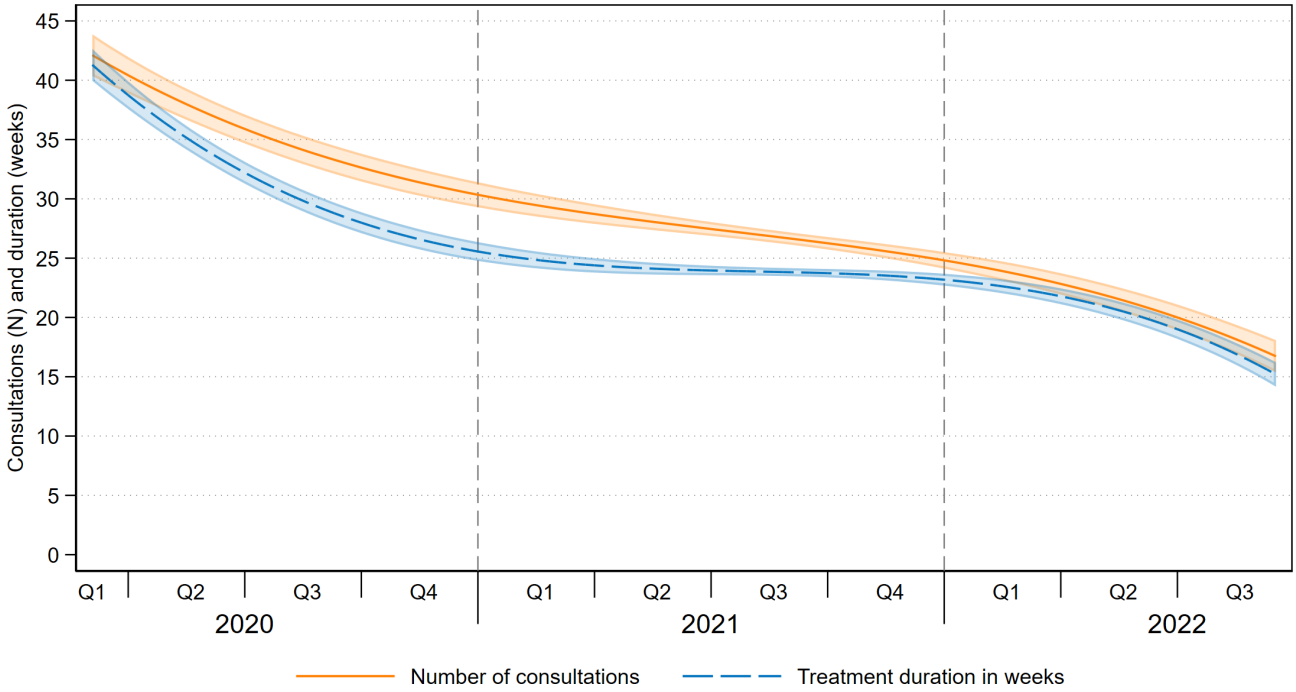

**Table .** Models for the duration (in weeks) and the number of consultations in closed physical therapy treatment trajectories for COVID-19 that started in the period 2020 to 2022 in Dutch primary care (N=66,652)[a].

| Variable | Duration (wk) | | Number of consultations | |
|---|---|---|---|---|
| | β (SE) | *P* value | β (SE) | *P* value |
| Constant | 24.0 (0.22) | <.001[b] | 27.7 (0.32) | <.001[b] |
| Time | −0.022 (0.01) | .07 | −0.092 (0.02) | <.001[b] |
| Time$^2$ | $9.1\times10^{-4}$ ($1.1\times10^{-4}$) | <.001[b] | $3.5\times10^{-4}$ ($1.5\times10^{-4}$) | .01 |
| Time$^3$ | $-4.0\times10^{-5}$ ($3.0\times10^{-6}$) | <.001[b] | $-2.3\times10^{-5}$ ($3.9\times10^{-6}$) | <.001[b] |
| Age group (y)[c] | | | | |
| 18 - 39 | −1.3 (0.15) | <.001[b] | −1.9 (0.20) | <.001[b] |
| 60 - 79 | 0.5 (0.14) | <.001[b] | 1.4 (0.18) | <.001[b] |
| >80 | −2.6 (0.30) | <.001[b] | −4.0 (0.39) | <.001[b] |
| Women[d] | 1.5 (0.12) | <.001[b] | 0.048 (0.16) | .76 |
| Alpha[e] | −0.6 (0.26) | .02 | −0.9 (0.34) | .008[f] |
| Delta[e] | −2.3 (0.53) | <.001[b] | −1.0 (0.68) | .13 |
| Omicron[e] | −3.1 (0.68) | <.001[b] | −2.7 (0.88) | .002[f] |

[a]For one patient within this selection, information on gender was missing.

[b]*P*<.001.

[c]Patients aged 40 to 59 years were the reference group for the age variable.

[d]Men was the reference group for gender.

[e]Original Wuhan virus type was the reference group for Alpha, Delta, and Omicron.

[f]*P*<.01.

Both models show a significant parabolic effect of the age categories (*P*<.001) on the amount of physical therapy provided, with a maximum among older patients aged 60 to 79 years. Overall, the duration of the treatment trajectory for patients aged between 18 to 39 years was 1.3 weeks shorter than for the reference group of patients in the 40 to 59 years age group and

XSL•FO
RenderX

1.8 weeks (1.3 plus 0.5) shorter than for the 60 to 79 years age group (Table 2). Overall, the number of consultations within a treatment trajectory was also highest for the age group of 60 to 79 years, namely 1.4 consultations higher than for the reference age group of patients (40 to 59 y) and 3.3 and 5.4 consultations higher, respectively, than for patients in the age groups 18 to 39 years and 80 years and older (Table 2). Gender was only significant in the model for the duration of the treatment trajectory, with an overall 1.5-week longer duration of the treatment trajectory for women than for men (*P*<.001).

Multimedia Appendix 3 shows the results of the regression analyses for the subset of closed treatment trajectories where it was possible to correct for the number of comorbidities (5307 treatment trajectories in total). The addition of the categories was not significant for the duration of the closed treatment trajectories (one comorbidity: β 0.649, SE 0.496; *P*=.19; more than one comorbidity: β 1.265, SE 0.707; *P*=.07), nor for the number of consultations in the closed treatment trajectories (one comorbidity: β 0.869, SE 0.665; *P*=.19; more than one comorbidity: β 1.008, SE 0.947; *P*=.29).

### Registered Use of Recommended Outcome Measures

Table 3 shows the use of and the scores on the outcome measures within closed physical therapy treatment trajectories for COVID-19. Only for the PSFS, 6MWT, and grip strength were there more than 1000 baseline and posttest registrations. Overall, the PSFS was registered in 78% of the closed treatment trajectories (52,040/66,653), at baseline-only in 51% (n=33,836) and at baseline and as posttest in an additional 27% (n=18,204). A score on the 6MWT was registered as baseline in 28% (n=18,419) and as both baseline and posttest in an additional 11% (n=7316). For grip strength, this was in 15% (n=10,122) and 5% (n=3448) of the closed treatment trajectories, respectively.

XSL•FO
RenderX

**Table .** Usage of and scores on recommended outcome measures at baseline and at posttest in the closed physical therapy treatment trajectories for COVID-19 that started in the period 2020 to 2022 in Dutch primary care.

| Test | Number of measurements | | Scores on repeated measurements, median (IQR) | | |
|---|---|---|---|---|---|
| | Baseline[a], n | Repeated measurement, n (outliers) | Baseline | Posttest | Difference |
| 6MWT[b] (m) | 25,735 | 7028 (288) | 418 (349-483) | 507 (440-575) | 83 (40-140) |
| 5TST[c] (s) | 2281 | 501 | —[d] | 9 (7.3 - 12) | — |

| PSFS[f] (points) | 52,040 | 18,096 (108) | 8 (7-10) | 1 (0 - 4) | -6 (–8 to –4) |
| FSS[g] (points) | 897 | 191 | — | 3.7 (2.3 - 5) | — |
| GS[h]: men (kg) | | | | | |
| Left | 4276 | 1139 | — | — | — |
| Right | 4265 | 1135 | — | — | — |
| Unknown | 646 | 173 | — | — | — |
| Selected[i] | N/A[j] | 1196 (120) | 40 (32-47) | 45 (38-53) | 5 (2-9) |
| GS: women (kg) | | | | | |
| Left | 7496 | 1839 | — | — | — |
| Right | 7493 | 1838 | — | — | — |
| Unknown | 1117 | 268 | — | — | — |
| Selected | N/A | 2013 (119) | 26 (20-30) | 30 (25-35) | 4 (1-7) |
| GS: all (kg) selected | N/A | 3209 (239) | 30 (22-38) | 34 (27-43) | 4 (2-8) |
| GPE[k]: recovery | — | 10,736 | — | 2 (1-2) | — |
| GPE: satisfaction | — | 6632 | — | 1 (1-2) | — |

[a]Numbers differ from Table 1, as the numbers in this table are given within the subset of closed treatment trajectories.

[b]6MWT: 6-minute walking test.

[c]5TSTS: 5-times sit-to-stand test.

[d]Not applicable.

[e]SPPB: Short Physical Performance Battery.

[f]PSFS: Patient-Specific Functional Scale.

[g]FSS: Fatigue Severity Scale.

[h]GS: grip strength.

[i]Scores for chosen hand.

[j]N/A: not available.

[k]GPE: global perceived effect.

On the PSFS, where a lower score reflects improvement, the median difference score was −6 (IQR −8 to −4) points over 18,096 closed treatment trajectories (Table 3). For the 6MWT and grip strength, higher scores reflect improvement. On the 6MWT, a median difference score of 83 (IQR 40-140) m was found (n=7028). On grip strength, median difference scores of 5 (IQR 2-9) kg for men and of 4 (IQR 1-7) kg for women were found over, respectively, 1196 and 2013 closed treatment trajectories.

The GPE-recovery was registered in 10,736 closed treatment trajectories, of which 81.6% (n=8761) indicated that the recovery was “much” to “very much better” since the beginning of the treatment. In 94.4% (n=6259) of the closed treatment trajectories in which GPE satisfaction was registered (n=6632), “very” to “very much satisfaction” with the treatment was indicated.

## Discussion

### Principal Findings

This retrospective cohort study, using real-world routinely recorded data of more than 60,000 patients from EHRs of physical therapy practices, provides insight into developments in the use of physical therapy after COVID-19 in the Dutch adult population during the first 2.5 years of the pandemic. Both the relative incidence of starting physical therapy and the amount of health care provided differed between groups of age and gender. Furthermore, more than 4 out of 5 of the treatment

XSL•FO
RenderX

trajectories included at least one measurement using an outcome measure that was recommended in Dutch treatment guidelines.

The retrospective cohort in this study seems representative of developments concerning coronavirus in the Netherlands during the first 2.5 years of the pandemic. For all subgroups of age and gender, the peak number of patients starting physical therapy after COVID-19 was in 2021, ranging from mid-2021 toward the end of 2021 for older age (>40 y) vs younger age groups (<40 y). These peaks are in accordance with the spread of coronavirus throughout the Netherlands, with peaks in the number of infections throughout 2021 and rapidly increasing infection rates among younger age groups, particularly with the Omicron variant. Furthermore, almost half of the treatment trajectories were for patients aged 40 to 59 years, and most of the patients were women. This is similar to characteristics of patients in a prospective study on allied health care in the Netherlands, with the inclusion period between March and June 2021, in which 64% of the participants were women and the mean age lay around 50 years [33]. Therefore, we expect that these data are representative of the provided physical therapy for COVID-19 in primary care in the Netherlands. The large sample size and use of real-world data increase the external validity of the findings.

The amount of physical therapy received was high for patients who started physical therapy after a COVID-19 infection in the beginning of the pandemic, but it rapidly decreased over the course of 2020. Notably, despite the reimbursement of 50 consultations over a period of 6 months for physical therapy after COVID-19 from the basic health insurance coverage [34], the number of consultations patients received was just over half of this number (28 consultations) for closed treatment trajectories. The latter indicates that the amount of physical therapy patients received was rapidly adjusted over time and that the possibility of declaring a large number of consultations for these patients has not been fully exploited by practitioners and patients. Notably, the amount of physical therapy received by patients after a COVID-19 infection showed a significant parabolic effect with age, with overall a maximum number of consultations and duration of the treatment trajectory among older patients aged 60 to 79 years. They had in general 3 consultations more per treatment trajectory than patients aged 18 to 39 years and 5 consultations more than patients aged 80 years or older. The number of consultations did not differ between men and women, but, on average, the treatment trajectory of women was 1.5 weeks longer, indicating a lower frequency of physical therapy for women compared to men.

The diagnostic code used in the primary physical therapy setting in the Netherlands does not allow for a differentiation between acute and postacute COVID-19, nor does it provide information on the type of symptom due to COVID-19 for which the patient sought help from the physical therapist. However, as, in the majority of the treatment trajectories, the patients visited the physical therapist after 3 to 12 weeks or after more than 12 weeks from the start of the symptoms for which the patient visited the physical therapist, the findings seem to apply primarily to patients with (early) postacute COVID-19. Additionally, the registered measures at baseline provide insight into the clinical profile at the start of the treatment trajectory of the patients visiting the physical therapist after a COVID-19 infection. In 83.2% (59,184/71,152) of the treatment trajectories, at least one measurement using any of the recommended outcome measures was registered at baseline. The baseline scores found in the present study are similar to the ones found in the nationwide prospective study, with a total of 992 patients, for the FSS [19], PSFS, 6MWT, 5TSTS, and grip strength [35]. Overall, these scores indicate severe fatigue [30], declined functional capacity by the 6MWT [36], and lower functional lower-limb strength [37] at baseline in this population, although there were no impairments in mobility according to the SPPB [38] nor weak grip strength for men or women [39].

Besides baseline measures, measures at posttest were also analyzed. In the majority of treatment trajectories (>80%), high perceived recovery and high satisfaction with the received physical therapy received were registered with the GPE. When interpreting these results, however, it is necessary to keep in mind that we made secondary use of routinely recorded health care data that were not registered for the goals of the present study. The outcome measures in the registries are not validated and the data might be biased to an extent as it is recorded in the EHRs by the therapists for different use than research. Furthermore, the lack of a control group in this study and knowledge on the specific content of the provided physical therapy does not allow for conclusions on causal relations or effectiveness. Therefore, caution is required when interpreting these measurement outcomes. There were 3 outcome measures for which a substantial sample size of closed treatment trajectories with both a baseline and posttest were available. On these, patients showed, on average, clinically relevant improvements from baseline to posttest in functional capacity (a >30.2 m increase on the 6MWT [40]) and patient-reported functional status (a >2.3 point decrease on the PSFS [41]) but not in grip strength (<5.0 - 6.5 kg [29]). This is in accordance with previous studies and a recent meta-analysis showing a significant increase in the 6MWT [35,42,43] and PSFS [35] compared to a control group or to baseline, but there was no clinically relevant improvement for grip strength [35,43]. Although the baseline scores and general direction of changes from baseline to posttest are similar to the ones found in the prospective study [35], the changes reported in this study are greater. As mentioned above, it is therefore important to underline that the study design in the present study only shows improvement over time at the population level within this specific population and does not allow for a distinction between natural healing over time, the effects of possible other interventions, or the effects of physical therapy.

Notably, although most of the literature supports the use of physical exercise–based rehabilitation for persons with long COVID-19 as a potentially promising and, although symptom-dependent, effective therapy [4,43-46], there are also concerns regarding the possible detrimental effect of physical exercise. A recent systematic review and meta-analysis reported that more than half of the individuals with postacute COVID-19 syndrome perceived postexertional malaise [47], and an intensive longitudinal cohort study showed that physical activity was, among other activities, associated with subsequently increased severity of various symptoms [48]. It is therefore

XSL•FO
RenderX

important that red flags, such as exertional desaturation and cardiac impairment following COVID-19, are ruled out before considering physical exercise training and that patients are assessed for postexertional symptom exacerbation, after which interventions should be modified accordingly [17,44,49]. In the present study, it is not possible to determine which patients would officially be classified as having postacute COVID-19, only that patients in the cohort were referred by a health care professional, as that was a prerequisite for reimbursement via basic health insurance.

### Limitations

There are some limitations to the present study that are important to be mentioned. First of all, the observational nature of this type of study does not allow for conclusions on causal relations or effectiveness of the health care provided. Importantly, only patients who sought physical therapy for COVID-19 at a physical therapy practice participating in one of the registries are represented in the data. Therefore, no information from a control group nor from the underlying Dutch population is available (we have no information on people who do not visit a [affiliated] physical therapist). Second, as described earlier, use of outcome measures in the registries has not been validated, and for example, it is often unknown whether a patient-reported outcome such as the PSFS or GPE is indeed answered by the patient or instead by the therapist. Third, as the amount of physical therapy provided is based on treatment trajectories that are closed, naturally the proportion of shorter closed treatment trajectories is higher near the end of the data collection. However, the impact on the current results is likely modest, as we purposefully excluded the last 22 weeks in the data for the analyses of closed treatment trajectories, and the decline is already consistently visible well before the end of the data collection. Further, the addition of registered information on comorbidities was only possible for a small subgroup, and the combination of these lower numbers and the perhaps coarse outcome of “none,” “one,” or “more than one” registered comorbidities hampers the possibility to draw conclusions based on these data. Lastly, information on other possible confounders such as social economic position or ethnic origin was not available.

### Conclusions

The present study shows the possibilities of using routinely collected health care data to gain insight into real-world physical therapy provision in primary care for COVID-19. The relative incidence of starting a physical therapy treatment trajectory for COVID-19 in primary care differed mainly between younger adults and middle-aged to older adults and was in accordance with the course of the pandemic in the Netherlands. Overall, patients showed severe perceived fatigue, declined functional capacity, and lower-limb strength at the start of the physical therapy and were satisfied with the treatment received. Furthermore, the amount of physical therapy provided declined over the first 2.5 years of the pandemic, differed between groups of age and between men and women, and was generally lower than the amount reimbursed by the Dutch government via the basic health insurance.

## Acknowledgments

The authors would like to thank all physical therapy practices that participate in the various national registries: the Netherlands Institute for Health Services Research Primary Care Database (Nivel-PCD); the Dutch National Data Registry (LDK) of the Association for Quality in Physical Therapy (SKF); the National Registry Exercise Therapy (LDO); and the National Clinical Registry (LDF) of the Royal Dutch Society for Physical Therapy (KNGF). Generative AI was not used in any stage of preparation for this manuscript.

## Funding

This project was funded by ZonMw Efficiency Studies (10390062010001) and received additional funding to set up the data-collection tool from the Royal Dutch Society for Physiotherapy, the Association for Quality in Physical Therapy, the Nivel Netherlands Institute for Health Services Research, Stichting Revalidatie en Wetenschap, and Maastricht University. The funding sources were not involved in data collection and analysis or in the publication process of the manuscript.

## Data Availability

In the present study, data from the Nivel Primary Care Database (Nivel-PCD) have been used. However, access to data in Nivel-PCD is subject to the Nivel-PCD governance codes. Requests for data access can be directed to gegevensaanvragen@nivel.nl. Restrictions involve establishing a data-sharing agreement and obtaining approval from the appropriate Nivel-PCD governance bodies (privacy committee and steering committee).

## Abstract

**Background:** Antimicrobial resistance is a public health crisis exacerbated by the irrational use of antibiotics, particularly in low- and middle-income countries. Pakistan, one of the highest consumers of antibiotics globally, faces unique challenges, including unregulated sales, overuse of broad-spectrum antibiotics, and inadequate stewardship programs.

**Objective:** This study aimed to analyze antibiotic consumption trends in Pakistan from 2016 to 2023, project future use through 2028, and evaluate the subsequent implications for antimicrobial resistance and antimicrobial stewardship programs.

**Methods:** Antibiotic sales data were retrieved for Pakistan from the IQVIA MIDAS database spanning 2016 to 2023. Data were converted to defined daily doses (DDDs) and DDD per 1000 inhabitants per day (DID) using the World Health Organization Anatomical Therapeutic Chemical classification system. Data cleaning, statistical analyses, and data visualization were performed using R software (version 4.3.2) and Microsoft Excel. Trends were analyzed using linear regression, while future projections (2024 - 2028) were developed using trend-based models. Descriptive analysis was performed, and visualizations were used to illustrate findings.

**Results:** The total antibiotic consumption in Pakistan from 2016 to 2023 was 12.88 billion DDDs. Broad-spectrum penicillins and fluoroquinolones, each accounting for 37.7 DID, were the most consumed classes. The analysis revealed significant increases in the consumption of macrolides (+76%; rising from 2.26 to 3.99 DID) and cephalosporins (+36%; from 2.87 to 3.89 DID) from 2016 to 2023, with macrolides projected to reach 5.79 DID by 2028. Reserve antibiotics, including oxazolidinones (+354%; from 0.03-to 0.014 DID) and glycylcycline (+236%; from 0.001 to 0.0003 DID), also showed appreciable increases, reflecting greater reliance on last-line therapies. In contrast, aminoglycosides (−36%; from 0.013 to 0.14 DID) and narrow-spectrum penicillins (−30%; from 0.008 to 0.005 DID) experienced notable declines.

**Conclusions:** The study highlights a concerning overreliance on broad-spectrum and reserve antibiotics in Pakistan, thus underscoring the urgent need for robust antimicrobial stewardship programs and stricter regulation of over-the-counter antibiotic sales to rationalize antibiotic use. Future efforts should focus on addressing gaps in prescribing practices, improving diagnostic capacity, and monitoring stewardship program outcomes to mitigate resistance development and preserve antibiotic efficacy.

## Introduction

Antibiotics have revolutionized modern medicine, playing a critical role in preventing and treating bacterial infections [1]. However, their widespread and often irrational use has led to an appreciable increase in antimicrobial resistance (AMR) in recent years [2]. AMR is one of the greatest public health challenges of the 21st century, threatening the effectiveness of antibiotics and the ability to treat common infections, ultimately increasing morbidity, mortality, and health care costs [2-4]. In

XSL•FO
RenderX

low- and middle-income countries (LMICs), including Pakistan, where health care systems are underresourced and antibiotic use is often unregulated, this issue becomes even more pronounced [5-8].

Pakistan is among the top consumers of antibiotics globally, a distinction that underscores the urgent need for comprehensive surveillance and targeted interventions to address current concerns with their overuse [9]. Key factors driving high antibiotic consumption in the country include easy availability of over-the-counter antibiotics, an insufficient health care infrastructure, lack of awareness among prescribers and the public regarding antibiotics and AMR, and sociocultural practices that promote self-medication [5,6,10]. The unregulated sale of antibiotics and the proliferation of generic brands further exacerbate the problem, leading to overuse and misuse of broad-spectrum antibiotics including those from the World Health Organization (WHO) Watch List [7,11-13]. The COVID-19 pandemic has further complicated the landscape of antibiotic use [14-16]. There was an unprecedented surge in the use of antibiotics during the early stages of the pandemic, driven by the misperception that antibiotics could prevent or treat COVID-19 [16-18]. These challenges, compounded by inadequate national stewardship policies and concerns with limited knowledge and antimicrobial stewardship activities, have contributed to a significant rise in AMR in Pakistan, posing a major threat to public health and economic stability [10,19].

Surveillance of antibiotic consumption is a cornerstone in combating AMR, providing insights into use patterns and identifying areas for intervention [9,20]. The number of defined daily doses (DDDs) per 1000 inhabitants per day (DID) is a standardized metric recommended by the WHO for measuring antibiotic consumption. This metric allows for meaningful comparisons over time and across countries [21]. Understanding trends in antibiotic consumption, particularly in the context of Pakistan, is crucial for informing national policies, optimizing antimicrobial stewardship programs (ASPs), and aligning with the global action plan on AMR [5]. Assessing antibiotic use patterns across sectors has gained importance following recent deliberations of the United Nations General Assembly (UNGA) on AMR, which emphasize increasing the use of antibiotics from the WHO Access List to help reduce AMR [22]. This is important in Pakistan, along with other LMICs, where we see high rates of use of antibiotics from the Watch and Reserve lists with their greater resistance potential [9,12]. Such trends must be reversed if Pakistan is to meet its National Action Plan targets and the UNGA goal of achieving 70% of antibiotic use from Access List antibiotics [22]. Previous studies have highlighted high consumption rates of antibiotics, including cephalosporins, fluoroquinolones, and macrolides, in Pakistan; however, there is currently a lack of comprehensive analyses regarding long-term trends and projections for antibiotic use in Pakistan [9,17]. This gap in knowledge hinders the country's ability to meet its National Action Plan on AMR, which is already a challenge, and contribute meaningfully to global efforts in reducing antibiotic misuse [5]. This study provides a detailed analysis of antibiotic consumption trends in Pakistan from 2016 to 2023, with projections through 2028. By analyzing consumption data and forecasting across 13 major antibiotic classes, this study establishes a counterfactual baseline of expected use and aims to highlight secular trends; identify statistically significant changes; and assess the impact of potential interventions, such as the COVID-19 pandemic, on use patterns. The findings are intended to inform policymakers, health care providers, and researchers about the current state of antibiotic use in Pakistan and the critical need for targeted stewardship efforts.

## Methods

### Data Source and Collection

Antibiotic consumption data for Pakistan were retrieved from the comprehensive IQVIA MIDAS database, which consolidates pharmaceutical sales data, as reported in a recent study by Klein et al [9]. The data covered the period from 2016 to 2023 and included retail pharmacy sales, capturing estimated use trends for antibiotics across the country. The sales data, recorded in estimated grams of active ingredients, were systematically converted into DDD using the Anatomical Therapeutic Chemical classification system and methodologies recommended by the WHO Collaborating Centre for Drug Statistics Methodology. The DDD conversion accounted for variations in the route of administration (oral and parenteral) for each molecule.

### Data Processing

Antibiotic molecules were classified according to the Anatomical Therapeutic Chemical or DDD Index 2026 [23]. For combination drugs, components were broken into their individual active molecules, and consumption was attributed to the main antibiotic molecule based on its 1 daily dose. Antibiotic consumption rates were calculated as DID, enabling cross-year and cross-population comparison. Population data for Pakistan were sourced from the World Bank and national government statistics.

### Study Period and Variables

The study analyzed 13 antibiotic classes, including macrolides, cephalosporins, fluoroquinolones, carbapenems, tetracyclines, and others. Variables included annual DIDs for each antibiotic class, percentage changes from 2016 to 2023, and projections (2024 - 2028).

### Statistical Analysis

Antibiotic classes were categorized as increasing, decreasing, or stable based on percentage changes in DIDs. Classes with changes >10% were considered increasing, <−10% as decreasing, and between −10% to 10% as stable. This operational threshold was adopted by the authors as a pragmatic balance between clinical relevance and statistical sensitivity. Data cleaning, statistical analyses, and data visualization were performed using R software (version 4.3.2; R Foundation for Statistical Computing; Posit) and Microsoft Excel. For each antibiotic class, linear regression models were applied to evaluate trends from 2016 to 2023. Slope coefficients indicated the rate of annual change. Future antibiotic use (2024 - 2028) was projected using the coefficients from linear regression models. The projections assumed a consistent linear trend in use, with results expressed in DIDs. A +10% or −10% SE

XSL•FO
RenderX

margin was incorporated to reflect potential variability due to external factors such as policy changes and AMR management programs. Line graphs with distinct markers were used to show historical trends and projections. Bar charts were used to compare percentage changes, emphasizing significant trends.

### Ethical Considerations

Ethics approval for the study was obtained from the Research Ethics Committee of the Department of Pharmacy Practice, Faculty of Pharmacy, Bahauddin Zakariya University, Multan (BZU-FOPDPP-2456). Participant consent was not required as the study was based on aggregated sales data and did not involve human participants or identifiable personal information. All data were aggregated and anonymized, ensuring compliance with ethical standards for research.

## Results

The analysis of antibiotic use in Pakistan between 2016 and 2023, alongside projections for 2024 to 2028, revealed important trends and insights. Table 1 and Table S1 in Multimedia Appendix 1 highlight the annual consumption of antibiotics as DDDs and DID. The total antibiotic consumption in Pakistan during the study period from 2016 to 2023 was measured at an estimated 12.88 billion DDDs. Among the antibiotic classes, broad-spectrum penicillins and fluoroquinolones were the most consumed, contributing significantly to the total DDDs. These findings emphasize the dominant role of these classes in driving overall antibiotic use, highlighting their critical impact on AMR trends. Over the study period, macrolides exhibited the highest growth (+76%), increasing from 2.26 to 3.98 DID, and are projected to reach 5.79 DID by 2028. Similarly, cephalosporins increased by 35.8% from 2.86 to 3.89 DID, with projections suggesting further growth to 4.76 DID. Conversely, tetracyclines showed a slight decline (−3.3%) from 2.19 to 2.12 DID, with projections indicating a continued decrease to 2.00 DID by 2028.

**Table .** Consumption pattern of antibiotics as defined daily dose (DDD) per 1000 inhabitants per day (DID) in Pakistan.

| Antibiotic class | Year-wise DDD per 1000 DID | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | 2016 | 2017 | 2018 | 2019 | 2020 | 2021 | 2022 | 2023 |
| Broad-spectrum penicillins | 4.8475 | 4.5654 | 4.6502 | 4.7367 | 4.5420 | 4.6185 | 4.9834 | 4.7300 |
| Fluoroquinolones | 4.5628 | 4.4010 | 4.6072 | 4.5863 | 4.3664 | 4.8303 | 5.2147 | 5.1958 |
| Cephalosporins | 2.8666 | 2.8807 | 3.1315 | 3.2945 | 3.1519 | 3.6104 | 3.9696 | 3.8936 |
| Macrolides | 2.2590 | 2.2778 | 2.5770 | 2.6436 | 3.3594 | 3.9336 | 4.1285 | 3.9864 |
| Tetracyclines | 2.1930 | 2.2175 | 2.2884 | 2.2098 | 2.1028 | 2.1524 | 2.0863 | 2.1199 |
| Sulfonamides | 1.2224 | 1.0970 | 1.1353 | 1.2119 | 1.1897 | 1.0901 | 1.0633 | 1.0125 |
| Aminoglycosides | 0.1324 | 0.1164 | 0.1049 | 0.0849 | 0.0797 | 0.0876 | 0.0992 | 0.0851 |
| Oxazolidinones | 0.0313 | 0.0428 | 0.0555 | 0.0632 | 0.0707 | 0.1026 | 0.1209 | 0.1420 |
| Narrow-spectrum penicillins | 0.0084 | 0.0069 | 0.0098 | 0.0087 | 0.0069 | 0.0086 | 0.0083 | 0.0059 |
| Carbapenems | 0.0071 | 0.0076 | 0.0094 | 0.0101 | 0.0106 | 0.0207 | 0.0210 | 0.0218 |
| Glycopeptide | 0.0015 | 0.0014 | 0.0018 | 0.0021 | 0.0025 | 0.0038 | 0.0034 | 0.0045 |
| Glycylcycline | 0.0001 | 0.0001 | 0.0001 | 0.0002 | 0.0001 | 0.0002 | 0.0002 | 0.0003 |
| Other antibacterials | 0.0460 | 0.0451 | 0.0453 | 0.0470 | 0.0448 | 0.0469 | 0.0441 | 0.0377 |

Table 2 presents year-on-year percentage changes. Significant increases were observed for carbapenems (+207%), glycopeptides (+191%), and glycylcycline (+236%), driven largely by higher demand in clinical settings. Oxazolidinones exhibited the most dramatic increase (+354%), reflecting increased reliance on reserve antibiotics. In contrast, aminoglycosides (−36%), narrow-spectrum penicillins (−30%), and sulfonamides (−17%) experienced a notable decline, possibly due to shifts in prescribing preferences. Figure 1 illustrates trends in antibiotic use, with aminoglycosides showing a significant reduction and oxazolidinones exhibiting the largest increase in consumption over the previous 8 years (2016 - 2023).

**Figure 1.** Cluster changes in consumption between 2016 and 2023.

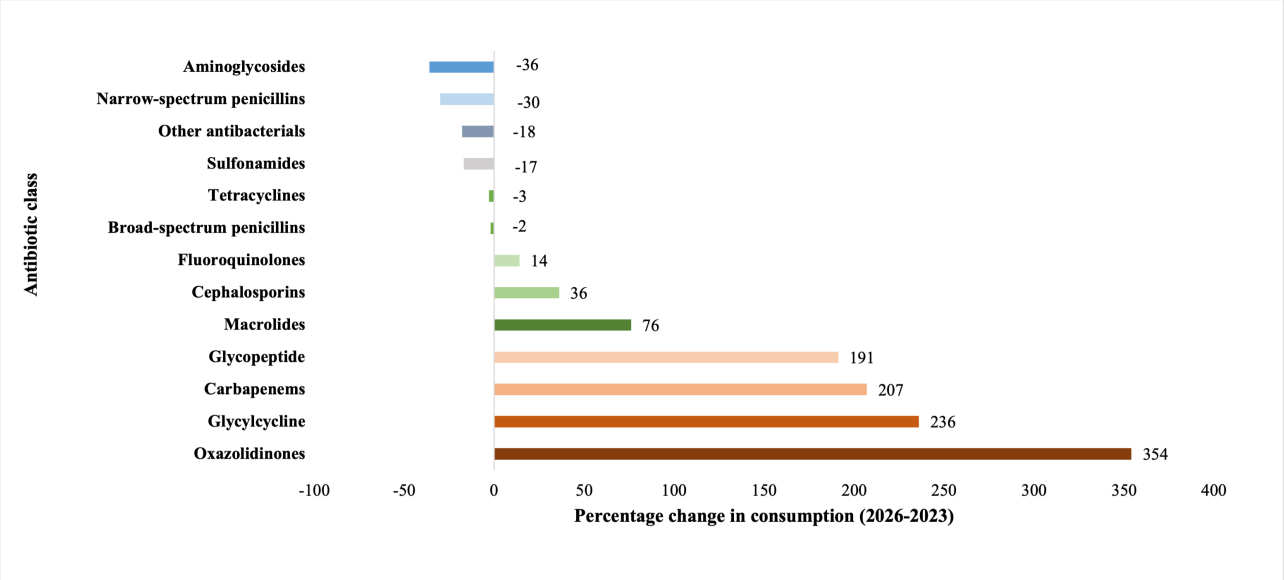

**Table .** Percentage change in consumption.

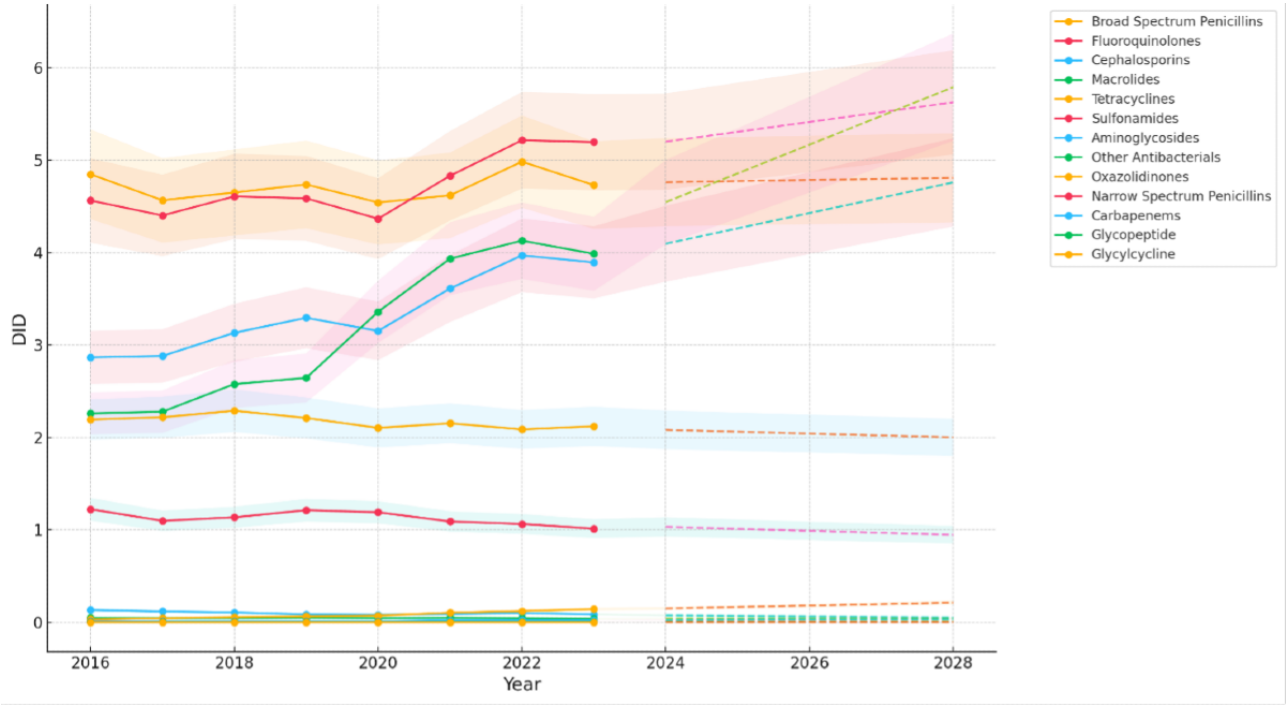

| Antibiotic class | Year-wise change in consumption (%) | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | (2016 - 2017) | (2017 - 2018) | (2018 - 2019) | (2019 - 2020) | (2020 - 2021) | (2021 - 2022) | (2022 - 2023) | (2016 - 2023) |
| Broad-spectrum penicillins | −6 | 2 | 2 | −4 | 2 | 8 | −5 | −2 |
| Fluoroquinolones | −4 | 5 | 0 | −5 | 11 | 8 | 0 | 14 |
| Cephalosporins | 0 | 9 | 5 | −4 | 15 | 10 | −2 | 36 |
| Macrolides | 1 | 13 | 3 | 27 | 17 | 5 | −3 | 76 |
| Tetracyclines | 1 | 3 | -3 | −5 | 2 | −3 | 2 | −3 |
| Sulfonamides | −10 | 3 | 7 | −2 | -8 | −2 | −5 | −17 |
| Aminoglycosides | −12 | −10 | −19 | −6 | 10 | 13 | −14 | −36 |
| Oxazolidinones | 37 | 30 | 14 | 12 | 45 | 18 | 18 | 354 |
| Narrow-spectrum penicillins | −18 | 41 | −11 | −21 | 26 | −3 | −29 | −30 |
| Carbapenems | 7 | 24 | 7 | 5 | 95 | 1 | 4 | 207 |
| Glycopeptide | −12 | 30 | 23 | 17 | 52 | −10 | 30 | 191 |
| Glycylcycline | −10 | 2 | 96 | −9 | 60 | 10 | 17 | 236 |
| Other antibacterials | −2 | 0 | 4 | −5 | 5 | −6 | −15 | −18 |

Figure 2 demonstrates historical trends and future projections until 2028, with projections indicated by dotted lines. Broad-spectrum antibiotics such as macrolides and cephalosporins show steep upward trajectories (2.25 DID to 5.78 DID and 2.86 DID to 4.75 DID, respectively), signaling the potential overuse of these agents, whereas fluoroquinolones, a critical group, are projected to increase modestly to 5.63 DID by 2028. The inclusion of a +10% or −10% margin of error reflects variability due to external factors such as policy changes or antimicrobial stewardship interventions.

XSL•FO
RenderX

**Figure 2.** Trends and projections of antibiotic use in Pakistan (2016 - 2028). DID: defined daily dose per 1000 inhabitants per day.

## Discussion

### Overview

This study analyzed antibiotic consumption trends in Pakistan from 2016 to 2023, with projections through 2028, highlighting critical insights into patterns of use and their implications for AMR and ASP. The findings align with global trends but also underscore the unique challenges faced by LMICs, such as Pakistan, in managing antibiotic consumption [24]. The total antibiotic consumption in Pakistan was measured at 12.88 billion DDDs, reflecting a 17% increase since 2016. This trend parallels global findings, where antibiotic consumption rose by 20.9% during a similar period, although the growth rate was slower compared to the 35.5% increase observed from 2008 to 2015 [25]. However, the COVID-19 pandemic significantly impacted global antibiotic use, leading to temporary reductions, particularly in high-income countries, where outpatient antibiotic use is dominant [9,26-28]. In Pakistan, as in other LMICs, a rebound was observed postpandemic, with consumption exceeding prepandemic levels by 2023, driven by unregulated access and increased reliance on broad-spectrum antibiotics [28,29].

Broad-spectrum penicillins and fluoroquinolones were the most consumed antibiotic classes in Pakistan, accounting for 37.7 DID each in 2023. This heavy reliance on broad-spectrum antibiotics is consistent with trends observed in other LMICs such as India and Bangladesh, where similar patterns have been linked to limited diagnostic capacity and the widespread availability of over-the-counter antibiotics [9,30,31]. In contrast, reserve antibiotics, including carbapenems, oxazolidinones, and glycylcycline, showed dramatic increases in use. These trends highlight the growing demand for last-line antibiotics in critical care settings, reflecting rising resistance to first-line therapies [13,32]. Several factors contribute to the accelerated rise in antibiotic use in developing countries, including environmental, socioeconomic, and cultural determinants, with economic growth appearing to be the most influential driver in lower-income settings [9]. During the COVID-19 pandemic, antibiotic sales also increased considerably due to empirical use in the setting of diagnostic uncertainty and concerns about bacterial coinfections [33]. The projected escalation in the use of macrolides and cephalosporins (2.25 DID to 5.78 DID and 2.86 DID to 4.75 DID, respectively) reflects an increasing dependence on broad-spectrum antibiotics. This growing dependence on Watch group antibiotics deviates from the WHO's recommended target of maintaining at least 60% of total consumption within the Access category, potentially accelerating the selection of multidrug-resistant pathogens [33].

Economic growth, urbanization, and health care infrastructure gaps are significant drivers of antibiotic overuse in Pakistan. As seen in other middle-income countries, rising gross domestic product and rapid urbanization often correlate with increased antibiotic consumption [34]. However, this growth comes at the expense of proper regulatory oversight, leading to widespread misuse. In Pakistan, the lack of robust ASPs and weak enforcement of prescription-only antibiotic policies exacerbate the problem [6,12,35]. The WHO's Access, Watch, and Reserve (AWaRe) classification system has been pivotal in promoting rational antibiotic use globally [36]. However, in Pakistan, as in many LMICs, the Watch and Reserve categories dominate consumption, reflecting poor alignment with the AWaRe recommendations [25]. In contrast, high-income countries have successfully reduced the use of high-risk antibiotics such as fluoroquinolones through stringent regulatory warnings and public awareness campaigns [9,37]. The rising consumption of fluoroquinolones and reserve antibiotics in Pakistan highlights the urgent need for similar regulatory interventions [17]. This study underscores the critical need for comprehensive ASPs tailored to the local context [38].

XSL•FO
RenderX

Strengthening regulatory frameworks, enhancing diagnostic capacity, and promoting public awareness are essential to curbing antibiotic misuse [39,40]. Investments in preventive measures, such as improved water, sanitation, and hygiene infrastructure, along with robust vaccination programs, could also significantly reduce the burden of infectious diseases and, consequently, the need for antibiotics in Pakistan [41,42].

### Principal Findings

The major findings of the study are as follows:

- Total antibiotic consumption in Pakistan (2016 - 2023) reached 12.88 billion DDDs, with broad-spectrum penicillins and fluoroquinolones accounting for nearly half.
- Annual consumption of macrolides (+76%) and cephalosporins (+36%) increased sharply, with macrolides projected to reach 5.79 DID by 2028.
- Reserve antibiotics, including oxazolidinones and glycylcycline, showed marked growth, reflecting increased use of last-line therapies, while aminoglycosides and narrow-spectrum penicillins declined.

### Study Limitations and Future Research

While the data in this report provide valuable insights, they have inherent limitations. First, the IQVIA MIDAS data primarily capture retail pharmacy sales and do not include hospital procurement or inpatient use, which may lead to underrepresentation of antibiotics predominantly used in hospital settings (eg, carbapenems and glycopeptides) or for severe infections. No distinction was made between prescription-only and over-the-counter antibiotics, as consumption estimates were derived from aggregated sales data. Second, the dataset lacks indication-level, health care setting–level, and prescriber-level information, preventing analysis of the clinical context or appropriateness of antibiotic use. Third, the projections for 2024 to 2028 assume linear trends, which may not account for unforeseen policy changes, health care developments, or epidemics. The study does not address regional variations within Pakistan, which could provide additional insights into localized drivers of antibiotic use. Additionally, the study focused exclusively on human antibiotic consumption, excluding veterinary and agricultural use, which are critical components of a One Health approach to AMR. Future research should integrate these dimensions to provide a more comprehensive understanding of antibiotic use trends.

### Conclusions

The findings of this study highlight the urgent need for targeted interventions to optimize antibiotic use in Pakistan. The high reliance on broad-spectrum and reserve antibiotics, coupled with the rapid rebound in consumption after the pandemic, underscores the importance of strengthening ASPs and regulatory oversight. By aligning national policies with global frameworks following UNGA recommendations, Pakistan can mitigate the risks of AMR and ensure sustainable antibiotic use.

## Acknowledgments

The authors would like to extend their gratitude to Eili Y Klein for their invaluable support and for allowing the use of data from their insightful study on antibiotic consumption, which significantly informed this work. The authors also extend their appreciation to Umm Al-Qura University, Saudi Arabia, for funding this research work through Grant Number 26UQU4320605GSSR01. QuillBot was used to improve the language and readability of the manuscript.

## Abstract

**Background:** Ensuring affordable and quality primary health care for urban populations remains a persistent challenge in resource-constrained countries such as Bangladesh. The country's fragmented and pluralistic urban health system exacerbates these challenges, making it particularly difficult to deliver primary health care to urban residents. In Bangladesh, the Aalo Clinic has been piloted to provide essential health services to low-income urban residents, including slum dwellers.

**Objective:** This study aimed to assess how this model affects health care–seeking behavior from medically trained providers (MTPs) for managing chronic diseases.

**Methods:** We conducted implementation research from October 2021 to August 2023 using a cross-sectional study design. To assess the effectiveness of the Aalo Clinic model, the baseline survey was conducted from January to February 2022, and the end-line surveys were carried out from April to June 2023 in the Korail, Mirpur, Shyampur, Dhalpur, and Tongi-Ershadnagar slums, which are adjacent to the clinics. In the baseline survey, we randomly selected 2000 households (with 9196 members), while 2033 households (with 8223 members) were interviewed in the end-line survey. We considered 8919 individuals in the baseline and 7994 individuals in the end-line, all aged 1 year or older. We used descriptive analysis and chi-squared tests to assess changes in health care usage from MTPs and applied logistic regression models to assess the model's influence on health care usage from MTPs while controlling for other factors.

**Results:** Among slum dwellers, awareness of Aalo Clinic increased by approximately 62 percentage points, from 11.46% (n=227) at baseline to 73.36% (n=1473) at end-line. The usage of health care for the management of chronic diseases from Aalo Clinics' MTPs was significantly higher at the end-line period (n=63, 11.13%) compared to the baseline period (n=6, 0.59%). Regression analysis indicated that slum dwellers were approximately 23 times more likely (95% CI 8.77-61.80) to use health care from Aalo Clinic for chronic diseases in the end-line period compared to the baseline. However, there was no substantial change in health care usage from non-MTPs, which remained stable at around 38% (baseline: n=388; end-line: n=218) in both periods, and local drug stores continue to be the primary source for managing chronic diseases.

**Conclusions:** Usage of Aalo Clinic MTPs for chronic disease care increased substantially compared to other MTPs among slum dwellers. However, reliance on non-MTPs, particularly local drug stores, remained stable. Ensuring the availability of essential medicines may further reduce dependence on non-MTPs among low-income urban slum residents. Future longitudinal studies are needed to evaluate the long-term impact on chronic disease management in Bangladesh.

## Introduction

In low- and middle-income countries (LMICs) such as Bangladesh, ensuring affordable and quality health care remains a persistent challenge, particularly in urban areas where the provision of basic health care is limited [1]. This challenge contributes to the global setback in making significant progress toward achieving universal health coverage (UHC) by 2030: a key objective of the sustainable development goals [2]. To address this issue of providing affordable and quality health care, the World Health Organization recommends strengthening health systems with a primary health care (PHC) approach, as it can significantly contribute to delivering essential health care services [3].

Bangladesh has achieved significant success in health, leading to reduced maternal and child mortality rates [4]. However, the pressing challenge now is to improve the health of impoverished urban populations. Rapid urbanization is underway, with large numbers of rural residents migrating to cities, driven by poverty, climate change, and the hope for better economic opportunities. Currently, approximately 40% of Bangladesh's population resides in urban areas, with an estimated annual growth rate of 3% [5]. A significant portion of these urban residents live in informal settlements, such as slums, which have a concerning growth rate of 7% [6]. Cities with inadequate infrastructure are struggling to accommodate this continuous influx of people, resulting in impoverished slum dwellers facing challenges in accessing health care, among other difficulties. This situation highlights the weakness in the government's health system implementation and the basic health care for slum dwellers [7,8].

The Ministry of Health and Family Welfare has the mandate for health across the country, but urban PHC is mostly delivered by the Ministry of Local Government and Rural Development Cooperation or the Local Governance Institutions, due to a decree providing them the authority to deliver PHC in urban areas [7,9]. However, with its limited capacity, it is currently unable to provide adequate PHC. As a result, access to quality PHC for urban populations, particularly vulnerable individuals such as slum dwellers, is limited. Evidence showed that fragmented health care delivery in urban areas has been caused by unclear roles, poor planning, and a lack of coordination between the 2 authorities, among other factors [8]. Consequently, untrained informal providers, for example, drug sellers and low-quality private clinics, are relied upon by underserved populations [7,8,10-12], which worsens the health of slum dwellers and leads to catastrophic health care expenditure [13,14].

Evidence shows that nongovernmental organizations (NGOs) and development partners have tackled problems in slums with innovative strategies [7,9,15-18]. To overcome the existing barriers to accessing health care, particularly essential high-quality PHC services for urban dwellers, an urban PHC model, namely the Aalo Clinic, is being piloted in selected urban low-income areas since 2021 [19]. We aimed to assess the implementational effect of the Aalo Clinic model in prompting health care usage from medically trained providers (MTPs) for chronic diseases and to identify factors that influence the health care–seeking behavior of the patients.

## Methods

### Description of Aalo Clinic model

With a view to providing accessible and affordable care to the urban poor, this model has been developed based on setting up a static clinic, namely the Aalo Clinic, and outreach services through "Dorgoray Shasthya Sheba"[20]. The key features of this model are shown in Textbox 1.

XSL•FO
RenderX

**Textbox 1.** Key features of the Aalo Clinic model.

- Offers free medical treatment to city residents.
- Patients receive treatment for common, seasonal, and noncommunicable diseases, as well as Expanded Programme on Immunization vaccination and family planning services.
- Provides free medicines: a total of 23 different types of medications are currently being administered.
- Free 10 examinations are performed, including complete blood count, creatinine, erythrocyte count, dengue, and diabetes.
- Every step is digitized, from patient registration to prescription writing to test results.
- Once a patient has registered, clinicians can access information about their prior medical history for any future visits or follow-up care.
- The standard time for doctors to see a patient is 8-10 minutes.
- Operates 6 days a week, except Fridays and public holidays, in 2 shifts: morning shift from 8:30 AM to 2:30 PM and evening shift from 3 PM to 9 PM.
- Well-equipped (infrastructure, health workforce, or equipment) to provide primary health care services.
- Provides outreach health care services through mobile vans in the static Aalo Clinic areas, where patients can receive counseling services from paramedics, and if required, patients are referred to Aalo Clinics.
- Arranges awareness-raising activities for the respective community.
- Provides appropriate referral if required for more specialized care.
- Provides 25%-40% discounted diagnostic tests for patients referred from Aalo Clinics.
- Routinely monitors clinic performance for quality assurance.
- Records beneficiaries' feedback to cater service according to their need.

In the Aalo Clinic model, services have been provided according to the essential service package. The currently available outpatient services at the Aalo Clinics and outreach points are listed in Textbox 2.

XSL•FO
RenderX

**Textbox 2.** Health care services offered by the Aalo Clinic model for the urban slum populations in Bangladesh.

**Maternal, neonatal, child, and adolescent health care preconception, antenatal, delivery, and postnatal**

- Maternal and newborn care (antenatal care, postnatal care, and delivery referral, newborn care, etc)
- Child health and immunization (Integrated Management of Childhood Illness, acute respiratory infection, diarrhea, growth monitoring and promotion, Expanded Programme on Immunization, etc)
- Adolescent health (sexual and reproductive health, reproductive tract infection or sexually transmitted infection, dysmenorrhea, tetanus toxoid vaccine, nutrition, and counseling on mental health)
- Nutrition
- Child nutrition: assessment of nutrition status, prevention of malnutrition, and management of malnutrition
- Promote exclusive breastfeeding, complementary feeding, water, sanitation, and hygiene for children, and growth monitoring and promotion
- Support to moderate acute malnutrition children and refer severe acute malnutrition children
- Maternal nutrition (BMI screening of malnourished pregnant women, mid-upper arm circumference, and counseling for food)

**Noncommunicable diseases**

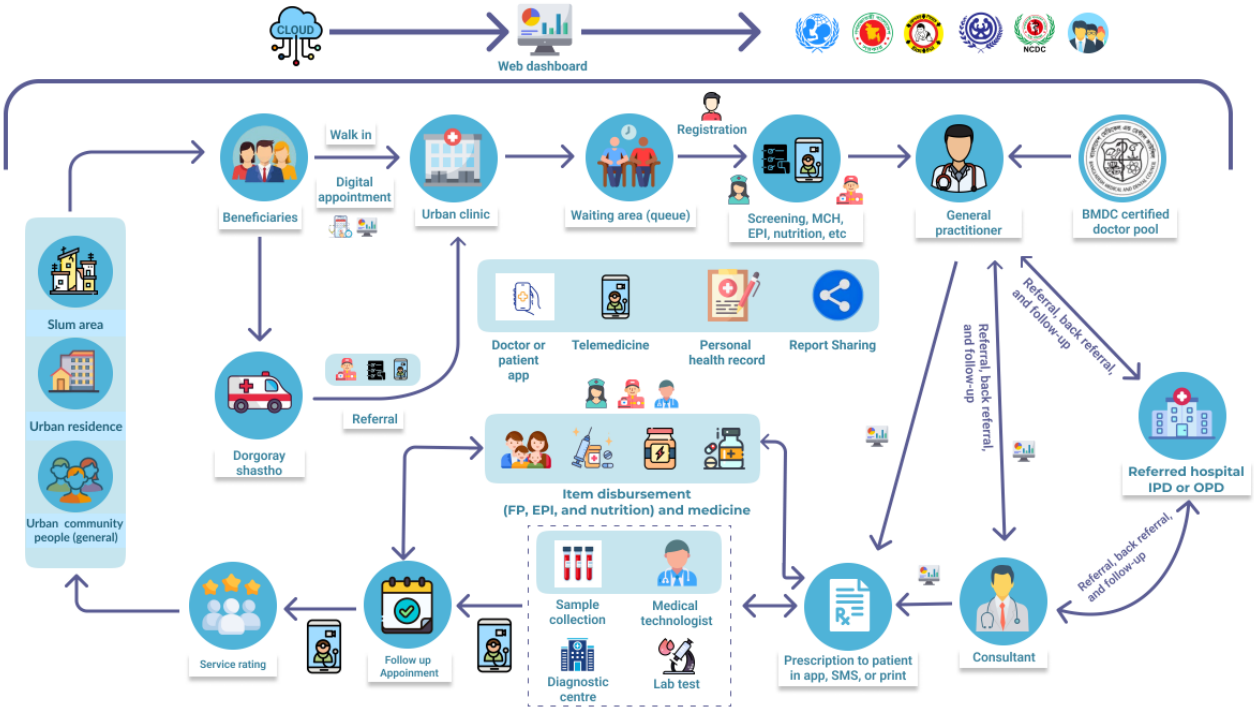
- Noncommunicable disease (hypertension, diabetes mellitus, chronic obstructive pulmonary disease, etc) consultation and referral
- Mental health consultation
- Sexual and gender-based violence

**Management of other common conditions**

- Eye care and referral
- Skin care and referral
- Geriatric (older adult) care and referral
- Minor infection and disease
- Health education and counseling

Family planning (method selection counseling, provide oral contraceptive pill, condom, injectables, and intrauterine device)

Communicable diseases (consultation on communicable diseases, referral, and consultation on sexually transmitted infection or sexually transmitted disease)



Laboratory urinalysis, Hb estimation, blood grouping and Rh typing, blood sugar, complete blood count, and electrocardiogram

The health care services of Aalo Clinic are delivered in a structured way. During the first visit to the Aalo Clinic, a patient got registered on an IT-based system using their mobile phone number. Following that, the patient receives an automated serial number to get on the queue for general practitioners (GPs). After the screening by the GPs, the patient obtains free diagnostic tests and medicines depending on the prescriptions. The doctor can refer to a higher level of health care facilities if required. Figure 1 shows the overall service flow of the Aalo Clinics.

## Study Design

We conducted implementation research with the Aalo Clinic model between October 2021 and August 2023. With this study as a key component, we carried out repeated cross-sectional household surveys with selected slum dwellers, a primary focus group of this model, to assess the effects of the model on the usage of PHC for managing chronic diseases. The baseline survey was conducted from January to February 2022, shortly after the model's service delivery began, while the end-line survey took place from April to June 2023, one year after its implementation. While both surveys targeted the same population group, the same households were not necessarily sampled at both time points.

## Study Setting and Population

The Aalo Clinic model has been implemented in 6 selected areas with Dhaka North City Corporation, Dhaka South City Corporation, Gazipur City Corporation, and Narayanganj City Corporation. In Dhaka North City Corporation, 2 Aalo Clinics were established and located adjacent to the Korail and Mirpur slums. In Dhaka South City Corporation, 2 Aalo Clinics were also established, which are located adjacent to the Shyampur and Dhalpur slums. Whereas 1 clinic was established in Gazipur City Corporation within the Tongi-Ershadnagar slum and another was established in Narayanganj City Corporation. Urban Health and Demographic Surveillance System (UHDSS) of icddr,b (International Centre for Diarrhoeal Disease Research, Bangladesh), was used as the sampling frame in this study, which includes Korail, Mirpur, Shyampur, Dhalpur, and Tongi-Ershadnagar slums. The UHDSS covers approximately 31,577 households. Details about the UHDSS and its coverage are available elsewhere [10]. However, the inclusion criteria were households covered under UHDSS in the selected slums, household members who had been living with the selected household for at least 6 months before the survey, and households that voluntarily expressed interest in participating in the current study. The exclusion criteria were households not covered by the UHDSS and those not interested in participating in this study.

## Sample Size and Sampling

The household survey served the purpose of assessing the usage of the services of Aalo Clinic to assess the effectiveness of the model in increasing usage of PHC. Concerning this, we aimed to assess the awareness level of the Aalo Clinic model among slum households and expected that approximately 30% of households would be aware of this model and use health care after its implementation. Mahmood et al [12] conducted a study in the same setting and found that 32.2% of sick household members in urban slums used health care from formal health care providers. Considering this proportion, a 5% error level for a 95% CI, and a design effect of 1.2, applied conservatively to account for potential intracluster correlation within slum communities, we estimated a required sample size of 387 for each slum. Furthermore, we considered a nonresponse rate of 10% and projected that the required sample size of 430 households needs to be approached to participate in each study area (total 430×5=2150 households). Finally, we interviewed 2000 households in the baseline survey and 2033 households in the end-line survey. It is important to mention that the sample distribution did not align with the population size of each slum. An equal number of households were sampled from each slum to ensure reliable results. This uniform approach facilitated homogeneity in data collection and supported effective comparative analysis. However, we considered 8919 individuals

XSL•FO
RenderX

in the baseline and 7994 individuals in the end-line satisfying the inclusion criteria for chronic disease, with a minimum age of household members 1 year preceding the survey.

A systematic random sampling method was applied to select the households. For each slum, we established an interval between the selected households based on household size and approached them accordingly. For example, approximately 14,000 households reside in the Korail slum and 2300 in the Shyampur slum. For Korail, we used an interval of 32 (14,000/430), and for Shyampur, an interval of 5 (2300/430). If a selected household had multiple eligible members, we randomly chose one to participate in this study using the lottery method. In cases where a household had no eligible member, we proceeded to the next household until we found an eligible participant.

### Data Collection Tool and Variables

We used a pretested and identical semistructured questionnaire to conduct the baseline and end-line surveys. Data were collected through face-to-face interviews with adult household members aged 18 years or older. A total of 12 trained field research assistants were recruited to carry out each survey under the supervision of a field research supervisor. To ensure data quality, this study's investigators regularly supervised the data collection team and monitored the data to promptly address any issues that arose during the data collection process in this study's areas. Information on the household members' demographics, socioeconomic characteristics, illness, health care usage, providers, and knowledge about the Aalo Clinic was collected. Household knowledge, awareness, and usage of the Aalo Clinic were assessed through respondent interviews. Awareness was defined as whether the respondent had ever heard of the Aalo Clinic, while knowledge required correctly identifying it as a local health care facility and naming at least one of its services. Usage referred to any household member receiving services from the Aalo Clinic before the survey, including consultations, disease care, diagnostics, or referrals. Respondents were also asked about their sources of information regarding the Aalo Clinic.

Usually, slum dwellers used health care from drug sellers, quacks, doctors' chambers, community-based health facilities run by government organizations and NGOs, private clinics and hospitals, government hospitals, medical colleges, and specialized health care institutes [10,12]. In this study, MTPs included doctors with at least an MBBS degree, whether GPs or specialized doctors, who provide health care services through government or nongovernment medical colleges, hospitals, private clinics, or any form of institutional health facilities. These health care organizations hire medically trained staff. In contrast, drug sellers and traditional healers who lack formal training in providing clinical services are categorized as non-MTPs in this study. A similar classification could be found elsewhere [18,21,22]. However, we divided the MTPs based on the Aalo Clinic and other health care facilities that functioned with the MTPs to assess the usage of health care from the MTPs of the Aalo Clinic model.

Evidence reported that in the context of LMICs, the income of informal workers is not stable due to seasonal variations, frequent migration, etc [23,24]. Therefore, to measure the socioeconomic status of slum households, we used asset quintiles rather than income levels. We categorized wealth status into 5 quintiles based on the available assets in the household, such as access to utility services, improved sanitation and drinking water facilities, modern technologies, furniture, etc. These asset variables were used to estimate an asset score through principal component analysis: a robust and validated method widely used in similar contexts. After adjusting for household size, the asset score was used to categorize household wealth status [25]. It is noted that the assessment of wealth quintiles is relative to the current study population and is not comparable to the wealth distribution in the general population of Bangladesh.

### Data Analysis

The background information of the surveyed households, their members, and the health service usage patterns of the sick members are reported as categorical variables with frequency (n) and percentage (%). Out-of-pocket expenditure is presented as the mean and median in Bangladeshi Taka, with US $1=BDT 110. Descriptive analysis was performed to assess distributional changes among surveyed households between the baseline and end-line periods. Additionally, several inferential statistical tests were conducted to assess significant changes between the waves: the Wilcoxon rank sum test for 2 categorical variables, the Kruskal-Wallis test for more than 2 categorical variables, and the *t* test for continuous variables. These ensured the statistical rigor.

Cross-tabulation and chi-squared test were performed to assess the changes in health care usage from MTP among this study's population between the 2 waves. Further, 3 logistic regression models were applied in assessing the impact of the Aalo Clinic on health care usage from the MTP while controlling for other covariates. This analytic approach enables robust estimation of intervention impact while controlling for potential confounders. In the first model, the binary dependent variable was the "status of health care utilization from the Aalo Clinic" (1=used Aalo Clinic MTP services; 0=did not use Aalo Clinic MTP services). In the second model, the dependent variable was "MTP utilization other than Aalo Clinic" (1=used non–Aalo Clinic MTP services; 0=did not use non–Aalo Clinic MTP services). In the third model, the dependent variable was "status of health care utilization from non-MTPs" (1=used care from non-MTPs; 0=did not use services from non-MTPs). Independent predictor variables included age, sex, marital status, education, occupation, asset quintiles, distance of households, survey type, severity of illness, knowledge, and total health care expenditure. A *P* value of <.05 was considered statistically significant. Data analysis was conducted using Stata SE (version 16.0; StataCorp LLC).

### Ethical Considerations

Ethical approval for this study was obtained from the institutional review board of the icddr,b before data collection (PR#22020). Informed written consent was taken from all the respondents before data collection, after explaining this study's objectives, the voluntary nature of participation, confidentiality assurances, and their right to withdraw at any time without

XSL•FO
RenderX

repercussions. For participants unable to read or write, the consent form was read aloud, and consent was documented via thumb impressions in the presence of an impartial witness. All data were anonymized to ensure privacy and confidentiality, with no personally identifiable information collected or disclosed. Data were stored securely with restricted access to authorized research team members only. No financial or material compensation was provided to participants for their involvement in this study. This paper does not include any images or supplementary materials that could reveal the identity of individual participants.

## Results

### Sociodemographic Characteristics of This Study's Participants

Both in baseline and end-line surveys, the proportion of males and females was almost equal. At the end-line survey, the proportion of members with no education (n=3047, 38.12%) and secondary and above (n=2485, 31.09%) increased slightly compared to the baseline period. Further, no substantial change was observed in terms of wealth quintiles between the periods. However, there was a sizable increase in the percentage of respondents who knew about Aalo Clinic at the end-line (n=1473, 73.36%) compared to baseline (n=227, 11.46%). Table 1 presents detailed information on the background characteristics of this study's population.

## Source of Information About Aalo Clinic

Community networks were the primary source of knowledge about Aalo Clinic in both baseline (n=124, 43.06%) and end-line (n=1030, 41.35%) periods. During the baseline period, mass media channels were the second most common source (n=70, 24.31%). By the end-line, individual and family networks became the second most common source of information (n=636, 25.53%). Further details are presented in Figure 2.

**Figure 2.** Sources of information about the Aalo Clinic model among urban slum populations in Bangladesh during baseline (January to February 2022) and end-line (April to June 2023) household surveys.

XSL•FO

### Chronic Illness and Pattern of Health Care Usage and Expenditure

Around 19% (n=1511) of individuals had a chronic illness at the end-line period, whereas the ratio was about 16% (n=1414) in the baseline period. At the end-line, the highest number of people (n=327, 21.64%) endured chronic musculoskeletal problems, while at the baseline, cardiovascular disease was more common (n=286, 20.23%). At the baseline, around 84% (n=1188) of participants required regular treatment for chronic diseases, but only around 71% (n=1010) received treatment in the past 3 months. At the end-line, around 82% (n=1236) needed regular treatment, but only around 38% (n=566) reported receiving it in the past 3 months. Health care usage from private facilities was significantly lower at the end-line (n=202, 35.69% from n=459, 45.45%), while it was higher for Aalo Clinic (n=63, 11.13% from n=6, 0.59%). However, usage from local drug stores remained almost the same, with 36.63% (n=209) at baseline and 36.93% (n=370) at end-line. Details about the diseases, pattern of health care usage, and expenditures are shown in Table 2.

## Health Care Seeking Behavior

Figure 3 presents the preference of health care providers for chronic disease among slum dwellers. Health care usage from MTP at Aalo Clinic was significantly higher, rising from 0.59% (n=6) in the baseline period to 11.13% (n=63) in the end-line period. In both periods, non–Aalo Clinics and local drug sellers were the main health care sources, with non–Aalo Clinics at 60.40% (n=610) in the baseline and 50.53% (n=285) in the end-line, and local drug sellers at 36.24% (n=366) in the baseline and 35.87% (n=206) in the end-line. Reliance on non-MTPs declined slightly, and although this reduction was statistically significant, the magnitude of change was minimal.

XSL•FO
RenderX

**Figure 3.** Health care–seeking behavior for chronic diseases by type of health care providers among urban slum populations in Bangladesh during baseline and end-line surveys.

## Health Care Usage of Chronic Disease Across Various Health Care Providers

At baseline, female patients (n=6, 0.98%), married individuals (n=4, 0.53%), those with no education (n=5, 0.97%), household heads with secondary education or higher (n=3, 0.97%), the unemployed (n=5, 1.33%), irregular earners (n=6, 0.97%), individuals from the richest households (n=3, 1.02%), and those who experienced a reduction in working performance due to chronic illness (n=5, 0.60%) predominantly used health care services from Aalo Clinic compared to their counterparts. A similar pattern was observed at the end-line period for the usage of Aalo Clinic MTPs. Females (n=54, 13.64%), widows or divorced individuals (n=14, 12.96%), household heads with no education (n=26, 11.82%), the unemployed (n=43, 15.69%), currently employed household heads (n=43, 9.45%), irregular earners (n=51, 15.6%), those in the richest asset quintile (n=19, 10.73%), and those who experienced a reduction in working performance due to chronic illness (n=59, 12.72%) also predominantly used health care services from Aalo Clinic compared to their counterparts. Table 3 presents a detailed distribution of patients' health care usage across various providers between 2 periods.

## Econometric Analysis

Factors associated with health care usage for chronic disease from MTPs of Aalo Clinic, non–Aalo Clinic, and non-MTPs are shown in Table 4. Female household members were over 3 times more likely (odds ratio [OR] 3.68, 95% CI 1.54-8.79) to use services from MTPs at Aalo Clinic compared to their male counterparts. Furthermore, individuals residing within the nearby areas were 2 times more likely (OR 2.77, 95% CI 1.08-7.11), and individuals residing within a moderate distance from Aalo Clinic were 3 times more likely (OR 3.23, 95% CI 1.23-8.48) to use its services compared to those living at a longer distance. Compared to the baseline period, household members were 23 times more likely (OR 23.28, 95% CI 8.77-61.80) to use MTPs at Aalo Clinic during the end-line period. Patients whose daily performance decreased due to chronic illnesses were 3 times more likely (OR 3.27, 95% CI 1.16-9.23) to take services from MTPs at Aalo Clinic during the end-line period. Additionally, household members who had knowledge about Aalo Clinic were twice as likely (OR 2.13, 95% CI 1.09-4.14) to use its MTPs compared to those without such knowledge.

[e]*P*<.001.

On the other hand, patients were 2 times more likely (OR 2.05, 95% CI 1.33-3.16) to use non–Aalo Clinic MTPs if their household head had a secondary or higher education level compared to those whose household head had only a primary education level. Individuals residing nearby or within a moderate distance from non–Aalo Clinic MTPs were less likely to use these services compared to those living at a longer distance. Individuals from the richest asset quintiles were about 1.5 times more likely (OR 1.49, 95% CI 0.91-2.45) to use non–Aalo Clinic MTPs compared to those in the middle quintile of this study's population. During the end-line period, household members were less likely (OR 0.33, 95% CI 0.23-0.48) to use non–Aalo Clinic MTPs compared to the baseline period. Moreover, patients whose daily performance decreased due to chronic illnesses were 2 times more likely (OR 2.13, 95% CI 1.36-3.36) to take services from MTPs at non–Aalo Clinics during the end-line period.

Further, we found that households where the household head had an education of secondary or above level were less likely (OR 0.58, 95% CI 0.38-0.87) to use non-MTPs compared to others. Individuals residing nearby and within a moderate distance from non-MTPs were about 23 times and 10 times more likely (OR 23.15, 95% CI 13.92-38.47 and OR 10.23, 95% CI 6.11-17.12) to use these services compared to those living at a longer distance, respectively. Members' richest asset quintiles were less likely (OR 0.73, 95% CI 0.45-1.16) to use non-MTPs compared to those in the middle quintile. Additionally, household members who possessed knowledge about Aalo Clinic were less likely (OR 0.68, 95% CI 0.41-1.10) to use non-MTPs compared to those without such knowledge. However, the association was not statistically significant.

## Discussion

### Principal Results and Comparison With Prior Work

The pilot Aalo Clinic model offered an essential package of health services, including chronic diseases, and an opportunity for outpatient PHC for the urban low-income population.

We found that health care use from Aalo Clinic MTPs for chronic diseases was significantly associated with higher use compared to other MTPs. The Aalo Clinic's unique features, such as the availability of affordable and quality health care services for chronic diseases, may significantly influence its impact on the community. The multivariate logistic regression analysis demonstrated a significant effect that individuals were over 23 times more likely to use Aalo Clinic MTP services at end-line than baseline. A similar initiative, namely the "Mohalla Clinic" in Delhi, India, has been implemented [26], and its impact aligns with the findings of this study to make primary care accessible and affordable from MTP for urban underserved populations [27,28]. However, despite these positive trends, the intervention did not substantially reduce the usage of health care from non-MTPs. Non-MTP providers remain prevalent and widely trusted within these communities. The continued reliance on non-MTPs in slum areas can be attributed to several factors, including deeply rooted health care–seeking behaviors, cultural preferences, limited medicine supply, and the convenience and accessibility of informal providers such as drug sellers and traditional healers. Shifting patient preferences away from non-MTPs is a complex and gradual process that requires sustained engagement.

Knowledgeable individuals can make informed decisions when choosing health care providers [29]. The integration of awareness measures in our analysis is a strength, offering a

XSL•FO
RenderX

deeper understanding of demand-side dynamics. Among the slum population, knowledge about Aalo Clinic increased significantly, which may be associated with greater usage of health care services from Aalo Clinic MTPs compared to other MTPs. A study conducted by Hasan et al [21] identified factors that influence health care usage from the MTP of a government-sponsored health protection scheme in Bangladesh. The scheme covers the population who are below the poverty line and live in semiurban and rural areas. However, this study reported that households with knowledge about the scheme were significantly associated with higher health care usage from the MTP of that scheme.

While evidence from LMICs often shows higher health care usage among males [30-32], our study found that females were more likely to access Aalo Clinic MTP services. Several contextual factors may explain this finding. The strategic placement of Aalo Clinics within slum areas enhances accessibility, while the provision of privacy, reduced costs, and shorter travel distances are particularly important for women in the urban poor settings of Bangladesh. These factors likely contribute to the higher uptake of services among females at Aalo Clinics compared to other MTPs. This observation is consistent with findings from studies among similar and general populations in Bangladesh [33,34], highlighting the importance of placing clinics close to communities to reduce sex-based access barriers.

This study identified a noteworthy pattern in health care usage, demonstrating a significant association between the distance from households and the type of health care provider. Our findings indicate that individuals are more motivated to seek care from providers located in closer proximity, irrespective of whether the provider is an MTP or a non-MTP. This observation aligns with previous studies, which have similarly highlighted the critical role of proximity in influencing health care–seeking behavior [35,36]. On the other hand, the significant positive association between longer distance and higher health care usage, specifically from non–Aalo Clinic MTPs, reveals an interesting trend. This could be indicative of several factors, such as specialization of health facilities for specific services, reputation, and the referral system [37]. Non–Aalo Clinic MTPs provide advanced laboratory tests, specialist consultations, and inpatient care unavailable at the more basic primary care level of Aalo Clinics. This may be associated with patients traveling from farther away or being referred to non–Aalo Clinic MTPs for services not offered locally, resulting in higher usage of these more distant providers. Hasan et al [21] also found that, though health care, medicine, and diagnostic services are free in a government-sponsored health protection scheme, a higher proportion of people still sought care from other MTPs located within a similar or greater distance.

Though there was no significant difference in health care usage from Aalo Clinic MTPs across asset quintiles, a significant difference was observed in the usage of health care services from non–Aalo Clinic MTPs and non-MTPs across asset quintiles. Patients who use health care from non–Aalo Clinic MTPs where those who belong to the richest quintiles were more likely to use health care from non–Aalo Clinic MTPs; whereas those who use health care from non-MTPs, among those who belong to the richest quintiles, were less likely to seek health care from non-MTPs. Ahmed et al [18] conducted a study in Bangladesh and showed a similar finding that individuals of the richest households are more likely to use health care than individuals of the poorest households. Moreover, evidence reported that people who belong to the richest quintiles are less likely to use health care from non-MTPs [38,39].

Nevertheless, the Aalo Clinic model has been delivering free-of-cost essential health care services for chronic diseases for the low-income slum population, a substantial portion of them opt for informal providers, such as drug sellers. This behavior may be rooted in long-standing historical and cultural patterns of health care seeking within these communities. Traditionally, many slum residents have relied on informal providers such as drug sellers, traditional healers, or unlicensed practitioners due to their easy accessibility, flexible hours, and lower immediate costs. These providers are often trusted members of the community who offer quick remedies, sometimes with payment options that formal providers cannot match. Additionally, limited awareness of the benefits of MTPs, coupled with barriers such as distance, cost, and social norms, has reinforced preferences for informal care.

Consequently, changing these entrenched behaviors will require sustained time and concerted efforts. The widespread presence of informal providers, combined with the lower travel time and out-of-pocket costs associated with accessing them, further perpetuates their use. To effectively address this challenge, it is crucial to establish and maintain satellite clinic services within the community over an extended period. These clinics can serve as accessible platforms for educating slum residents on the importance of regularly using qualified MTPs for chronic disease management, while minimizing travel and financial barriers.

Both affordability and quality of health care are critical components of UHC. Thus, it is important to emphasize these. Though Aalo Clinic has made notable advancements in enhancing access to quality PHC, concerns regarding the affordability of its services remain, primarily due to associated costs. Despite the clinic's strategic location for slum dwellers and its provision of free registration, consultations, essential medicines, and diagnostic or laboratory services, users may still incur significant health care expenses or face higher opportunity costs. These financial burdens may often arise from the limited availability of certain medicines and laboratory services at Aalo Clinics, necessitating that patients seek these resources externally, thereby increasing out-of-pocket payments. To mitigate this affordability issue, it is imperative to ensure that Aalo Clinics are adequately stocked with essential medicines and laboratory services. Close collaboration with government stakeholders responsible for urban PHC provision should be pursued to address these gaps effectively. Enhancing the operational readiness of the model could help reduce out-of-pocket expenses and improve equitable access to affordable health care services, thereby advancing progress toward UHC.

XSL•FO
RenderX

Even though the Aalo Clinic model is associated with higher health care usage, it faces a significant challenge in the form of extended waiting times for accessing services. This issue likely arises from either an influx of patients or an inadequate number of health care providers. Each Aalo Clinic center is staffed with only 1 male and 1 female GP per shift, which may prove insufficient given the patient load. Research indicates that longer waiting times are often negatively correlated with perceived quality of care [40]. To address this issue effectively, it is crucial to improve both the infrastructure and human resource capacity of the Aalo Clinic. Enhancing these aspects could help mitigate waiting times and improve overall patient satisfaction and service delivery.

### Limitations

One of the key limitations is that we were unable to account for seasonal variations in health care usage because the baseline survey was conducted from January to February 2022, while the end-line survey occurred between April and June 2023. Additionally, our reliance on self-reported data introduces the possibility of recall bias. Furthermore, the repeated cross-sectional design of this study limits our ability to make causal inferences about the relationship between significant factors and health care usage. Therefore, to better understand these associations over time, future research using a longitudinal design is warranted. As we did not follow the same households over time, it is difficult to determine whether observed changes are directly attributable to the Aalo Clinic intervention or influenced by external factors, such as other NGOs, government schemes, or broader contextual changes in the urban health system. Finally, the use of equal sample sizes across slums, regardless of population size, may limit generalizability, although it allowed for better cross-site comparison.

## Conclusions

The Aalo Clinic model is significantly associated with increased usage of MTPs for chronic disease care, with patients showing a shift in preference from other MTPs, particularly private providers, to Aalo Clinics. Although there was a statistically significant but modest reduction in reliance on non-MTPs, informal providers continue to serve as an important source of care in low-income, underserved slum areas. To support continuity of care for chronic diseases requiring regular treatment, Aalo Clinic authorities should maintain consistent availability of essential medications. Future longitudinal research is warranted to better understand the drivers of patient preferences for chronic diseases and the longer-term impact of the Aalo Clinic model before scale-up, providing evidence to inform strategies for strengthening urban PHC and advancing progress toward UHC for low-income slum populations in Bangladesh.

## Acknowledgments

We sincerely acknowledge the funding support provided by the Swedish International Development Cooperation Agency (Sida) through UNICEF (United Nations International Children's Emergency Fund; 02150). We extend our gratitude to UNICEF, our direct donor. We also sincerely acknowledge the cooperation and support of Nari Maitree, PHD (Partners in Health and Development), and CMED (Cloud-Based Medical System) throughout this study. icddr,b (International Centre for Diarrhoeal Disease Research, Bangladesh) is also thankful to the Governments of Bangladesh and Canada for providing unrestricted or institutional support. All authors declared that they had insufficient funding to support open access publication of this paper, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this paper.

## Data Availability

The datasets used and/or analyzed during this study are available from the corresponding author upon reasonable request.

## Funding

This study was funded by UNICEF, with support from Sida (02150). The funder, UNICEF Bangladesh, had no involvement in this study’s design, data collection, analysis, and interpretation.

## Authors' Contributions

MGR and SSM conceptualized the research idea. MGR, MZH, and SSM performed the data analysis and interpretation. MGR and SSM were responsible for writing the manuscript. MZH, KIT, HAP, KN, MWH, MZH, CS, MAJ, and MV contributed to writing, reviewing, and revising the manuscript. All authors read and approved the final manuscript.

## Conflicts of Interest

## Abstract

**Background:** As communication technology advances and the digital divide grows, a deeper understanding of the influence of different information sources on vaccine uptake by generations can inform targeted public health interventions in times of future crisis. While the COVID-19 pandemic highlighted the role of media sources on the decision to receive vaccines, no studies have focused on the impact of the type and number of information sources in a population-based sample in California.

**Objective:** In this study, we examined associations between Californians' self-reported most relied upon COVID-19 information sources, categorized by type and measured as a count, and their COVID-19 vaccination status using data collected from the 2022 California Health Interview Survey. To address differences in information preferences and vaccine uptake by age, we also tested for potential effect modification of the relationship between relied upon COVID-19 information sources and vaccination status by generational membership (eg, Generation Z, millennials, Generation X, baby boomers, and Silent Generation).

**Methods:** We conducted a secondary analysis of cross-sectional data from the 2022 California Health Interview Survey. Vaccine status (any or none) was modeled as a function of information sources (or count) controlling for important sociodemographic and health confounding variables. Interaction terms of information sources (or count) by generational status were added to the models to test effect modification, and if significant, the models were stratified by generation. All analysis was survey-weighted to account for the complex survey sampling design.

**Results:** Compared to relying on traditional news media for COVID-19 information, relying on word of mouth (odds ratio [OR] 0.6), social media (OR 0.62), and doctors (OR 0.41) for COVID-19 information was associated with lower odds of being vaccinated for COVID-19. A dose-response relationship was identified, with each additional information source associated with 9% higher odds of being vaccinated for COVID-19. In stratified models, social media, compared to traditional news media, was associated with lower odds of vaccination for Generation X, baby boomers, and the Silent Generation.

**Conclusions:** Health information preferences, especially for traditional news media, are associated with COVID-19 vaccine uptake, and the information sources differ by generation. These findings provide information for stakeholders interested in vaccine hesitancy, health informatics, messaging strategies, health literacy, and future health information outreach programs during epidemics or pandemics. Dissemination of public health information should include multiple information sources to reach all individual preferences across different generations.

## Introduction

### Background

#### *Information Sources on COVID-19 Vaccination*

The sources of information individuals consult and rely on have been linked to decisions on vaccination [1]. Nontraditional information sources such as social media and word of mouth vary in their reliability and verifiability and are not held to the same standards of peer review or fact-checking in the same way as information from government, news outlets, and health care [2]. Information and misinformation about COVID-19 can have dangerous consequences [3], because of the novelty of the disease and changes in information as more evidence is produced [4].

XSL•FO
RenderX

Studies in Sierra Leone and Italy have shown that the type and number of information sources used can significantly impact vaccine intention and uptake [5,6]. In an earlier study using the California Health Interview Survey (CHIS), people who reported using health care providers as their primary information source about vaccines have higher odds of human papillomavirus vaccine receipt or intention [7]. Another study found that obtaining vaccine information from the internet or relatives is associated with lower vaccination rates for measles, mumps, and rubella, and hepatitis B virus [1]. Additionally, when individuals used more than one information source to make measles, mumps, and rubella, or hepatitis B virus vaccine decisions, there was higher reported vaccine hesitancy [1]. On the contrary, a more recent study found that relying on and consulting more sources was associated with higher odds of COVID-19 vaccine uptake [8].

### *Vaccination Hesitancy and Uptake*

Access to vaccinations and vaccination hesitancy (ie, the refusal or reluctance to receive vaccinations despite availability) are independent and joint contributors to vaccine uptake [9]. Vaccine hesitancy has been a persistent public health problem since the inception of vaccines [10], and in 2019, it was identified by the World Health Organization (WHO) as one of the top 10 global health threats [11]. Mass media, the technology used to reach the public such as radio, television, or newspapers, has historically played a significant role in influencing health beliefs and behaviors, including vaccine hesitancy and uptake [10,12].

### *Vaccination Uptake, Hesitancy, and Age*

In 2021, vaccination uptake differed by generation, with coverage lowest among individuals aged 18 to 29 years and highest among individuals aged 65 years or older [13]. Prior literature indicates that younger adults tend to be more vaccine hesitant than members of older generations [10,12]. Few papers before the COVID-19 pandemic examined the role of information sources in vaccine uptake, perhaps because the issues were less politicized, people trusted information about vaccines from the health care and government sectors, and vaccine rates were higher overall [14]. With the COVID-19 pandemic, misinformation about vaccines became more prevalent and the question of vaccine uptake became polarized with political affiliation [14]. In one paper, social media use, often associated with younger age, is associated with higher odds of COVID-19 vaccine hesitancy [12]. There is also evidence that identified sources of information including government, science, and discussing vaccination with family and friends positively influenced COVID-19 vaccine intention [10]. However, to our knowledge, no studies have explicitly examined COVID-19 vaccine uptake by generation and information source.

Generational membership including Generation Z (Gen Z; born 1995 - 2012), millennials (born 1980 - 1994), Generation X (Gen X; born 1965 - 1979), baby boomers (born 1946 - 1964), and the Silent Generation (born 1925 - 1945) is associated with varying historical, technological, social, economic, and political circumstances, which may impact the amount and type of information sources consumed [15,16]. Media preferences and trust vary by age group with one nationally representative survey study finding that 9.5% of Gen Z participants trust their social media contacts mostly to completely (Facebook and Twitter, subsequently rebranded X) for COVID-19 information, compared to 3.8% of Silent Generation, 6.3% of millennials, 5.9% of Gen X, and 6% of baby boomer participants [15]. In the same study, 44.6% of Gen Z participants agreed or strongly agreed with the statement "COVID-19 vaccines have many known harmful side effects," compared to 44.7% of millennials, 43.2% of Gen X, 31.8% of baby boomers, and 18.7% of the Silent Generation participants [15]. However, no studies to our knowledge have examined the potential effect modification of the association between media preferences and vaccine uptake by age or generational status.

Given this context of varying trusted information sources and vaccine decision making, the WHO and Centers for Disease Control and Prevention (CDC) have monitored public communication on digital and nondigital platforms related to COVID-19 to address misinformation and promote accurate public health information [17,18]. These include social media, online platforms, news, radio, and television [17]. The WHO described an excess of both accurate and inaccurate information as an "infodemic" requiring coordinated management and has since created a framework to identify and respond to misinformation [17]. As a result, the CDC formed an Insights Unit to track and analyze information using a social listening protocol, resulting in reports that guided public health messaging [18].

## Gaps in the Literature

Taken together, previous literature includes investigations of the influence of different information sources on vaccination decisions across various demographics, yet there remain gaps in understanding these dynamics across the range of information sources at the population level. Studies are also needed to focus on the number of information sources as well as the type [19] and to consider differences in these associations by generation.

## Goal of This Study

To address these gaps, the current study leverages CHIS, a population-based California survey, to examine associations between the type and number of the most relied upon information sources and COVID-19 vaccination status. Most relied upon sources were a specific term created by CHIS referring to the highest ranked source. We hypothesized that the use of specific types of information sources such as "your doctor" is associated with higher rates of vaccination when compared to traditional news media (eg, television, radio, and newspaper). We also tested the effect modification of the relationship between information sources (type and number) and vaccination status by generational membership, hypothesizing that the impact of traditional news media sources on vaccination status will be greater among older adults and the impact of digital media sources (eg, social media) on vaccination status will be greater among younger adults. Additionally, we hypothesized that identifying social media as the most relied upon information source would be associated with lower odds of vaccination. The study findings can improve our understanding of media preferences as influences on health

XSL•FO
RenderX

decision behaviors and vaccine hesitancy and inform public health messaging efforts tailored to generational differences.

## Methods

We conducted a secondary analysis of cross-sectional data from the 2022 CHIS.

### Data Source

The CHIS is a population-based survey of noninstitutionalized Californians collected by Social Science Research Solutions, a research company, for the University of California, Los Angeles Center for Health Policy Research [20]. The 2021 - 2022 CHIS data were collected between March 18, 2021, and November 30, 2022, using a mixed-mode method surveying (phone and internet) of the representative population of Californians and geographically stratified address-based sampling. Of the adult interviews conducted, 89.5% were completed online, and 10.5% were over the telephone. CHIS strategically over-samples to account for households abstaining from participation and added a prepaid cell phone sample to reach individuals left out of general address-based sampling frameworks. Interviews were held in the following languages: Spanish, English, Chinese (Cantonese and Mandarin), Korean, Tagalog, and Vietnamese.

### Sample

The study sample included all adult Californians responding to the 2021 - 2022 CHIS survey (N=21,463) [20]. No additional exclusion criteria were applied and there were no missing data.

### Ethical Considerations

The University of California Davis Institutional Review Board reviewed this study and determined it was not human participants research and therefore was exempt from further review based on the use of publicly available data without identifying information (IRBNet ID 2233309). As a secondary analysis of existing data, informed consent was not obtained by the study investigators. Information about informed consent of CHIS participants is available online [20].

### Variables and Measurement

#### *Dependent Variable*

Vaccine uptake, operationalized as self-reported vaccination status, is the dependent variable for both aims. Participants were asked, “Have you been fully vaccinated, partially vaccinated, or are you not vaccinated, for COVID-19?” Being fully vaccinated was defined in the CHIS as receiving 2 shots of the Pfizer or Moderna vaccine, 1 shot of the Johnson & Johnson vaccine, or 2 shots of the AstraZeneca or Sinovac vaccine (which are available in other countries, not in the United States). Partially vaccinated, not explicitly defined by the survey documentation, was interpreted to mean a vaccination series that had been initiated but not completed. Vaccinations were still being distributed to priority groups, through November 2022; therefore, to fully capture intent to vaccinate in our cohort, we categorized any level of vaccination (partial or full) as “Vaccinated” (yes=1) and “Not Vaccinated” as the reference group (no=0).

#### *Independent Variables*

Participants were asked about their most relied upon sources of COVID-19 information, categorized into 12 possible categories: newspapers, radio, television, family, friends, community leaders, religious leaders, social media, doctors, governmental agencies, places of employment, and none of the above. For the examination of the type of information source, the response options were recoded into 6 categories: traditional news media (television, radio, and newspapers), word of mouth (family, friends, religious leaders, and community leaders), social media, your doctor, your employer, or governmental agency, or none of these. The reference group was reporting traditional news media as the most reliable source. For the number of sources, the independent variable is a count of the original 12 information sources with a range of 0 to 11.

#### *Covariates*

Sociodemographic variables were included in the models as potential confounders. This included age categorized by generational membership, which was also examined as an effect modifier: Gen Z (reference group; aged 12 - 25 y), millennials (aged 26 - 39 y), Gen X (aged 40 - 54 y), baby boomers (aged 55 - 74 y), and Silent Generation (aged ≥75 y) [16]. The University of Southern California generational age ranges generally matched the CHIS age categories with some exceptions around cut-off years, for instance, the millennial category featuring young members from Gen X.

Following Joshi et al’s [21] conceptual framework on the factors that influence vaccine acceptance and hesitancy, the covariates were selected as relevant to this study and as important social and structural determinants of COVID-19 vaccination uptake [22]. They include race or ethnicity, urbanicity, self-reported sex, educational attainment, marital status, insurance status, and income. Reported race and ethnicities include White non-Hispanic (reference group), Hispanic, African American or non-Hispanic, American Indian or Alaskan Native, Asian, and Other or Two or More Races. Urbanicity was categorized as urban (reference group), mixed urbanicity, suburban, and rural. Self-reported sex was categorized as male (reference group) or female. Educational attainment was categorized as having no high school diploma (reference group), a high school diploma, some college degree, bachelor’s degree, master’s degree, or PhD. Marital status was categorized as married or living with a partner (reference group), widowed, divorced, separated, or never married. Insurance status was categorized as yes (reference group). Income was recoded into four categories: (1) less than US $39,999 (reference group); (2) US $40,000 to $79,999; (3) US $80,000 to $149,999; and (4) US $150,000 to over US $180,000.

### Statistical Analysis

All analyses were conducted with Stata 18 (StataCorp LLC) and CHIS survey weights were applied to account for the complex survey sampling design. We used descriptive statistics to summarize all study variables and to compare vaccination status by generation. Multivariable logistic regression was used to model information sources first as categories, then as counts, as functions of vaccination status in models adjusted for all

XSL•FO
RenderX

covariates. We also tested the effect modification of these associations by generational membership by adding information source by generation interaction terms to the models. If any of the source by generation interaction terms were significant, we conducted and reported stratified models by generation. Statistical significance was set at $P<.05$.

## Results

### Sample Description

Before applying survey weights, most participants were baby boomers aged 55 to 74 years (n=8905, 41.49%), followed by Gen X aged 40 to 54 years (n=5328, 24.82%), and millennials aged 26 to 39 years (n=3598, 16.76%; Table 1). Most participants were female (n=12,238, 57.02%). Over half held a master's degree or PhD (54.5%, n=11,699) and 33.2% (n=7116) had some college, vocational education, or an associate's degree. Almost half of the participants identified as White, non-Hispanic (n=10,432, 48.6%), followed by Hispanic (n=5719, 26.7%), Asian (n=3234, 15.1%), African American (n=1072, 5%), American Indian or Alaska Native (n=129, 0.6%), and two or more races (n=877, 4.1%). Less than half lived in urban areas (n=8956, 41.7%) and 31.9% (n=6855) lived in suburban areas. More than half of the participants were married (n=12,104, 56.4%) and 33.1% (n=7107) had an annual income greater than or equal to US $150,000. Most participants had health insurance (n=20,666, 96.3%). Just over half relied on traditional news media (ie, television, radio, and newspaper) as their primary source of COVID-19 information (n=11,356, 52.9%).

| Governmental agency or employer | 3733 (17.39) |
| None of these | 1231 (5.74) |

Most participants were vaccinated for COVID-19 (n=19,836, 92.4%), and the vaccination rates increased slightly with age (from 88.97% among Gen Z to 96% in the Silent Generation). Among survey respondents who were vaccinated, the most relied upon information sources were their employer or government (95%) and traditional news media (94.6%). Vaccination rate was lowest (n=936, 76%) among those reporting no sources of information, whereas the highest vaccination rates (93% - 95%) were found for those reporting between 2 and 7 resources (Table 2). Among survey respondents who did not use any information sources, 76% (n=936) were vaccinated for COVID-19, whereas this rate was 80.6% (n=29) among those who used 11 resources.

**Table .** COVID-19 vaccination status by source count (N=21,463).

| Source count | Total (N=21,463) | Vaccinated (n=19,836), n (%) |

## Regression of Vaccination Status on Information Source Type

In the fully adjusted logistic regression model of information source type and vaccination status (Table 3), compared to respondents using traditional news media for information about COVID-19, those relying on word of mouth had 40% lower odds ($P$<.002); those using social media had 38% lower odds ($P$<.001); those relying on their doctors had 59% lower odds ($P$<.001); and those reporting “none of these” had 79% lower odds of being vaccinated for COVID-19 ($P$<.001). There were no significant differences between using employers or governmental agencies and receiving a COVID-19 vaccination compared to traditional news media.

### Regression of Vaccination Status on Information Source Count

In the fully adjusted model examining the count of relied upon information sources and vaccination status, each additional source was associated with 9% higher odds of being vaccinated for COVID-19 (*P*<.001; Table 3). In this model, the odds of being vaccinated were higher among Gen X, baby boomers, and Silent Generation when compared to Gen Z. Covariates in this model associated with higher odds of vaccination included an annual income of over US $40,000 (compared to <US $40,000), self-reporting race or ethnicity as Hispanic, Asian, or two or more races (compared to White non-Hispanic), never being married (compared to married or living with a partner), self-reporting male, and attaining postgraduate education (compared to no high school diploma). Covariates associated with lower odds of vaccination in the source count model included self-reporting race or ethnicity as African American (compared to White non-Hispanic), living in a rural or suburban environment (compared to urban), and attaining a high school diploma or completing some college (compared to no high school diploma).

### Effect Modification

We found significant effect modification of the associations of type of information source and vaccination status by generation. Accordingly, we conducted full models stratified by generation (Table 4). For each generation, 2 models were run, one with information source type and one with information source count as the primary independent variable.

XSL•FO
RenderX

**Table .** Multivariable regression models of vaccination status stratified by generation[a].

| Information sources | Generation Z (18-25 y; n=1106) | | Millennial (26-39 y; n=3598) | | Generation X (40-54 y; n=5328) | | Baby boomers (55-74 y; n=8905) | | Silent Generation (≥75 y; n=2526) | |
|---|---|---|---|---|---|---|---|---|---|---|

[a]All estimates are survey weighted and generalized to a sample of N=29,560,694.

[b]Not applicable.

In the sample restricted to Gen Z, the only information source type associated with vaccination status was “none of these,” which was associated with lower odds of being vaccinated compared to traditional news media (odds ratio [OR] 0.39, 95% CI 0.18 - 0.84; Table 4). Source count was significantly associated with higher odds of vaccination uptake (OR 1.18, 95% CI 1.003 - 1.38; Table 4). In the sample restricted to millennials, only “none of these” information sources (compared to traditional news media) was associated with lower odds of vaccination (OR 0.36, 95% CI 0.16 - 0.74). Source count was not significantly associated with vaccination uptake for millennials. In the sample restricted to Gen X, word of mouth (OR 0.41, 95% CI 0.23 - 0.74), social media (OR 0.63, 95% CI 0.40 - 0.98), your doctor (OR 0.29, 95% CI 0.17 - 0.50), and “none of these” (OR 0.24, 95% CI 0.13 - 0.46) were significantly associated with lower odds of vaccination compared to traditional news media. Source count was significantly associated with higher odds of vaccination for Gen X (OR 1.13, 95% CI 1.03 - 1.24).

In the sample restricted to baby boomers, social media (OR 0.18, 95% CI 0.11 - 0.30), your doctor (OR 0.47, 95% CI 0.33 - 0.67), and “none of these” (OR 0.09, 95% CI 0.06 - 0.13) were significantly associated with lower odds of vaccination compared to traditional news media. Source count was significantly associated with higher odds of vaccination for baby boomers (OR 1.11, 95% CI 1.001 - 1.24). In the sample restricted to the Silent Generation, social media (OR 0.16, 95% CI 0.05 - 0.51) and “none of these” (OR 0.10, 95% CI 0.04 - 0.24) were associated with lower odds of vaccination when compared to traditional news media. Source count approached but did not reach statistical significance for the Silent Generation.

## Discussion

### Principal Findings

In this large population-based sample of adult Californians, we find that both the identified most-relied-upon information source and the count of identified sources are robust predictors of the COVID-19 vaccination status. This supports previous evidence that information sources are associated with vaccination status [1,5]. This study contributes new knowledge to the associations between vaccine status, number of sources used, source type, and examines variation in these associations by generational membership. Thus, these are important factors to consider in the future during research and public health program development when the need arises.

In line with previous literature that found social media to be associated with negative views towards COVID-19 vaccination receipt, we found that use of social media was associated with lower odds of vaccination status compared to traditional news media and controlling for covariates. When stratified by

XSL•FO
RenderX

generation, this association held among Gen X, baby boomers, and the Silent Generation. This divergence may be explained by the personalization of social media feeds and the potential for algorithmic information silos. Similar to our findings, Moon et al [12] found higher social media use was a significant predictor of COVID-19 vaccine hesitancy. In this study, this was true across older generations such as Gen X, baby boomers, and the Silent Generation. Future research may be warranted to explore how targeted advertising or recommended pages via an algorithm may be able to amplify vaccination information to combat the spread of misinformation.

In this analysis, we relied upon traditional news media as the reference category. We found in all generational groups, with the exception of Gen Z and millennials, that relying on social media for vaccine information compared to traditional news media was associated with lower odds of vaccination uptake. Among Gen Z and millennials, relying on social media compared to traditional news media was not associated with vaccination uptake. This means that although these generational groups tend to use social media more than others, its influence is not different than that of traditional news media. These groups may view traditional news media through social media platforms, thereby minimizing the difference in the influence of these information sources. While other researchers have identified relationships between social media use and vaccine hesitancy [12], they were unable to detail what type of content was being consumed through social media. Social media may include short-form clips of traditional news media information. These inconsistencies warrant further research to better understand how different generations consume social media and how this, in turn, may impact vaccination uptake.

Our findings consistently showed that respondents reporting “none of these” information sources had lower odds of being vaccinated across all generations. The deeper meaning behind this response is unclear, though it could represent those who abstain from media or do not interact with the listed sources; this may represent a gap in the listed responses to the survey question. For instance, alternate popular sources such as podcasts were not among the multiple-choice answers provided by CHIS. It is also possible that those who did not fully understand the question or preferred not to answer selected this option.

While reporting “your doctor” as the most relied upon information source was associated with lower odds of vaccination, this was in comparison to traditional news media. At the time of this survey, information surrounding COVID-19 and vaccinations was communicated heavily through various traditional and nontraditional media sources. This finding does not indicate that doctors were not perceived as reliable sources of information for COVID-19, but rather that traditional news media sources likely played a more central role in distributing COVID-19 vaccination information and related public health messaging.

Consistent with past studies, we found that relying on a higher number of information sources was associated with higher COVID-19 vaccination rates, possibly due to accumulating greater knowledge about vaccine-related information [7,8]. Our results further identified a dose-response relationship with a greater quantity of relied-upon information sources being associated with increasing odds of being vaccinated for COVID-19. These results suggest that people who engage in more health information-seeking behaviors may be more successful in garnering accurate and updated public health advice. It is also plausible that individuals seeking multiple sources of information have a greater propensity to be vaccinated due to other personal characteristics allied with health promotion.

It should be mentioned that the vaccination rates across each generation in this sample surpassed both state and national averages [23]. This study found that Gen Z had the lowest COVID-19 vaccination rates among all generations, while the Silent Generation had the highest. In comparison, California data shows that individuals aged 40 to 69 years exhibited both higher hesitancy and higher likelihood of vaccination compared to other age groups [12]. The concept of generational imprinting can suggest that the generation that grew up during poliovirus vaccination development may view COVID-19 vaccinations in a positive light and therefore may desire to receive the vaccination as soon as they can [15]. The high rate of Silent Generation vaccine receipt in our sample may be explained by the timing of the survey, during which vaccine rollout was made available to older adults and health care workers first.

These findings on COVID-19 vaccination patterns among Californians have important public health implications about the role of information sources. They illuminate the need to tailor messaging by generation based on preferred information sources. This will support accurate and trustworthy information reaching all audiences, as the sources of information used are linked to knowledge, vaccine intention, and vaccination rates. Accessing a variety of sources may contribute to shaping knowledge and behaviors regarding vaccination. Reliance on diverse information sources could combat algorithmic information silos, with those who access multiple, reliable sources being more likely to be informed about the benefits and risks of vaccines and thereby influencing their vaccination decisions. This information contributes to our understanding of the information sources used by age generations in the context of the COVID-19 pandemic and may inform strategies for promoting health equity and widespread immunization in similar, future health contexts.

## Limitations

This study had several limitations. First, due to the cross-sectional study design, we cannot establish temporal precedence or causation. Second, the data were collected during the COVID-19 pandemic, and we cannot conclude that the findings would hold before or after the pandemic. Third, because the CHIS data were collected in 2021 and 2022, there was not equal access to vaccination for all participants as vaccines were just becoming available to the public. Accordingly, we combined those who were partially vaccinated with those who were fully vaccinated into one “vaccinated” category. Partial vaccination does not necessarily indicate an intention to become fully vaccinated. We have no assurance that partially vaccinated individuals completed the vaccination series, and if they did

XSL•FO
RenderX

not, we do not know whether vaccine hesitancy was a contributing factor. Additionally, COVID-19 vaccination status is time-dependent, as vaccine availability differed across age groups and months in 2021 and 2022 when the data were collected. The CHIS dataset does not include the interview month, resulting in the inability to adjust for survey timing. Combining these categories may introduce misclassification bias and may inflate the rates of vaccination in the study and underestimate underlying vaccine hesitancy. Also, we are unable to identify the amount, quality, or precise source of information in any of the relied upon categories. For instance, social media platforms include a variety of information sources such as clinician influencers, friends and family, public health, and traditional news.

Fourth, we can only speculate about the information source choice "none of these" and what this meant to respondents. Our finding that this choice was consistently associated with lower odds of vaccination warrants follow-up in future studies, perhaps with cognitive interviews or other qualitative approaches designed to more fully understand this selection. This information would be helpful in informing public health guidance and messaging, building trust within community-academic partnerships, and efforts to improve health literacy in the community.

Fifth, because this is a secondary data analysis, our findings are subject to unmeasured confounding. Greater information about vaccination intentions could have further elucidated the findings given that these data were collected in the early phases of vaccine rollout. In addition, the CHIS categorical age ranges fit the generational age cutoffs closely with a few exceptions [16]. For instance, millennials are defined as those born between 1980 and 1994, corresponding to those aged 28 to 42 years in 2022. However, the CHIS survey had categorical age ranges that did not perfectly fit (26-29 y, 30-34 y, and 35-39 y) these generational groupings. As a result, our generational membership included or missed some members with ages close to the cut points, for example, millennials included the young members of Gen X. In addition, there may be limitations to generalizability as a result of the "healthy user effect" or positive selection bias [24]. Our sample had higher than average vaccination rates, which may relate to participants being more likely to participate in a study about health [23,24]. As a result, our sample may have different characteristics from the population of interest, as the vaccination rates in our sample were higher than the California state average [23]. Finally, because the CHIS survey is a population-based sample of California residents, findings may not be generalizable beyond California.

Today's political climate has seen a rise in antivaccine attitudes [25] alongside the perpetuation of false narratives linking vaccines to autism in children [26]. These events may risk delaying the development of new vaccines and undermining public confidence in vaccine experts. Within this context, a deeper understanding of how information sources influence vaccine decision-making may be more pertinent than ever.

## Conclusions

Our findings suggest that an effective approach to disseminating accurate public health information should include multiple methods to reach all generational preferences of the public. The findings from this study on COVID-19 vaccination patterns in California provide important contributions for stakeholders interested in vaccine hesitancy, health informatics, and health literacy. They identify the importance of understanding generational differences in how people rely on media during a pandemic. These findings may also not be limited to vaccination use, and further research could expand to explore other preventative health care behaviors such as screenings, or other public health aspects that are discussed by media sources.

## Acknowledgments

The authors would like to thank the anonymous reviewers for their insightful feedback and the University of California Davis Betty Irene Moore School of Nursing for its continued support.

## Funding

JFZ is supported by the National Institutes of Health under grant T32 5T32NR021294-02. JFZ, MS, and GRF receive funding through scholarships at the University of California Davis Betty Irene Moore School of Nursing to support their doctoral studies. No external financial support or grants were received from any public, commercial, or not-for-profit entities for the research, authorship, or publication of this article.

## Data Availability

The datasets generated or analyzed during this study are publicly available in the California Health Interview Survey (CHIS) repository and can be accessed by creating a free online account [20].

## Conflicts of Interest

None declared.

## Abstract

**Background:** A large wave of COVID-19 caused by SARS-CoV-2 Omicron subvariants began in Beijing in early December 2022.

**Objective:** This study aimed to evaluate the COVID-19 vaccine effectiveness (VE) in mitigating the risk of COVID-19–related hospitalization during the epidemic.

**Methods:** We conducted a retrospective cohort study linking regional health care data and vaccination registry routinely collected in Beijing. All electronic medical records on COVID-19–related hospital discharges of older inpatients aged ≥80 years during November 2022 and February 2023 were included. Poisson regressions were used to estimate incidence risk ratio of COVID-19–related hospitalization, severe or critical cases, and in-hospital death compared with unvaccinated groups, adjusting for gender and age. VE was calculated as 1 minus incidence risk ratio×100%.

**Results:** A total of 53,789 individuals aged ≥80 years were included, 28,423 (52.84%) were male, 45,270 (84.16%) were aged 80 - 89 years, and 8519 (15.84%) were aged ≥90 years. Overall, 30,531 (56.76%) were in the vaccine group, with 4524 (8.41%) of the total participants receiving partial vaccination, 20.91% completing the primary series, and 14,761 (27.44%) receiving one booster. Additionally, 23,258 (43.24%) were in the unvaccinated group. Of the 53,789 hospitalized individuals, 17,916 (33.31%) had a COVID-19 diagnosis, 3535 (6.57%) had COVID-19–related hospitalization, 961 (1.79%) were COVID-19 severe or critical cases, and 4130 (7.68%) had in-hospital death. The analysis revealed that the VE of booster vaccination in preventing COVID-19–related hospital, severe or critical COVID-19, and in-hospital death was 63.5% (95% CI 59.8% - 66.9%), 66.9% (95% CI 60.1% - 72.6%) and 79.4% (95% CI 77% - 81.5%), the VE of primary series 56% (95% CI 51.4% - 60.2%), 66.8% (95% CI 59% - 73%) and 66.4% (95% CI 63% - 69.5%).

**Conclusions:** The first booster vaccination was associated with significantly reduced the risk of COVID-19–related severe outcomes in older inpatients aged ≥80 years during the Omicron-dominant period. Considering the potential selection bias and unmeasured confounders, these estimates may reflect both the VE and the better baseline health status of the vaccinated older individuals.

## Introduction

COVID-19 vaccines have saved millions of lives worldwide by providing strong protection against serious illness, hospitalization, and death [1]. As SARS-CoV-2 evolves, changes in the receptor-binding domain of the spike protein are capable of evading antibodies induced by vaccination or infection; this waning immunity and reduced vaccine effectiveness (VE) have been observed [2,3]. Since 2022, SARS-CoV-2 Omicron and its sub-lineages (including BA.1, BA.2, BA.4, BA.5, XBB, BQ.1, and JN.1) have emerged and become the dominant circulating variants worldwide [4]. A serological study demonstrated that 3 to 5 doses of the ancestral monovalent vaccine elicited neutralizing antibodies with a narrow breadth against Omicron BA.5 and BA.2.75, while failing to neutralize BQ.1.1 and XBB sublineages [5]. Although severe COVID-19 and death are currently less prevalent in the Omicron-dominant era than in previous years [5], SARS-CoV-2 continues to cause significant morbidity and mortality, especially among the older population and those with existing medical conditions, including high blood pressure, diabetes, obesity, immunosuppression, cancer, and pregnancy [1]. The World Health Organization recommends that older adults as a priority group should be included in the long-term vaccine immunization strategy. However, as the continuous evolution of SARS-CoV-2 persists, it is probable that both the currently available and newly updated variant-specific vaccines will fall behind the viral antigenic evolution [6,7].

In China, the COVID-19 vaccine was approved for emergency use in July 2020, and a territory-wide massive vaccination program was launched, first in all adults aged 18 years and older at the end of March 2021, then expanding to adolescents aged 12 - 17 years in July 2021, and to children 3 - 11 years in October 2021. The coverage of the primary COVID-19 vaccine among the entire population, individuals aged ≥60 years, and those aged ≥80 years was estimated at 90.4%, 86.6%, and 66.4%, respectively [8]. Randomized clinical trials have shown that COVID-19 vaccines provided moderate protection against SARS-CoV-2 infection [9-14]. Post-market studies have shown moderate or high levels of protection against severe illness, hospitalization, and death in Chinese adults [15,16]. However, few data are available for those aged 80 years and older, especially regarding the risk of COVID-19–related hospitalization after the first booster dose during the Omicron period. Older people are at a higher risk of severe disease outcomes from COVID-19 infection, with higher rates of hospitalization and mortality than other ages, even after receiving the booster dose [17,18]. To guide the rational use of COVID-19 vaccines, it is crucial to evaluate and update their real-world effectiveness of COVID-19 vaccines, especially in older adults.

Beijing is the capital city of China, with a population of 21.8 million in 2024. According to the Beijing Immunization Information Management System data, inactivated vaccines constituted 99.55% (63.52 million doses) of Beijing's administered COVID-19 vaccination through November 2022. China, including Beijing, adhered to a "zero-COVID-19" policy from April 2020 to early December 2022, which interrupted the transmission of SARS-CoV-2 in varying-scale COVID-19 outbreaks caused by variants [19]. Since December 2022, the zero-COVID policy has been rapidly lifted nationwide, with a major wave of Omicron sublineages. In Beijing, the cumulative infection attack rate was estimated to be 75.7% [20,21], caused by the Omicron BF.7 sub-lineage primary [22]. The roll-out of the fourth vaccine dose commenced in December 2022. In this study, we assessed the real-world VE of COVID-19 vaccines against COVID-19–related hospitalization during the Omicron wave in a well-traced cohort of older adults aged ≥80 years in Beijing.

## Methods

### Study Population and Design

We conducted a retrospective cohort study in Beijing. This study included Beijing residents enrolled in the Beijing Hospital Utilization Information System (BHUIS), an electronic platform managed by the Beijing Municipal Health Commission's Information Center (BMHCIC). The system aggregates standardized inpatient demographic and discharge records from all tertiary and secondary hospitals, as well as more than 50% of primary care facilities across the city, capturing 94% of all hospital admissions in Beijing between 2022 - 2023. In this study, individuals recorded in BHUIS were eligible for inclusion if he or she was aged ≥80 years (with a birth date on or before November 1, 1942), residents of Beijing, and admitted to the hospital between November 1, 2022 and February 28, 2023 (the starting and ending date of the Omicron wave). We excluded individuals who met any one criteria: individuals who had a previous COVID-19 infection before November 1, 2022 recorded in the National Notifiable Infectious Disease Surveillance System (NNIDSS); those who had any COVID-19 vaccination recorded after November 1, 2022, to avoid misclassification of exposure status due to overlapping seroconversion periods and outcome observation windows; those who received four doses of COVID-19 vaccine, as this subgroup (n=424) was undersampled for robust statistical analysis and risked exposure misclassification given their distinct vaccination timeline (eg, fourth doses administered since December in 2022).

### Data Source

We obtained complete electronic medical records of older adults aged ≥80 years who were admitted to the hospital between November 1, 2022 and February 28, 2023 from the BMHCIC. BMHCIC performed data queries and abstraction in BHUIS on December 30, 2023, to account for delays in reporting. All hospital discharges in the study cohort were downloaded and included in the study. The retrieved variables included patient name, age, identification card number, hospital case number, in-hospital deaths, discharge diagnosis (principal and secondary diagnosis), date of admission, and postal code of the residing address. To avoid duplicated hospitalizations, we retained records with the earliest admission date of the same individual who had multiple hospitalizations during a 21-day period. For records occurring 21 days apart, we considered it a new event of hospitalization for the same person.

XSL•FO
RenderX

We collected the vaccination history of individuals (ie, vaccine type, dosage, and date of injection) from the Beijing Center for Disease Control and Prevention, by linking hospitalization records with the Beijing Immunization Information Management System (IIS). The IIS is a web-based system akin to other computerized population-based databases previously documented in the literature [23], in which COVID-19 vaccine recipient information can be readily queried and retrieved using the vaccinee's identification card number as an identifier. A "double match" technique, using an individual's name and identification card number as identifiers, was used to link and acquire individual's COVID-19 vaccine exposure. In our study, vaccine information recorded in the IIS can be viewed as a complete record of the study cohort, as every dose of COVID-19 vaccine administered in the administrative region was required to be entered into the IIS by nurses through client application software.

### Exposures

Based on the individual's COVID-19 vaccine history before the Omicron wave started, we categorized the study cohort into four groups, (1) unvaccinated (no history of COVID-19 vaccination before November 1, 2022), (2) partially vaccinated (≥14 d after receipt of the first vaccine dose and before completing the full primary series), (3) completed primary series (≥14 d after completing the full primary series and before receipt of the first booster dose), and (4) completed the first booster vaccination (≥7 d after receipt of the booster dose). According to China's COVID-19 Vaccines Immunization Schedule, the primary series of COVID-19 vaccine entailed two doses of inactivated vaccine, one dose of adenovirus vector vaccine, or three doses of recombination vaccine, while the booster vaccination involved an additional one dose of inactivated vaccine, adenovirus vector vaccine, or recombination vaccine after the recipient had completed the primary series.

### Outcomes and Covariates

The primary study outcome was hospitalization with COVID-19–related disease, defined as hospital discharge diagnosed with code U07.1 in the *International Statistical Classification of Diseases and Related Health Problems 10th Revision, 10th Revision (ICD-10)*. All hospitalizations with COVID-19 had a positive nucleic acid amplification test. Other outcomes evaluated in the study included COVID-19–related hospitalization, severe or critical illness, and in-hospital death. Considering the high infection rate of SARS-CoV-2, only inpatients with COVID-19 *ICD-10* code in "principal diagnosis" were defined as COVID-19–related hospitalization. Severe or critical illness was assessed by doctors based on the criteria provided in the Diagnosis and Treatment Protocol for COVID-19 (Version 10) [24]. Severe illness was defined as any of the following: (1) respiratory distress (ie, respiration rate ≥30 breaths per min), (2) oxygen saturation ≤93 % at rest, (3) the ratio of arterial partial pressure of oxygen and fraction of inspired oxygen ≤300 mmHg, or (4) chest imaging showing obvious lesion progression (>50% increase within 24 - 48 h). Critical COVID-19 was defined as any of the following: (1) respiratory failure requiring mechanical ventilation, (2) shock, or (3) other organ failure requiring intensive care unit admission. In-hospital death with COVID-19 was defined as the death record of inpatients with COVID-19–related disease, the use of all-cause in-hospital mortality in patients diagnosed with COVID-19 cannot represent or estimate the specific COVID-19 mortality, due to the inability to definitively attribute death causation using available health care data. We controlled for several patient-level characteristics (ie, sex and age) by stratifying the analysis of the association between vaccination and outcome within these variables.

### Statistics Analysis

For comparison of baseline characteristics, we used the chi-square test or Fisher exact test for categorical variables as appropriate and Bonferroni method for their pairwise comparisons, used Kruskal-Wallis test for continuous variables and Mann-Whitney *U* test for their pairwise comparisons. We calculated the risk of COVID-19 among hospitalized patients during the study period by dividing the total number of inpatients diagnosed with COVID-19–related diseases by the size of the study cohort. The 95% CI was estimated using the normal approximation of Poisson distribution. The association (ie, incidence risk ratio) between vaccination and COVID-19–related hospitalization, severe or critical illness, and death was evaluated by comparing the risk between vaccinated and unvaccinated groups using Poisson regression models with a robust variance estimator, adjusting for sex and age. The VE was estimated as ([1-incidence risk ratio]×100%) for partially vaccinated, primary series, and booster vaccination. We conducted a sensitivity analysis restricting the outcome to hospitalizations with severe or critical COVID-19 as the principal diagnosis. Data cleaning was performed in MySQL 5.7 because of its high-performance data management capabilities. All statistical analyses were conducted using SPSS 20.0 (IBM Corp). All *P* values were 2-sided and considered significant at $P<.05$. Considering that our data consisted of almost all inpatient cases during the specified time, and 33,724 excluded records reflected cleaning and cohort eligibility criteria (Figure S1) in Multimedia Appendix 1, no survey weights were used in the analyses.

### Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki and approved by the Human Research Ethics Committee of the Beijing Center for Disease Prevention and Control (approval number: 2022 - 14), the retrospective analysis without additional informed consent was approved by the review board. To safeguard participant information, all the data were deidentified after linkage. Additionally, access to the data was restricted to authorized research personnel only.

## Results

### Basic Characteristics of Study Population

A total of 87,513 records were registered in the study. After removing 28,551 duplicate case records (84.7% of exclusions), 1570 (4.6%) whose birthday did not meet the criteria, and 3603 (10.7%) who were vaccinated between November in 2022 and February in 2023 and ineligible for inclusion, 53,789 individuals were included in the study cohort. Of these, 28,423 (52.84%)

XSL•FO
RenderX

were male. A total of 30,531 (56.76%) belonged to the vaccination group, while 23,258 (43.24%) were unvaccinated, as detailed in Table 1. The vaccine rollout in the study cohort was shown in Figure 1.

**Table .** Basic characteristics of the hospitalized older patients with COVID-19 cohort by vaccination status in Beijing during the Omicron wave from November 2022 to February 2023.

| Characteristics | Total, n (%) | Unvaccinated, n (%) | Partially vaccinated, n (%) | Primary vaccination, n (%) | Booster vaccination, n (%) | Chi-square (*df*)/*H* value | *P* value |
|---|---|---|---|---|---|---|---|
| No. of persons | 53,789 | 23,258 (43.24) | 4524 (8.41) | 11,246 (20.91) | 14,761 (27.44) | —[e] | —[e] |
| Sex | | | | | | | |
| Male | 28,423 (52.84) | 11,723 (50.40)[a(1)] | 2177 (48.12)[a(2)] | 5647 (50.21)[a(1,2)] | 8876 (60.13)[a(3)] | 44.86[b,c] | <.001 |
| Female | 25,366 (47.16) | 11,535 (49.60)[a(1)] | (51.88)[a(2)] | 99 (49.79)[a(1,2)] | 5885 (39.87)[a(3)] | | |

**Figure 1.** Temporal trends in COVID-19 vaccination coverage and hospitalization with COVID-19 incidence among adults aged ≥80 years from November 2022 to February 2023 in Beijing, China. (A) Cumulative daily coverage of COVID-19 vaccination, with the x-axis representing the vaccination date. This data aims to show the progression of vaccination over time. (B) The number and cumulative incidence of hospitalizations with COVID-19, where the x-axis indicates the admission date.

## Hospitalization and VE

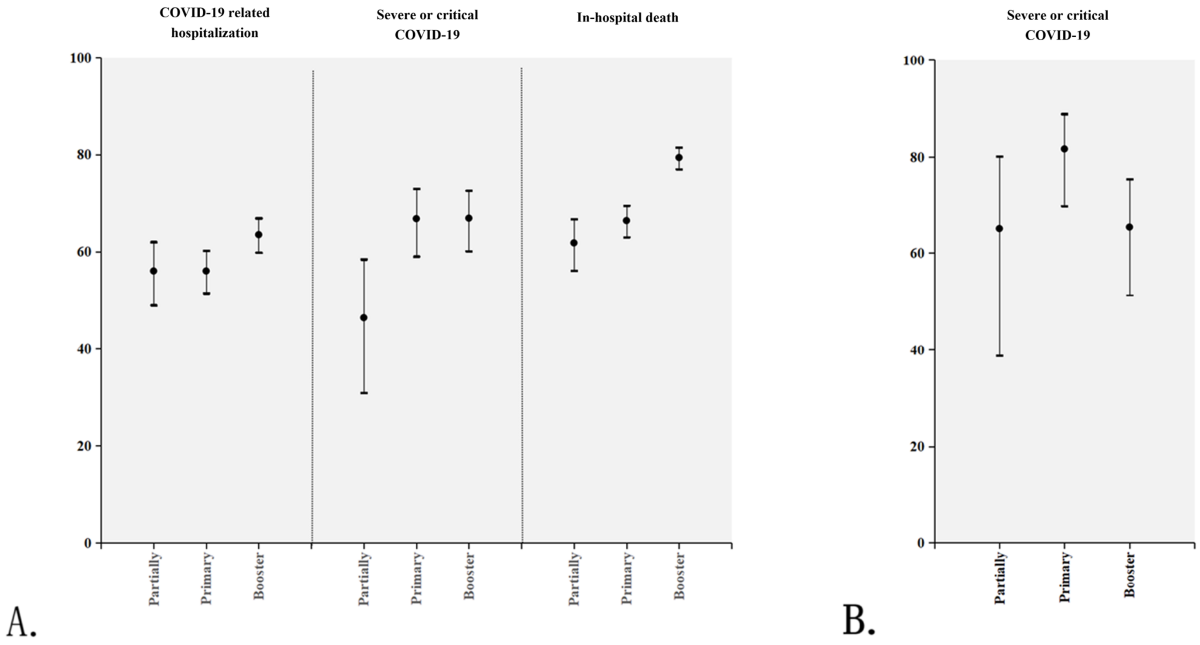
There were 17,916 (33.31%) individuals hospitalized with COVID-19, and the proportion of COVID-19 in males (36.60%, 10,403/28,423) was higher than that in females (29.62%, 7513/25,366) ($P$<.001). The proportion in inpatients aged ≥90 years (44.99%, 3833/8519) was higher than that in inpatients aged 80 - 89 years (31.11%, 14,083/45,270) ($P$<.001). Of these, 3535 (6.57%) were COVID-19–related hospitalization, 961 (1.79%) were COVID-19 severe or critical cases, and 4130 (7.68%) were in-hospital deaths in the study cohort. The incidence of hospitalization with COVID-19–related disease was estimated to be 2.66 % among 673 thousand people aged 80 years and older in Beijing. Most cases occurred in December and January of the following year (Figure 1).

The risk of COVID-19–related hospitalization in the unvaccinated group (9.76%, 2269 cases) was higher than that in the vaccinated group (partially vaccinated: 4.49%, 203/4524 cases; primary series: 4.49%, 505/11,246 cases; booster vaccination: 3.78%, 558/14,761 cases). The effectiveness of COVID-19 immunization in preventing COVID-19–related

XSL•FO
RenderX

hospitalization was 56% (95% CI 49% - 62%), 56% (95% CI 51.4% - 60.2%), 63.5% (95% CI 59.8% - 66.9%) for partial immunization, primary series, and booster vaccination, respectively (Figure 2). Figure 3 shows the VE stratified by the time interval between the last dose and hospital admission. VE of primary series was 63.7% (95% CI 58.9% - 68%) and 73.7% (95% CI 66.5% - 79.4%) during 6 - 12 months and ≥12 months, respectively. VE of booster was 43.1% (95% CI 24.4% - 57.2%) for <6 months, 44.9% (95% CI 36.5% - 52.2%) during 6 - 12 months, and 73.3% (95% CI 69.6% - 76.5%) during ≥12 months.

**Figure 2.** Adjusted vaccine effectiveness against severe outcomes by immunization status in adults aged ≥80 years during Omicron circulation, Beijing, China (November 2022 to February 2023) (Cohort study of hospitalized patients; vaccine effectiveness estimates via Poisson regression). (A) VE against COVID-19–related hospitalization, severe or critical disease, and in-hospital death; (B) Sensitivity analysis restricting to cases with severe or critical COVID-19 as principal diagnosis.



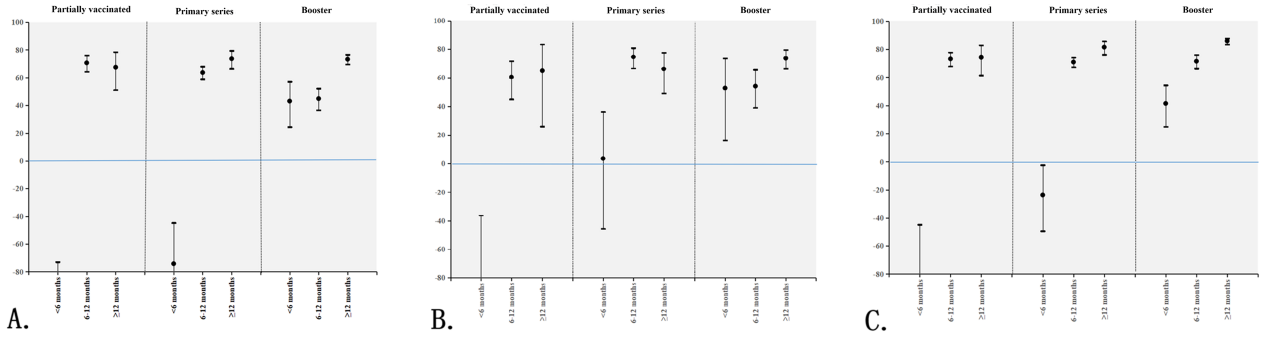


**Figure 3.** Stratified vaccine effectiveness with 95% CI by the time interval between the last vaccination dose and hospital admission for COVID-19 related outcomes among the older inpatients aged ≥80 years during the Omicron circulation (November 2022 to February 2023) in Beijing, China. (A) Hospitalization (principal diagnosis); (B) Severe or critical disease (principal or secondary diagnosis); (C) In-hospital death. Transverse lines that cross the vertical blue line at zero indicate no statistical significance.

The risk of severe or critical COVID-19 in the unvaccinated group (2.8%, 652 cases) was higher than that of the vaccinated group (0.92% - 1.48%). The effectiveness of COVID-19 vaccines against severe or critical COVID-19 was 46.4% (95% CI 30.9% - 58.4%), 66.8% (95% CI 59% - 73%) and 66.9% (95% CI 60.1% - 72.6%) for partial immunization, primary series, and booster vaccination, respectively (Figure 2). VE of primary series was 74.6% (95% CI 66.6% - 80.7%) during 6 - 12 months, and 66.2% (95% CI 49% - 77.6%) ≥12 months following vaccination. VE of booster was 52.9% (95% CI 16.2% - 73.5%) for <6 months, 54.2% (95% CI 39% - 65.6%) during 6 - 12 months, and 73.6% (95% CI 66.3% - 79.4%) for ≥12 months following vaccination (Figure 3).

The risk of in-hospital death with COVID-19 disease in the unvaccinated group (12.86%, 2990/23,258 cases) was higher than that of the vaccinated group (partially vaccinated: 5.11%, 231/4524 cases; primary series: 4.48%, 504/11,246 cases; booster vaccination: 2.74%, 405/14,761 cases). The effectiveness of booster vaccination against in-hospital deaths

XSL•FO
RenderX

was 79.4% (95% CI 77% - 81.5%), higher than that of primary series (66.4% [95% CI 63% - 69.5%]). The effectiveness of partial COVID-19 immunization in preventing in-hospital death was 61.8% (95% CI 56.1% - 66.7%) (Figure 2). VE of primary series was 71% (95% CI 67.3% - 74.3%) during 6 - 12 months, and 81.6% (95% CI 76.2% - 85.8%) ≥12 months following vaccination. VE of booster was 41.5% (95% CI 24.9% - 54.5%) for <6 months, 71.6% (95% CI 66.4% - 76%) during 6 - 12 months, and 86% (95% CI 83.6% - 87.9%) for ≥12 months following vaccination (Figure 3).

While VE generally declined with time since vaccination, the point estimate for ≥12 months post-booster appeared higher than the 6 - 12 months group. This anomaly might be attributable to the survivor bias, the population in this ≥12 months cohort opted for vaccination earlier (before November 2021) because they were in better health and awareness of health protection, which could lead to an overestimation of VE.

### Sensitivity Analysis

If only the older individuals with severe or critical COVID-19 in "principal diagnosis" were analyzed, the VE against hospitalization decreased to 65.1% (95% CI 38.8% - 80.1%), 81.6% (95% CI 69.8% - 88.8%), 65.4% (95% CI 51.3% - 75.4%) for partial immunization, primary series, and booster vaccination, respectively (Figure 2). The VE of the booster was comparable to the findings of the main analysis, with varying precision due to reduced case counts (n=42 vs n=138 in main analysis). A similar pattern was observed in the stratified analysis based on different vaccination intervals (Table S1 and Table S2 in Multimedia Appendix 2 for time-stratified results).

## Discussion

### Principal Findings

During an Omicron BF.7-predominant wave of COVID-19 in Beijing city, we used electronic individual-level hospitalization records matching with record-documented COVID-19 vaccination status to calculate the characteristics and vaccination status of the inpatients aged ≥80 years and estimate the real-world effectiveness of domestic COVID-19 vaccines. This study shows that the proportion of hospitalizations diagnosed with COVID-19 disease in vaccination groups was significantly lower for those who had not been vaccinated. When given according to the recommended schedule of a 2-dose primary series followed by a booster dose 6 months later, the VE against COVID-19–related hospitalization outcomes was 63.5% - 79.4%. These results represent absolute modest VE associated with vaccine-induced protection for inpatients aged ≥80 years, uninfluenced by hybrid immunity.

COVID-19–associated hospitalization rates remain higher among older adults relative to rates among younger adults, adolescents, and children [25]. The Omicron variant of SARS-CoV-2 has been reported as more transmissible, but less severe, than previous variants. In the study of all hospitalization for population aged 80 years and older, 33.31% of inpatients had COVID-19–related diagnosis, the incidence of hospitalization with COVID-19 disease in ≥80-year-old people was estimated as 2.66% in the United Kingdom [26], the proportion of older adults aged ≥80 years who were hospitalized in all COVID-19 cases with Omicron (15.2%) was highest compared with other age groups of participants (1.47% - 5.80%). Compared with other Omicron variants, the studies in New England [27] found that 3.1% of patients infected with Omicron BA.2 required admission to hospitalization for general population (The mean age is 49.5). Up to now, older adults still were listed as the highest priority groups in the COVID-19 vaccination guidance [28]. In comparison with other countries, China initiated its vaccine roll-out campaign relatively early [29]. Despite the coverage of primary series for people aged 18 years and older in Beijing having already raised to a high level before the Omicron epidemic wave and quickly carrying out the booster program, 30% of adults aged 80 years and older remained unvaccinated or partially vaccinated, only 46.7% completing the booster shots [30]. China has the highest number of older individuals globally [31]. To prevent excessive disease severity and mortality owing to vaccination hesitancy, devoting greater effort toward vaccinating the older population is warranted given the uncertainty regarding future epidemic waves with frequent emergence of virus variants.

The effectiveness of the COVID-19 vaccines has relatively well maintained over time against the Omicron variant and its sublineages for severe disease compared to pre-Omicron variants of concern [4]. Our analysis demonstrated the primary series effectiveness against hospitalization and mortality was slightly higher than that reported in Brazilian test-negative case-control studies for those aged ≥80 years who completed primary series of CoronaVac (inactivated vaccine) during the Gamma variant predominance (38.9% [21.4% - 52.5%] and 44% [20.3% - 60.6%], respectively) [32]. This difference may be due to several factors. Circulating variants and prior infection status played significant roles. Other elements, such as the time interval between vaccination and the outcome, hospitalization criteria, population distribution, and research methods can also influence the calculated VE. However, similar to the conclusions found in most studies, our estimated VE of booster against COVID-19–related hospital admissions was higher than that of the primary series. One study in China indicated that a completed vaccination with a booster reduced the risk of asymptomatic or mild Delta or Omicron variant COVID-19 progressing to pneumonia [33]. In the study of quarantined close contacts of BA.2-infected individuals in China [34], primary series VE against pneumonia or worse infection was 66% (95% CI 57% - 73%) and 91% (95% CI 91% - 96%), booster dose VE was 74% (95% CI 69% - 79%) and 93% (95% CI 87% - 97%), respectively. Among individuals 80 years and older in the McMenamin study, VE increased from 58% to 97% when boosted [15]. In a prospective cohort study across UK nations, data on 30 million people aged ≥18 years from primary care, testing, vaccination, hospitalization, and mortality were linked. They found that compared with received primary doses, the first booster of BNT162b2 (tozinameran; Pfizer-BioNTech) or mRNA-1273 (elasomeran; Moderna) could have reduced severe outcomes (hospitalization or death) due to Omicron B.1.1.529 variant (the rate decreased from 8.8 to 7.6 events per 1000 person-y) [18]. Compared with the observed VEs in aforementioned studies conducted during the stages of Alpha,

XSL•FO
RenderX

Gamma, and initial Omicron predominance [15,35,36], our estimated result, which focuses on the period of Omicron BF.7 predominance and BA.5.2, was lower. This study also evaluated VE against in-hospital deaths with COVID-19 disease, but it was difficult to determine whether the deaths marked among inpatients with the U07.1 *ICD-10* code were actually caused by COVID-19 disease, so the direct protective effect could not be calculated due to many confounding factors (such as the reason for hospitalization, treatment measures, etc). Moreover, in line with previous research, a decline in VE was observed as age increased. During the Omicron BA.2 subvariant wave in Hong Kong, VE against severe or fatal disease was 96.3% (94.9% - 97.3%) for 2 doses of BNT162b2 and 91.7% (88.7% - 94%) for 2 doses of CoronaVac in those aged 20 - 59 years, reducing to 86.9% (80.5% - 91.3%) and 58.2% (45.1% - 68.2%) among those aged 80 years or older [15]. A parallel pattern emerged in a Shanghai Omicron BA.2 outbreak, where 3 doses of inactivated vaccines showed 96.0% (91% - 98.3%) effectiveness against severe or critical COVID-19 in the 60 - 69 age cohort, decreasing to 66.8% (−22.5% to 91%) among people aged ≥90 years [16]. Older people have a less complete immune response to antigens and a reduced ability to develop robust immunity after infections or vaccination because of the age-related decline in the functioning of the immune system [37].

For the primary and booster immunizations of the COVID-19–inactivated vaccine, the GMT against the wild-type strain declined gradually during the 12 months after the primary immunization and was lower against the Delta and Omicron variant spike proteins [38]. It is necessary to estimate the protective effect of different intervals after the latest vaccination and how long vaccinated individuals should be evaluated before future epidemic trends. As of November in 2022, the COVID-19 mass vaccination has completed and most people have gotten the latest dose for 12 months and longer. There were too few COVID-19 cases with 6 months between the last dose and exposure to estimate reliable VEs stratified by time; results are shown in Supplementary Table S2 in Multimedia Appendix 2. VE of vaccination in more than 12 months and during 6 months and 12 months after the last dose has remained 52% - 86%. The highest VE observed in the ≥12-month post-vaccination group contradicts established immune waning patterns. This paradox may reflect methodological biases, one is healthy survivor bias, the population in this ≥12-month cohort opted for vaccination earlier on because they were in better health and awareness of health protection, or the healthiest individuals survived long enough to be in the ≥12 months group, all these could lead to an overestimation of VE. Additionally, temporal confounding may have occurred, the ≥12 months group may have been infected later in the wave when hospital triage and treatment protocols improved, or the virus variant and the population's immunity status may have changed over the study period. In addition, as more than 4 doses of vaccine have been administered worldwide, it is necessary to further track and monitor the vaccination situation and VE in China.

### Strengths and Limitations

One of the strengths of this study is the effective linkage between hospital admission data and vaccination records, which enables a low-cost and large-scale real-world evaluation of vaccine effects in the population. Specifically, this approach provides valuable insights into the effectiveness of prototype inactivated COVID-19 vaccines in protecting the eldest adults. The other one is our results reveal that, among inpatients aged 80 years and above who have not had a previous SARS-CoV-2 infection, there is a moderately significant level of protection. Importantly, this protection remains independent of hybrid immunity. In the context of multiple global epidemics, especially those involving Omicron variant strains, most people have experienced one or more infections. When evaluating the protective effect of vaccination against Omicron, it is difficult to exclude the confounding effects of previous infections with SARS-CoV-2 variants. However, this study still offers unique evidence for the basic protective effect of inactivated vaccines.

Our study had several limitations. First, the foremost concern is unmeasured confounding from fundamental health status differences between vaccinated and unvaccinated groups. The unvaccinated group was significantly older (86 vs 83 y) and had more females (49.60% vs 39.87%; $P<.001$) than the booster group, suggesting poorer baseline health or frailty limiting vaccine access. Critically linked is our inability to stratify by underlying diseases, a key unmeasured confounder. While we adjusted for available confounders (age and sex), unmeasured factors may persist, and the VE estimates may be influenced by unmeasured health status differences between the groups, as the unvaccinated group's inherently poorer health may lead to worse outcomes independent of vaccination status. Future studies should use targeted designs that prospectively enroll subgroups stratified by specific comorbidities, implement propensity score matching to further mitigate confounding. Second, use of all-cause in-hospital mortality among patients diagnosed with COVID-19 cannot represent or estimate the specific COVID-19 directly caused by COVID-19. This misclassification could introduce bias into the estimates of VE against such in-hospital deaths. Third, there might have been potential selection bias in our cohort design without nonhospitalized individuals. Considering the hospitalized population may have worse physical conditions than those of the nonhospitalized population, the evaluation based on hospitalized cases may underestimate the value of VE. During the establishment of the cohort, eliminating individuals who were vaccinated during the study period would introduce a selection bias to the results, which cannot represent the true situation of the population. The composition of the inpatients in this study was close to the age distribution of permanent residents in Beijing (83.09% were 80 - 89 y old, 16.91% were ≥90 y old), but the difference in gender composition (56.24% were female and 43.76% were male), although estimated VE was adjusted for age and gender would decrease this bias, our results still can only be limited to representing the hospitalized population, may not be generalizable to nonhospitalized or younger populations. Another point to consider is that, compared with experimental studies, the observational study cannot absolutely control external conditions; therefore, there could be unmeasured confounding variables.

XSL•FO
RenderX

## Conclusions

In conclusion, booster vaccination was associated with significantly reduced risk of COVID-19–related severe or critical illness or in-hospital deaths in older inpatients aged ≥80 years during an Omicron-dominant period. Offering a booster dose and regularly monitoring the coverage and VE of COVID-19 vaccines remains the mainstay for mitigating impacts of upcoming epidemics. While our results demonstrate a significant association between booster vaccination and reduced severe outcomes, these estimates may reflect both VE and the better baseline health status of the vaccinated older individuals.

## Abstract

**Background:** As SARS-CoV-2 continues to evolve and vaccine-induced protection wanes over time, future annual or periodic COVID-19 vaccination may become important for long-term disease control. China’s adjustment of national COVID-19 response policies provided an opportunity to assess vaccination attitudes after extensive prior vaccination and widespread SARS-CoV-2 exposure. Evidence remains limited on physicians’ and medical trainees’ willingness to receive future COVID-19 vaccination and to support COVID-19 vaccination for older adults and young children.

**Objective:** This study aimed to evaluate willingness to receive future annual COVID-19 vaccination among physicians and medical trainees in China, identify factors associated with hesitancy toward future vaccination, and assess willingness to support COVID-19 vaccination for older adults and young children.

**Methods:** A nationwide, multicenter cross-sectional survey was conducted from February to April 2023, shortly after China adjusted its national COVID-19 response policies. Physicians and medical trainees were recruited from 21 public hospitals across 7 regions of China using prespecified recruitment targets for each hospital and career-stage group. Participants completed a confidential, self-administered electronic questionnaire. Modified Poisson regression models with robust SEs were used to estimate adjusted prevalence ratios (aPRs) and 95% CIs.

**Results:** The analysis included 3169 participants comprising 2877 physicians (90.8%) and 292 medical trainees (9.2%). Overall, 1899 participants (59.9%) were willing to receive future annual COVID-19 vaccination, although 3074 (97%) had previously received at least 1 dose of a COVID-19 vaccine. Among previously vaccinated participants, 2862 (93.1%) had received an inactivated vaccine. Overall, 2857 participants (90.2%) were willing to support COVID-19 vaccination for older adults, and 2320 (73.2%) were willing to support vaccination for young children. Lack of willingness to receive influenza vaccination was strongly associated with hesitancy toward future annual COVID-19 vaccination (aPR 4.11; 95% CI 3.71 - 4.55), as was no prior COVID-19

XSL•FO
RenderX

vaccination (aPR 1.27; 95% CI 1.11 - 1.46). Participants with hesitancy toward future annual COVID-19 vaccination were more likely to report hesitancy to support vaccination for older adults (aPR 5.13; 95% CI 3.95 - 6.66) and young children (aPR 2.88; 95% CI 2.54 - 3.27). Among participants hesitant about future annual vaccination, the most commonly reported concerns were vaccine effectiveness (674/1270, 53.1%), vaccine safety (424/1270, 33.4%), and insufficient disclosure of clinical trial data (368/1270, 29%).

**Conclusions:** Hesitancy toward future annual COVID-19 vaccination was substantial among physicians and medical trainees in China despite near-universal prior vaccination. The most commonly reported concerns were related to vaccine effectiveness, vaccine safety, and clinical data transparency. Clear and timely communication of vaccine evidence to clinical professionals may support future routine or periodic COVID-19 vaccination strategies and strengthen vaccination support for older adults and young children.

## Introduction

Vaccine hesitancy remains a major public health challenge. The World Health Organization identified vaccine hesitancy as one of the major threats to global health, and the Strategic Advisory Group of Experts Working Group defined vaccine hesitancy as a delay in acceptance or refusal of vaccination despite the availability of vaccination services [1,2]. Vaccine willingness is context specific and may vary across time, place, and vaccine type, reflecting perceived disease risk, confidence in vaccine safety and effectiveness, access-related constraints, information seeking and deliberation, and broader social or policy contexts [2-4]. These issues are particularly relevant for vaccines that may require repeated, annual, or risk-based use.

COVID-19 vaccination illustrates this challenge. COVID-19 vaccines have substantially reduced severe disease and mortality worldwide [5,6]. However, SARS-CoV-2 continues to evolve, and vaccine-induced protection, particularly against infection and symptomatic disease, may wane over time [7,8]. As COVID-19 shifts from emergency pandemic response to longer-term disease management, the relevant public health question has moved from primary vaccine acceptance to willingness to receive future annual or periodic vaccination [9]. Physicians and medical trainees are a key population in this context because they are both potential vaccine recipients and trusted sources of vaccine information for patients and the public [1,10]. Their confidence in vaccine effectiveness, safety, and clinical evidence may influence both their own vaccination decisions and their willingness to support vaccination for others, including older adults and young children.

The early 2023 period in China provided a useful setting for examining willingness to continue COVID-19 vaccination after large-scale prior vaccination and changing perceived disease risk. By late 2022, more than 3.4 billion COVID-19 vaccine doses had been administered nationwide [11], and COVID-19 vaccines available in China included domestically produced inactivated vaccines, adenoviral-vector vaccines, and recombinant protein vaccines [12-14]. Shortly before we conducted this survey, China adjusted its national COVID-19 response policies, marking a shift from emergency containment toward longer-term management of SARS-CoV-2 infection [15]. We therefore conducted a nationwide cross-sectional survey in 21 public hospitals across 7 regions of China to evaluate willingness to receive future annual COVID-19 vaccination among physicians and medical trainees, identify factors associated with hesitancy, assess willingness to support COVID-19 vaccination for older adults and young children, and assess willingness to receive influenza vaccination as a comparative reference for periodic vaccination.

## Methods

### Study Design and Setting

This was a nationwide, multicenter, cross-sectional questionnaire survey conducted from February to April 2023 in 21 public hospitals across 7 geographic regions of China: North China, Northeast China, East China, Central China, Northwest China, Southwest China, and South China. The participating hospitals were located in 15 provinces, municipalities, and autonomous regions.

A pilot survey was conducted in December 2022 among 108 physicians and medical trainees to assess questionnaire clarity and the feasibility of electronically administering the survey. The pilot confirmed the feasibility of the survey procedures, informed refinement of the questionnaire, and provided data for sample-size planning. Pilot participants were not included in the final analysis.

### Questionnaire Development

The questionnaire was developed based on literature review, expert consultation, and pilot testing. Content validity was assessed through expert review using the content validity ratio (CVR). Internal consistency was evaluated using the Cronbach $\alpha$, with values of 0.65 for the confidence domain and 0.68 for the complacency domain. The questionnaire can be found in Multimedia Appendix 1.

### Participants and Recruitment

Eligible participants were physicians and medical trainees working or training at the participating hospitals during the study period. The survey focused on the physician workforce across career stages because physicians' vaccination attitudes may influence patient counseling and vaccination-related clinical decisions, while medical trainees represent the earliest stage of physician training. Recruitment was organized at the hospital

XSL•FO
RenderX

level using prespecified target numbers for each hospital and career-stage group, including medical trainees who had not begun standardized residency training, residents or physicians undergoing standardized residency training, attending physicians, associate chief physicians, and chief physicians.

At each hospital, 2 designated investigators coordinated recruitment and questionnaire distribution. To ensure broad representation across clinical departments, investigators sought to include participants from departments directly involved in COVID-19 care, including pulmonary and critical care medicine, emergency medicine, infectious diseases, and intensive care medicine, as well as other departments caring for patients at increased risk of severe COVID-19. Participants with and without experience treating patients with COVID-19 were actively recruited. Representation across clinical departments and experience treating patients with COVID-19 were recruitment targets rather than prespecified quotas.

The final questionnaire was self-administered electronically through Wenjuanxing (Changsha Ranxing Information Technology Co Ltd), and the survey link was distributed through direct electronic invitations and department-level WeChat (Tencent Holdings Limited) groups. Recruitment continued until the prespecified target numbers for each hospital and career-stage group were reached. Because the questionnaire link was distributed through both direct electronic invitations and department-level WeChat groups, the exact number of individuals who received or viewed the invitation could not be precisely determined; therefore, a response rate could not be calculated. The survey platform allowed only 1 submission per WeChat ID to reduce duplicate responses.

The sample size was estimated using PASS version 21.0 (NCSS, LLC) based on pilot survey data. The calculation incorporated a design effect of 1.2 to account for potential clustering within hospitals. Each hospital aimed to recruit approximately 150 eligible participants, yielding a target sample size of approximately 3150 participants across 21 hospitals. All submitted questionnaires with complete outcome and covariate information required for the main analyses were included in the final analytic dataset.

### Study Outcomes and Measures

The primary outcome was hesitancy toward future annual COVID-19 vaccination, assessed using the following question: “Would you proactively receive the COVID-19 vaccine every year in the future?” Participants who answered “no” were classified as having hesitancy toward future annual COVID-19 vaccination and were asked to select reasons for hesitancy.

Secondary outcomes were hesitancy to support COVID-19 vaccination for older adults and for young children in participants’ families. These outcomes were assessed using the following questions: “If older adults in your family aged over 65 years have no clear contraindications, would you support their COVID-19 vaccination?” and “If there are children younger than 6 years in your family, would you support their COVID-19 vaccination?” Participants who answered “no” were classified as having hesitancy to support COVID-19 vaccination for the corresponding group.

The questionnaire collected information on age, education level, geographic region, hospital classification, clinical department, career stage, SARS-CoV-2 infection history, experience treating patients with COVID-19, prior COVID-19 vaccination, type of COVID-19 vaccine received, willingness to receive influenza vaccination, and selected perceptions related to COVID-19. Data on sex and income were not collected in this survey.

Regions were categorized as low, middle, or high according to the Human Development Index (HDI) of the province-level administrative regions in which the participating hospitals were located. Hospitals were classified as top grade A tertiary hospitals, other grade A tertiary hospitals, and nontertiary or other hospitals based on China’s hospital classification system and prespecified hospital ranking criteria. Clinical departments were categorized as COVID-19–related internal medicine departments, other internal medicine departments, surgical departments, or other departments. Educational attainment was categorized as doctoral degree, master’s degree, and college degree or lower.

### Ethical Considerations

The study protocol was reviewed and approved by the Ethics Review Committee for Biomedical Research Involving Human Subjects of the Chinese Academy of Medical Sciences and Peking Union Medical College (approval number CAMS&PUMC-IEC-2023‐030). This study was conducted in accordance with the Declaration of Helsinki. Before completing the questionnaire, all participants provided electronic informed consent (Multimedia Appendix 2).

The questionnaire did not collect participants’ names, national identification numbers, home addresses, or other identifying information for research analysis. Mobile phone numbers were collected solely for distributing participant compensation and were excluded from the analytic dataset. The WeChat ID restriction was used only to prevent duplicate submissions, and WeChat identifiers were not included in the analytic dataset. Survey data were stored in a password-protected database accessible only to authorized study investigators. Participants received CNY 50 (US $1=CNY 6.87 as of March 1, 2023) after completing the questionnaire.

### Statistical Analysis

Participant characteristics were summarized as frequencies and percentages and compared according to hesitancy toward future annual COVID-19 vaccination (Table 1). Group comparisons were conducted according to expected cell counts. The Pearson $\chi^2$ test was used when all expected cell counts were 5 or greater, and the Fisher exact test was used when any expected cell count was less than 5. All tests were 2-sided, and a $P$ value <.05 was considered statistically significant.

[a]HDI: Human Development Index.

Because the primary and secondary outcomes were common, modified Poisson regression models with robust SEs were used to estimate unadjusted prevalence ratios (PRs), adjusted prevalence ratios (aPRs), and 95% CIs. All multivariable models were adjusted for age, education level, HDI level, hospital classification, clinical department, career stage, SARS-CoV-2 infection history, experience treating patients with COVID-19, and prior COVID-19 vaccination. The model for hesitancy toward future annual COVID-19 vaccination additionally included willingness to receive influenza vaccination, whereas the models for hesitancy to support vaccination for older adults and young children included participants' own hesitancy toward future annual COVID-19 vaccination. Full univariable and multivariable modified Poisson regression results are reported in Table S4 in Multimedia Appendix 3. All analyses were performed using R software (version 4.3.2; R Foundation for Statistical Computing).

## Results

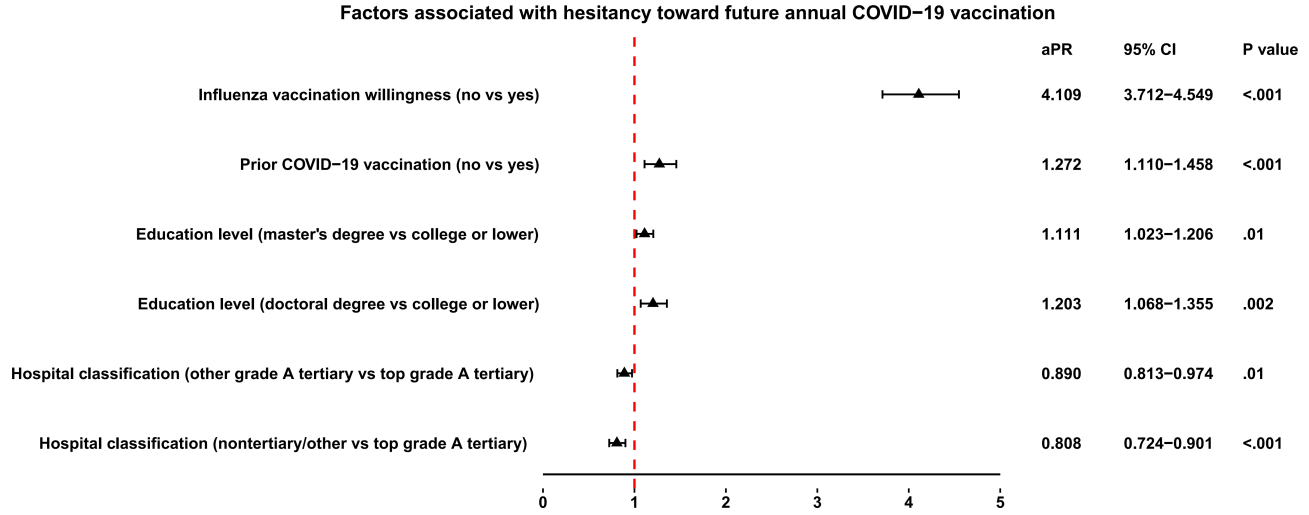
### Participant Characteristics

Among the 3169 participants included in the final analysis, the largest age group was 30 to 39 years (1337/3169, 42.2%), followed by 20 to 29 years (1125/3169, 35.5%). Overall, 1173 participants (37.01%) were residents, 1010 (31.87%) were attending physicians, 694 (21.9%) were associate chief or chief physicians, and 292 (9.2%) were medical trainees. Most participants reported a history of SARS-CoV-2 infection (2954/3169, 93.2%) and experience treating patients with COVID-19 (2568/3169, 81%).

Participant characteristics stratified by hesitancy toward future annual COVID-19 vaccination are shown in Table 1. Participants with and without hesitancy differed by age (*P*=.001), education level (*P*<.001), HDI level (*P*=.007), hospital classification (*P*<.001), career stage (*P*=.005), prior COVID-19 vaccination (*P*<.001), and willingness to receive influenza vaccination (*P*<.001). No significant differences were observed for clinical department, SARS-CoV-2 infection history, or experience treating patients with COVID-19.

### Future Annual COVID-19 Vaccination Willingness and Associated Factors

Overall, 1899 of 3169 participants (59.9%) were willing to receive future annual COVID-19 vaccination, whereas 1270 (40.1%) were classified as having hesitancy toward future annual COVID-19 vaccination. Most participants had previously received at least 1 dose of a COVID-19 vaccine (3074/3169, 97%). Among previously vaccinated participants, 2862 of 3074 (93.1%) had received an inactivated vaccine, and 1864 (60.6%) were willing to receive future annual COVID-19 vaccination. Vaccine types previously received and preferred vaccine types among participants willing to receive future COVID-19 vaccination are shown in Figure S1 of Multimedia Appendix 3.



In addition, 1932 participants (61%) were willing to receive influenza vaccination. Among participants willing to receive influenza vaccination, 1587 of 1932 (82.1%) were also willing to receive future annual COVID-19 vaccination compared with 312 of 1237 (25.2%) among those unwilling to receive influenza vaccination.

In adjusted analyses, unwillingness to receive influenza vaccination was strongly associated with a higher prevalence of hesitancy toward future annual COVID-19 vaccination (aPR 4.11; 95% CI 3.71 - 4.55). Not having previously received COVID-19 vaccination was also associated with a higher prevalence of hesitancy (aPR 1.27; 95% CI 1.11 - 1.46). Compared with participants with college-level education or lower, those with a master's degree (aPR 1.11; 95% CI 1.02 - 1.21) or doctoral degree (aPR 1.20; 95% CI 1.07 - 1.36) had a higher prevalence of hesitancy. Compared with participants from top grade A tertiary hospitals, those from other grade A tertiary hospitals (aPR 0.89; 95% CI 0.81 - 0.97) and nontertiary or other hospitals (aPR 0.81; 95% CI 0.72 - 0.90) had a lower prevalence of hesitancy (Figure 1). Full results for this outcome are shown in Table S4A of Multimedia Appendix 3.

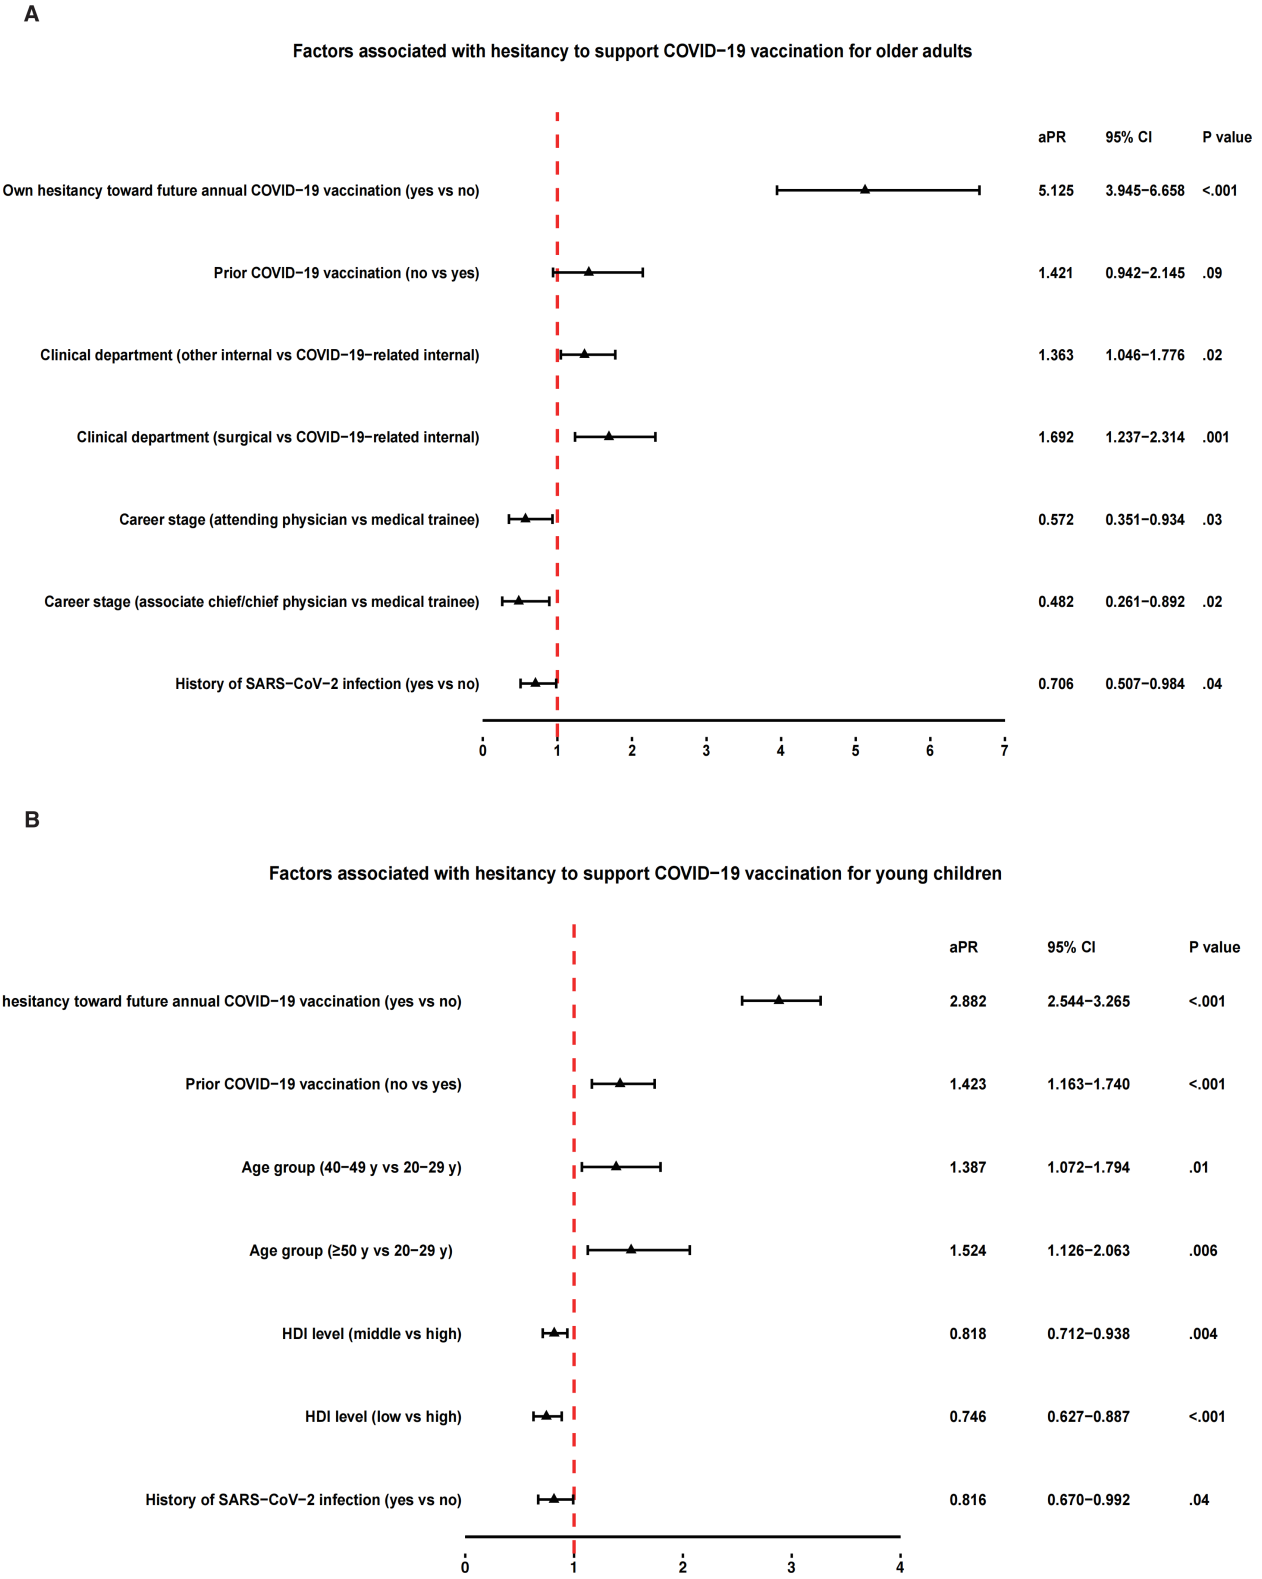
**Figure 1.** Factors associated with hesitancy toward future annual COVID-19 vaccination among physicians and medical trainees. Adjusted prevalence ratios (aPRs) and 95% CIs were estimated using modified Poisson regression models with robust SEs. Full model results are shown in Table S4A of Multimedia Appendix 3.

## Support for COVID-19 Vaccination for Older Adults and Young Children

Overall, 2857 of 3169 participants (90.2%) were willing to support COVID-19 vaccination for adults aged over 65 years without contraindications, and 2320 (73.2%) were willing to support vaccination for children younger than 6 years. For both target groups, the proportion willing to support vaccination was lower among participants with hesitancy toward future annual COVID-19 vaccination. Among hesitant participants, 1026 of 1270 (80.8%) supported vaccination for older adults and 705 (55.5%) supported vaccination for young children compared with 1831 of 1899 (96.4%) and 1615 (85%), respectively, among those willing to receive future annual COVID-19 vaccination.



In adjusted analyses, participants who were hesitant about receiving future annual COVID-19 vaccination themselves had a higher prevalence of hesitancy to support COVID-19 vaccination for older adults (aPR 5.13; 95% CI 3.95 - 6.66). Hesitancy to support vaccination for older adults was also higher among participants from other internal medicine departments (aPR 1.36; 95% CI 1.05 - 1.78) and surgical departments (aPR 1.69; 95% CI 1.24 - 2.31) compared with those from COVID-19–related internal medicine departments. Attending physicians (aPR 0.57; 95% CI 0.35 - 0.93), associate chief or chief physicians (aPR 0.48; 95% CI 0.26 - 0.89), and participants with a history of SARS-CoV-2 infection (aPR 0.71; 95% CI 0.51 - 0.98) had a lower prevalence of hesitancy to support vaccination for older adults (Figure 2A). Full results for this outcome are shown in Table S4B of Multimedia Appendix 3.

Similar associations were observed for hesitancy to support vaccination for young children. Participants who were hesitant about receiving future annual COVID-19 vaccination themselves had a higher prevalence of hesitancy to support COVID-19 vaccination for young children (aPR 2.88; 95% CI 2.54 - 3.27). Not having previously received COVID-19 vaccination was also associated with a higher prevalence of hesitancy to support vaccination for young children (aPR 1.42; 95% CI 1.16 - 1.74). Compared with participants aged 20 to 29 years, those aged 40 to 49 years (aPR 1.39; 95% CI 1.07 - 1.79) and 50 years or older (aPR 1.52; 95% CI 1.13 - 2.06) had a higher prevalence of hesitancy. Participants from middle-HDI regions (aPR 0.82; 95% CI 0.71 - 0.94), from low-HDI regions (aPR 0.75; 95% CI 0.63 - 0.89), and with a history of SARS-CoV-2 infection (aPR 0.82; 95% CI 0.67 - 0.99) had a lower prevalence of hesitancy to support vaccination for young children (Figure 2B). Full results for this outcome are shown in Table S4C of Multimedia Appendix 3.

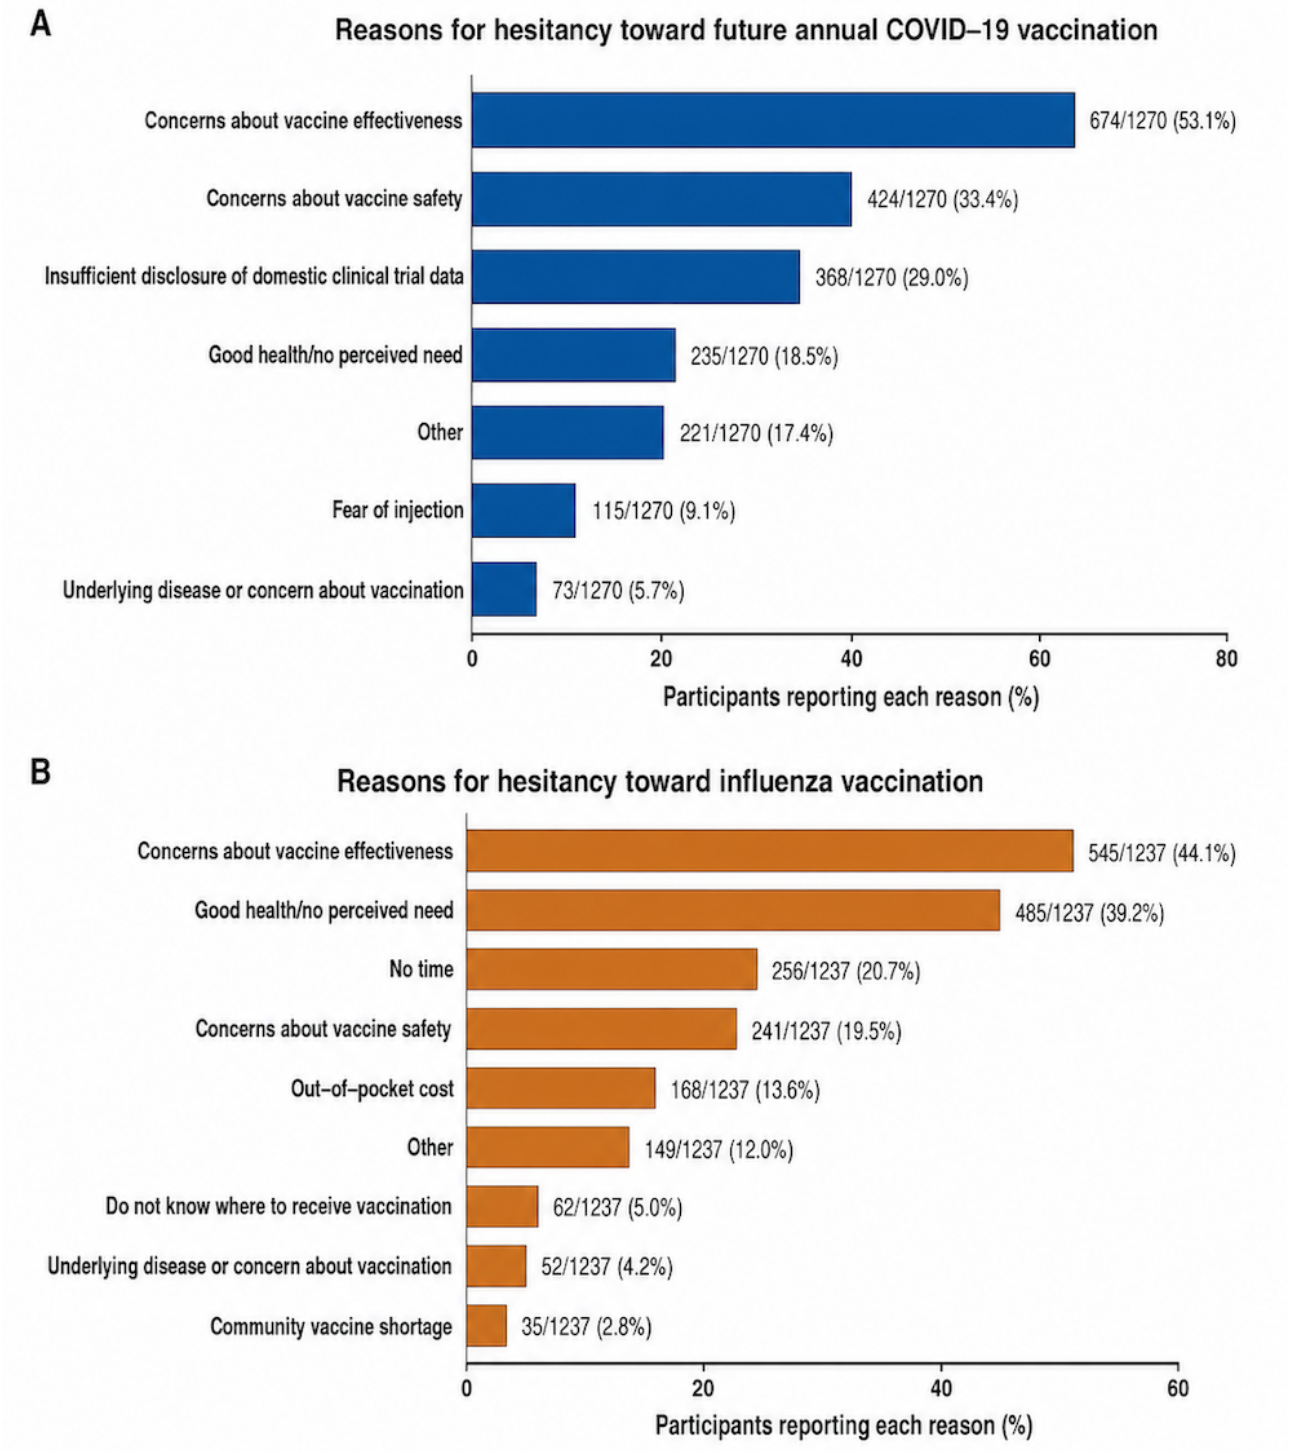
**Figure 2.** Factors associated with hesitancy to support COVID-19 vaccination for older adults aged over 65 years without clear contraindications (A) and children aged less than 6 years (B). Adjusted prevalence ratios (aPRs) and 95% CIs were estimated using modified Poisson regression models with robust standard errors. The vertical dashed line indicates an aPR of 1. Full model results are shown in Table S4B for older adults and Table S4C (Multimedia Appendix 3) for young children.



## Reported Reasons for Vaccine Hesitancy

Among participants with hesitancy toward future annual COVID-19 vaccination, the most frequently reported reasons were concerns about vaccine effectiveness (674/1270, 53.1%), concerns about vaccine safety (424/1270, 33.4%), and insufficient disclosure of domestic clinical trial data (368/1270, 29%). Additional responses included perceiving vaccination as unnecessary because they were in good health (235/1270, 18.5%), other reasons (221/1270, 17.4%), fear of injection (115/1270, 9.1%), and concerns about underlying disease or contraindications to vaccination (73/1270, 5.7%) (Figure 3A).

XSL•FO
RenderX

**Figure 3.** Reasons for hesitancy toward periodic COVID-19 and influenza vaccination among physicians and medical trainees.

Among participants with influenza vaccination hesitancy, the most frequently reported reasons were concerns about vaccine effectiveness (545/1237, 44.1%), perception of vaccination as unnecessary because they were in good health (485/1237, 39.2%), lack of time (256/1237, 20.7%), and concerns about vaccine safety (241/1237, 19.5%). Additional responses included out-of-pocket cost (168/1237, 13.6%), other reasons (149/1237, 12%), not knowing where to receive vaccination (62/1237, 5%), concerns about underlying disease or contraindications to vaccination (52/1237, 4.2%), and community vaccine shortage (35/1237, 2.8%) (Figure 3B).

## Discussion

This nationwide, multicenter, cross-sectional survey, conducted during the early 2023 transition from emergency COVID-19 response to longer-term disease management, showed a marked divergence between prior COVID-19 vaccination uptake and willingness to receive future annual vaccination among physicians and medical trainees in China. Despite near-universal prior vaccination in 3169 participants, 1899 (59.9%) participants were willing to receive future annual vaccination, a proportion similar to the 1932 (61%) willing to receive influenza vaccination. Participants' own hesitancy was also associated

XSL•FO
RenderX

with hesitancy to support COVID-19 vaccination for older adults and young children. The leading concerns involved vaccine effectiveness, vaccine safety, and clinical trial data transparency.

This divergence suggests that high prior COVID-19 vaccination uptake should not be assumed to indicate sustained willingness to receive repeated or periodic vaccination. Because vaccine hesitancy is context specific and may vary by time, place, and vaccine type [2,4,16], this pattern should not be interpreted simply as general vaccine refusal. Rather, it highlights the importance of distinguishing initial vaccine uptake during an emergency response from willingness to receive repeated vaccination in the postemergency phase of COVID-19 management. This distinction is particularly relevant to the study period, when China had recently adjusted its national COVID-19 response policies and the World Health Organization subsequently declared that COVID-19 was no longer a Public Health Emergency of International Concern [15,17].

Concerns about vaccine effectiveness, vaccine safety, and transparency of clinical trial data have also been reported among health care workers [18-20]. In this professional population, these concerns suggest that generic reassurance may be insufficient. The higher prevalence of hesitancy among participants with a master's or doctoral degree and among those from top grade A tertiary hospitals further suggests that hesitancy may not simply reflect a lack of knowledge or general vaccine refusal. Rather, it may be partly evidence sensitive: physicians and medical trainees may question repeated vaccination when updated evidence is perceived as incomplete or insufficiently transparent [2,3,21].

The association between participants' own vaccination hesitancy and their support for vaccination among older adults and young children is important because physicians and medical trainees may influence vaccination decisions beyond their personal vaccination behavior; health care providers' vaccine perceptions and communication can shape patient receptivity and vaccine uptake [10]. Support for vaccination was higher for older adults than for young children, suggesting that participants did not hold a uniform attitude toward COVID-19 vaccination across target groups. Rather, their support appeared to vary according to the perceived benefit-risk rationale for each recipient group. This pattern is consistent with the clearer risk-based rationale for vaccinating older adults given that older age is a major risk factor for severe COVID-19 outcomes [22]. Previous studies have also documented population-specific determinants of vaccination attitudes among older adults and parents of young children [23,24]. Support for COVID-19 vaccination may therefore depend not only on participants' own vaccine confidence but also on how clearly the rationale is communicated for each target population.

The strong association between unwillingness to receive influenza vaccination and hesitancy toward future annual COVID-19 vaccination provides additional insight. Influenza vaccination is an established example of periodic respiratory-virus vaccination for health care personnel [25,26]. The observed association may therefore reflect broader attitudes toward repeated vaccination rather than attitudes toward COVID-19 vaccination alone. However, this comparison should be interpreted cautiously. COVID-19 vaccination and influenza vaccination differ in their history, policy context, perceived urgency, and public communication environment. Therefore, influenza vaccination willingness should be viewed as a useful comparative reference for periodic vaccination attitudes, not as a direct equivalent of future COVID-19 vaccination willingness.

These findings suggest that future vaccination strategies for physicians and medical trainees should move beyond general promotional messages and emphasize transparent, regularly updated, and clinically interpretable evidence on vaccine effectiveness, safety, durability of protection, variant relevance, and benefit-risk profiles after prior vaccination and SARS-CoV-2 infection. Hospitals and professional organizations could incorporate such evidence into continuing medical education and develop target population–specific communication materials to support discussions with older adults and parents of young children. Prospective studies are needed to evaluate whether these approaches improve vaccination confidence and subsequent vaccination behavior.

This study has several strengths, including its large multicenter sample across 7 geographic regions of China and its assessment of both participants' own vaccination willingness and their support for vaccination among older adults and young children. However, several limitations should be considered. First, the cross-sectional design precludes causal inference and cannot capture changes in vaccination attitudes over time. Second, participants were recruited from public hospitals using predefined recruitment targets rather than probability sampling and were limited to physicians and medical trainees, which may restrict the generalizability of the findings. Because the questionnaire was distributed through direct invitations and department-level WeChat groups, the response rate could not be calculated, and selection bias remains possible. Third, willingness to receive vaccination and willingness to support vaccination for older adults and young children were self-reported and may not reflect actual future behavior or real-world clinical recommendation practices. Fourth, sex and income data were not collected, preventing assessment of these factors. Fifth, because reasons for hesitancy toward COVID-19 and influenza vaccination were assessed using vaccine-specific response options, comparisons between the two vaccines should be interpreted descriptively rather than as direct item-by-item comparisons.

In conclusion, high prior COVID-19 vaccination uptake did not translate into similarly high willingness to receive future annual vaccination among physicians and medical trainees. Future vaccination strategies should address concerns about the evidence supporting repeated vaccination and the differing levels of support observed for older adults and young children.

## Abstract

**Background:** Vaccine hesitancy remains a persistent global challenge, especially in the context of major public health emergencies. While individual-level factors have been widely studied, whether and how household and community contexts shape hesitancy clustering has received little attention.

**Objective:** This study aimed to assess household- and community-level clustering of COVID-19 booster vaccine hesitancy (CBVH), identify key associated factors, and explore potential intervention targets.

**Methods:** In March 2023, a household-based cross-sectional survey was conducted among Chinese adults across 4 provinces. Concurrent CBVH was defined as hesitancy reported for both current and future booster intentions within the same survey. The analytical samples included 5462 participants for current CBVH, 5437 for future CBVH, and 5407 for concurrent CBVH. Three-level logistic regression models were used to quantify variance attributable to individual, household, and community levels and to identify associated factors. Network analysis was also used to examine interrelationships among key factors and identify central intervention targets.

**Results:** Among 5407 participants, 1461 (27.0%) exhibited concurrent CBVH. The unweighted prevalence of current and future CBVH was 28.4% (1553/5462) and 30.1% (1636/5437), respectively. The corresponding poststratified prevalence estimates were 30.88% and 32.55%, respectively. In the null model, the combined household- and community-level intraclass correlation coefficients were 77.73% (95% CI 72.40% - 82.29%) and 78.84% (95% CI 73.57% - 83.30%), respectively. Prior COVID-19 vaccination, self-efficacy, perceived benefits, trust in vaccine developers, and knowledge of the vaccine were associated with lower CBVH, while perceived barriers, perceived severity, household income, chronic disease, history of allergies, and living in the eastern region were associated with higher hesitancy. Network analysis revealed that self-efficacy and prior COVID-19 vaccination had the strongest associations with CBVH. Perceived barriers and trust in vaccine developers formed the strongest association among nodes. The current and future CBVH networks showed similar configurations.

**Conclusions:** The substantial household and community clustering highlights the need for group interventions. Household-centered vaccine education, community-based vaccine counseling services, and transparent vaccine communication may help reduce vaccine hesitancy and strengthen preparedness for future infectious disease outbreaks.

## Introduction

Vaccine hesitancy, defined as the delay in acceptance or refusal of vaccination despite the availability of immunization services [1], was recognized by the World Health Organization as one of the top 10 threats to global health [2]. Critically, its principal risk is driving immunization coverage below the herd immunity threshold, ultimately compromising population-level protection

XSL•FO
RenderX

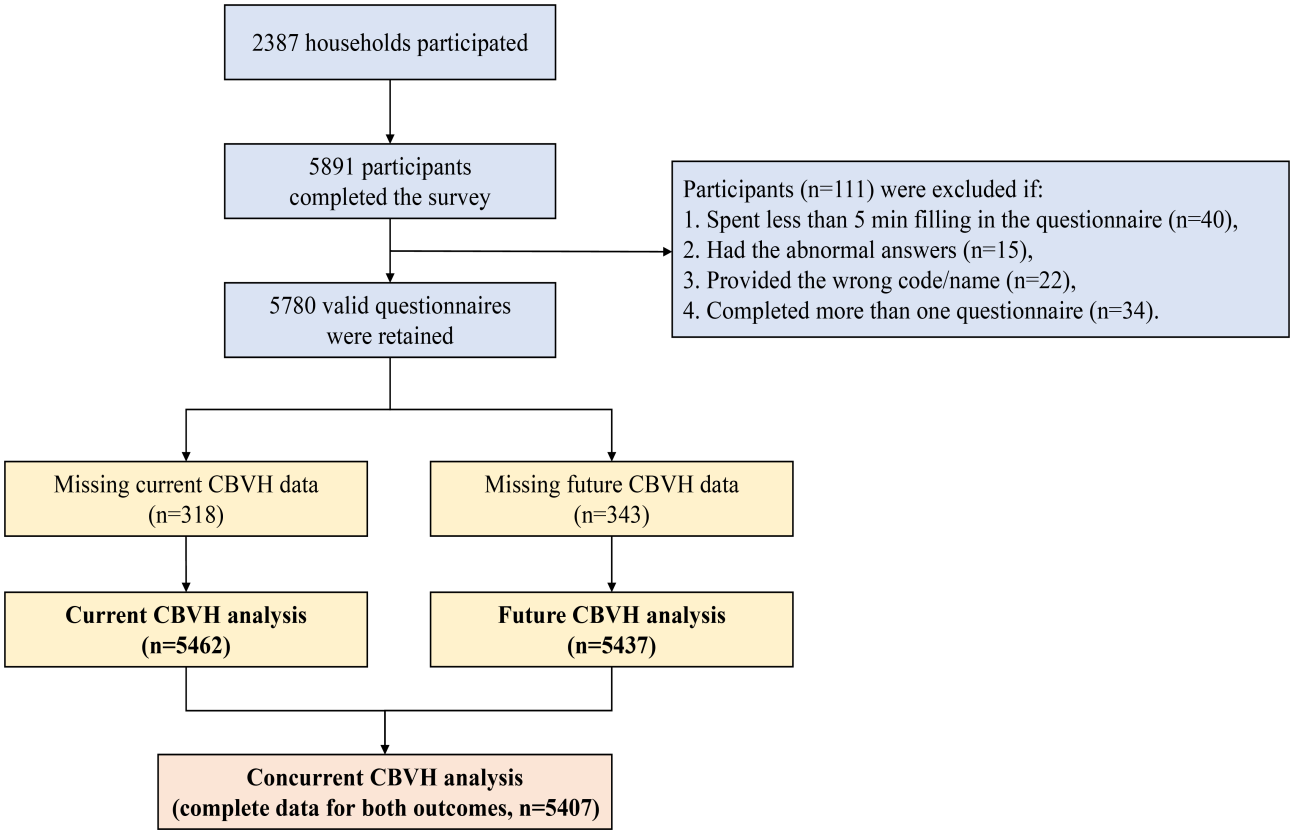
[3]. The COVID-19 pandemic brought this issue into sharp focus. While vaccines were estimated to have prevented millions of deaths, vaccine hesitancy persisted and has continued into the postpandemic era. Recent evidence suggests that vaccine hesitancy may persist over time and extend beyond a single pathogen or vaccination context [4]. A cohort study of over 1.1 million individuals in England found that concerns about vaccine effectiveness and health effects declined over time, whereas hesitancy linked to low trust, low perceived risk, and broader opposition to vaccination was more persistent [5]. A multinational survey spanning 23 countries with 23,000 participants revealed that among individuals who had completed their primary vaccination series, the COVID-19 booster vaccine hesitancy (CBVH) rate was 12.1%, with Russia exhibiting the highest rate at 28.9% [6]. In China, a repeated cross-sectional study demonstrated an increase in COVID-19 vaccine hesitancy, rising from 8.39% in 2021 to 29.72% in 2023 [7]. Therefore, understanding vaccine hesitancy is critical not only for addressing remaining COVID-19 challenges but also for strengthening global preparedness against future outbreaks.

Existing studies have identified the individual correlates of COVID-19 vaccine hesitancy [7-9], including sociodemographic characteristics (eg, sex, age, and education level), health-related factors (eg, chronic diseases, drinking, and smoking), trust in the medical system, and exposure to misinformation. In addition, the Health Belief Model posits that psychological perceptions, including perceived susceptibility, perceived severity, perceived benefits, perceived barriers, cues to action, and self-efficacy, are key factors in vaccine hesitancy. The Social Ecological Model further recognizes that health behaviors are shaped not only by individual factors but also by interpersonal relationships and community contexts [10]. At the household level, shared information, norms, health experiences, and decision-making processes may produce similar attitudes toward vaccination among family members [11]. However, most household-level research has focused on parental decisions about childhood vaccination or has treated family influence as an individual-level exposure [12,13]. At the community level, community engagement may promote vaccine uptake and ensure the effective implementation of health equity interventions [14]. A study involving 7241 residents from 71 communities in China found that community-level differences accounted for 2.4% to 3.7% of the variation in COVID-19 vaccine refusal and 8.5% to 9.6% of the variation in delayed COVID-19 vaccination [15]. Other studies have reported geographic clustering and associations with regional socioeconomic conditions, racial or ethnic composition, political orientation, and religious context [16,17]. Few studies, however, have examined individual-, household-, and community-level clustering within a multilevel framework. A study conducted in the Dominican Republic investigated COVID-19 vaccine hesitancy using a 3-level multilevel framework and demonstrated significant spatial clustering [18]. However, the relative contributions of household and community contexts to overall clustering were not comprehensively characterized. More importantly, no study has evaluated these multilevel interactions within China, a unique sociocultural and administrative landscape characterized by a strong collectivist culture, family-oriented decision-making, and community-based health governance [19]. Crucially, it remains unclear to what extent CBVH clusters within households and communities and how its associated individual-, household-, and community-level factors are conditionally interconnected. Addressing these gaps may provide important evidence for designing tailored, multitiered immunization strategies and optimizing precision public health interventions in China and similar settings.

In this study, we analyzed data from a multicenter, household-based survey conducted across 4 provinces in China. This study aimed to assess the extent of household- and community-level clustering of CBVH, identify key factors associated with CBVH, and further explore interrelationship patterns and identify central nodes as potential intervention targets. By integrating multilevel and network approaches, we sought to provide a more comprehensive understanding of the factors associated with vaccine hesitancy and to inform multilevel intervention planning for future pandemic responses and vaccination campaigns.

## Methods

### Procedures and Participants



We used a stratified random sampling method to conduct a multicenter, observational study of vaccine hesitancy in Chinese households. The study was reported in accordance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines (Checklist 1). Four cities were selected from China's 4 major economic regions: Eastern (Changzhou, Jiangsu), Central (Zhengzhou, Henan), Western (Xining, Qinghai), and Northeastern (Mudanjiang, Heilongjiang). These regions differ in economic development, health care resources, and cultural norms. The minimum sample sizes for each region were determined based on the population proportions of China's Seventh National Population Census (2020). Within each city, at least 2 urban and 2 rural areas were randomly selected for sampling, followed by a random selection of households within each identified area. All eligible members aged 18 years and above were invited to participate, as vaccination decisions for minors are generally made by parents or guardians [20]. This survey was conducted in March 2023. Participants completed either an online questionnaire administered through the Wenjuanxing platform or a paper questionnaire with the assistance of survey staff. To reduce selection and information bias, trained staff thoroughly reviewed all questionnaires based on the exclusion criteria. Finally, a total of 5891 participants aged 18 years and above from 2387 households were enrolled.

Following rigorous data cleaning to exclude invalid questionnaires, 5780 participants were included in this analysis. We further excluded participants with missing data on current and future CBVH, yielding a final analytical sample of 5462 participants for the analysis of current CBVH and 5437 participants for the analysis of future CBVH. Among them, 5407 participants responded to both questions and were subsequently included in the concurrent CBVH analysis. The detailed participant flow is shown in Figure 1.

## Ethical Considerations

This study was conducted in accordance with the Declaration of Helsinki. This survey project was approved by the Life Science Ethics Review Committee of Zhengzhou University (approval number: 2021-01-12-05), and all participants provided written informed consent. All data were handled confidentially, and no compensation was provided.

## Assessments

### *Outcomes*

The primary outcomes were current and future CBVH, which were self-reported. Participants were asked 2 questions: “At present, would you like to get a booster vaccination of the COVID-19 vaccine?” and “In the future, would you like to get a booster vaccination of the COVID-19 vaccine?” Participants could choose one response from the following options: “(1) willing,” “(2) hesitant or delayed,” “(3) refused,” and “(4) not applicable.” According to the definition of vaccine hesitancy [9], option (1) was regarded as “acceptance,” and options (2) and (3) were merged into “hesitancy.” In addition, participants were excluded if they selected the option “(4) not applicable.” In this study, concurrent CBVH was defined as hesitancy reported for both current and future booster intentions within the same survey.

### *Covariates*

The questionnaire included (1) sociodemographic characteristics: age, sex, ethnicity, religion, marital status, educational level, employment status, region, coresidence status, number of children, number of older adults, annual household income, smoking status, and drinking status; (2) health conditions: history of allergies, chronic diseases, and prior COVID-19 vaccination status; (3) awareness of the COVID-19 vaccine: sources of COVID-19 vaccine information and knowledge of the COVID-19 vaccine; (4) self-perception: perceived severity, perceived susceptibility, perceived benefits, perceived barriers, self-efficacy, and cues to action; (5) trust in the medical system: trust in doctors and vaccine developers; and (6) convenience of vaccination: distance and time to the vaccination point. Details of the items, response formats, scoring, and internal consistency are provided in Table S1 in Multimedia Appendix 1. Vaccine knowledge and self-perception variables were categorized using quartile-based cutoffs.

## Statistical Analysis

Descriptive analyses were conducted to characterize the study sample. For continuous variables, means and SDs were calculated; for categorical variables, frequencies and percentages were reported. Chi-square and 2-tailed independent-samples *t* tests were used to examine differences between participants with and without CBVH. Poststratification weighting was used to adjust the sample according to the age, sex, and region distributions reported in the Seventh National Population Census of China (2020) [21]. Participants with missing outcome data were excluded from the corresponding outcome-specific analysis. No covariate data were missing after data cleaning.

A 3-level logistic regression modeling approach was used due to the hierarchical structure of our data. Specifically, individuals were nested within households, and households within communities. Fixed effects were presented as adjusted odds ratios (aORs) with corresponding 95% CIs. Random effects

XSL•FO
RenderX

were assessed using random-intercept variances, the variance partition coefficient (VPC), the intraclass correlation coefficient (ICC), the median odds ratio (MOR), and proportional changes in variance (PCV). The community- and household-level VPCs indicate the proportions of overall variation attributable to differences between communities and households, respectively. The combined ICC represents clustering among individuals in the same household and includes both household- and community-level variances [22]. The MOR represents the median odds ratio between higher- and lower-risk clusters and quantifies unexplained heterogeneity on the odds-ratio scale, whereas the PCV quantifies the proportional change in the corresponding variance relative to model 0 [23]. The individual-level residual variance was fixed at $\pi^2/3$, and 95% CIs were estimated using the delta method. Four models were fitted sequentially. First, a null model with only household- and community-level random intercepts was fitted to partition the variance. Subsequently, 3 multivariable models were built: model 1 adjusted for individual-level factors, including age, sex, ethnicity, religion, marital status, educational level, employment status, coresidence status, smoking status, drinking status, chronic disease, history of allergies, prior COVID-19 vaccination status, source of COVID-19 vaccine information, knowledge of COVID-19 vaccine, perceived severity, perceived susceptibility, perceived benefits, perceived barriers, self-efficacy, cues to action, trust in doctors, and trust in vaccine developers; model 2 further adjusted for household-level factors, including number of children, number of older adults, and annual household income; and model 3 further adjusted for community-level factors, including region, distance to vaccination point, and time to vaccination point. Model fit was evaluated using the Akaike information criterion (AIC), Bayesian information criterion (BIC), and log-likelihood (LL), with better fit indicated by lower AIC and BIC values and higher log-likelihood.

Then, network analysis was conducted to visualize and quantify complex interrelationships among factors that were statistically significantly associated with CBVH within multilevel models. The current and future CBVH networks were estimated using mixed graphical models, which allow continuous, binary, and multicategorical variables within a single analytical framework [24]. Only pairwise interactions were estimated ($k$=2). Least absolute shrinkage and selection operator regularization [25], combined with extended Bayesian information criterion model selection ($\gamma$=0.50), were applied to obtain conservative and sparse network estimates [26]. Nodes represented the included variables, whereas edges represented pairwise conditional associations after controlling for all other variables in the network. Positive and negative associations were represented by green and red edges, respectively, with thicker edges indicating stronger associations. For multicategorical variables, the edge weight was summarized using the mean absolute magnitude of category-specific parameters and was displayed in gray because a single direction could not be assigned. Node predictability indicates the extent to which a node could be predicted by its adjacent nodes [27]. It was quantified using the proportion of explained variance ($R^2$) for continuous variables and the proportion of correct classifications (CC) for categorical variables. Centrality indices, including strength, betweenness, and closeness, were calculated to identify the most influential nodes within the network. Edge-weight accuracy was evaluated using nonparametric bootstrapping with 1000 replicates, from which 95% CIs were obtained. The correlation stability coefficient (CS-C) was reported, with a threshold of 0.25 or higher, and ideally above 0.50 [28]. We also ranked the edges directly connected to the CBVH node and displayed them in a heatmap [29]. Signs were retained for continuous and binary variables, while multicategorical edges were summarized using mean absolute parameter values and compared descriptively.

To evaluate the robustness of the primary findings, 3 sensitivity analyses were performed. Because religious beliefs [30] and allergy history [31] have been identified as important determinants of vaccine hesitancy, the analyses were repeated after separately excluding participants reporting religious beliefs and those with a history of allergies. Participants from the eastern region were excluded to assess the robustness of the results with respect to the uneven regional sample distribution. All statistical analyses were performed using Stata (version 18.0; StataCorp LLC) and R (version 4.4.2; R Foundation for Statistical Computing), with a 2-tailed $P$ value of <.05 considered statistically significant.

## Results

### Characteristics of Participants

The unweighted prevalence of current and future CBVH was 28.4% (1553/5462) and 30.1% (1636/5437), respectively. After poststratification, the corresponding prevalence estimates were 30.88% and 32.55%, respectively (Figure S1 in Multimedia Appendix 1). Among the 5407 participants with complete data for both outcomes, 1461 (27.0%) exhibited concurrent CBVH. In the current CBVH analytical sample (n=5462), participants were distributed across all age groups, and 46.5% (n=2538) were male participants. Most participants were married (n=4832, 88.5%) and employed (n=5038, 92.2%). The future CBVH analytical sample (n=5437) showed a similar distribution. For both groups, we found that age, educational level, employment, region, number of children, annual household income, smoking status, drinking status, history of allergies, chronic disease, prior COVID-19 vaccination status, source of COVID-19 vaccine information, knowledge of the COVID-19 vaccine, perceived severity, perceived susceptibility, perceived benefits, perceived barriers, self-efficacy, cues to action, trust in doctors, trust in vaccine developers, distance to the vaccination point, and time to the vaccination point all differed between participants with and without CBVH (all $P$<.05). The detailed characteristics are presented in Table 1.

[a]The category boundaries were as follows: vaccine knowledge: level 1: 0 - 1, level 2: 2 - 3, level 3: 4 - 5, and level 4: ≥6; perceived severity: level 1: ≤8, level 2: 9, level 3: 10 - 11, and level 4: ≥12; perceived susceptibility: level 1: ≤6, level 2: 7 - 8, level 3: 9 - 10, and level 4: ≥11; perceived benefits: level 1: ≤8, level 2: 9 - 11, and level 3: ≥12; perceived barriers: level 1: ≤7, level 2: 8 - 9, level 3: 10 - 11, and level 4: ≥12; and self-efficacy: level 1: ≤11, level 2: 12 - 15, and level 3: ≥16. Higher levels indicate higher scores. Because of the tied scores, perceived benefits and self-efficacy had 3 observed levels rather than 4.

[b]Not applicable.

## Factors Associated With Current and Future CBVH

Table 2 presents the variance components, clustering measures, and model fit statistics for the 4 models. In model 0, the combined household- and community-level ICCs were 77.73% (95% CI 72.40% - 82.29%) for current CBVH and 78.84% (95% CI 73.57% - 83.30%) for future CBVH, supporting the use of 3-level models. After controlling for all variables, the ICCs remained high at 71.94% (95% CI 66.30% - 76.96%) and 72.52% (95% CI 66.97% - 77.45%), respectively. From model 0 to model 3, community-level variance decreased substantially (current CBVH: 3.89-1.36 and future CBVH: 4.29-1.49), whereas household-level variance changed modestly (current CBVH: 7.60-7.07 and future CBVH: 7.97-7.19). In model 3, the MORs for current and future CBVH were 15.96 (95% CI 11.32 - 23.62) and 16.62 (95% CI 11.75 - 24.70), respectively. This indicates a median 16-fold difference in the odds of hesitancy when comparing 2 individuals with identical covariates from different household-community contexts. Overall, relative to model 0, model 3 accounted for 26.57% and 29.17% of the higher-level variance for current and future CBVH, with most of the reduction occurring at the community level.

As shown in Figure 2, in the current CBVH analytical sample, participants with level 3 self-efficacy (aOR 0.01, 95% CI 0.01 - 0.02) and level 3 perceived benefits (aOR 0.45, 95% CI 0.25 - 0.81) had lower odds of CBVH than those at level 1. Conversely, participants with level 4 perceived barriers (aOR 4.81, 95% CI 2.41 - 9.64) and level 4 perceived severity (aOR 2.82, 95% CI 1.74 - 4.57) had higher odds than those at level 1. Compared with receiving cues to action from multiple channels, cues derived from social pressure (aOR 2.93, 95% CI 1.08 - 7.94) were associated with higher odds of CBVH. Regarding trust in the medical system, higher trust in doctors (aOR 0.97, 95% CI 0.94 - 0.99) and in vaccine developers (aOR 0.89, 95% CI 0.84 - 0.94) were both associated with lower odds of CBVH. Participants with level 3 vaccine knowledge also had lower odds than those at level 1 (aOR 0.48, 95% CI 0.30 - 0.76). Several sociodemographic and health characteristics were also associated with CBVH. Compared with those living with others, individuals living alone had lower odds of CBVH (aOR 0.28, 95% CI 0.10 - 0.78). Compared with residents in eastern China, those living in the central (aOR 0.12, 95% CI 0.03 - 0.47) and northeastern regions (aOR 0.15, 95% CI 0.03 - 0.89) exhibited lower odds of CBVH. Prior COVID-19 vaccination was also associated with lower odds of CBVH (aOR 0.12, 95% CI 0.06 - 0.23). Conversely, higher annual household income was associated with increased odds of CBVH (aOR 1.01, 95% CI 1.00 - 1.01). Additionally, having chronic diseases (aOR 1.48, 95% CI 1.04 - 2.12) or a history of allergies (aOR 1.66, 95% CI 1.04 - 2.66) was associated with increased odds of CBVH. Similar associations were observed in the future CBVH analytical sample.

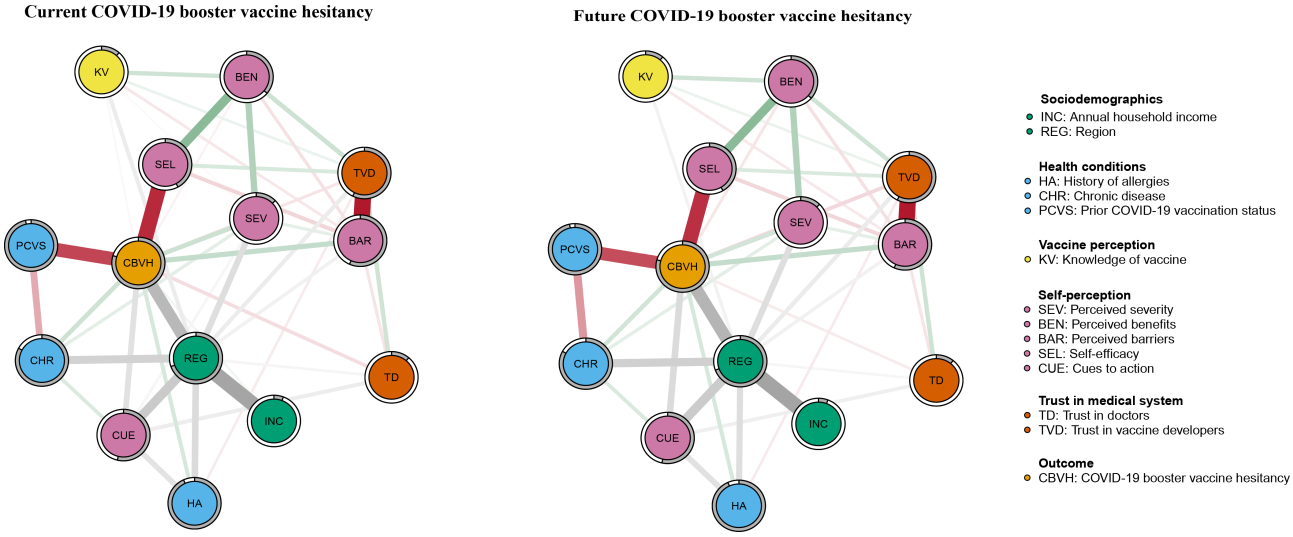
**Figure 2.** Multilevel logistic regression results for factors associated with current and future COVID-19 booster vaccine hesitancy (CBVH). Adjusted for age, sex, ethnicity, religion, marital status, educational level, employment status, coresidence status, smoking status, drinking status, chronic diseases, history of allergies, prior COVID-19 vaccination status, source of COVID-19 vaccine information, knowledge of the COVID-19 vaccine, perceived severity, perceived susceptibility, perceived benefits, perceived barriers, self-efficacy, cues to action, trust in doctors, trust in vaccine developers, number of children, number of older adults, annual household income, region, distance to the vaccination point, and time to the vaccination point. The category boundaries were as follows: vaccine knowledge: level 1: 0 - 1, level 2: 2 - 3, level 3: 4 - 5, and level 4: ≥6; perceived severity: level 1: ≤8, level 2: 9, level 3: 10 - 11, and level 4: ≥12; perceived susceptibility: level 1: ≤6, level 2: 7 - 8, level 3: 9 - 10, and level 4: ≥11; perceived benefits: level 1: ≤8, level 2: 9 - 11, and level 3: ≥12; perceived barriers: level 1: ≤7, level 2: 8 - 9, level 3: 10 - 11, and level 4: ≥12; and self-efficacy: level 1: ≤11, level 2: 12 - 15, and level 3: ≥16. "*" and red lines indicate estimates from the current CBVH multilevel logistic regression model, whereas "**" and blue lines represent estimates from the future CBVH multilevel logistic regression model. aOR: adjusted odds ratio.

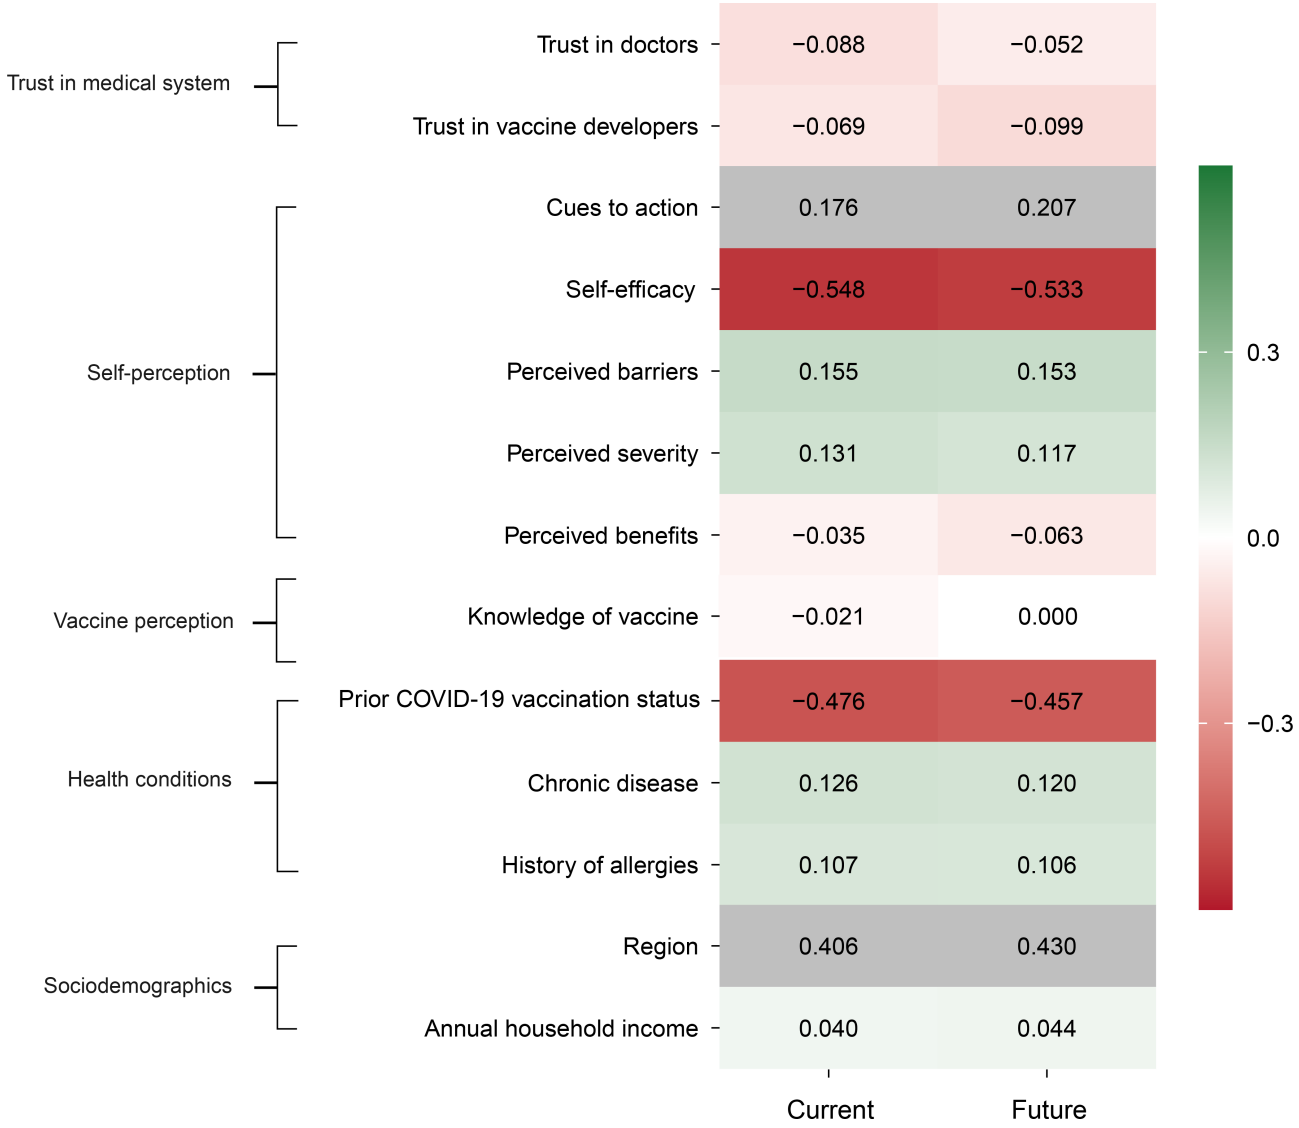


## Network Structure and Conditional Associations With CBVH

The network analysis included 14 nodes and is presented in Figure 3. The current and future CBVH networks retained 43 and 41 of the 91 possible edges, corresponding to network densities of 47.3% (43/91) and 45.1% (41/91), respectively. The CC of the CBVH node was 79.6% (4350/5462) in the current network and 79.3% (4311/5437) in the future network. Overall, the 2 networks showed similar configurations.

XSL•FO
RenderX

**Figure 3.** Networks of factors associated with current and future COVID-19 booster vaccine hesitancy. Green and red edges indicate positive and negative conditional associations, respectively, with thicker edges representing larger absolute edge weights. Edges involving multicategorical variables are shown in gray because their category-specific parameters were summarized by the mean of their absolute magnitude and therefore have no single direction. Node colors indicate variable domains. The ring surrounding each node represents its statistical predictability from adjacent nodes, quantified using explained variance ($R^2$) for continuous variables and classification accuracy for categorical variables.



The magnitudes of conditional associations between study factors and CBVH are presented in Figure 4. In both networks, self-efficacy (current CBVH: −0.548 and future CBVH: −0.533) and prior COVID-19 vaccination status (current CBVH: −0.476 and future CBVH: −0.457) showed the largest conditional associations with CBVH. Region (current CBVH: 0.406 and future CBVH: 0.430) and cues to action (current CBVH: 0.176 and future CBVH: 0.207) also showed large edge weights. Because these are multicategorical variables, the values represent absolute edge magnitudes without a single direction. Edge weights for perceived barriers, perceived severity, chronic disease, and allergy history varied little between networks. Trust in doctors had a larger absolute association with current CBVH (−0.088 vs −0.052), whereas trust in vaccine developers (−0.069 vs −0.099) and perceived benefits (−0.035 vs −0.063) had larger absolute associations with future CBVH. Beyond the CBVH-related edges, the strongest edge weight in both networks was observed between perceived barriers and trust in vaccine developers (weight=0.593).

XSL•FO
RenderX

**Figure 4.** Conditional associations of factors with current and future COVID-19 booster vaccine hesitancy (CBVH). Values represent edge weights for the conditional associations between each study factor and the CBVH node after accounting for all other variables in the mixed graphical model. For continuous and binary variables, positive and negative values indicate the direction of the statistical association, while larger absolute values indicate stronger associations. For the multicategorical variables region and cues to action, values represent the mean absolute magnitude of the category-specific parameters and therefore do not indicate a single direction; these cells are shown in gray. A value of zero indicates that no direct edge with CBVH was retained after regularization.

Centrality indices and bootstrap results are provided in Figures S2 to S4 in Multimedia Appendix 1. The case-dropping bootstrap analysis indicated stability for strength (CS-C: current CBVH=0.750 and future CBVH=0.672) and betweenness (CS-C: current CBVH=0.672 and future CBVH=0.672). Nonparametric bootstrap analysis supported the accuracy of the strongest edge estimates.

### Sensitivity Analysis

Three sensitivity analyses were performed, separately excluding participants with religious beliefs, those with a history of allergies, and those from the eastern region (Tables S2-S4 in Multimedia Appendix 1). The factors associated with CBVH were largely consistent with those in the primary analysis. Additionally, the combined household- and community-level ICCs ranged from 64.96% to 74.15% across the 3 analyses, remaining comparable to the primary estimates of 71.94% for current and 72.52% for future CBVH.

## Discussion

### Principal Findings

This study investigated factors associated with CBVH in a sample from 4 provinces in China, finding that 27.0% (1461/5407) exhibited concurrent CBVH, while the poststratification prevalence of current and future CBVH was 30.88% and 32.55%, respectively. Our findings revealed substantial clustering of CBVH at both the household and community levels (77.73% for current and 78.84% for future). Additionally, network analysis showed that self-efficacy and prior COVID-19 vaccination had the strongest conditional associations with CBVH. The strongest association between non-CBVH nodes was between perceived barriers and trust in vaccine developers. The current and future networks showed broadly similar configurations, supporting the prioritization of factors consistently associated with both outcomes. In general, our results provide insights for developing targeted interventions

XSL•FO
RenderX

at the household and community levels to enhance vaccination coverage and strengthen pandemic preparedness.

The observed clustering aligns with social norms theory, which posits that behavior is not only driven by personal motivation or legal enforcement but also influenced by perceptions of others' behaviors and expectations [32]. At the community level, 2 mechanisms may explain the clustering. First, social selection may produce residential homogeneity. People living in the same community often share similar sociodemographic characteristics, health literacy, and cultural values, which may lead to similar vaccine attitudes [33]. Residents may also face shared structural barriers, including distance to vaccination sites, limited transportation options, unequal access to digital systems, and uneven implementation of public health measures [34,35]. Second, social contagion may spread vaccine-related information and attitudes through neighbors, local groups, and social networks. Vaccine hesitancy may cluster geographically when hesitant views are widespread within a community [36,37]. At the household level, the unique relational structure of the family may make these mechanisms more pronounced. Families often operate under a centralized decision-making hierarchy, whereby one member (eg, parents or adult children) assumes primary responsibility for health decisions [38]. A previous study found that when the family decision-maker was hesitant, 65.1% of other household members tended to follow suit [13]. Notably, household-level variance decreased only modestly after adjustment for measured household characteristics, including household size and income. Future studies should examine other household-level factors, such as decision-making patterns, shared values, and family communication [13,39].

Our findings highlight several key factors associated with CBVH. Higher vaccine knowledge was associated with lower hesitancy, consistent with studies showing that limited vaccine understanding increases hesitancy [40,41]. Self-perception factors, including self-efficacy, perceived benefits, and perceived barriers, were also associated with CBVH [9,42]. Therefore, future interventions may prioritize these modifiable self-perception factors. For instance, motivational interviewing [43] or targeted health education [44] may strengthen vaccination self-efficacy and perceived benefits, while transparent communication regarding vaccine safety and efficacy may help improve perceived benefits [45]. Additionally, we observed a positive association between perceived severity and CBVH. One possible explanation is that during severe outbreaks, individuals may rely more on nonvaccine protective behaviors, such as improved hygiene, reduced mobility, and timely testing, which may be associated with a reduced perceived need for vaccination [46]. Higher trust in doctors and vaccine developers was associated with lower CBVH, underscoring the importance of credible health communication [47]. By contrast, chronic diseases and a history of allergies were associated with higher hesitancy, possibly because these participants were more concerned about their health conditions and adverse reactions [48,49]. Similarly, cues to action were associated with CBVH and have been verified in previous studies [50,51]. Compared with cues from multiple channels, cues based mainly on personal experience or social pressure were linked to higher hesitancy. Living alone was associated with lower CBVH in our study. However, the subgroup of participants living alone was small, and future studies with larger samples are needed to confirm this association. Notably, residents in central and northeastern China, as well as lower-income households, exhibited lower CBVH rates. This may be attributable to the free provision of COVID-19 booster vaccines in China [52], which alleviates financial barriers. This pattern is also consistent with the inverse equity hypothesis, which suggests that hesitancy may emerge first among more socioeconomically advantaged groups [53]. Given the markedly higher CBVH observed in eastern China, we repeated the analysis after excluding this region. Substantial clustering persisted, suggesting that the observed clustering was not driven solely by regional composition.

The network analysis illustrated interrelationships among factors associated with CBVH. Among the factors directly linked to CBVH, self-efficacy showed the strongest association. This finding is consistent with health behavior frameworks in which self-efficacy has been associated with preventive behaviors [54]. Prior COVID-19 vaccination status showed the second strongest direct association. This accords with evidence that vaccination history is associated with booster acceptance and subsequent uptake [55]. Region and cues to action also showed large edge weights. Although these multicategorical estimates did not indicate a uniform direction, they suggest that regional and communication-related factors warrant consideration alongside psychological factors. Beyond the edges directly connected to CBVH, perceived barriers and trust in vaccine developers had the strongest edge in both networks, suggesting that safety and effectiveness may be closely linked to confidence in vaccine producers. A prior study also showed that individuals with less concern about infection severity and lower trust in vaccine effectiveness were more likely to be hesitant [56]. The current and future networks were similar. These findings highlight factors that may warrant further evaluation in intervention studies.

Nevertheless, several limitations should be acknowledged. First, the cross-sectional design limits causal inference, and longitudinal studies are needed to confirm the observed relationships. Second, because CBVH was not a rare outcome, the odds ratios do not approximate prevalence ratios and should be interpreted as measures of association. Third, CBVH was assessed via self-report, which may have introduced reporting bias or social desirability effects. Finally, although our sampling strategy ensured geographic diversity across 4 major provinces, substantial regional heterogeneity may limit the generalizability of the findings.

## Conclusions

In this multicenter household-based study, we found that vaccine hesitancy clustered substantially within households and communities, highlighting the importance of household- and community-level interventions. Self-efficacy and prior vaccination were most directly associated with hesitancy, while perceived barriers and trust in vaccine developers showed the strongest associations within the network. Effective strategies such as regular family-centered vaccine education delivered through community platforms, community-based vaccine counseling services, and transparent dissemination of

XSL•FO
RenderX

vaccine-related information and policies may help address vaccine hesitancy. These insights offer a framework for strengthening vaccination strategies and preparedness in future infectious disease outbreaks.

# Indications for Medical Cannabis and Their Alignment With US-Wide Disease Prevalences in the US' Largest Medical Cannabis Program: Cross-Sectional Study

## Abstract

This research letter compared the prevalence of qualifying conditions among patients certified to use medical cannabis in Florida to population-based prevalence estimates for the same conditions and observed marked discrepancies. These findings highlight conditions that appear to be significant reasons for patients to consider medical cannabis, providing important research priorities for future research on its effectiveness and safety.

***(JMIR Public Health Surveill 2026;12:e89716)*** doi:10.2196/89716

**KEYWORDS**

medical marijuana; cannabis; qualifying condition; prevalence; cross-sectional studies; medical marijuana use registry

## Introduction

The participation in medical cannabis (MC) programs has expanded rapidly in the United States—from 678,408 registered patients in 2016 to 2,974,433 in 2020 and approximately 3,641,949 in December 2024; in Florida alone, 921,698 patients were participating in the statewide MC program as of August 2025 [1-3]. Given the rapid expansion and persistent evidence gaps on therapeutic benefits and risks, rigorous studies of MC safety and effectiveness are urgently needed [4-6]. Understanding patients' and certifying providers' preferences can help identify high-priority research areas, for example when qualifying medical conditions (QMCs) with limited evidence on medical cannabis safety and effectiveness are overrepresented among certified patients relative to their prevalence in the general population. While prior studies report the most frequently certified conditions in medical cannabis programs, little is known about how conditions for which MC is used aligns with disease prevalences, and hence patient and provider preferences across different conditions to explore medical cannabis as alternative or supplemental treatment [2,7]. The objective of this study was to compare the prevalence of QMCs among medical cannabis patients in Florida to population-based prevalences of these conditions.

## Methods

We analyzed data from the Florida Medical Marijuana Use Registry to identify QMC among patients with a MC certification in 2025.

The Medical Marijuana Use Registry includes data from all Florida patients who were certified by a physician to receive MC for one or more legally QMCs (the condition that is intended to be treated). Data is generated via standardized online templates from physicians authorized to order medical cannabis for patients. We excluded records with a missing patient identifier or recorded sex, non-resident status or implausible certification dates (closure date preceding the start date).

We extracted US-specific disease prevalences from peer-reviewed literature and scientific reports, focusing on Florida or, if unavailable, the southern United States, or the United States. We prioritized reports that estimated prevalence across the entire population over reports for selected subpopulation, eg, only those with private health insurance.

Allowing multiple QMCs per patient, we calculated condition-specific prevalences by dividing the number of patients with a specific qualifying medical condition on their MC certification in 2025 by the total number of patients with MC certification in 2025. Patients with multiple QMCs were only counted once in the denominator. We then computed prevalence ratios by dividing the Medical Marijuana Use

XSL•FO
RenderX

Registry data-derived prevalence for each qualifying medical condition by the population-based prevalence of this condition in Florida.

We supplemented reported prevalence with the level of evidence supporting the effectiveness of medical cannabis for each condition based on the National Academy of Sciences, Engineering, and Medicine report from 2017 that comprehensively investigated the evidence for health effects in cannabis and cannabinoids and an update from a recent published comprehensive mapping review [4,5]. Data analysis was conducted with SAS software (version 9.4).

### Ethical Considerations

This study was approved by the University of Florida Institutional Review Board (IRB202002648) and Florida Department of Health IRB [2020 - 101-UFL]. Informed consent was waived. Data in this research did not involve participant compensation. Confidentiality of the data was ensured through anonymity and stringent security measures.

## Results

Of 779,673 qualifying patients in the Medical Marijuana Use Registry in 2025, 8493 (1.09%) were excluded: 7304 (0.94%) nonresidents, 1186 (0.15%) with implausible certification dates, and 3 (<0.01%) with missing recorded sex—yielding 771,180 qualifying patients. The median age was 46.0 years (IQR 34.0 - 61.0); 342,258 (44.38%) were female and 428,922 (55.62%) were male. The most prevalent QMCs per 100,000 patients certified to use medical cannabis in Florida in 2025 (Table 1) were posttraumatic stress disorder (PTSD) (81,519), chronic pain (24,081), and multiple sclerosis (12,938). The three QMCs with the lowest prevalence per 100,000 certified patients were acquired immunodeficiency syndrome (AIDS) (174), amyotrophic lateral sclerosis (ALS) (302), and human immunodeficiency virus (HIV) (860). When compared to population-based prevalences, most conditions were more common in the Medical Marijuana Use Registry.

We observed pronounced variations in the ratio of Medical Marijuana Use Registry-based and general population prevalences across QMCs. Notably, ALS demonstrated the highest ratio (77.4), indicating a substantially higher representation among medical cannabis users. This was followed by MS (47.5), and Crohn's disease (10.4). In contrast, chronic nonmalignant pain (1.0) had similar, and conditions like AIDS (0.6) had lower representation in the Medical Marijuana Use Registry than in the general population. The level of evidence supporting effectiveness of medical cannabis as treatment was substantial for epilepsy, multiple sclerosis, and chronic non-malignant pain, and limited or insufficient for the remainder.

## Discussion

In this cross-sectional study, we found that the prevalence of QMCs among certified MC users in Florida differed from general population disease prevalences suggesting that patients' and physicians' perceptions of MC's role as alternative treatment differs across conditions [18]. Indications with limited or substantial evidence for medical cannabis's effectiveness were evenly distributed among under- and overrepresented conditions, indicating that the level of evidence for medical cannabis's effectiveness is not the dominant factor in driving certifications for MC. This finding aligns with previous research suggesting that the evidence base for a qualifying condition appears not to be the main aspect facilitating certifications for medical cannabis [7].

Our study's limitations include its geographic confinement to Florida, inability to ascertain patients' primary reason for MC use as this might be different from certifiable conditions under Florida law, and variation in physician certification practices of registry recorded QMCs. We also relied on prevalence estimates from different sources that were not always specific to Florida and used different approaches. Future studies should test reproducibility in other states, develop state-specific general-population prevalence estimates for QMCs to improve comparisons, and examine the relationship between patients'

XSL•FO
RenderX

QMCs in the Medical Marijuana Use Registry and patients' documented medical histories.

To conclude, our findings define important research priorities regarding the evaluation of both effectiveness and safety of MC for conditions that appear to be important reasons for patients to consider MC. Future studies to investigate the effectiveness and safety of cannabis should consider these research priorities.

## Acknowledgments

## Abstract

Semiautomated web scraping and content analysis tools can be used to identify and summarize municipal climate reports, lending high-level insight into policy priorities across broad geographic and political units. A semiautomated content analysis of reports within the Greater Boston Inner Core uncovers homogeneity in climate priority and variation in community outreach efforts. Across the study area, reports highlighted floods and storms as focal hazards. Surveys and community meetings were common outreach tools, but municipalities varied in their approach. The analytic framework and tools used in this analysis may be of use to others seeking to improve existing environmental policy or coordinate policy decisions across communities.

***(JMIR Public Health Surveill 2026;12:e100771)*** doi:10.2196/100771

**KEYWORDS**

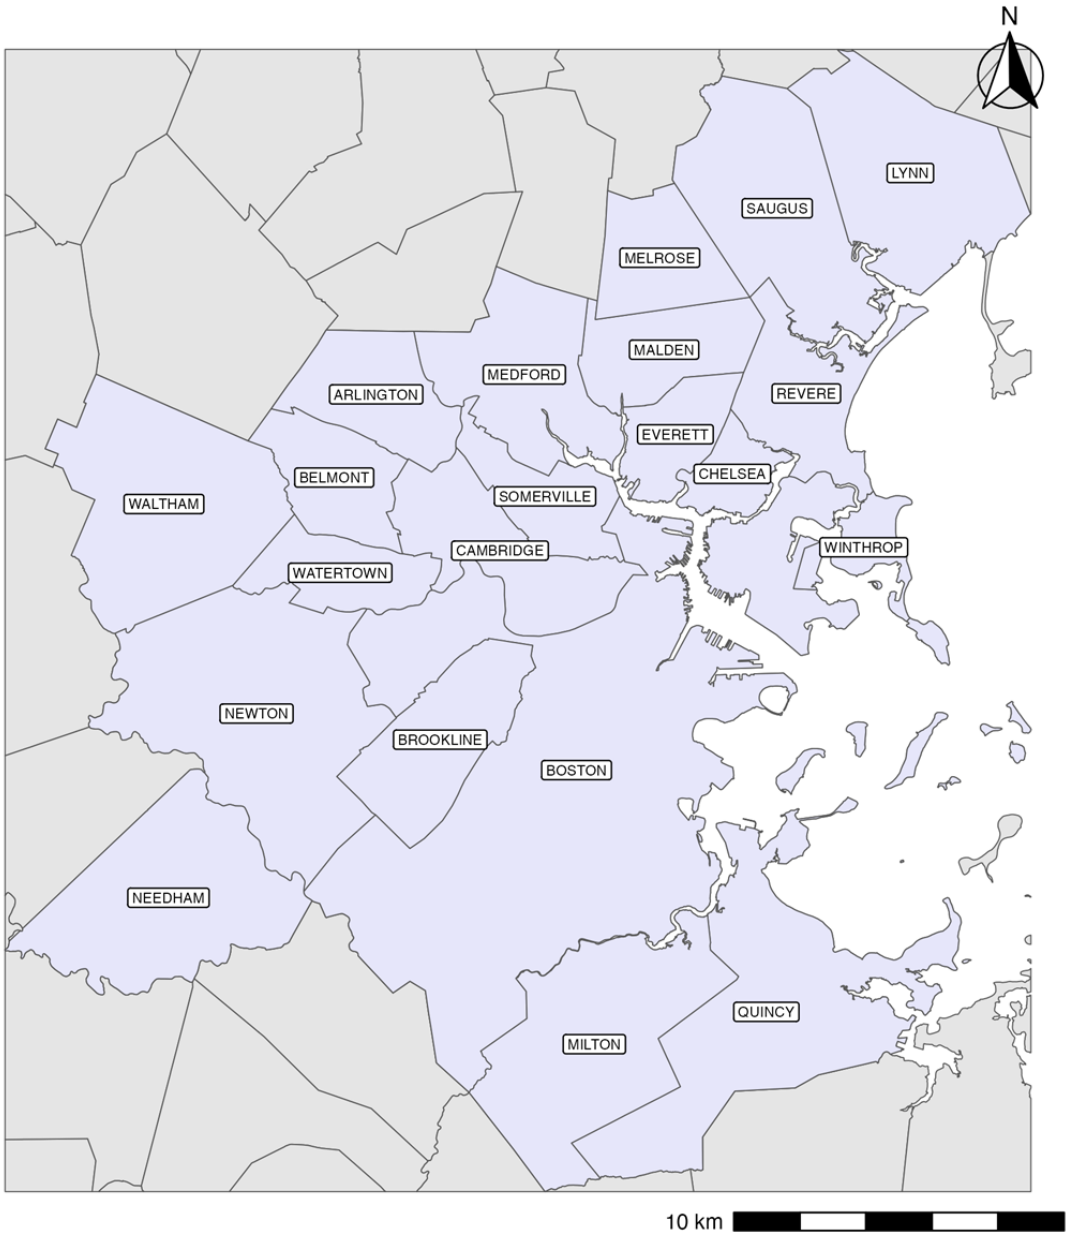
climate resilience; community planning; hazard identification; outreach strategies; content analysis

## Introduction

The frequency and severity of extreme weather events is increasing, and municipalities respond with strategies to protect residents [1]. Although communities are unique, there may be overlaps in how neighboring communities perceive hazards and plan resilience strategies. Therefore, analysis of municipal reports can provide valuable insights for coordination.

Manual synthesis of municipal documents within a larger metropolitan area is time-consuming. Individual documents may differ in length, format, and online location. These challenges affect the consistency and completeness of identified hazards.

We present a semiautomated framework for acquiring relevant text and synthesizing climate hazards of concerns and outreach strategies used by communities within a given region. We employ API-based Google searches and content analysis, the process by which text-rich documents are converted into text that is computer-legible [2], to assess concerns raised by municipalities across the Greater Boston area [3]. This framework can be used to synthesize climate concerns across other major metropolitan areas.



## Methods

The 21 municipalities in the Greater Boston region (Figure 1) contain 1.6 million individuals across municipalities that range in population size (18,558 to 689,326) and median household income (US $68,331 to US $154,398). Common environmental hazards include urban heat islands and flooding [4]. We analyzed municipal reports addressing extreme weather resilience published between 2017 and 2024.

XSL•FO
RenderX

**Figure 1.** Map of the Greater Boston Inner Core.

We searched for climate resilience and hazard mitigation plans manually (Figure S1 in Multimedia Appendix 1) and via a Massachusetts government repository [5]. We then used Google's Programmable Search Engine API [6], which provides search results without bias from user data [7]. We created queries combining community name and terms related to reporting, for example, "Boston" AND "climate" AND ("hazard" OR "resilience" OR "vulnerability") AND "report."

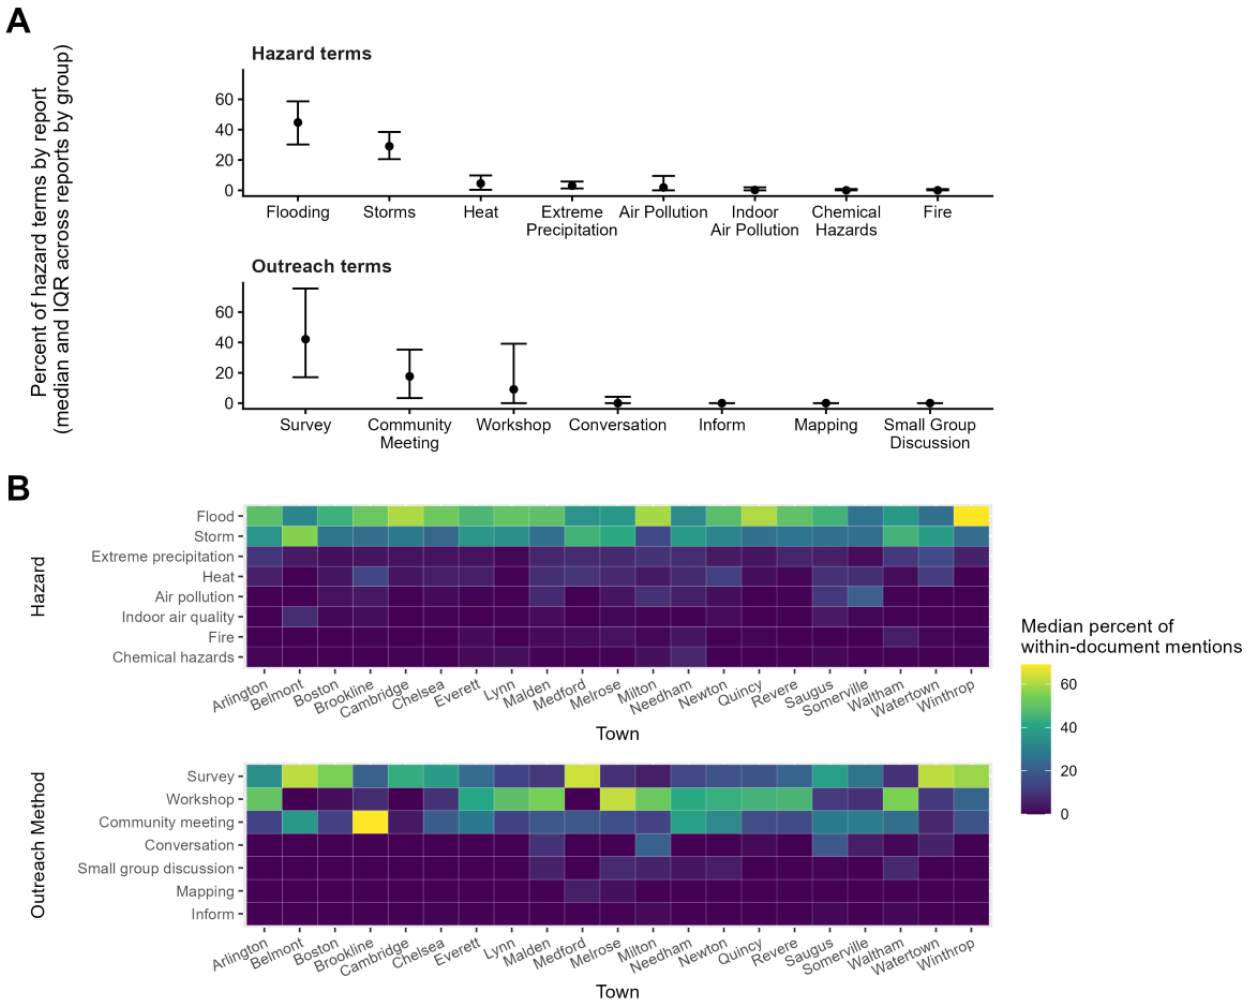
These queries resulted in 751 documents, which we filtered for relevance using Python (version 3.13.13) and R (version 4.5.1; R Foundation for Statistical Computing) scripts. We excluded reports where "Massachusetts" was not the most common US state mentioned, the most common town was not a Massachusetts town, and the words "community" or "climate" did not appear. We reviewed the remaining reports and kept 123. We took a convenience sample of 1 report per town and manually created a dictionary of key terms related to hazards of concern and strategies for community outreach (see Tables S1 and S2 in Multimedia Appendix 1). We then tokenized and normalized each PDF, calculated the frequency of each dictionary-based term, and calculated the total number of hazard or outreach terms within each document.

We then calculated metrics to compare the frequency of referenced hazards and outreach efforts across towns with varying quantities of climate documents and across documents with different lengths. We assessed the percentage of documents that contained a specific hazard or outreach term, calculated the proportion of terms related to each term, and calculated summary statistics of these proportions in the full region and within each municipality.

## Ethical Considerations

This study used publicly available reports to characterize priorities and trends across communities. Because these data

XSL•FO
RenderX



were not gathered from individuals and involve no direct interaction with human participants, this study does not require human subjects research approval through the Boston University Institutional Review Board.

## Results

### Hazards of Concern

Hazard frequencies were similar across communities (Figure 2A). Flooding was mentioned proportionately the most within reports, accounting for a median of 44.7% (IQR 30.2% - 58.7%) of mentioned hazards per report. Next most common were storms (29.1%, IQR 20.5% - 38.4%), heat (4.5%, IQR 0.3% - 9.8%), and extreme precipitation (3%, IQR 1.2% - 5.8%).

**Figure 2.** (A) Medians and IQRs of the per-report percentage of hazard terms represented by all reports in the Greater Boston Inner Core. (B) A heatmap representing the median per-report percentage of hazard and outreach terms across municipalities within the Greater Boston Inner Core.

Flooding and storms were also mentioned most often across reports, with each hazard appearing in 97.6% of reports. Extreme precipitation and heat were the third (86.2%) and fourth (79.7%) (see Table S3 in Multimedia Appendix 1). Air pollution, indoor air, chemical hazards, and fire were discussed less frequently.

### Reported Outreach Strategies

Surveys had the highest mentions by proportion within reports (Figure 2B), with a median proportion of 42.2% (IQR 17.1% - 75.5%) of all outreach terms. Community meetings amounted to 17.6% of per-report mentions (IQR 3.3%-32.3%), followed by workshops with 9.1% (IQR 0%-39.2%).

Surveys were also mentioned most often across reports, appearing in 94.3% of reports. Community meetings and workshops were also frequently mentioned, appearing in 78% and 65.9% of reports, respectively (see Table S3 in Multimedia Appendix 1).

Outreach strategies varied by community. For example, the IQR of per-report percent of survey terms was 17.1% to 75.5%, and for community meeting it was 3.3% to 35.3%.

XSL•FO
RenderX

## Discussion

### Principal Findings

Semiautomated methods captured and summarized municipal text addressing climate resilience in the Greater Boston Inner Core. Concerns related to climate hazards were consistent across the study area and predominantly cited flooding and storms, despite variation in population size, median income, and proximity to water. Though helpful for policy prioritization, homogeneous climate concerns may signify gaps in acknowledgment of other key hazards—for example, heat [8]. Reported outreach strategies were less consistent across communities, which may indicate opportunities for coordination across cities and towns.

### Comparison With Existing Studies

This study provides an approach to surveying past initiatives that is more scalable than a manual literature review and leverages content analysis as an effective means of analyzing municipal broadcasts. It builds upon Divay and Micheau's [9] content analysis of citizen engagement and recognition by focusing on a policy area. It shares content analysis methodology with the assessment by Tang et al [10] of smart city archetypes and adds a semiautomated approach to document retrieval and analysis.

### Limitations

While our Google search methodology is generalizable, search criteria and restrictions may have impacted our sample. Additionally, our dictionary approach may miss references to hazards or outreach and does not account for hazard co-occurrence. While our qualitative evaluation of 21 initial climate resilience reports helped us anticipate document content, we may have missed terminology or conversations unique to specific municipalities. Additionally, the frequency of community outreach terms does not reflect the breadth, depth, or impact of outreach and may not represent on-the-ground engagement. Finally, we cannot infer the rationale behind highlighted hazards without additional policy context.

### Conclusions

As weather events become more extreme and communities work in parallel to develop action plans, community coalitions may use semiautomated techniques to identify and synthesize publicly available municipal reports related to climate hazards. With limited resources available for climate mitigation, pooling concerns could lead to shared strategies that benefit multiple communities. Additional research may explore how variation in policy discussion is tied to municipal characteristics such as population density, income, or proximity to natural environments.

### Funding

Research funding included the United States Environmental Protection Agency (EPA) under assistance agreement RD-84048001 to Boston University, until the assistance agreement was terminated in May 2025 for no longer effectuating agency priorities. Additional support was provided by the Boston University Research Continuity Fund and CHDS Supplemental Research Award.

### Data Availability

All processing scripts are available on GitHub [11]. Data will be made available upon request.

### Conflicts of Interest

None declared.

## Abstract

This cross-sectional analysis of more than 19 million e-commerce orders from Sweden and Norway indicates that nicotine pouches have overtaken traditional snus in market share in both countries, reinforcing the potential of nicotine pouches as a harm reduction tool.

***(JMIR Public Health Surveill 2026;12:e85490)*** doi:10.2196/85490

**KEYWORDS**

Norway; Sweden; market research; sales; nicotine pouch; snus; harm reduction

## Introduction

Nicotine pouches (NPs) are rapidly gaining market traction, particularly in countries with established smokeless tobacco use. They differ from snus, a widely used smokeless tobacco product in Scandinavia, in that they do not contain any tobacco leaf. Chemical analyses confirmed that NPs contain substantially fewer and lower levels of toxicants compared with snus, with toxicant profiles similar to pharmaceutical nicotine replacement therapies [1]. Nicotine is dependence forming and should not be used by vulnerable populations such as youth, pregnant women, and individuals with certain health conditions; however, for adults who choose to use nicotine, NPs are increasingly popular. The United States is the largest NP market, and emerging evidence suggests that daily NP use is most common among adults who recently quit another product and rare among people who never used nicotine [2]. This encouraging trend suggests that NPs—originally designed as a harm reduction tool [3]—are indeed displacing more harmful products. This study examines whether a similar pattern is emerging in two Nordic countries where snus has traditionally been the dominant tobacco product.

## Methods

### Study Design

This cross-sectional study analyzed HAYPP Group AB (Stockholm, Sweden) sales data from January 1, 2018, to September 17, 2025, on 19,528,087 purchases of snus and NPs by 1,721,752 customers from seven e-commerce websites in two countries (Sweden: snusbolaget.se, haypp.se, nettotobak.se, and snusnetto.se; Norway: snuslageret.no, snushjem.no, and snus.com). In both countries, purchases are age-verified with government-issued identification numbers that encode each customer's birth date and gender. This information is authenticated by payment service providers. After anonymization (permanently removing all identifiers), aggregated data were used to calculate volume shares by product and by gender. The number of cans of NPs or snus sold in each year was divided by the total number of cans of both products sold in each country.

### Ethical Considerations

Under Swedish law (Ethical Review Act, SFS 2003:460 [4]), ethical approval is required for research involving physical intervention on humans, biological material traceable to individuals, or processing of sensitive personal data. This study analyzed fully anonymized, aggregated sales data without any personal identifiers or direct human participation. Therefore, it falls outside the scope of the Act and was not submitted for ethical review. Under the European Union (EU) General Data Protection Regulation (GDPR 2016/679 [5]), ethical approval was not required for this market research study because it used fully anonymized sales data, and no personal data or direct human participation was involved. The study complies with the International Chamber of Commerce/European Society for Opinion and Market Research (ICC/ESOMAR) International

XSL•FO
RenderX

Code on Market, Opinion and Social Research, and Data Analytics [6].

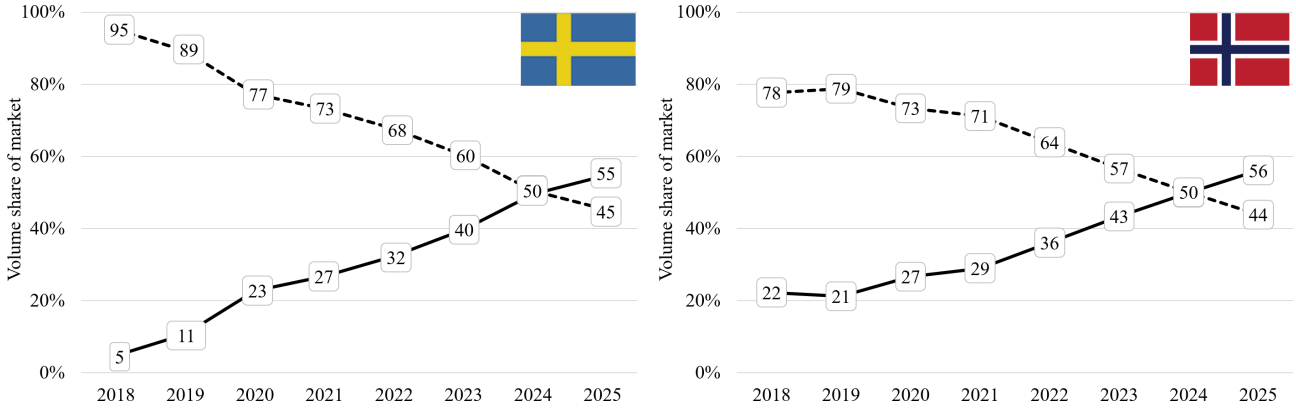
All customers consented to use of their anonymized, aggregated data when reviewing and accepting the privacy policy [7]. No compensation was provided for the use of these sales data.

## Results

The sales data cover 13,995,343 and 5,532,744 individual orders from 1,253,066 and 468,686 unique customers in Sweden and Norway, respectively. NPs surpassed snus in market share in 2025 in both countries (Figure 1). The Swedish NP volume share rose from 5% in 2018 to 55% in 2025, while snus declined from 95% to 45%. In Norway, the NP share rose from 22% to 56% over the same period, with snus declining from 78% to 44%.

Women first purchased more NPs than snus in 2022 (Figure 2) due to their lower 2018 market shares of snus (~25%). Men still purchase more snus than NPs in both countries, but this could change in 2026 if trends persist.

**Figure 1.** Cross-sectional volume shares of the oral nicotine product markets (2018 - 2025) for nicotine pouches (NP, solid lines) and snus (dotted lines) in Sweden (left) and Norway (right).



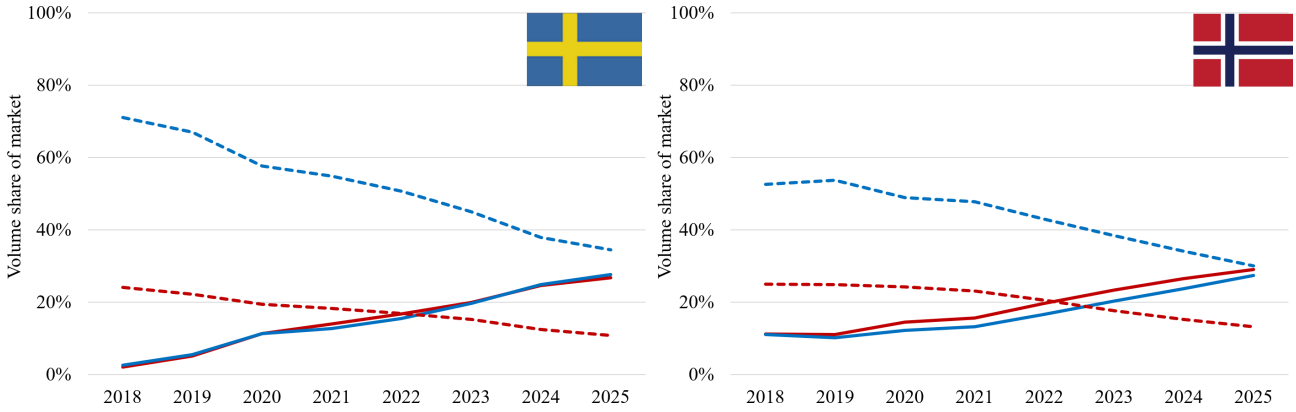


**Figure 2.** Cross-sectional volume shares of the oral nicotine product markets (2018 - 2025) for men (blue) and women (red) for nicotine pouches (NP, solid lines) and snus (dotted lines) in Sweden (left) and Norway (right).

## Discussion

This descriptive analysis is the first cross-country comparison of NP and snus sales trends in Scandinavia. Data from more than 19 million e-commerce orders show that NPs overtook snus in the market share in Sweden and Norway in 2025, offering early evidence of market displacement in both countries. Taken together with US findings [2], these results suggest that NPs could be reshaping nicotine consumption in ways aligned with tobacco harm reduction, although ongoing monitoring and regulation will be critical to maximize benefits and minimize risks.

Although these observations do not reflect individual-level use, they highlight important shifts in consumer behavior that mirror the original “Swedish experience” where 50 years ago, men shifted from cigarettes to snus [8], and daily smoking decreased from 40% to 15% between 1976 and 2002 [9]. Over the same time frame, daily smoking rates for Swedish women dropped from 34% to 20% [9]. A similar trend materialized in Norway after low-nitrosamine snus was introduced in the 1990s, with men moving away from cigarettes before women [10,11]. The EU banned snus in 1992, but Sweden obtained an exemption. Norway is not part of the EU. Long-term epidemiological data indicate that this shift offers a substantial harm reduction benefit, as evidenced by low incidences of tobacco-related disease in Sweden compared to the rest of the EU [12].

The US Food & Drug Administration recognizes snus as a lower-risk alternative to cigarettes, authorizing eight products with the claim: “Using General Snus instead of cigarettes puts you at a lower risk of mouth cancer, heart disease, lung cancer, stroke, emphysema, and chronic bronchitis” [13]. NPs contain even fewer toxicants [1], placing them at the lowest risk end of the non-medicinal tobacco and nicotine product continuum. Maximizing public health would require encouraging switching

XSL•FO
RenderX

from higher-risk products to lower-risk products such as NPs, clear regulation, youth access prevention, and efforts to support cessation among current users who would like to stop using nicotine.

A limitation of this study is its reliance on sales data from a single e-commerce company. However, these platforms account for considerable snus and NP market shares in both countries. National surveys currently lack comparable precision. Statistik Sentrabyrå (Norway) does not distinguish between snus and NPs, and Folkhälsomyndigheten (Sweden) only began differentiating between snus and NPs in 2022. While future surveys will provide more nuanced nationally representative information, these market data likely offer a more accurate and timelier picture of an evolving Nordic nicotine landscape. Future research should explore user transitions across cigarettes, snus, NPs, and cessation, alongside long-term health and policy effects.

## Acknowledgments

The sponsor HAYPP Group AB was involved in study design; the collection, analysis, and interpretation of data; the writing of the report; and the decision to submit the article for publication.

## Funding

HAYPP Group AB is an online e-commerce company that sells non-combustible nicotine products and is the sponsor of this research. The Group operates independently and is not under the ownership or control of any tobacco or nicotine manufacturers.

## Abstract

This research letter examines sex work and substance use associations in a sample of sexual and gender minoritized individuals recruited online in San Francisco, California. This study found that a history of sex work was prevalent and that people with a history of sex work were more likely to recently report using controlled substances and experience domestic violence.

***(JMIR Public Health Surveill 2026;12:e83555)*** doi:10.2196/83555

**KEYWORDS**

sex work; substance use; domestic violence; intimate partner violence; online recruitment; sexual and gender minoritized community health; social media

## Introduction

Sexual and gender minoritized (SGM) communities experience victimization because of structural oppression [1]. The confluence of social exclusion, economic hardship, and the internet supports the formation of a sex work economy [2,3]. People in sex work experience health inequities due to their unique occupational health exposures [4]. Yet there is little research on online help-seeking SGM populations [5]. We address this gap and characterize the prevalence of sex work history among SGM individuals seeking help online and their sexual and substance use–related prevention and treatment needs.

## Methods

### Ethical Considerations

The study was approved by the University of California, San Francisco institutional review board (20-33169). Participants provided informed consent, could opt out anytime, and received US $30. Data were deidentified to protect participants' privacy and confidentiality.

### Study Design and Recruitment

This is a cross-sectional analysis of 409 people recruited online in San Francisco by using social medial advertisements on Facebook, Instagram, and Grindr in 2022-2024. Advertisements sought out potential participants seeking help for substance use, mental health, and HIV. Once they clicked on the advertisement and were directed to a study interest website, they were contacted by staff to screen for eligibility, informed consent was obtained electronically, and they completed a baseline assessment. Eligibility criteria included aged 18 years or older, seeking help for substance use prevention/treatment or related health topics (eg, HIV, mental health), live in San Francisco, identify as a man who had sex with men or a trans woman, and had smartphone access.

### Measures and Analysis

We analyzed the following demographics: age, race/ethnicity, gender identity, sexual orientation, HIV status, housing stability,

XSL•FO
RenderX

and socioeconomic status. Recent substance use was measured by asking how many days in the last 30 days, if any, did they use each of the following substances: tobacco, vaping products, binge drinking (having 5 or more alcoholic beverages at the same time or within a couple of hours of each other for people assigned male sex at birth), marijuana, prescription opioids, nonprescription opioids, other prescription drugs, illicit drugs (crack/cocaine, amphetamine/methamphetamine, hallucinogens, inhalants), and injection drug use [6]. Responses were recoded dichotomously for any recent use (yes/no). We measured participants' history of sex work if they had ever had sex with someone in exchange for money, drugs, or shelter (yes/no) [6]. We assessed participants' risk perception of harm when engaging in condomless sex and sex while using drugs or alcohol. Responses were dichotomized into low risk (no risk, slight risk, unknown risk) and high risk (moderate risk, great risk). Self-efficacy to refuse condomless sex was assessed by participants' agreement with the statement, "I could refuse if someone wanted to have sex without a condom or dental dam" [6]. Responses were dichotomized into agree (strongly agree, agree) and disagree (disagree, strongly disagree). Domestic violence was measured by asking participants if anyone with whom they had an intimate relationship had emotionally, physically, or sexually abused them in the last 3 months (yes/no) [6]. STATA version 17 was used to create logistic regression models to test associations between history of sex work and recent substance use and sexual risk outcomes, adjusted for age, gender identity, race/ethnicity, socioeconomic status, and housing stability.

## Results

Many participants (168/409, 41.08%) reported a history of sex work. The most frequently reported in the last 30 days was illicit drugs (227/409, 55.50%) followed by marijuana (220/409, 53.79%), binge drinking (160/409, 39.12%), and tobacco (155/409, 37.90%). A majority of participants perceived condomless sex (287/409, 70.17%) and sex while using drugs or alcohol (349/409, 85.33%) as high risk and could refuse condomless sex (361/409, 88.26%). Almost 22.98% (94/409) had experienced domestic violence in the last 3 months (Table 1).

Adjusting for potential confounders, people with a history of sex work (Figure 1) were more likely to report using tobacco (adjusted odds ratio [aOR] 2.38, 95% CI 1.51-3.76), prescription opioid drugs (aOR 4.48, 95% CI 1.04-19.21), other prescription drugs (aOR 2.23, 95% CI 1.17-4.26), illicit drugs (aOR 2.04, 95% CI 1.32-3.16), and have injected drugs (aOR 4.72, 95% CI 2.14-10.40) compared to people with no sex work history. People with a history of sex work had 4.11 times the odds of experiencing domestic violence recently compared to counterparts with no sex work history (95% CI 2.40-7.01). No statistically significant association was observed between history of sex work and self-efficacy to refuse condomless sex.

**Figure 1.** Associations between history of sex work and recent substance use and between sexual risk perception and violence among sexual and gender minoritized people recruited online in San Francisco, California, 2022-2024 (N=409). aOR: adjusted odds ratio.

## Discussion

We found that SGM participants with a history of sex work were more likely to report recent use of controlled substances. Although no statistically significant associations exist between history of sex work and sexual risk perception level and self-efficacy to refuse condom use, our findings indicate that domestic violence may be heightened for SGM people with a history of sex work. SGM populations report similar or greater rates of domestic or intimate partner violence compared to their non-SGM counterparts [7], and intimate partner violence is a common experience among people who engage in sex work [8]. Relationship dynamics among SGM partnerships can vary in composition with relationship to sexual and gender roles, power, and how violence is enacted and experienced. A recent systematic literature review found that bidirectional violence was the most common among SGM intimate partners compared to non-SGM partners [9]. The interplay between substance use, violence, and trauma are complex and must be explored in future [10]. This study has limited generalizability because of its design and possible sampling bias toward people seeking help online who may be experiencing heightened risk. Despite this, these findings reinforce the need for substance use prevention efforts to serve people with a history of sex work and address domestic violence as a unique violence exposure. Although stigma remains a significant barrier for people engaged in sex work and those using substances, addressing domestic violence may offer a whole-person alternative to intervene on the material impacts of violence and substance use behaviors that may be both enabling and coping mechanisms of violence. Public health interventions that cross-train substance use providers about domestic violence and sex work literacy, and conversely, are needed to better facilitate screening, referral, and treatment.

### Acknowledgments

## Abstract

**Background:** Digital mailbox platforms established by authorities for secure communication with the general populace are increasingly available for distribution of surveys. While such solutions constitute an attractive way of easily distributing surveys, nonresponse remains a critical problem, warranting measures to increase participation.

**Objective:** We aimed to investigate questionnaire characteristics predicting participation and the effect of reminders among men in a survey distributed through a national digital mailbox solution.

**Methods:** This study used an internet-based survey among men aged 45 to 70 years; the survey was sent out in 2 waves through a digital mailbox used by Danish authorities. Predictors for response were analyzed using logistic regression.

**Results:** Of 24,000 invitations, 22,288 participants accepted, with 6756 (30.3%) completing the survey. We found some evidence suggesting a rule of thumb that reminders may add another half to the response rate achieved in a preceding invitation, with 21% and 10% of responses obtained before and after the reminder, respectively (in the first wave). Longer questionnaire variants (odds ratio [OR] 0.77, 95% CI 0.66 - 0.88; *P*<.001 [longest vs shortest variants]), questionnaires with attached informational material (OR 0.92, 95% CI 0.85 - 0.98; *P*=.02[with vs without material]), or with potentially distressful emotional content (OR 0.91, 95% CI 0.85 - 0.98; *P*=.008 [most vs least distressful content]) tended to yield lower response rates. Furthermore, older age was associated with a higher response rate when comparing the oldest (65 - 70 years) to the youngest (45 - 55 years) age groups (OR 2.49, 95% CI 2.31 - 2.70; *P*<.001).

**Conclusions:** We confirmed some previous findings obtained with other modes of survey distribution on the association between response rates and questionnaire characteristics, showing that it is important to pay attention to specific characteristics when designing internet-based surveys distributed through digital mailboxes. Nonresponse may constitute a considerable and increasing challenge, and reminders may help substantially increase participation.

## Introduction

In many countries, electronic survey distribution through internet-based services and web platforms is a relatively new opportunity for research, and it is being increasingly used for gathering data to inform policy and practice [1]. The Danish digital mailbox (e-Boks) is one example [1], with similar digital mailbox solutions available in a rising number of countries (Norway, Sweden, Greenland, and Ireland) [2]. Survey delivery through this channel has provided many new advantages and opportunities for easy survey distribution and straightforward subsequent analysis of the gathered electronic data. Furthermore, a digital mailbox with web access constitutes an easy platform for potential respondents to access and fill out surveys without requiring, for example, manually filling out and posting paper material; therefore, it could be hypothesized that such platforms would promote research participation. Despite these advantages, nonparticipation remains a critical challenge for internet-based surveys, including those distributed via digital mailboxes, with potential implications for practice, policymaking, and public opinion [1]. Moreover, there is significant evidence from multiple studies that participation rates in public health surveys have been generally decreasing for the last several decades [3,4]. Correspondingly, there is emerging evidence that participation in web-based health-related surveys is declining [5-7]. Various

XSL•FO
RenderX

measures have been proposed to mitigate this, such as use of monetary incentives to increase response rates [6]. Another traditional approach is to use reminders [7,8].

In parallel, previous research has demonstrated that participation varies with geography, with participation usually being higher in less-populated areas [9-13]; participation also usually increases with older age, although this tendency can change when older people are less familiar with, for example, digital platforms [5-7,13-17].

Participation may, however, also be dependent on features of the survey [18]. Most of our knowledge on this point derives from surveys from the predigital era. Hence, limited research exists on internet-based solutions and, particularly, on surveys distributed through national-level web platforms. This paper reports on experiences from a research project using a national authority's digital mailbox solution, focusing on survey characteristics that predict response rates and the effect of reminders.

## Methods

### Overview

This is a secondary analysis of data obtained from a large, cross-sectional, national-level web survey about health care user involvement in decision-making regarding prostate-specific antigen (PSA) testing; the survey was distributed among adult men aged 45 to 70 years; this age range was chosen based on US Preventive Services Task Force and European recommendations for PSA screening for early detection of prostate cancer [19,20]. The survey was developed with public and patient involvement and has been previously described in detail [21]. We previously reported an overall good representation of the general population of men aged 45 to 70 years in our sample; however, response rates tended to increase with older age and a location of residence that was rural and had a lower tax base, fewer people with higher education, and fewer people with non-Western backgrounds [13]. In agreement with prior research, our analysis also suggested that the response rate may have varied across different versions of the questionnaire [13,18,22-24].

The questionnaire contained items covering sociodemographic information, personality (using the validated Big Five Inventory-10 [25]), preferences for control regarding health care decision-making (using the validated Control Preferences Scale [26]), purpose-designed health-related questions, and hypothetical case vignettes concerning PSA screening for prostate cancer in men. Each scenario had an identical core structure but differed regarding the degree of patient involvement, particularly information delivery (5 levels, from "no information" to "substantiated information," ie, fully shared decision-making with a decision aid provided as an attached PDF information sheet); the decision to have a PSA test or not; and 3 different outcomes (no prostate cancer, diagnosis of a treatable prostate cancer, and diagnosis of an eventually lethal prostate cancer) potentially posing 3 different levels of distress. Because of differences in scenario content, questionnaire variants inevitably had various lengths (ie, word count), ranging from short to long variants requiring participants to read through extensive survey material and ranging from variants with low potential for emotional distress to variants with high potential for distress. To ensure a quasi-random assignment of participants, they were sorted by date of birth and then consecutively allocated into 1 of the 30 different case vignette scenarios driving the key "exposure" variable.

In Denmark, all residents are registered in a civil registration system with a unique personal identification number. The sample for the study was identified through use of these civil registration numbers, which were obtained from the Danish Health Data Authority. Civil registration numbers permit matching to national-level statistical data on age and region and to municipal-level data from the Danish municipal statistical database [27] on the residential location of individuals, including data on rurality (ie, population density), socioeconomic surroundings (ie, municipal tax base), municipal educational level, and municipal proportion of residents with a non-Western background. The latter data are commonly used as a standard measure of state and municipality in Denmark, as well as for research purposes [28,29].

We used REDCap and distributed the survey through the digital mailbox e-Boks, which was introduced by the Danish authorities in 2001; from 2014 onward it has been a mandatory communication platform used by Danish authorities for secure communication with residents of Denmark. Residents receive an email and/or text message when they receive new mail in their private e-Boks account, which can be accessed directly with multifactor authentication to safeguard data security. e-Boks has a very high coverage of the Danish adult population, with only a small proportion of residents having actively deregistered (in 2017 this was 9.9%) [30].

To ensure a sufficient sample size, we obtained permission to invite 2 independent random samples of men aged 45 to 70 years in 2 waves, each receiving an initial invitation; a 14-day reminder sent to nonrespondents. The 2 waves were unconnected in so far as they were 2 different nonoverlapping random samples of the population. We sent out the first (winter) wave of invitations on January 24, 2019, with the 14-day reminders sent on February 7, 2019. We launched the second (spring) wave on March 7, 2019, with the 14-day reminders sent to nonrespondents on March 21, 2019.

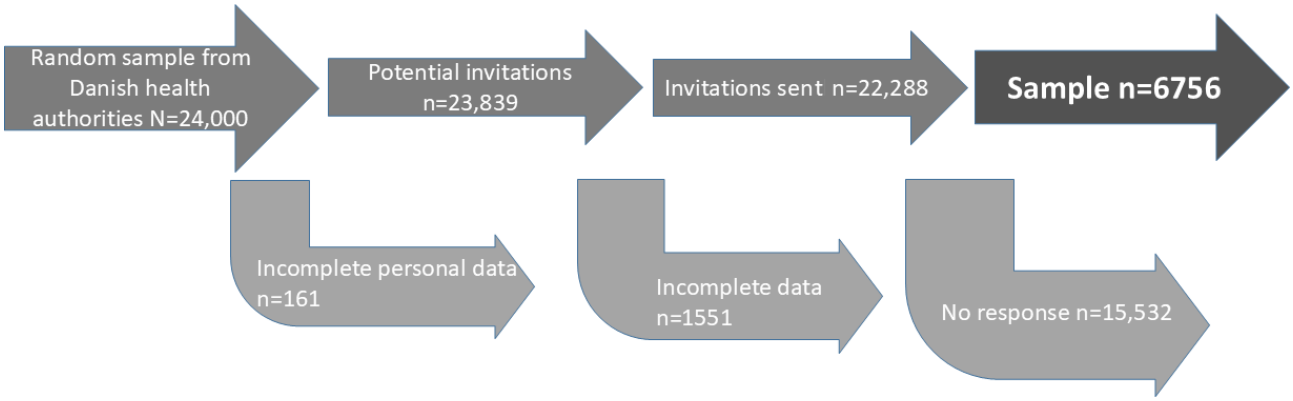
### Statistics and Power Analysis

Power calculations and the required sample size for conducting the main study have been previously reported [31]. Categorical characteristics were reported as counts and proportions, while numerical characteristics (eg, response time) were reported as medians with IQRs or means with SDs. Odds ratios (ORs) and *P* values for predictors of response to the questionnaire were estimated by logistic regression, both for each predictor on its own and in a multivariate model adjusting for all predictors mutually. As we previously found that response rates varied with age, rurality, tax base, education, and background, we included these variables in our analysis [13]. We did not use survey weights, as our invited sample was a random sample of the total population; hence, it represented a balanced sample. The participating individuals were not perfectly representative

XSL•FO
RenderX

of the population, but as our outcome was completion of the survey and not the answers provided to the survey, applying weights would have counteracted the purpose of the study, that is, to investigate patterns in who responds to a survey.

## Ethical Considerations



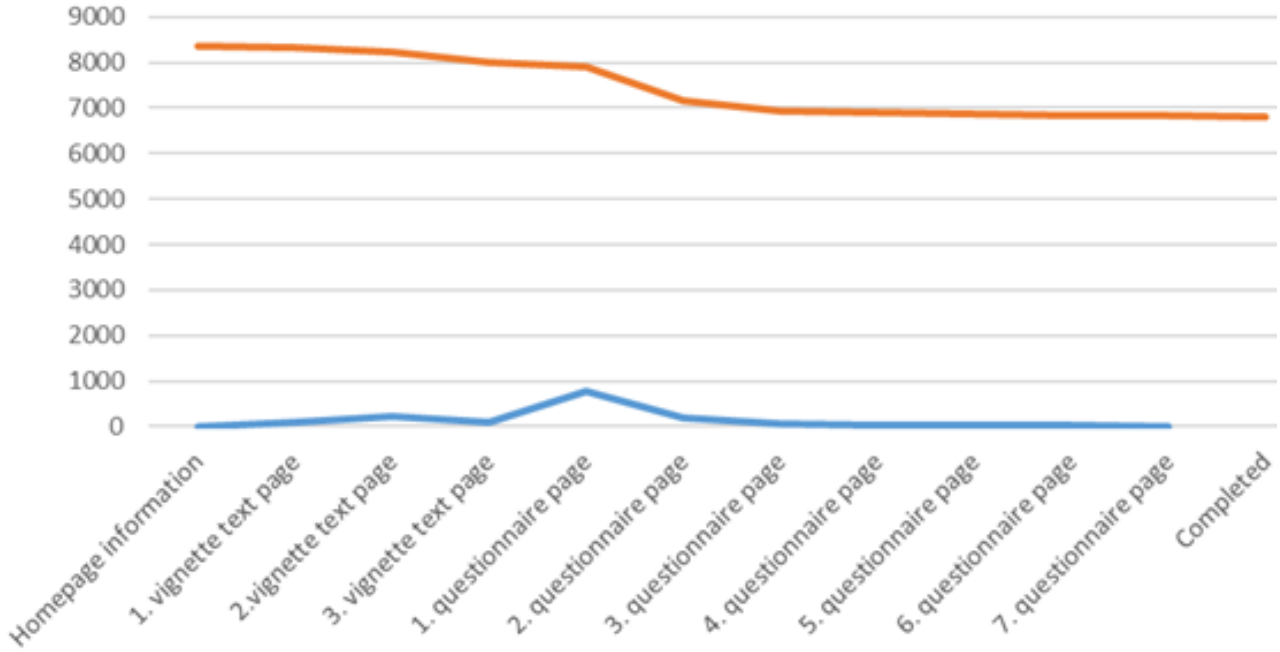
According to Regional Committees on Health Research Ethics for Southern Denmark assessment 2018 - 1906, the project was in accordance with Danish research ethics legislation. Furthermore, use of personal data was approved by the Danish Data Protection Agency (assessment 18/31191). Informed consent for survey participation was obtained through the email invitation delivered to participants in the digital mailbox and, following pseudonymization, the data were stored in a secured environment. Participants received no compensation.

## Results

Of 24,000 potential invitees, we excluded 161 (0.67%) from the study, as at the time of the survey, they were no longer aged between 45 and 70 years. Of the 23,839 invitations sent out, 1551 (6.5%) were undeliverable because no digital mailbox was available and were marked incomplete. This number is in accordance with the expected compliance with the Danish national digital mailbox infrastructure [32]. Among the 22,288 people successfully invited through the digital mailbox, 15,532 (69.7%) provided partial or no response, and 6756 (30.3%) completed the questionnaire (Figure 1).

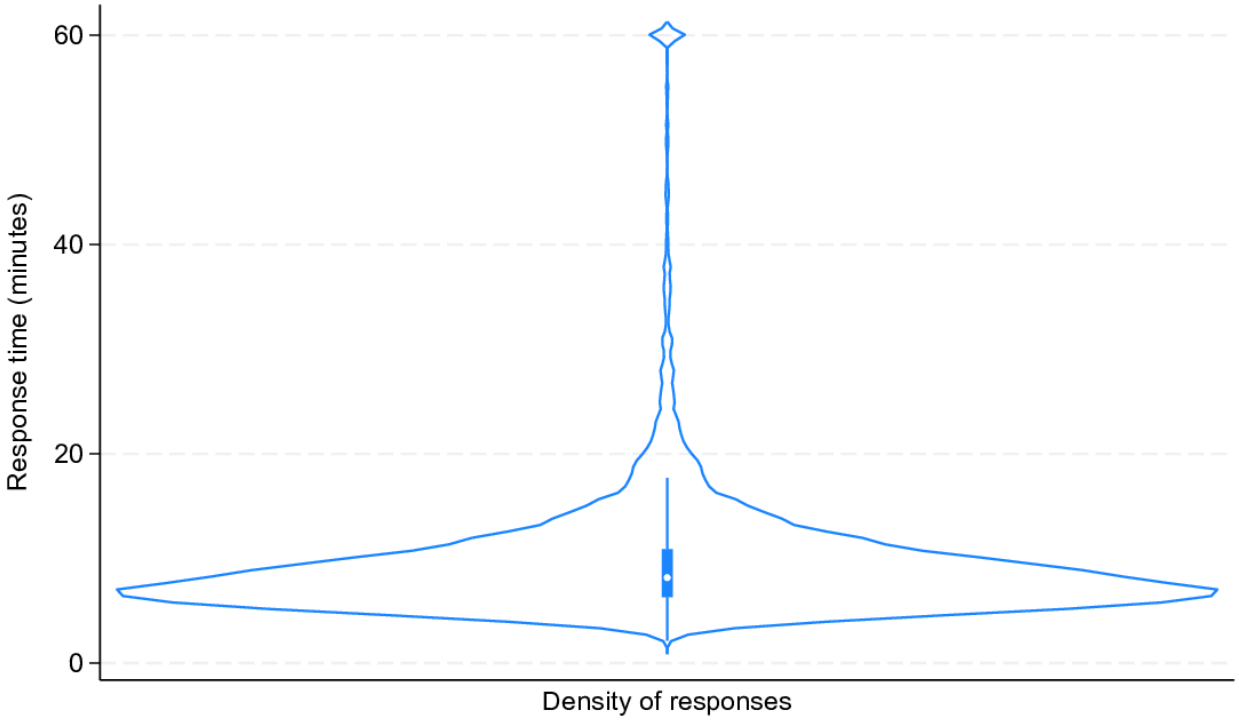
Following the first wave, 30.6% (3395/11,111) of respondents provided a complete response, including 20.6% (2293/11,111) before the 14-day reminder and an additional 9.9% (1102/11,111) after the reminder. Following the second wave, the complete response rate was 30.1% (3361/11,177), including 21.0% (2352/11,177) before the reminder and 9.0% (1009/11,177) after the reminder.

**Figure 1.** Flow chart showing retrieved sample from authorities, invitations sent out, and responses achieved constituting the sample.



Among respondents, 30% (2022/6756) responded on the day the survey was launched (Thursday), 28% (1883/6756) on the second day (Friday), 14% (948/6756) on the third day (Saturday), 10% (648/6756) on the fourth day (Sunday), 8% (567/6756) on the fifth day (Monday), 6% (387/6756) on the sixth day (Tuesday), and 4% (301/6756) on the seventh day (Wednesday), showing a gradual decrease. Most participants responded in the afternoon and early evening.

Among 1579 people who started the questionnaire but did not complete it (a number that might include people who started more than once), 1564 finished the survey homepage describing the purpose of the survey, participants' rights, the handling of research data, and the instructions, which included pilot-testing information that the survey would take approximately 10 minutes to fill out. After this, 1477 finished the first case vignette text page, 1251 the second page, and 1149 the third page. The majority of dropouts occurred after the first questionnaire page, with only 378 remaining. Following the second questionnaire page (including variants with extra text), 177 remained; 120 remained after the third questionnaire page, 97 after the fourth questionnaire page, 79 after the fifth questionnaire page, 61 after the sixth questionnaire page; finally, 51 people remained after the seventh questionnaire page but then dropped out before finalizing the questionnaire (Figure 2).



XSL•FO
RenderX

**Figure 2.** Remaining participants and number of dropouts through the questionnaire, from the homepage and to the pages of the questionnaire itself. The orange curve shows remaining participants at each stage and the blue curve shows the number of dropouts.

The average response time was 11.1 (SD 46.7) minutes and the median response time was 8.2 (IQR 6.3-10.9) minutes. The large difference between the average and median response times was because some responders needed several hours to complete the survey (Figure 3). There was some correlation between the time used to respond to the questionnaire and the number of middle-category responses, but this only reached statistical significance for questionnaire items 2 ($P$<.001) and 9 ($P$=.02). The median age of respondents was 59 (IQR 53-65) years. Other survey respondent characteristics are presented in Table 1.

**Figure 3.** Violin plot of response times in minutes, with 33 responses of more than 60 minutes winsorized to 60 minutes to improve readability.

# Discussion

## Summary of Main Study Findings

This study examined questionnaire characteristics that predicted participation in an internet-based survey that used a national digital mailbox; the results showed that reminders added another half to the response rate, while longer questionnaire variants, questionnaires with attached informational material, and questionnaires with potentially distressful emotional content tended to yield lower response rates. Below, we discuss these findings in the context of the existing literature.

## Study Findings and Comparison to Existing Literature

### Questionnaire Length and Content

We found that the response rate was inversely associated with the length of the questionnaire. Among those who started completing the questionnaire but gave up, the majority stopped immediately after switching from the first introductory text page to the first questionnaire item requiring a response. After this point, the dropout rates were greatest for the earlier items. Many dropouts, however, also occurred during the part of the questionnaire with vignette variants that had more text material. Corresponding with this, various previous studies have found a relationship between increasing questionnaire length and decreasing response rates in both mail and internet surveys [18,22-24], a relationship that was also established in a Cochrane review of postal and electronic surveys [8]. The relationship between questionnaire length and response rate seems to hold whether looking at the number of survey pages, screens, or items or at the time to complete the questionnaire [18]. In our survey, the average response time was 11 minutes, while some previous research has suggested that a completion time of no more than 13 minutes is necessary to obtain a good response rate [18]. Likewise, our finding that questionnaire variants with more potential to cause distress had statistically significantly lower response rates confirms findings from the Cochrane review [8] and a widely held belief that questions causing emotional discomfort decrease participation [18,33].

### Geographical and Target Group Factors

We found that older men had higher response rates than younger men. On the other hand, people residing in areas with a higher tax base, areas with a higher proportion of residents with higher education, and areas with more residents with a non-Western background had lower response rates than people living in lower tax-base areas, areas with fewer people with higher education, and areas with fewer people with a non-Western background. In addition, response rates were lower in urban areas than in rural areas. There has been a paucity of research on the role of geographical factors in survey response rates [18]. However,

XSL•FO
RenderX

in a Norwegian study using data from a national survey of patient experiences with maternity care, Sjetne et al [16] found that the likelihood of responding to surveys was strongly influenced by geographical location. In our study, we found that response rates were lowest in the Danish Capital Region. Corresponding with this, in addition to an overall decline in survey participation rates, Tolonen and colleagues [12] found an overall lower participation rate in the capital region. Regarding target group characteristics affecting response rates, Sjetne et al [16] found that the likelihood of responding to a survey was strongly influenced by background variables, including age. Hence, older age was associated with higher response probability. Likewise, in a previous national study conducted with women in the United Kingdom, respondents were more likely to be older, married, living in the least-deprived areas, and to be born in the United Kingdom [17]. Hence, our findings suggest that older people may not necessarily be less inclined to participate in research making use of web surveys and digital platforms. Findings of higher participation among older people thereby contradict previous digital health technology evaluation studies highlighting nonparticipation by older people and those with less experience with digital platforms [34].

### Effect of Reminders

Previous studies have found large variation in the effect of reminders [18,35]. Some variation may, however, be explained by differences between paper-based and internet surveys. For example, Cantuaria and Blanes-Vidal [35] compared survey responses collected with mail and internet methods and found that reminders had a stronger effect on increasing internet survey response rates than mail response rates. Their study was relatively small; they initially invited all participants through mail, finding that 2 reminders added a little more than half to the response rate in the mail survey and almost doubled the number of internet responses [35]. We made no such comparison, as we invited all participants via the Danish digital mailbox and only used 1 reminder; moreover, our reminder did not achieve the same effectiveness as the one sent to internet participants by Cantuaria and Blanes-Vidal [35]. In our study, there was a 31% response rate following the first wave, including 21% before the 14-day reminder and an additional 10% after the reminder. Likewise, in the second wave, the reminder added roughly 50% to the response rate, suggesting a rule of thumb that reminders may add another half to the response rate achieved by an initial invitation. Previous survey studies have suggested comparable effects of reminders. For example, a Danish national self-administered health survey found that cumulative response rates after first, second, and third mailings were 36.7%, 50.3% and 59.5%, respectively [14]. A recent Danish national self-administered health survey found that the cumulative response proportions were 19.1%, 28.9%, and 37.2%, simultaneously pointing to a tendency toward declining participation in public health surveys [7]. Even if it did not investigate authorities' digital mailbox solutions as a mode of survey distribution, a Cochrane review of methods to increase the response to postal and electronic questionnaires found a similar pattern, and findings from previous studies suggest that our rule of thumb may extend to additional reminders, a way of increasing response rates often used in survey research [8]. In parallel, ethical considerations related to respect for people's right to prioritize their time and resources might speak in favor of limiting the use of reminders.

The Cochrane review found that, for postal questionnaire studies, the odds of response significantly increased when using a special (for example registered or certified) delivery service [8]. Thus, using modes of invitations signaling authority and quality may be beneficial in terms of promoting participation; however, this again gives rise to ethical considerations. For example, exposing large numbers of people to surveys causing emotional distress or exposing people to low-quality questionnaire studies that take advantage of platforms established by authorities to communicate important information may undermine people's trust in the platform. The "quality stamp" only works if its credibility is not watered down through overuse by researchers and by people starting to perceive the platform as irrelevant. An overall response rate just exceeding 30% to a public health survey benefiting from the web and platform opportunities described in our study is not high. Our findings should be seen in the context of emerging evidence that participation in web-based, health-related surveys is decreasing [5-7]. Among the possible causes of decreasing participation are, again, survey fatigue, with the increasing number of surveys being sent out making people less likely to respond to any single request [3-7].

### Limitations

A limitation of this study was that it only included men aged 45 to 70. Response rates have previously been found to be greater among women than men [5,36]. Another limitation was that the study was conducted using data from 2019; it could be claimed that much has changed in the digital world since then. Still, electronic surveys are widely used for research, and digital mailboxes are an increasingly used channel for distributing electronic surveys in countries with such platforms. Moreover, we did not test whether people who responded after the reminder differed from those who responded before in terms of, for example, response patterns.

It can be questioned whether findings on participation and response rates to surveys distributed via a mandatory, high-population coverage, authority-provided digital mailbox can be generalized, or to what extent, to voluntary or low-coverage mailboxes. High-coverage and mandatory systems may tend to decrease coverage bias, while voluntary or low-coverage systems may suffer to a higher extent from nonresponse bias and self-selection errors. Additionally, in mandatory systems, individuals are legally required to register and check their mailboxes. As has been discussed above, when a survey is distributed through a mandatory system, recipients may associate it with official or legal duties, driving up response rates. Contrarily, voluntary platforms lack this legal obligation and authoritative weight. Moreover, in mandatory systems with almost complete population coverage, the sampling frame matches the target population, while in voluntary or low-coverage systems, certain demographics (eg, older people, low-income individuals, and those with lower digital literacy) may be structurally excluded or less likely to opt in, thereby

XSL•FO
RenderX

skewing results. Finally, in voluntary systems, respondents who choose to engage may have stronger preexisting opinions on the survey topic than nonrespondents. Mandatory systems may thus capture a broader spectrum of the public, including indifferent individuals. Thus, the findings of the present study may be generalizable to other mandatory or high-coverage systems, whereas estimating the general population's behavior in areas with voluntary or lower-coverage digital mailbox solutions may to some extent require statistical correction. The latter can be done, for example, through use of propensity score matching (thereby modeling the probability of an individual responding through use of administrative data, followed by reweighting of the sample to match nonparticipants) or through adjustment of data using known population benchmarks (eg, age, education, and income level) to correct for misrepresented groups.

As indicated in the Methods section, the assignment procedure was based on date-of-birth sorting rather than truly random sorting, representing a potential limitation.

Finally, the study only investigated a limited number of factors that can affect survey participation and did not examine factors such as question wording (eg, keeping questions simple), display type (eg, graphics and progress indicators), use of incentives (eg, gifts), or whether the survey is specifically aimed at the invited group (eg, a survey about an illness sent to people with that illness) [6,8,18].

## Conclusion

Online surveys are now routinely used for gathering data in social research, public health, and related disciplines, and in some countries, surveys increasingly use web platforms provided by national authorities. However, nonparticipation remains a problem that can bias findings. In our study, survey characteristics such as length, file attachment, and emotionally distressful content were associated with lower response rates. Our study therefore largely confirms what is already known from predigital survey research and online research using other modes of survey distribution. Existing patterns seemingly hold in a national digital mailbox setting, thereby emphasizing that traditional principles regarding survey design and factors affecting survey participation also apply to newer technologies. This underscores the importance of considering these factors when conducting internet-based surveys distributed through digital mailboxes. Hence, questionnaires should be kept as short as possible, and the estimated completion time should be communicated honestly. Response rates can also still be considerably increased through reminders. Nonetheless, participation in public health surveys continues to decline, and despite easier procedures, it is therefore more important than ever that researchers, before launching a new survey, evaluate if the required information is already available through, for example, existing datasets, or whether it can be obtained through other means.

## Acknowledgments

No AI was used in any portion of the manuscript generation.

## Funding

This study was funded by the Danish Health Insurance Foundation (grant 17-B-0038) and the Lilly and Herbert Hansen Foundation (grant 100063).

## Abstract

**Background:** Urban communities affected by chronic violence face persistent challenges in accessing primary health care (PHC). Although violence is widely recognized as a determinant of health inequities, there exists limited evidence on how direct exposure to violent events is related to individuals' perceptions of difficulty in accessing PHC services in highly vulnerable urban environments.

**Objective:** The study aims to examine how sociodemographic characteristics and exposure to violent events are associated with perceived difficulty in accessing PHC in standardized hypothetical mental health scenarios among residents of a community affected by chronic urban violence in Rio de Janeiro.

**Methods:** A cross-sectional survey was conducted between October 8 and November 1, 2024, with 1006 adult residents who completed 4 PHC vignettes and reported past-year exposure to violent events. Participants completed a structured questionnaire that included sociodemographic information, past-year exposure to interpersonal violence, and evaluations of 4 hypothetical vignettes describing different clinical or social situations. Vignette responses were recorded using an ordinal Likert-type scale ranging from "very easy" to "extremely difficult." Descriptive analyses were performed for all variables, and associations between sociodemographic characteristics and violence indicators were examined using Pearson chi-square tests, with effect sizes estimated using the $\phi$ coefficient or Cramér *V*, as appropriate, and their respective 95% CIs. Differences in vignette ratings across sociodemographic groups were assessed using Kruskal-Wallis tests. To explore the underlying relationships among violence indicators, vignette responses, and sociodemographic variables, exploratory factor analysis and multiple correspondence analysis were conducted.

**Results:** Violence exposure was frequent. Threats of harm were reported by 27.7% (157/567) of Black participants and 30.5% (72/236) of non-Black participants. Slapping was reported by 20.8% (118/567) of Black individuals and 28% (66/236) of non-Black individuals, while being pushed or restrained affected 21.2% (50/236) and 26.7% (63/236), respectively. Significant sex differences emerged for being punched or kicked (female 17.2% [75/435] vs male 23.9% [88/368]; *P*=.02). Kruskal-Wallis tests indicated few differences in vignette-based perceptions across groups, except for race in the alcohol-dependence vignette ($\chi^2_1$=7.384, *P*=.006). Factor analysis identified 2 dimensions: violence variables loaded strongly on one factor (0.83 - 0.96) and vignette responses on another (0.66 - 0.83). Multiple correspondence analysis results showed that forms of violence contributed mainly to Dimension 1 (9% - 15%) and vignette categories to Dimension 2 (7% - 12%).

**Conclusions:** Exposure to violence was widespread, with differences in some forms of violence observed between men and women. Violence-related variables and vignette-based perceptions of difficulty accessing PHC were predominantly represented by distinct dimensions in the exploratory multivariate analyses. Strengthening PHC in violence-affected urban settings requires addressing structural barriers that shape residents' access to health care.

## Introduction

Urban violence constitutes a major public health challenge and is closely linked to structural inequalities, social exclusion, and territorial segregation in large urban centers. Foundational analyses emphasize that violence functions both as a determinant and an outcome of broader social processes, shaping patterns of illness, emotional distress, and access to essential services [1-7]. These processes disproportionately affect populations living in deprived territories, where state presence is limited and residents routinely navigate environments marked by chronic insecurity. More recent evidence from Rio de Janeiro reinforces the complex relationship between armed violence and adverse living conditions, showing that violence is embedded in broader territorial and social dynamics rather than reflecting a simple linear association with socioeconomic deprivation [8].

These dynamics have historically been particularly evident in favelas and other socioeconomically vulnerable urban territories. Long-term research on the city's favelas has documented profound transformations in living conditions alongside the persistence of social marginalization, inequality, and violence, demonstrating how improvements in some dimensions of urban life may coexist with enduring processes of social exclusion [9].

In Rio de Janeiro, neighborhoods such as the Manguinhos hub of favelas exemplify how structural inequities intersect with urban violence. Historical accounts and community-based documentation describe Manguinhos as a territory characterized by fragmented urban development, precarious infrastructure, and recurrent episodes of armed conflict, all of which affect the daily lives of residents [10]. The historical formation of Manguinhos has involved heterogeneous processes of occupation, housing interventions, urbanization policies, and disputes over urban space, reflecting broader processes that have shaped the development of favelas in Rio de Janeiro [11]. In this territory, residents experience restricted mobility, environmental hazards, and constant exposure to situations of risk, illustrating how violence shapes daily trajectories, emotional well-being, and opportunities for social participation [12].

In Brazil, PHC is organized within the Unified Health System (Sistema Único de Saúde), primarily through the Family Health Strategy (FHS), a community- and territory-based model in which multidisciplinary teams are responsible for defined populations. The expansion of the FHS has substantially increased access to PHC; however, important barriers persist, including insufficient funding and service capacity, large populations assigned to individual teams, shortages and unequal distribution of health professionals, organizational constraints, and difficulties in ensuring timely and continuous care [13]. These challenges may be particularly relevant in socioeconomically vulnerable territories, where structural and territorial conditions can interact with the organization of health services and further constrain access to care.

The consequences of armed violence in vulnerable territories may also extend to the organization and provision of health care. Health services operating in violence-affected communities may experience disruptions in their activities, while health professionals and residents may face constraints that interfere with the provision and use of care. Recent evidence from vulnerable communities in Rio de Janeiro has shown that armed violence may interact with the functioning of primary health care (PHC) services. In particular, the presence or absence of physicians in PHC teams partially mediated associations between armed violence and selected self-reported health conditions, highlighting the interconnected relationships among territorial violence, health outcomes, and health service organization [14].

International research reinforces the evidence that living in contexts of concentrated poverty and community violence is associated with multiple health consequences, including chronic stress, reduced social cohesion, and behavioral adaptations to perceived danger [15-17]. Studies in diverse global settings demonstrate that residents of high-violence neighborhoods tend to alter their routines, avoid moving through certain areas, and develop heightened perceptions of threat, which may influence their engagement with public services and their interpretations of hypothetical or real situations involving risk or conflict [17]. In the context of PHC, these territorial and social constraints are particularly relevant because access depends not only on the availability of services but also on individuals' ability to reach, engage with, and use them within the conditions of their everyday lives [18].

Understanding how individuals perceive situations of violence in such contexts is essential for public health. Perception-based data capture dimensions of insecurity, emotional burden, and daily constraints that are not fully captured by official indicators or epidemiological records. Examining how sociodemographic characteristics intersect with reported experiences of violence helps illuminate patterns of vulnerability within territories marked by persistent inequality. Understanding perceptions of access to health care is also relevant in these settings, as perceived barriers may capture dimensions of accessibility that are not fully reflected by indicators of service availability or usage [8,19]. Examining exposure to violence alongside sociodemographic characteristics may therefore help clarify whether direct experiences of violent events are associated with how residents perceive potential difficulties in obtaining PHC.

Despite growing recognition of violence as an important determinant of health and emerging evidence concerning the effects of armed violence on health services in vulnerable urban territories [14], there remains limited evidence on whether individual exposure to interpersonal violence is associated with perceived difficulty in accessing PHC. This distinction is important because the effects of violence on territories and on the organization and functioning of health services do not

XSL•FO
RenderX

necessarily imply that individuals who have personally experienced violence perceive greater difficulty in obtaining care. Examining this relationship may help distinguish individual experiences of violence from broader structural, organizational, and territorial barriers to health care access.

The objective of this study is to examine how sociodemographic characteristics and exposure to violent events are associated with perceived difficulty in accessing PHC in standardized hypothetical mental health scenarios, among residents of a community affected by chronic urban violence in Rio de Janeiro.

## Methods

### Study Design and Participants

This is a cross-sectional analytical study including 1006 adults residing in Manguinhos, a community affected by armed violence in Rio de Janeiro, Brazil. The reporting of this study followed the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines (Checklist 1). Participants were recruited between October 8 and November 1, 2024, using a quota sampling strategy based on sex and age group to approximate the demographic distribution of the local adult population. A formal a priori power analysis was not performed because the study used a nonprobability quota sampling design nested within a broader population survey. A target of 1000 interviews was established to allow proportional allocation of participants according to sex and age group based on secondary population data provided by the Pereira Passos Institute. The final analytical sample comprised 1006 participants. Recruitment was conducted in public spaces throughout the community by trained interviewers. Individuals were eligible if they were 18 years or older, resided in the study area, and agreed to participate by providing written informed consent. All participants completed a structured questionnaire covering sociodemographic characteristics, exposure to interpersonal violence, and evaluations of 4 vignettes addressing clinical and social conditions.

Quota sampling has limitations compared with probability sampling, particularly regarding representativeness; however, it was chosen to facilitate the recruitment of participants living in an impoverished community with a large proportion of residents in unstable housing (eg, shacks and provisional shelters built with fragile materials) and a highly mobile population. Potential participants were screened for eligibility before the questionnaire was administered. Individuals who did not meet the eligibility criteria were not enrolled, and the electronic questionnaire was programmed to terminate automatically for ineligible respondents. Consequently, all completed questionnaires included in the analyses were obtained from eligible participants.

### Study Variables

Sociodemographic characteristics included sex, age group, and race/color. Exposure to interpersonal violence was assessed with dichotomous questions that asked whether participants had experienced threats, various forms of physical aggression, or attacks involving objects such as knives or firearms in the past year.

Race/color was self-reported according to the Brazilian census classification. For analytical purposes, participants who self-identified as Black or Brown were categorized as Black, whereas those who self-identified as White, Asian, or Indigenous were categorized as non-Black.

Participants also evaluated 4 standardized narrative vignettes describing a hypothetical case of depression and anxiety, a hypothetical case of alcohol dependence, a person with a disadvantaged background but without mental health problems, and a neutral (control) vignette. The complete wording of the vignettes is provided in Multimedia Appendix 1. After reading each vignette, participants answered the following question: “If you had a relative or acquaintance living in the situation described above, how would you rate the level of difficulty they would have in receiving care at the PHC unit serving your neighborhood?” Responses were recorded using a 5-point Likert scale ranging from “very easy” to “extremely difficult,” with an additional “don’t know/no answer” option. The vignette responses were analyzed descriptively and subsequently incorporated into exploratory factor analysis and multiple correspondence analysis (MCA) to investigate the underlying structure of perceived difficulty in accessing PHC.

### Analytical Procedures

Descriptive analyses included absolute and relative frequencies for all variables. Associations between sociodemographic characteristics and violence indicators were examined using Pearson chi-square tests, and the effect size was calculated using the $\phi$ coefficient or Cramér *V*, with their respective 95% CIs [20].

Differences in vignette ratings according to sex, age, and race/color were analyzed using Kruskal-Wallis tests, given the ordinal distribution of the responses. Although the Kruskal-Wallis test is rank-based and distinct from the chi-square test of independence, its test statistic (*H*) asymptotically follows a chi-square distribution. Therefore, the results are reported using the chi-square statistic ($\chi^2$) and corresponding *P* values.

### Correlation Matrix and Factor Analysis

A mixed correlation matrix was computed to explore the relationships among vignette responses, violence indicators, and sociodemographic variables. Polychoric correlations were used for ordinal items, tetrachoric correlations for dichotomous variables, and Pearson correlations for numerically recoded sociodemographic variables. This matrix was used as input for the exploratory factor analysis, conducted using principal axis factoring with oblimin rotation [21]. The number of factors was determined based on eigenvalues and parallel analysis. Factor loadings, communalities, and explained variance were examined to support interpretation [22].

### MCA

Given the predominantly categorical nature of the dataset, MCA was subsequently carried out to identify multivariate patterns of association between categories of vignette responses, interpersonal violence indicators, and sociodemographic variables. The analysis produced eigenvalues, explained inertia,

XSL•FO
RenderX

category coordinates, squared cosine ($cos^2$) values, and contribution percentages for the main dimensions, which guided the interpretation of the underlying structure.

All analyses were performed in R software (version 4.4.2; R Foundation for Statistical Computing), using the packages *tidyverse* [23], *psych* [24], *FactoMineR* [25], *factoextra* [26], and *MASS* [27].

### Ethical Considerations

The study was approved by the Research Ethics Committee of the Oswaldo Cruz Foundation (FIOCRUZ), under CAAE (Certificado de Apresentação para Apreciação Ética [Certificate of Presentation for Ethical Consideration]) number 78822424.9.0000.5241 (approval number 6.873.690). All participants were informed about the study objectives, the voluntary nature of participation, and guarantees of confidentiality. They signed the informed consent form, in accordance with resolution number 466/2012 of the Brazilian National Health Committee on Ethics.

All data were deidentified prior to analysis, and no personally identifiable information was included in the analytical dataset. Participant confidentiality was maintained throughout the study.

Participants did not receive financial compensation for their participation.

## Results

Table 1 presents the distribution of sociodemographic characteristics according to different situations of violence reported in the previous 12 months. For the question “Has someone threatened to harm or injure someone important to you?,” the proportions were similar across race categories: among non-Black participants, 69.5% (164/236) responded “no” and 30.5% (72/236) “yes,” while among Black participants, 72.3% (410/567) responded “no” and 27.7% (157/567) “yes” ($P$=.47, $\phi$=0.028, 95% CI 0.000 - 0.097). Regarding sex, 72.4% (315/435) of women and 70.4% (259/368) of men reported no such threat ($P$=.58, $\phi$=0.022, 95% CI 0.000 - 0.103). Across age groups, the distribution also showed similar percentages, with “no” responses ranging from 69.7% (140/201) to 72.7% (208/286) ($P$=.76, Cramer $V$=0.044, 95% CI 0.000 - 0.103).

[a]The ϕ coefficient was calculated for the race and sex variables, whereas Cramér *V* was calculated for age group.

[b]Chi-square test.

A high proportion of both Black and non-Black participants reported not having been slapped: 72.0% (170/236) of non-Black individuals and 79.2% (449/567) of Black individuals answered "no" (*P*=.04, ϕ=0.078, 95% CI 0.008 - 0.146). Among women, 79.8% (347/435) reported not having been slapped, compared to 73.9% (272/368) of men (*P*=.06, ϕ=0.069, 95% CI 0.000 - 0.138). Across age groups, the proportion of "no" responses varied from 73.1% (147/201) to 82.5% (236/286; *P*=.02, Cramer *V*=0.097, 95% CI 0.008 - 0.161; Table 1).

For being pushed or grabbed forcefully, or having an object thrown with the intention of causing harm, 73.3% (173/236) of non-Black individuals and 78.8% (447/567) of Black participants reported "no" (*P*=.11, ϕ=0.060, 95% CI 0.000 - 0.129). Women reported not experiencing this event in 80.5% (350/435) of cases compared with 73.4% (270/368) of men (*P*=.02, ϕ=0.084, 95% CI 0.015 - 0.153). Across age groups, "no" responses ranged from 75.6% (152/201) to 80.1% (229/286; *P*=.36, Cramer*V*=0.051, 95% CI 0.000 - 0.111; Table 1).

Physical aggression involving punching, kicking, or pulling hair was not reported by 76.3% (180/236) of non-Black participants and 81.1% (460/567) of Black participants (*P*=.14, ϕ=0.055, 95% CI 0.000 - 0.124). A difference between sexes was observed in the proportions of "yes" responses: 17.2% (75/435) among women and 23.9% (88/368) among men (*P*=.02, ϕ=0.083, 95% CI 0.014 - 0.151). Across age groups, "yes" responses ranged from 16.1% (46/286) to 22.9% (46/201) across groups (*P*=.09, Cramer *V*=0.078, 95% CI 0.000 - 0.141; Table 1).

Most participants reported not experiencing attempted or actual strangulation, suffocation, or burning in the previous 12 months. This proportion was slightly higher among Black participants (513/567, 90.5%) than among non-Black participants (204/236, 86.4%), although the difference was not statistically significant

XSL•FO
RenderX

(*P*=.12, ϕ=0.059, 95% CI 0.000 - 0.128). A similar pattern was observed by sex: 90.1% (392/435) of women and 88.3% (325/368) of men reported not experiencing these acts (*P*=.48, ϕ=0.029, 95% CI 0.000 - 0.098). Across age groups, the proportion reporting no such violence ranged from 87.3% (276/316) to 92.3% (264/286; *P*=.12, Cramer *V*=0.073, 95% CI 0.000 - 0.136; Table 1).

For threats or injuries involving a knife, firearm, or another weapon, 87.3% (206/236) of non-Black participants and 90.5% (513/567) of Black participants responded "no" (*P*=.22, ϕ=0.047, 95% CI 0.000 - 0.116). Women reported not experiencing this type of violence in 90.6% (394/435) of cases, compared with 88.3% (325/368; *P*=.35, ϕ=0.037, 95% CI 0.000 - 0.106). Across age groups, "no" responses ranged from 87.6% (176/201) to 92.7% (265/286; *P*=.10, Cramer *V*=0.076, 95% CI 0.000 - 0.139; Table 1).

Sex comparisons revealed similar vignette response scores for the depression vignette ($\chi^2_1$=0.51, *P*=.48), the alcohol-dependence vignette ($\chi^2_1$=0.04, *P*=.84), the vignette without mental health problems ($\chi^2_1$=0.15, *P*=.70), and the control vignette ($\chi^2_1$=0.01, *P*=.91; Table 2).

**Table .** Comparison of vignette response scores by sex, race/color, and age group.

| Grouping variable and vignette | Chi-square (*df*) statistic | *P* value |
|---|---|---|
| Sex | | |
| Depression vignette | 0.508 (1) | .48 |
| Alcohol-dependence vignette | 0.041 (1) | .84 |
| No mental health problems vignette | 0.146 (1) | .70 |
| Control vignette | 0.013 (1) | .91 |
| Race/color | | |
| Depression vignette | 0.009 (1) | .92 |
| Alcohol-dependence vignette | 7.384 (1) | .006 |
| No mental health problems vignette | 3.140 (1) | .08 |
| Control vignette | 0.429 (1) | .51 |
| Age group | | |
| Depression vignette | 1.565 (2) | .46 |
| Alcohol-dependence vignette | 1.561 (2) | .46 |
| No mental health problems vignette | 4.340 (2) | .11 |
| Control vignette | 0.125 (2) | .94 |

Race and color comparisons revealed similar vignette response scores for the depression vignette ($\chi^2_1$=0.01, *P*=.92), the vignette without mental health problems ($\chi^2_1$=3.14, *P*=.08), and the control vignette ($\chi^2_1$=0.43, *P*=.51). A statistically significant difference was observed only for the alcohol-dependence vignette ($\chi^2_1$=7.38, *P*=.006; Table 2).

Age-group comparisons revealed similar vignette response scores for the depression vignette ($\chi^2_2$=1.57, *P*=.46), the alcohol-dependence vignette ($\chi^2_2$=1.56, *P*=.46), the vignette without mental health problems ($\chi^2_2$=4.34, *P*=.11), and the control vignette ($\chi^2_2$=0.13, *P*=.94; Table 2).

Table 3 presents the factor loadings for the 2-factor solution derived from principal axis factoring with oblimin rotation. The 4 vignette items loaded more strongly on Factor 2, with values of 0.73 for the depression vignette, 0.83 for the alcohol-dependence vignette, 0.80 for the vignette without mental health problems, and 0.66 for the control vignette.

XSL•FO
RenderX

**Table .** Factor loadings[a] for a 2-factor solution.

| Variable | Factor 1 (PA1[b]) | Factor 2 (PA2) | $h^2$ |
|---|---|---|---|
| Depression vignette | 0.05 | 0.73 | 0.54 |
| Alcohol-dependence vignette | 0.00 | 0.83 | 0.70 |
| No mental health problems vignette | −0.02 | 0.80 | 0.63 |
| Control vignette | −0.04 | 0.66 | 0.43 |
| Threatened to hurt or injure someone important | 0.83 | 0.02 | 0.69 |
| Slapped (past 12 months) | 0.94 | 0.05 | 0.89 |
| Pushed/held down (past 12 months) | 0.95 | −0.02 | 0.90 |
| Punched/kicked (past 12 months) | 0.96 | 0.00 | 0.92 |
| Strangled/suffocated/burned (past 12 months) | 0.92 | −0.05 | 0.85 |
| Threatened/attacked with a weapon | 0.84 | −0.01 | 0.71 |
| Sex | 0.10 | 0.11 | 0.02 |
| Age group | −0.10 | −0.12 | 0.03 |
| Race/color | −0.08 | −0.02 | 0.01 |

[a]Factor loadings were obtained using principal axis factoring with oblimin rotation.

[b]PA: principal axis.

All 6 violence-related items loaded more strongly on Factor 1, with loadings ranging from 0.83 (threatened to harm or injure someone important) to 0.96 (punched or kicked in the past 12 months). The variable “threatened/attacked with a weapon” showed a loading of 0.84 on Factor 1, while “strangled/suffocated/burned” loaded 0.92 on the same factor (Table 3).

Sociodemographic variables showed low loadings on both factors, with values of 0.10 and 0.11 for sex, –0.10 and –0.12 for age group, and –0.08 and –0.02 for race/color. Communality values ($h^2$) ranged from 0.01 (race/color) to 0.92 (punched/kicked in the past 12 months; Table 3).

Table 4 displays the squared cosine ($cos^2$) values and the percentage contributions of each category to Dimensions 1 and 2 of the MCA. Across the violence-related variables, high $cos^2$ values on Dimension 1 were observed for the “yes” and “no” categories of punched/kicked (0.745), slapped (0.717), pushed/restrained (0.699), strangled/suffocated/burned (0.563), threatened or injured with a weapon (0.520), and threatened to hurt someone important (0.507). These categories also made the largest contributions to Dimension 1, with values ranging from 9.01% to 14.75% for the “yes” categories.

For the vignette response categories, the highest cos² values on Dimension 2 were observed for the "very easy" and "easy" categories across all 4 vignettes. In the depression vignette, cos² values were 0.335 and 0.251; in the alcohol-dependence vignette, 0.353 and 0.289; in the vignette without mental health problems, 0.343 and 0.216; and in the control vignette, 0.316 and 0.135. These categories also showed the highest contributions to Dimension 2, ranging from 6.96% to 12.27% (Table 4).

Sociodemographic variables showed low cos² values in both dimensions. For sex, cos² values were 0.011 for Dimension 1 and 0.013 for Dimension 2, with contributions below 0.25%. Age groups showed cos² values ranging from 0.004 to 0.015 for Dimension 1 and from 0.000 to 0.012 for Dimension 2. Race/color categories showed cos² values of 0.011 on Dimension 1 and 0.004 on Dimension 2, with contributions below 0.20% (Table 4).

## Discussion

The findings of this study indicate that exposure to interpersonal violence was frequent in the study population, while perceptions regarding the difficulty of the clinical and social situations described in the vignettes formed a distinct analytical dimension from violence exposure. In addition, perceived difficulty in accessing PHC showed limited variation across sociodemographic groups. This separation was consistently observed across exploratory multivariate analyses, including factor analysis and MCA, which revealed 2 clearly differentiated dimensions: one associated with violence-related experiences and another associated with perceived difficulty accessing PHC as assessed through the vignette scenarios. Differences between experiences and perceptions under stressful conditions have been documented in the psychological and public health literature. As discussed by Krieger [28], such challenging "crossroads" call for further theoretical development and innovative empirical studies.

Discrepancies between actual experiences of violence and individual or community perceptions of violence have been documented across diverse settings, ranging from local conflicts, such as turf wars [29], to large-scale and protracted conflicts [30]. Such differences in perceptions and responses may contribute to variation in psychological responses to adversity, including posttraumatic stress and resilience. However, resilience may be challenged by prolonged or cumulative exposure to adversity, as illustrated by recent analyses of the combined effects of war and environmental stressors [31].

The prevalence levels observed in the sample are consistent with global patterns of physical violence and threats, as documented in international epidemiological studies. Evidence from large multicountry surveys has repeatedly shown that exposure to physical or psychological aggression is widespread across different populations and settings [32-36].

Although most comparisons did not indicate statistically significant sociodemographic differences, the distribution of violence types within groups was broadly aligned with the international literature. Men reported higher frequencies of some forms of aggression, consistent with studies showing that men experience substantial levels of nonpartner physical violence, especially in community or nondomestic contexts [37-40].

At the same time, women reported higher exposure in certain categories in other international surveys, particularly those involving coercive control or severe violence [36,41]. Such patterns reinforce the notion that interpersonal violence is multifaceted and extends beyond intimate-partner contexts.

Limited variation was observed in vignette-response scores by sex, race/color, or age group, with only one statistically significant result (race/color in the alcohol-dependence vignette). International studies using vignette-based approaches have similarly documented variation in how individuals evaluate standardized health-related scenarios across sociodemographic groups [3,42].

Factor analysis results demonstrated a clear 2-factor structure: violence-related items loaded strongly on the first factor, and vignette-evaluation items loaded on the second, with minimal loadings of sociodemographic variables. This separation suggests that, in this sample, previous exposure to interpersonal violence and perceived difficulty accessing PHC through the

XSL•FO
RenderX

vignette scenarios represented distinct analytical dimensions [36].

The MCA results were consistent with this distinction, with "yes" categories for violence defining Dimension 1 and vignette categories defining Dimension 2. Similar patterns of violence clustering have been reported in multicountry studies examining violence and psychosocial variables [37,43,44].

Taken together, the results suggest that violence exposure and perceptions of difficulty accessing PHC appear to represent distinct dimensions in this sample. International literature indicates that interpersonal violence is a strong predictor of mental-health outcomes such as depression, anxiety, posttraumatic stress disorder, and suicidality [33,36,38]. These findings highlight the importance of distinguishing previous exposure to interpersonal violence from perceptions of difficulty accessing PHC, as both may be shaped by different individual, organizational, and contextual factors [45-48].

The limited differentiation in vignette responses across sociodemographic groups also suggests that perceived difficulty accessing PHC cannot be attributed to demographic characteristics alone. Broader structural, organizational, and territorial factors should therefore be considered when developing strategies to improve access to PHC in violence-affected communities [36,37,49,50].

Overall, the results indicate that, although exposure to violence was common and patterned in ways broadly consistent with international evidence, violence-related variables and vignette-based perceptions of difficulty accessing PHC were predominantly represented by distinct dimensions in the exploratory multivariate analyses. This distinction underscores the importance of considering perceived access as a multidimensional construct that may be influenced by factors beyond individual experiences of violence.

These findings also have important implications for the organization of PHC in violence-affected territories. The distinction observed between violence-related variables and vignette-based perceptions of difficulty accessing PHC in the exploratory multivariate analyses highlights the need to consider broader structural, organizational, and social factors that may shape perceived access. Consequently, strategies aimed at improving access should extend beyond the identification of violence exposure and include actions to strengthen service availability, continuity of care, welcoming practices, and coordination of care within PHC.

In the Brazilian context, these implications should be considered in relation to the organization of PHC and the structural conditions affecting access to care. Although the expansion of the FHS has contributed substantially to increased PHC coverage and access, persistent organizational and structural barriers may limit the ability of services to provide timely and continuous care, particularly in socially vulnerable territories [13]. In settings affected by chronic armed violence, these barriers may be compounded by disruptions in service functioning, restrictions on the mobility of residents and health professionals, and difficulties in maintaining stable health care teams. Recent evidence from impoverished communities in Rio de Janeiro has shown that armed violence can affect PHC functioning, with the presence or absence of physicians in primary care teams partially mediating the associations between exposure to armed violence and selected health conditions [14]. Thus, perceptions of difficulty in accessing PHC in Manguinhos should be interpreted not solely in relation to individual characteristics, but also within the broader context of territorial violence and the structural and organizational conditions that may shape access to health services.

However, the observed distinction between violence-related variables and vignette-based perceptions of difficulty accessing PHC should be interpreted with caution. It should not be interpreted as evidence that violence has no influence on perceived access to PHC. Rather, it may reflect the multidimensional nature of access, which is influenced by organizational characteristics of health services, previous experiences with care, social support, and contextual factors that were not directly assessed in this study.

This study has some limitations. First, its cross-sectional design precludes causal inference. Second, the outcome was based on responses to standardized hypothetical vignettes, which reflect perceived difficulty in accessing PHC rather than actual health care usage or experienced barriers to access. Although the vignettes were designed to assess perceived difficulty accessing PHC rather than mental health literacy, responses to hypothetical mental health scenarios may also be influenced by participants' beliefs and understanding of mental health conditions, which have been shown to vary within community populations. Third, although the analyses included key sociodemographic characteristics, other potentially relevant contextual and socioeconomic determinants of access, such as education, income, employment status, previous experiences with health services, and geographic accessibility, were not evaluated. These factors may influence perceived difficulty accessing PHC and should be considered in future studies using multivariable analytical approaches.

Furthermore, the distinction observed between violence-related variables and vignette-based perceptions of difficulty accessing PHC in the exploratory multivariate analyses should be interpreted with caution. This pattern should not be interpreted as evidence of the absence of an association between violence exposure and perceived difficulty accessing PHC. Future studies using complementary measures of access and multivariable analytical approaches may help clarify this relationship.

Understanding the factors that shape perceptions of access to PHC is essential for strengthening health systems in communities affected by chronic urban violence. Although violence-related variables and vignette-based perceptions of difficulty accessing PHC were predominantly represented by distinct dimensions in the exploratory multivariate analyses, the findings suggest that broader structural, organizational, and social determinants deserve greater attention in policies and interventions aimed at improving access. Future studies conducted in different contexts and using complementary measures of access are needed to further clarify these relationships and support the development of more equitable PHC services.

## Abstract

**Background:** Abortion is a common and safe medical intervention with a long history of practice in the United States. Despite this, inaccurate and misleading information persists, including falsehoods about the accessibility, legality, safety, and lived experience of abortion-related health care. Further, the prevalence and circulation of abortion myths online and offline have intensified following the overturning of Roe vs Wade in May 2022. While myths surrounding abortion have been widely documented, limited research has examined how these myths shape the everyday work of abortion health care providers and advocates, particularly in relation to patient–practitioner shared decision-making (SDM).

**Objective:** This study examines how abortion myths affect abortion health care professionals—including practitioners in states where abortion access is legal, and advocates connecting patients with care in states with limited abortion health care. Through interviews with advocates and professionals, we document the nature of circulating myths, the common information sources where myths are being spread, and the routes professionals take to debunk myths when they arise, or, similarly, the barriers that limit their ability or desire to debunk abortion myths.

**Methods:** We conducted in-depth qualitative interviews with abortion health care professionals across the WWAMI (Washington, Wyoming, Alaska, Montana, and Idaho) medical region. Interviews explored the types of abortion myths encountered in clinical settings, how providers respond to misinformation during patient interactions, and the perceived impact of myths on care delivery and SDM processes. Data were analyzed using an iterative constant comparative thematic analysis of the interview transcripts.

**Results:** Participants reported encountering a wide range of abortion-related myths from predominantly online (social media) and some offline sources, including misinformation about safety, legality, fertility impacts, and procedural experiences. Providers described dedicating substantial time to correcting misinformation, addressing fear and confusion, and rebuilding trust within clinical encounters. Myths were found to complicate SDM by shaping patients' expectations, emotional responses, and perceived options for care, in addition to taking up time and resources for providers of care to counter damaging myths.

**Conclusions:** Abortion myths have tangible effects on clinical practice and SDM, placing additional communicative and emotional labor on providers and potentially undermining patient autonomy. Addressing misinformation is therefore critical not only for public understanding but also for supporting equitable, patient-centered abortion care in a post-Roe landscape.

abortion; health myths; health information seeking; social media; health misinformation

## Introduction

### Background

Abortion is a common and safe medical intervention with a long history of practice within the United States; yet, misleading information around abortion (and pregnancy viability more broadly) persists [1,2]. Inaccurate information about abortion pertains to the realities of abortion health care (ie, information about medical interventions, medication, and aftercare) [3], falsehoods about the long-term impacts of having an abortion, and misleading information around the legality of, and access to, abortion health care [4]. The overturning of abortion protections upheld by Roe vs Wade in the 2022 Dobbs vs

XSL•FO
RenderX

Jackson Women's Health Organization ("Dobbs" for short) has exacerbated the conditions of uncertainty under which rumors and misinformation thrive [5], leading health researchers to call abortion misinformation "the next infodemic" [6]. Accordingly, given the advent of digital information-seeking for health, individuals seeking abortion information online may be met with a polluted information environment in which it is difficult to parse between falsehoods and scientific truth. Difficulties in information-seeking undermine an individual's ability to make informed health decisions and have additional negative ramifications for their relationships with health care providers.

To better understand the ramifications of online (and offline) health myths on patient-practitioner relationships, this paper examines the impact of abortion-related myths post Dobbs from the perspective of professionals involved in abortion health care and related advocacy, including abortion practitioners and advocates. Accurate knowledge is vital for shared decision-making (SDM) between patients and practitioners to occur, with persistent myths undermining the ability of practitioners to establish relationships of trust with patients and base decisions on a mutually agreed-upon knowledge foundation. Through in-depth interviews, we explore the types of myths health care professionals encounter and how they navigate abortion-related myths when they arise, and document their impacts. Our analysis offers insights into the interconnection among legal confusion, uncertainty, and the spread of misinformation, and highlights productive routes health care professionals use to counter the harmful effects of health myths and provide a foundation for SDM.

## Extant Research

### *Health Misinformation*

The spread of misleading health information is a longstanding concern for public health professionals and for science communication more broadly [7]. Further, the politicization of health-related topics has exacerbated the spread of misleading information [8], reducing the effectiveness of science communication around health and leading to significant public health impacts [9,10]. This is particularly acute in relation to abortion health care [11,12]. The overturning of historical protections of abortion access under Roe vs Wade marks a "new legal quagmire" for abortion access [13] and renews public conversation and contestation about abortion health care. Moreover, the Dobbs decision came at a time of renewed political and legislative attacks on bodily autonomy that leverage scientific misinformation as core evidence [14].

Extant research into the spread of misleading health claims primarily uses the term "misinformation" to capture the unintentional spread of nonfactual health information and "disinformation" to capture nonfactual information intentionally spread to mislead [15]. Similarly, public health scholars have used the term "myth" to describe the spread of health-related statements that are widely disseminated but have either no supportive scientific evidence or strong evidence to the contrary [16]. Given the politicization of the term "misinformation" and the nuances of scientific information that cannot necessarily be binned into the dichotomy of "true" or "false" [11], we use the term "abortion myths" throughout this work. Further, "myth" captures information that can be seen as misleading without attaching intentionality to its spread. Within the context of abortion-related information, there have historically been clear instances in which institutions have weaponized false information to intentionally discourage pregnant people from seeking out abortions. However, the complexities of the online space mean information provenance and the intentions of every poster and/or sharer of information are difficult to track. Accordingly, while we (and our interviewees) often refer to information as "misleading" given its nonfactual nature, the term "myth" affords space to avoid specific claims on intention.

### *Abortion Myths*

The scope of abortion-related myths and their spread in online and offline environments has been well-documented. Recent research, for example, highlights the prevalence of misleading information about abortion and herbal "at-home abortion remedies" on video-sharing site TikTok (ByteDance) [17]. Earlier work explored the spread of inaccurate information related to abortion and breast cancer, infertility, and mental health problems by pregnancy crisis centers [18,19]. Further research has highlighted the role of abortion myths in pro- and antiabortion advocacy. The work by Gantt-Shafer [20] examines the impact of myths on the overall climate around abortion, finding that media representations or misrepresentations of abortion can normalize rage as an acceptable response to the existence of abortion and further the demonization of people who seek out this form of health care.

Documenting the perspectives of health care providers is particularly necessary post Dobbs as abortion health care professionals navigate a new legal climate around abortion health care [21]. Myths that arise in conjunction with new laws exacerbate confusion around legality. Location-specific research points to these complexities. For instance, a report from the Idaho Coalition for Safe Healthcare found that Idaho—a state that outlawed abortion following the Dobbs decision—lost 22% of its obstetrics and gynecology (OB-GYNs) in the year following the decision. Doctors in the state have argued that the scope of Idaho's abortion ban is unclear, creating confusion on "what care they can and can't provide patients" [22]. As such, it is important to capture how legal confusions and the rumors that arise out of this confusion impact provider well-being.

Accordingly, in the wake of the Dobbs decision, a wave of perspectives papers in public health and medical journals have called for the active participation of health care professionals in reproductive justice advocacy work [23,24]. Within this has been a call for practitioners to consider illuminating abortion myths as part of the professional obligations of health care providers [25]. However, little research exists documenting the specific impacts of abortion myths these health care providers encounter and how they attempt to debunk misleading information about abortion when it arises.

### *Theories of SDM*

While SDM has become the norm for patient-practitioner relationships within the United States [26], there is no singular definition describing the process. According to Resnicow et al

XSL•FO
RenderX

[27], most models of SDM consider it a "collaborative process by which both the patient and health care provider contribute to medical decisions, with patients being full partners in decisions about their care..." In defining the underpinning theoretical mechanisms supporting SDM as a relational care route, Resnicow et al, present two relevant models—self-determination theory (SDT) and the difficulty × motivation matrix. SDT [28] proposes a continuum of motivational regulation—ranging from controlled motivation, that is, behavioral change emanating from external pressure and guidance, to autonomous motivation—self-determined change through internal motivation [28]. Further, SDT advances three fundamental human needs—competence, relatedness, and autonomy—that, once met, enhance behavior change by affording more autonomous motivation. Building on this, Resnicow et al [27] point toward their previously established difficulty × motivation matrix [29] to explain how the effectiveness and style of SDM needed may also be impacted by the degree of difficulty the behavioral change requires. More complex, repeated, and long-term health behaviors, for example, smoking cessation, dietary change, require more patient autonomy than one-off or less complex health decisions. Taken together, the theoretical underpinnings of SDM highlight the utility and necessity of patient autonomy in health decisions and foreground the role of information access (foundational for patient competency) in effective SDM.

Empirical studies of abortion health care examine the potential role of SDM in ensuring effective health outcomes and patient satisfaction [30]. Fagot [30] argues that SDM is an effective care strategy for patients seeking medication abortion, but one that is "multifaceted and difficult to implement in health care settings." Difficulty arises due to systemic barriers to accessing abortion care, such as cost, logistical barriers, and information overwhelm. Studies outside the US context confirm similar issues. Research by Frederico et al [31] in Mozambique highlighted how gender and power inequalities and a lack of knowledge at the national level surrounding the legality of abortion limit women's autonomy in decision-making around abortion health care. Shared-decision making thus requires health practitioners (and broader advocates) to uncover and attend to barriers that undermine the ability of patients to autonomously engage with health information and thus effectively uphold their role within the shared patient-practitioner decision-making relationship. One such barrier is increasing distrust in medical professionals [32], which is further connected with the rise of medical misinformation as individuals look elsewhere (increasingly online) for answers to their health queries, and the persistence (or perception) of health misinformation causes further distrust in health care providers [12]. However, there exists a dearth of research examining (1) the spread of abortion-related myths in the US-context post Dobbs, and (2) exploring how such myths impact practitioners in their ability to foreground SDM in their patient relationships.

To address current gaps in research, this project seeks to answer the following research questions (RQs):

- RQ1: what types of myths do providers and advocates encounter?
- RQ2: how do they navigate myths when they arise?
- RQ3: what impacts do they see myths having on abortion health care?

## Methods

### Sampling and Recruitment Methods

The research team conducted 14 semistructured, in-depth interviews with abortion health care providers and advocates between October 2023 and January 2024. Interviewees were recruited via email through snowball sampling [33] using email listservs and personal connections with researchers and practitioners in the WWAMI (Washington, Wyoming, Alaska, Montana, and Idaho) medical region, plus the neighboring state of Oregon. The inclusion criteria for interviews defined appropriate interviewees as individuals working or who have worked professionally within the US abortion space—either as licensed medical or adjacent health care professionals or reproductive rights advocates affiliated with professional organizations—who attest to having been impacted in some way by the spread of false or misleading information about abortion. Meeting the latter criteria was determined within the recruitment process through initial email advertisements (asking for participants who had encountered misinformation about abortion within their professional work) and in confirmation through sharing (and confirmation of awareness) of the research objectives within informed consent. We faced difficulties in recruiting health care providers in states, notably Idaho, where abortion access is banned. To expand our potential interview sample, we recruited advocates working within abortion and health care organizations to advance abortion access, in addition to health care practitioners who either practiced abortion lawfully under their home state's laws or provided general health care (usually OB-GYN and family-planning-related care) in banned states. Snowball sampling began with abortion health care providers within our university-affiliated hospital system, who then referred us to email listservs for abortion-related professionals and directly connected us with practitioners from other states within their professional networks. The email listservs used were aimed at either members of professional organizations associated with abortion and related health care or broader organizations and collectives engaged in work to advance abortion rights. Our resultant sample (Table 1) includes health care practitioners—in the main OB-GYNs and 2 primary care physicians and 2 abortion advocates—both working in abortion-specific organizations connecting individuals in banned states to health care and engaging in legislative advocacy.

| 012 | WY | Health care practitioner |
| 013 | ID | Abortion advocate |
| 014 | AK | Health care practitioner |

## Ethical Considerations

This project was reviewed by the Institutional Review Board at the University of Washington and deemed exempt from federal human participants review (STUDY00018372). The University of Washington's Human Subjects Division determined that this interview study qualified for exempt status (category 2). Accordingly, formal written informed consent was not obtained. Instead, interviewees were provided with a statement blurb about the purpose of the research project, how data (interview transcripts) would be obtained, anonymized, and analyzed, and contact details for this study's team (Multimedia Appendix 1). Study details were emailed to potential participants before scheduling an interview time, and we repeated this at the beginning of interviews (before recording), at which time this study's team repeated that participants could remove themselves and their data from this study at any time (Multimedia Appendix 1). Given the sensitive nature of this study's subject matter, interviewee privacy was of the utmost importance. Interviewees were given a number identifier that was not attached to their name and/or contact information, and only two biographical details—their state and a generalized professional title (Table 1)—were collected to ensure confidentiality. All participants were compensated for their time with a US $50 gift card.

## Research Team Positionality

All interviews were conducted by the lead author, with a secondary interviewer from the broader research team. The research team consists of social scientists from different disciplines researching issues related to health information-seeking, reproductive health and advocacy, and social media. Researchers were all PhDs trained in qualitative research methods, including interviews and thematic analysis. All of the research team were employed by the University of Washington either as full-time academic researchers or as doctoral students and research assistants. Researchers within the team identify as either female or nonbinary.

## Interview Protocol

Interviews were semistructured, following a general agenda with intentional space for participants to direct conversation based on what they wanted to share. A protocol was developed by the research team that focused on capturing the professional experiences of interviewees in relation to the informational climate surrounding abortion to answer the core RQs related to common myths (RQ1), how they navigate these myths in their professional work (RQ2), and the broader impacts they see abortion myths as having on abortion health care (RQ3). Specific questions in the agenda pertained to experiences of abortion myths within patient interactions, considerations of public knowledge around abortion health care and prominent myths and misconceptions, experiences of patient information-seeking about abortion, and strategies interviewees deploy when they encounter abortion myths in their patient interactions (see Multimedia Appendix 2 for interview protocol). Interviews were conducted via Zoom (Zoom Communications, Inc) and lasted, on average, 45 minutes.

Audio recordings were taken for transcripts to be obtained and then destroyed. The research team met to debrief after each interview and discuss emergent themes before formal coding. We continued interviews until the research team agreed that we had achieved data saturation [34], that is, we reached a point of "informational redundancy" [35], where new interviewees provided similar answers to several prior interviews.

## Data Analysis

Researchers conducted a grounded thematic analysis of the interview transcripts [36], starting from the interview dataset to ascertain common themes, then codifying themes into a specific codebook applied to interview transcripts to gauge prevalence, capture any contradictions or nuances between

XSL•FO
RenderX

perspectives, and surface appropriate descriptive quotes from interviews. An initial team of 4 researchers used qualitative data analysis software Atlas.TI to open-code the full set of transcripts to identify initial themes and points of interest. In the open-coding phase, researchers read through transcripts and labeled data (usually single sentences or brief paragraphs) of interest to the core RQs. Labels consisted of in vivo or descriptive codes. The full research team then met and used visual collaboration software Miro to undertake a collaborative clustering activity in which researchers colocated similar codes, identified salient themes from the clusters using a constant comparative method, and discussed connections between clusters. A smaller group of researchers then used the results of the clustering activity to form the basis of a codebook (Multimedia Appendix 3), which was used by the full research team to code all 14 transcripts. The findings section highlights the most pertinent themes that emerged from this analysis.

## Results

### RQ1: What Types of Myths Do Providers and Advocates Encounter?

Throughout the interview process, providers and advocates highlighted several central myths they encounter in their work that are predominantly procedural (around reproductive health and abortion as a medical intervention) or legal. Table 2 highlights the core thematic codes emergent from interview analysis regarding the types, sources, and routes to combating the central myths encountered by providers and advocates.

**Table .** Core themes emergent from interview analysis regarding major myths, sources of myths, and routes to combating myths.

| Core theme | Subthemes | Description |
|---|---|---|
| Sources of misinformation | Offline | Descriptions of offline sources of misinformation, for example, friends and family, church, legal framework, etc |
| Sources of misinformation | Online | Description of online sources of misinformation (not social media), for example, Google, websites |
| Sources of misinformation | Social media | Description of social media sources of information, for example, TikTok, Facebook (Meta), X (formerly known as Twitter), etc |
| Sources of misinformation | Crisis pregnancy centers | Explicit mentions of the role of crisis pregnancy centers in “care” giving and information-seeking |
| Types of misinformation | Procedural misinformation | Any misinformation related to abortion procedures and the risks and pain involved |
| Types of myths | Future risks and impacts | Misinformation related to potential future impacts of having an abortion, for example, breast cancer, mental health, and infertility |
| Types of myths | Legal misinformation | Misinformation related to the legality of getting, delivering, or assisting with an abortion |
| Types of myths | Misinformation in options counseling | Misinformation given during counseling, for example, around options available to patients |
| Types of myths | Misinformation regarding the reputation of the reproductive health field | Mentions of misinformation related to the reputation of health care providers (providers are “bad people”) and institutions such as Planned Parenthood |
| Strategies for combating myths | Barriers to addressing misconceptions | Mentions of the barriers that exist around addressing abortion misconceptions (ie, limited time with patients) |
| Strategies for combating myths | Communication strategies | Mentions of the ways providers communicate with patients about abortion, their misconceptions about abortion, and how they build interpersonal trust with patients |
| Strategies for combating myths | Evidence-based information sharing | Mentions of how providers share information with patients as a way to combat misconceptions |
| Strategies for combating myths | Using social media | Mentions of the use or potential of social media to combat misconceptions among a broader audience |
| Strategies for combating myths | Seeking out different perspectives | Intentionally seeking out differing perspectives about abortion to build understanding about what distinct ideas or misconceptions exist around abortion |

XSL•FO
RenderX

Procedural myths and misconceptions emerge mainly around the safety of abortion, both medication and procedural. Providers stressed that while much of the discourse around abortion presents it as a painful, dangerous, or risky procedure, it is exceedingly safe, especially compared to pregnancy, which can be very high-risk. One provider noted:

> *I think also there's a lot of disinformation about the safety of abortion in general. Where we know that it is much, much safer than continuing a pregnancy, and there's generally no significant risk of infertility or infection, or significant bleeding that is associated with having an abortion.* [D004]

Additionally, multiple providers noted that there are large gaps in public knowledge about medication abortion—mifepristone and misoprostol—which can be safely self-administered. D008 argued:

> *I think there's a lot of belief about abortion needing to be medicalized. And I think, like there are like organizations and then also people in the family planning community providing this care, who are trying to do more work and supporting people who choose to have abortions on their own as far as self-sourcing medication abortion, or self-managing. But I think there's—I guess I worry about patients who choose that even coming into the system with complications, or, you know, bleeding, or whatever it might be and then providers being like, Oh, you're so irresponsible for doing that. Whereas, like actually, abortion is really safe and you know, there are studies showing people do know how far along they are in pregnancy. They can take a questionnaire to self-assess. You know their risk for ectopic and like, safely have self-managed abortion.*

While procedural myths and misconceptions most commonly come from patients, myths around legality are also pervasive among the practitioners and advocates themselves—including myths about what was or was not legal and where. D003 noted:

> *Yeah, I mean, I think that it makes, it may impact, not just patients, but colleagues, staff. You know, misunderstandings about the legality of abortion like, persist in my own department about like what Washington State's laws mean, in fact. And so like, if we can't understand it as physicians and clinicians like, how are we gonna expect, you know, like other folks to understand it, if you know, if it's like, literally part of our job.*

However, while mounting legislation in some banned and restricted rural states often leads to confusion and/or misinformed assumptions about access, D009 also noted some of these assumptions predated the Dobbs decision and were rooted in preexisting rural community attitudes about abortion:

> *It's understandable that people don't quite know if it's legal or not. But even before that a lot of people just had an assumption. Oh, I didn't think it was legal in Wyoming, you know.*

Interviewees were also asked about the source of the myths and misconceptions they encountered in their industry and in their encounters with patients. Offline sources were identified as common sources of myths around abortion by our participants, with crisis pregnancy centers (CPCs) noted most frequently, followed by interpersonal relationships and other offline sources. On CPCs, 1 provider noted:

> *I mean, it's extremely angering whenever I even talk about them, because I do agree like not being a legal person myself, I don't completely understand the legal reasons they're allowed to exist and provide this false counseling and information to patients regarding like patients own health. Like people, are literally like pretending to put an ultrasound on, don't even know how to operate an ultrasound machine like lying to patients about how far along they are in pregnancy like trying to convert them to religions.*

Online sources were also highlighted by interviewees, including media such as informational websites (sometimes run by CPCs), news media, and social media. Many of the providers interviewed discussed actively avoiding social media (and even online news media in some cases) for several reasons, including a lack of free time but predominantly due to the volatility of social media and an impression that the amount of online misinformation would be overwhelming. One provider noted:

> *I haven't been on social media, for you know, many, many years, and so, in fact, that probably means that I'm not exposed to, you know, sources of kind of misinformation that other people are, and certainly patients might be exposed to.* [D006]

The aversion to online media expressed by participants could help explain why offline sources emerged as the leading source of abortion myths across interviews, despite extant research documenting the importance of social media in information-seeking. Moreover, it highlights a potential gap in knowledge for practitioners, as protecting their own mental well-being through staying away from social media also results in their (known) lack of awareness of the full extent of myths circulating on online platforms. Despite their personal avoidance of social media, interviewees did highlight the emergence of social media as a source of reproductive health myths from interactions with their patients, with specific mention of TikTok and Reddit.

In talking through the types of myths that were pervasive in their practice and/or geographic communities, interviewees reasoned why certain myths retained salience within the community or within the US more broadly, such as religion and language. The importance of religion in the framing of life and the sanctity of life led to a belief in myths around gestational limits, the availability of certain procedures, future fertility, and health, in addition to stigma and shame. One provider argued:

> *I think fear tactics are the most impactful where there is so much misinformation about the safety of abortion, and especially in religious worlds, the idea that abortion is a sin, or that someone will go to hell if they have an abortion, I think that is extremely impactful in people of faith, and in making them either*

XSL•FO
RenderX

> *feel extremely confused or, or making the decision very difficult for them, or actually making them change their decision. And I think that that is very unfortunate, and very negatively impactful both for the patient as well as for the providers taking care of them.* [D004]

Interviewees also discussed the weaponization of language around abortion, especially the use of sensationalized nontechnical terms which they saw as contributing to misleading narratives of abortion health care. For example, D014 discussed the use of the term "partial-birth abortion," which they implored is "not even a thing." According to The Guttmacher Institute, the term "partial-birth abortion" is a medically inaccurate term coined by the National Right to Life Committee [37]. The Cornell Legal Information Institute defines the practice as "an abortion in which the person performing the abortion— (A) deliberately and intentionally vaginally delivers a living fetus...for the purpose of performing an overt act that the person knows will kill the partially delivered living fetus; and (B) performs the overt act, other than completion of delivery, that kills the partially delivered living fetus" [38].

### RQ2: How Do They Navigate Myths When They Arise?

Interviewees expressed hesitancy at debunking abortion-related myths through outright fact-checking. D005 argued that they "don't like to try to fact check them [patients]. I just try to kind of nudge them towards openness."

Part of this hesitancy can be attributed to the intersection of the salience of abortion myths with growing distrust in medical institutions. Several interviewees highlighted the parallels between COVID-19 and reproductive health myths in the postpandemic climate, emphasizing an antigovernment, antiregulatory stance that contributes to myths about public health—propagated through nonmedical, sometimes adversarial sources. D005 discussed changing their entire approach when talking to patients under this newfound climate of medical distrust, while D008 noted their difficulty gaining back trust despite being an expert in their field:

> *And so there's the unknown. And then individuals hear things, and they think that's the truth. And then it's just misinformation. And then I think you also have a community of people that might be anti-medicine, anti-physician ever since Covid. And if anything does come out that has some type of credibility behind it, it is immediately dismissed because they just can't even go there because of lack of trust. And that's a whole other thing is trying to gain back trust of people to hear us to say, this is, this is how it works, this is how it is.*

Moreover, D008 argued institutional distrust may be particularly salient for marginalized patients seeking care, noting:

> *I think like fear is a much stronger emotion than others. And so I think it's easy if you hear something that instills fear in you like I think it's easy to like get stuck on that idea or that thought and focus on that especially if you are somebody who might not even trust the healthcare system like, who can you trust, you know, like, I think, patients for good reasons, like because of historical coercion, you know, forced sterilization, other things the healthcare system has perpetuated on marginalized populations.*

Such findings echo long-standing concerns around medical mistrust and its impact on maternal medicine, particularly within Black communities [39], in addition to rising concerns about how the overturn of Roe vs Wade will impact patient-provider trust [40].

Instead of directly debunking myths, interviewees advocated that a core part of their role (in health care provision and advocacy) was to understand the motivations underpinning the sharing of and belief in myths and to redirect patients toward better information. Interviewees saw this approach as a route to "non-judgmental care" (D006). To understand patients' information-seeking and reorient them away from misleading information, interviewees engage in several communications strategies, including providing evidence-based information from a variety of vetted online and offline sources and engaging in motivational interviewing (MI) techniques. Several interviewees highlighted the utility of providing patients with handouts or directing them to online resources in countering myths and allowing patients to access accurate information in their own time. Interviewees named the ACOG (American College of Obstetricians and Gynecologists), the National Abortion Federation, Planned Parenthood, and a host of locally specific abortion organizations as useful sites they directed patients toward. Several interviewees highlighted how overwhelming information-seeking and decision-making around abortion health care can be and how this necessitated that practitioners provide additional resources beyond the clinical appointment. As one interviewee argued:

> *I usually honestly print out an ACOG bulletin for them [patients]. I feel like that's helpful for me to be like, "hey this information is overwhelming when you're going through a conversation like this on a clinic visit"...I'll give them information from ACOG and then usually try to have them come back in a few days.* [D007]

In addition, MI, that is, asking open questions to explore a patient's perspectives and underlying rationale, emerged as a core practice across interviews. Interviewees summarized MI as follows:

> *I'll ask a little more about that belief, how they came to that belief, what their source was, how they feel about that particular piece of information.* [D004]

MI laid a foundation upon which practitioners felt more comfortable to dispel abortion-related myths. Interviewees saw the practice as less dismissive than simply fact-checking and afforded them the ability to build trust with their patients. Moreover, MI allowed abortion health care professionals to identify which patients are likely to change their minds, and when. D001 argued:

> *I basically do motivational interviewing like: "how willing and ready are you to think differently on this? Zero? Okay, moving on, not going to waste my breath.*

XSL•FO
RenderX

> *It's not worth my energy...[I have] limited time and resources with a patient that you have to choose to spend them wisely.*"

However, interviewees also named several complicating factors when navigating abortion-related myths when they arise in patient interactions. As highlighted previously, limited time with patients curtailed their ability to debunk myths both in terms of logistics—short consultation periods meant that debunking myths is not always a priority in caregiving—and in limiting the ability of health care professionals to build the trust necessary for debunking to be impactful. D003 summarized the impact of this limited interaction, explaining why it was unsurprising that patients trusted health care professionals less than those in their everyday circle:

> *I might be somebody with some fancy letters behind my name, but they're just meeting me and so if their auntie, their religious leader, their sibling, their best friend, you know some super trusted person. Like that carries a ton of weight with people and so it might just be that they may or may not believe me.*

Further, health care practitioners spoke about not always being aware of what information patients encountered, mostly due to them intentionally staying away from social media. The (nonmedical) abortion advocates interviewed were more aware of information spreading on social media, whereas common across the (medical) practitioners interviewed was a desire to stay away from social media and avoid abortion-related news coverage due to the mental health toll of being immersed in the subject matter in both their professional and personal lives. Practitioners knew from patient interactions that social media is playing a large part in information-seeking but had limited direct knowledge of the kinds of information that exist online. In these conversations, several interviewees named TikTok as a source of patient information-seeking. D014 argued:

> *TikTok is now the new doctor, [it] used to be Dr. Google. Now it's Dr. TikTok. I don't know how to dance! How am I supposed to compete with TikTok now that's where people are getting their information?*

As such, interviews demonstrated uncertainty among practitioners in engaging directly in fact-checking of abortion-related myths, predominantly because they do not always know the extent of misleading information a patient may have been exposed to and have not had the chance to sufficiently build trust and rapport with patients for fact-checking to be effective. D008 encapsulated such difficulties:

> *I think as a provider...I only know the surface level of what patients are even wondering about, because I wonder if patients even feel comfortable sometimes asking the questions they're really thinking.*

## RQ3: What Impacts Do They See Myths Having on Abortion Health Care?

Several interviewees noted how their perspectives were limited to the patients they encountered and that a hidden population of pregnant people who choose not to seek out health care providers or abortion advocates may be impacted by misleading information. D004 characterized antiabortion messaging as misinformation intentionally targeted to dissuade people from having abortions:

> *I think that there's a very intentional conscious output of misinformation that's driven by people who are against abortion access and do not want people to be having abortions.*

Further, interviewees highlighted how, despite sharing misinformed views on the safety of abortion, the potential of lasting consequences, the legality, and even the pain associated with procedures, patients still chose to go forward with terminations.

> *But patients have those fears because of that disinformation and present for care anyway, because they do not want to be, and cannot be, pregnant at that time.* [D003]

For those who do access care, abortion myths may act to amplify fear, cement stigma, and increase the emotional impacts of abortion health care [41]. In addition to the impacts of negative sentiments associated with abortion on patients, interviews highlighted how abortion myths have similarly led to negative implications for providers. Providers are subject to attacks on their credibility, on a professional and individual level, that emerge from misunderstandings about the nature of their abortion-related work. In addition to negatively impacting their well-being, such misinformed attacks have also led health care professionals to avoid abortion-related work. D001 argued that they would love to do abortions, but it "would be professional suicide where I'm at."

Interviewees spoke extensively about their physical safety and ensuring the physical safety of fellow abortion health care providers and advocates. One interviewee described a recent incident in which someone used a "shotgun to blast two holes in our [the clinic's] front door" (D006), another provider's clinic was burned down by an arsonist just before it was due to open (D009), and yet another recounted how their apartment had been broken into, trashed, and abortion-related messages were left on a whiteboard (D010). Interviewees saw such acts of violence and intimidation as associated with the sustained spread of myths within the antiabortion movement. Long-cemented myths about the nature of abortion procedures and about fetal development and viability have radicalizing effects for some, driving more extreme opponents to target abortion health care providers with violence and intimidation. Resultantly, across interviews, professionals highlighted the mental and physical toll of working within abortion health care and fears for their physical safety. In addition to concerns about physical safety, interviewees feared that the potential for violence could drive health care professionals out of abortion work. D006 argued:

> *That's [violence] the kind of thing that really has a potential for causing disruption. Right? If my colleagues quit because they're fearful for their own safety, then we can't see patients.*

At the extreme, abortion myths contribute to the escalation of antiabortion violence, and in the everyday, they reinforce long-standing stigma around abortion, abortion-seekers, and

XSL•FO
RenderX

abortion providers [42]. D001 described the community shaming they and their colleagues experienced, despite not performing abortions, because of misled beliefs about abortion health care:

> *I literally have patients who won't see me because they think I actually do abortions every day. My mentor here had someone stand up in church and yell at her and start screaming that she did abortions because she did D&Cs for miscarriages.*

Myths about abortion health care encompass a wide array of reproductive health topics and, notably, result in stigma around lifesaving, often emergency, care necessary for miscarriages. D001 described an interaction where they explained care options to a patient experiencing a stillbirth at 31 weeks, resulting in the patient sobbing that they did not "want to have an abortion" because they were equating the dilation and curettage procedure needed to safely complete a miscarriage with an elective abortion.

In contemplating the impacts of abortion myths and their interaction with societal stigma, interviewees also highlighted how these myths act as barriers to care because of the time needed to debunk myths and settle associated feelings of stigmatization.

> *If you spend more time sort of working to dispel this [stigma], this might delay someone getting an abortion.* [D002]

Delaying an abortion is not necessarily negative if patients are early enough in their pregnancy and live in a state that affords them options. However, recent and ongoing legal changes around gestational time limits complicate options for pregnant people; as D007 summarized, "if it turns into a second trimester, then they [may not] be able to find a place that does that."

The impact of abortion myths thus requires consideration of the legal framework for abortion, particularly post Dobbs. In addition to novel legal myths around abortion arising in the complicated landscape following the overturning of Roe vs Wade, interviews highlighted an uptick in abortion-related conversation, resulting in the potential for further amplification of abortion myths. D004 posited:

> *I don't know if ... there's necessarily more accurate information out there than there used to be, but there's definitely just more information in general, [more] talking about abortion.*

## Discussion

### Principal Findings

Interviews captured abortion professionals' perspectives on the types of myths circulating about abortion health care and the impact they are having on their work. The post-Dobbs context has brought to the fore a novel arena for abortion-related myths focused on legality. Interviewees expressed concern over the rapidly altering legal landscape around their work and how this leaves both the public and abortion professionals unclear on the legalities of specific abortion-related (and broader) procedures. Given this dynamic uncertainty, an undeniable information void has emerged for those seeking up-to-date information about the legality of abortion in their specific location.

An exploration of the nature of abortion myths in information-seeking, attempts to mitigate misleading information in the clinic, and the perceived impacts of abortion myths holds significant insights for models of SDM. Previous examinations of SDM in clinical settings explore the patient-side of SDM dynamics, in addition to the role of the practitioner in allowing for patient autonomy [43,44]. Interview findings cement the difficulties of engaging in SDM, and in particular, highlight how misleading and false information can undermine the foundations of patient competence, relatedness, and autonomy [29] central to SDT and thus at the core of effective SDM. In an information environment flooded with abortion-related myths, the ability of patients to engage autonomously in care-related discussions is further eroded, and the role of practitioners in debunking myths may complicate a patient's sense of autonomy. Moreover, uncertainty around abortion myths (specifically about legality) among practitioners highlights a need to attend further to the practitioner-side of SDM dynamics and not take for granted the competence and sense of autonomy felt by practitioners in their navigation of patient care plans.

Conversations also looked to understand practitioners' and advocates' perspectives on the information-seeking environment for abortion health care. Two key takeaways emerge from the analysis findings. First, online sources—including new social media sites such as TikTok—are primary sites for abortion-related information. However, professionals express concern over the credibility of information patients are accessing on these platforms, given the prevalence and diversity of myths they encounter in their work. Coupled with the fact that many interviewees acknowledged that they do not use social media, often purposefully to avoid personal overexposure to stigma and the negative emotional toll of encountering abortion myths, means they can only be reactive within patient interactions as they are not personally aware of the social media landscape. Emergent academic research is instructive in learning about the kinds of myths—for example, around safety, how to access and use oral abortive medications, legality, pain, etc [2,6]—but more work needs to be done to provide abortion health care professionals with knowledge about viral myths that does not require them to take on the individual burden of being active on social media. Further, as social media becomes a central authority for health information for patients, attending to the nature of health information accessible (and prominent) on social media platforms is crucial to building effective SDM.

Second, abortion health care professionals have developed useful communication strategies that enable productive conversations around myths. Instead of looking to directly fact-check or debunk myths presented to them, most interviewees described a communication process akin to MI—that is, asking open questions about the nature of the information presented and its utility or value to the patient. MI allows professionals to build a rapport with patients in addition to getting to the heart of why a specific abortion myth is particularly salient to that person. Accordingly, MI appears to be a core tool in enabling SDM to occur within a polluted information environment. Future

XSL•FO
RenderX

research should explore how MI techniques can be strengthened through proactive knowledge of what types of myths are spreading in the digital information environment and how MI impacts a patient's sense of autonomy in SDM relationships.

Finally, interviews capture a pernicious cycle of distrust. Distrust of abortion providers—often underpinned by stigma and/or misled views about abortion and providers—may lead information-seekers to look to online and alternative, mostly online, sources of information about abortion health care. In doing so, information-seekers encounter further myths about abortion procedures, the consequences or impacts of abortion, and the legality of abortion. These myths further fracture trust in abortion health care providers, and in the extreme, they can lead to the harassment of practitioners, as highlighted by several interviewees. Moreover, distrust at any level undermines the ability for SDM to occur, as patients are unwilling to engage in decision-making models that afford practitioners agency, and vice versa for practitioners concerned that patients cannot give informed consent without accessible, factual information. Effectively addressing distrust most often requires individual interactions [45], yet this is impossible to achieve if patients are too distrustful to talk to health care professionals about abortion, or even access health care at all.

### Limitations and Future Work

This research is necessarily limited by its focus on health care providers and advocates. Interviews capture the perspectives of abortion health care professionals, meaning that discussions of the impact of abortion myths are filtered through the experiences of these professionals, rather than directly capturing the lived experiences of those seeking abortion health care. Further, we recruited professionals with a preexisting awareness of the issue of misinformation in their field. While we anticipate that this is a common awareness within abortion health care, there may be practitioners who do not feel as acutely the impact of abortion myths on their work. As such, future research should supplement this understanding through interviews and/or survey work designed to document the spread and impact of abortion myths within patient and broader populations. In addition, interview research and subsequent analysis are grounded within the perspectives of the research team conducting this project. We recognize that our positionality, both as academic researchers and associated with our individual identities, may impact how interviewees responded to answers within the interview context and similarly biased our thematic analysis. Our research methodology is designed to reduce the impact of researcher bias, as is transparency in our reporting; however, research from outside of academia may identify additional or conflicting perspectives on abortion myths that we did not capture.

Further, as highlighted by practitioner concerns, this work only captures the perspectives of patients who access health care, excluding a large population of information-seekers who do not access abortion-related health care. Accessing this missing population is difficult, but future work should look to address this gap to gain further understanding of the impact of misleading abortion information. Finally, this work took place shortly after the Dobbs decision, wherein 13 states activated trigger laws that banned or heavily restricted abortion [46]. This immediate period can be characterized by heightened confusion, as states figure out how to enact said bans and as challenges have emerged around specific cases and restrictions more broadly. Longitudinal research should look to examine how abortion myths shift (in prevalence and nature), as the aftermath of the Dobbs decision becomes more embedded in the legal frameworks of low and no-access states.

## Conclusions

Misinformation, myths, and rumors thrive in conditions of uncertainty [47], and the legal complexity and uncertainty post Dobbs (Cohen et al, unpublished data, 2022) have created an environment ripe for the spread of novel and long-standing abortion myths. Moreover, the costs of myths within abortion health care are substantial. Interviews capture the strain abortion myths create in the ability of practitioners to pursue effective SDM with patients, including undermining trust in patient-practitioner relationships, delaying desired and/or essential health care to negative outcomes, and even causing violence and harassment directed at health care providers. The future of informed consent and effective SDM for abortion health care relies upon access to authoritative information. The current online information environment concerning abortion is muddled, with added complexity because of the idiosyncrasies of access according to geography and legality. Abortion myths are long-standing, underpinned by active disinformation spread by CPCs about the nature and impact of abortion procedures and by antiabortion activists. The resultant information environment is highly vulnerable to the spread of abortion myths that undermine patient autonomy. Accordingly, abortion health care exists as an important case study for understanding models of SDM in an era of information disorder. This project highlights how health myths undermine the conditions necessary for autonomy and self-determination within health decision-making, suggesting a need to update theories underpinning SDM to account for the realities of patient information seeking.

## Acknowledgments

The authors would like to thank the health care practitioners and advocates who gave their time and expertise to this research. Generative AI was not used in the preparation of this paper or broader project activities.

## Abstract

**Background:** The growing use of artificial intelligence (AI) chatbots for seeking health-related information is concerning, as they were not originally developed for delivering medical guidance. The quality of AI chatbots' responses relies heavily on their training data and is often limited in medical contexts due to their lack of specific training data in medical literature. Findings on the quality of AI chatbot responses related to health are mixed. Some studies showed the quality surpassed physicians' responses, while others revealed occasional major errors and low readability. This study addresses a critical gap by examining the performance of various AI chatbots in a complex, misinformation-rich environment.

**Objective:** This study examined AI chatbots' responses to human papillomavirus (HPV)–related questions by analyzing structure, linguistic features, information accuracy and currency, and vaccination stance.

**Methods:** We conducted a qualitative content analysis following the approach outlined by Schreier to examine 4 selected AI chatbots' (ChatGPT 4, Claude 3.7 Sonnet, DeepSeek V3, and Docus [General AI Doctor]) responses to HPV vaccine questions. These questions, simulated by young adults, were adapted from items on the Vaccine Conspiracy Beliefs Scale and Google Trends. The selection criteria for AI chatbots included popularity, accessibility, countries of origin, response update methods, and intended use. Two researchers, simulating a 22-year-old man or woman, collected 8 conversations between February 22 and 28, 2025. We used a deductive approach to develop initial code groups, then an inductive approach to generate codes. The responses were analyzed based on a comprehensive codebook, with codes examining response structure, linguistic features, information accuracy and currency, and vaccination stance. We also assessed readability using the Flesch-Kincaid Grade Level and Reading Ease Score.

**Results:** All AI chatbots cited evidence-based sources from reputable health organizations. We found no fabricated information or inaccuracies in numerical data. For complex questions, all AI chatbots appropriately deferred to health care professionals' suggestions. All AI chatbots maintained a neutral or provaccine stance, corresponding with scientific consensus. The mean and range of response lengths varied [word count; ChatGPT: 436.4 (218-954); Claude: 188.0 (138-255); DeepSeek: 510.0 (325-735); and Docus: 159.4 (61-200)], as did readability [Flesch-Kincaid Grade Level; ChatGPT: 10.7 (6.0-14.9); Claude: 13.2 (7.7-17.8); DeepSeek: 11.3 (7.0-14.7); and Docus: 12.2 (8.9-15.5); and Flesch-Kincaid Reading Ease Score; ChatGPT: 46.8 (25.4-72.2); Claude: 32.5 (6.3-67.3); DeepSeek: 43.7 (22.8-67.4); and Docus: 40.5 (19.6-58.2)]. ChatGPT and Claude offered personalized responses, while DeepSeek and Docus lacked this. Occasionally, some responses included broken or irrelevant links and medical jargon.

**Conclusions:** Amidst an online environment saturated with misinformation, AI chatbots have the potential to serve as an alternative source of accurate HPV-related information to conventional online platforms (websites and social media). Improvements

XSL•FO
RenderX

in readability, personalization, and link accuracy are still needed. Furthermore, we recommend that users treat AI chatbots as complements, not replacements, to health care professionals' guidance on clinical settings.

artificial intelligence; health communication; papillomavirus vaccines; large language models; qualitative research

## Introduction

Globally, human papillomavirus (HPV) was responsible for an estimated 620,000 new cancer cases in women and 70,000 in men in 2019 [1]. In the United States, HPV causes roughly 48,000 new cancer cases annually and is the most common sexually transmitted infection [2,3]. Although effective vaccines are available [4], uptake among eligible adults remains suboptimal. In 2022, only 57.7% of eligible women and 34.8% of eligible men (ages 19-26 years) had received more than one dose of the HPV vaccine [5]. Adequate knowledge about HPV vaccination plays a critical role in promoting vaccine uptake among eligible adults [6].

The internet has become a widely used resource for people seeking information on health-related topics, including the HPV vaccine [7,8]. Information about the HPV vaccine is a popular online search topic in the United States, with Google Trends indicating an annual search traffic growth of 8.6% from 2010 to 2021 [8]. Research has also demonstrated that HPV vaccine communication uses specific search terms (eg, #HPV and #HPVVaccine) that are prevalent on online social media platforms such as Instagram [9,10], YouTube [11], and Twitter (now known as X) [12]. While these online platforms serve as a powerful tool for disseminating health information, they also provide a potential space for inaccurate information to spread, including inadvertently false information (misinformation) and deliberate falsehoods (disinformation) [13,14]. On Instagram, a primarily visual platform, approximately 55.8% of postings regarding HPV were provaccine, whereas 42.2% had an antivaccine perspective [9]. Additionally, the hashtag *#Gardasil* on Instagram has been used to circulate conspiracy theories and unsupported and false claims of HPV vaccine-related injuries [10]. YouTube, a popular video-centric social media space, users-generated content regarding the HPV vaccine showed a greater number of likes in videos with a negative tone compared to those with a positive tone [11]. On X, a platform for brief text-based posts, content containing erroneous information regarding the HPV vaccine were 5.44 times more likely to be shared than educative content [12], indicating that inaccurate posts received higher audience engagement. Given these trends, the World Health Organization (WHO) has identified the "uncontrolled dissemination of misinformation," particularly on the topic of vaccination, as one of the most pressing health challenges for the coming decade [15].

The quality of online information related to the HPV vaccine could potentially influence vaccine decision-making [16]. Individuals who seek health information online showed lower acceptance of the HPV vaccination, which may be associated with discouraging information found online [17]. Furthermore, the overwhelming amount of information available online can lead to doubt and anxiety, making it challenging for individuals to make informed health decisions [18]. The abundance of information, much of which contains inaccurate information, may also contribute to low levels of HPV knowledge, as literature indicated that only 36.1% of young adults in the United States were aware that HPV causes more cancers than just cervical cancer [19]. This is concerning because knowledge of HPV correlates positively with HPV vaccination intention and uptake [20-22].

In recent years, there has been a growing inclination toward using internet-based artificial intelligence (AI) chatbots for accessing health-related information, including topics related to sexual health [23-26]. AI chatbots are digital systems created to mimic conversations with humans through text or voice, and their application in health care is rapidly expanding, ranging from answering general patient questions about sexual health to supporting medication adherence [25,27]. Large language models (LLMs) are AI tools built on multilayer recurrent neural networks and trained on extensive datasets of natural language to produce text that resembles human language [28]. AI chatbots are powered by LLMs, which are trained to generate human-like responses [29]. This generative ability relies on deep learning techniques, systems that mimic how the human brain handles information using neural networks to find patterns in data [30-32]. Examples of currently available AI chatbots based on deep learning include ChatGPT and DeepSeek [30,31,33], which analyze user input and then offer intelligent, contextually relevant responses for general purposes. In contrast, Docus is specifically designed to analyze health information, offer tailored health management, and provide laboratory test interpretations to facilitate health-related decision-making [34].

AI chatbots like ChatGPT are inevitably being used in support of health care settings, even though they were not originally intended for such purposes [35]. This is partly attributed to the user-friendly nature of LLMs used in the AI chatbot, making it convenient for individuals seeking health information [36]. Additionally, young adults aged <25 years and those identifying as technologically savvy had higher levels of AI chatbot acceptability [27,37]. However, it is important to note that the accuracy of AI chatbots' responses, which partly depends on the quality of their training data, is compromised in medical contexts due to the lack of specific training data in medical literature [35,38]. The inability of AI chatbots to clarify their decision-making process presents challenges in identifying and rectifying potential biases or errors [35,39,40].

Several studies have revealed complex and often contradictory findings regarding the quality of AI chatbots' responses on health-related topics. A study demonstrated that ChatGPT produced higher-quality responses than those provided by physicians from patients' questions pooled from a social media

XSL•FO
RenderX

forum [41]. A specific knowledge-based chatbot trained exclusively on HPV vaccine information outperformed general-purpose generative pretrained transformer models in both accuracy and relevance [42]. In tasks involving physician-generated medical questions, responses generated from ChatGPT 3.5 and ChatGPT 4 were rated as "nearly all correct" or "completely correct" 50% of the time [43]. However, for these, the median accuracy scores exceeded mean scores, suggesting the presence of occasional but substantial wrong answers [43]. Bing Copilot's responses to queries about prescription medications in the United States were found to be difficult to read, as indicated by low Flesch Reading Ease Scores, raising concerns about its readability and accessibility [44]. Although prior studies have evaluated AI chatbot responses, they typically focused on a single system, using physician-generated questions or purpose-built chatbots, which may not capture the full range of real-world interactions of various AI chatbots from the perspective of general public users.

While AI chatbots stand out as a remarkable technological feat, their application in providing health information raises concerns regarding the perpetuation of misinformation or inaccurate recommendations and therefore requires attention. To address this, the primary aim of this study is to investigate how 4 selected AI chatbots respond to HPV vaccine-related questions, with wording modified to reflect the language commonly used by young adults (22 years). The secondary aim of the study was to examine the content's structure and patterns, linguistic features, information accuracy, information currency, and the AI chatbots' stance on HPV vaccination, whether supportive, neutral, or contrary. This study distinguishes itself by conducting a qualitative content analysis of a diverse sample of both general-purpose and health-specific AI chatbots on HPV-related topics. By using questions tailored to the language of young adults, it provides a more ecologically valid assessment of AI chatbots' performance and their utility in the real world.

## Methods

### Question Set

We created semistructured questions adapted from the Vaccine Conspiracy Beliefs Scale (VCBS) items [45] and Google Trends query [46] as prompts asked in AI chatbots. The original VCBS consists of seven statements: (1) vaccine safety data are often fabricated, (2) immunizing children is harmful and this fact is covered up, (3) pharmaceutical companies cover up the dangers of vaccines, (4) people are deceived about vaccine efficacy, (5) vaccine efficacy data are often fabricated, (6) people are deceived about vaccine safety, and (7) the government is trying to cover up the link between vaccines and autism. We modified the original VCBS scripts to reflect language commonly used by young adults and tailored the content to focus specifically on the HPV vaccine (Multimedia Appendix 1). We also used Google Trends [46], a publicly accessible web service, to capture search-term volume for the Google search engine over time. In order to investigate potential questions regarding the HPV vaccine (search term: HPV vaccine) during the past 12 months (from January 1, 2024, to January 1, 2025). Google Trends recorded both top queries (the most popular or "evergreen" inquiries within the specified search parameters, maintaining relative consistency over time) and rising queries (the inquiries with the most substantial increase in search frequency compared to the previous time period, signifying a surge in relative interest) [46]. We identified HPV-related search terms from both top and rising queries and rephrased them into questions (Multimedia Appendix 1). Finally, 2 researchers (EC and MD) within the young adult age group reviewed the question set and provided feedback to ensure clarity and relevance to their communication style.

### Sample and Data Collection

We collected 8 conversations (2 each from ChatGPT 4, Claude 3.7 Sonnet, DeepSeek V3, and Docus [General AI Doctor]) of AI chatbots' responses to an HPV-related question set. The versions used for ChatGPT, Claude, and DeepSeek were the latest available without a paid subscription at the time of testing, while Docus was tested using the latest version available with a paid subscription. Our researchers started the "chat" by introducing users' assigned sex at birth (male or female) and age (22 years old) in order to simulate a young adult population. Supervised by female (LMS-R, KJL, NMR, and MLK) and male (RJD and RDH) faculty members, all of whom have PhDs, 3 trained female public health graduate students (AL, MD, and EC) gathered 2 conversations from each AI chatbot, using different IP addresses, on different days, and with different sex enactments, for a total of 8 conversations from all AI chatbots. We copied and pasted those responses into a word processor and then uploaded them into HyperRESEARCH 4.5.4 (Researchware, Inc), a qualitative data analysis software. Since no human participants were involved, we did not establish a relationship prior to the commencement of the study nor created field notes. Furthermore, we only followed our predefined questions set, without introducing any off-topic or unrelated prompts into the AI chatbots during the "chat." No one else was present during data collection, except for the research team members. The duration of each collection ranged from 14 minutes to 27 hours and 5 minutes; one AI chatbot's unpaid subscription enabled a wait time after inputting several prompts, and there were server errors that prolonged the data collection process.

### Rationale for Selecting the Reviewed AI Chatbots

The selected AI chatbots represented a diverse range of popularity, accessibility, country of origin, response update method, and intended use. ChatGPT had the highest global daily visits, while DeepSeek and Claude had lower visits [47]. ChatGPT was chosen primarily because it has the highest user traffic, making it likely that a significant number of young adults also engage with the platform. Due to the sudden surge in popularity of DeepSeek during the study period, as well as its origin in China, DeepSeek was selected for inclusion. Other than Docus (General AI Doctor), users could access reviewed AI chatbots without a subscription. ChatGPT and Claude were based in the United States, DeepSeek originated from China, and Docus originated from Armenia. We distinguished AI chatbots' update methods between dynamic and static by examining whether each AI chatbot accessed real-time updated online information (dynamic) or relied on fixed, pretrained

XSL•FO
RenderX

knowledge (static). We assessed the update methods by asking each AI chatbot, "What is the most recent information you can access?" ChatGPT responded with the current date (February 5, 2025), indicating dynamic updates, while Claude (October 2024), DeepSeek (June 2024), and Docus (October 2023) provided fixed cutoff dates, showing they rely on static knowledge. Other than Docus, which was developed specifically to provide health-related consultations, other AI chatbots were developed for general purposes (Table 1). Therefore, to add nuances to our study, Docus was included in this study because of its specific model.

**Table 1.** Artificial intelligence chatbots' characteristics for sample selection.

| | ChatGPT 4 | Claude 3.7 Sonnet | DeepSeek V3 | Docus (General AI Doctor) |
|---|---|---|---|---|
| Global daily visit [47] | 100-150 million | <15 million | <50 million | __[a] |
| Access | Free | Free | Free | Paid subscription |
| Originated from | United States | United States | China | Armenia |
| Information update methods | Dynamic | Static | Static | Static |
| Purpose | General | General | General | Health consultation |

[a]Not available.

## Data Analysis

We conducted a qualitative content analysis following the approach outlined by Schreier [48]. Initially, 3 researchers with qualitative methods training (AL, EC, and MD) thoroughly reviewed all AI chatbot responses to gain a general understanding of the data. During this phase, we identified preliminary ideas that could serve as potential code groups and codes. We adopted a deductive, concept-driven approach to develop initial code groups based on our research objectives and question set. Within these groups, we applied an inductive, data-driven approach to generate codes based on all AI chatbot responses. The code-building process involved the use of subsumption and progressive summarizing strategies. As we reviewed the responses, we identified a distinct idea and checked whether an existing code captured this idea. If the idea was already represented, we ensured the code was grouped under the appropriate code group. If not, we created a new code to reflect the previously uncaptured idea. This iterative process continued until no new ideas emerged, thereby automatically meeting the criteria of saturation.

After generating initial code drafts, 3 researchers (AL, EC, and MD) collaborated to compile code groups and codes into a single comprehensive codebook (Multimedia Appendix 2). We reviewed the codebook to ensure that each code was mutually exclusive, and the codebook was collectively exhaustive to represent our data. A faculty member (LMS-R) provided feedback on the codebook before its application. To enhance consistency in code application, researchers (AL, EC, and MD) met and pilot-coded a subset of the data. Due to the straightforward and descriptive nature of the codebook, no coding disagreements arose. During code application, 2 independent researchers double-coded each AI chatbot response. Any discrepancies in coding were discussed and resolved.

We analyzed AI chatbot responses based on structure and patterns, linguistic features, accuracy, information currency, and stance on the HPV vaccination. Structure and pattern captured the structural and content-related elements of responses, including organization format (eg, paragraphs, bullet points, and numbered lists), logical reasoning and relevance of information to the question, details and length, and how the response concluded (eg, with a summary, follow-up question, or suggested next steps). Linguistic features included the use specific terminology, use of user-centric (referencing users' age or sex) and emotional validation sentences (acknowledging user concerns and feeling or providing reassurance), use of language to convey statistics (eg, numeric vs relative terms), and assessed readability using the Flesch-Kincaid Grade Level and Reading Ease Score to determine suitability for lay audiences [49]. The Flesch-Kincaid Grade Level indicates the educational level required to understand a text passage, ranging from fifth grade (level 5) to college graduate (level 12+) [50,51]. The Flesch-Kincaid Reading Ease Score measures how easy it is to read a text passage, with scores ranging from 0 to 100 and higher scores indicating greater ease [52]. We adapted cutoff scores of ≤8 for the Flesch-Kincaid Grade Level and ≥50 for the Reading Ease Score to determine the readability for lay audiences [49]. Accuracy was assessed based on factual claims and numerical data in the AI chatbot responses, considering their alignment with current scientific evidence and HPV vaccine guidelines, including source credibility from reputable organizations (eg, the Centers for Disease Control and Prevention [CDC] and WHO) or peer-reviewed journals. Sources cited or links included in responses were manually checked to verify their credibility and to ensure they directed users to the information referenced in the AI chatbot's response. Our research team consists of experts in sexual health (AL [53,54], KJL [55,56], RDH [57,58], and MLK [59]), health communication (AL [60,61], LMS-R [62,63], RDH [64], and MLK [65]), LLM and AI (LMS-R [66,67]), and HPV vaccination (AL [54], NMR [68], and MLK [69]), ensuring content accuracy. Content was considered current if information or fact sheets were published within 12 months or studies published within 5 years from data collection. HPV vaccination stance was assessed from the response to each question and categorized as pro, neutral, or contra.

The Flesch-Kincaid scores, how the response concluded, and vaccination stance were also assessed from each AI chatbot's response to a question. However, we did not assess Flesch-Kincaid scores for responses containing links to avoid

XSL•FO
RenderX

potential skewed results. Since each response set included 21 to 24 questions, this resulted in a corresponding range of 21 to 24 data points per set for conclusion style and vaccination stance, while Flesch-Kincaid scores had a range of 9 to 21 data points for Grade Level and Reading Ease scores.

### Ethical Considerations

As no human subjects were involved, ethics board reviews were not required. Furthermore, this study adheres to the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist. Specifically, our Methods section includes information from domain 1 (research team and reflexivity), domain 2 (study design), and parts of domain 3 (analysis and findings). The remainder of domain 3 is reported in our Results section.

## Results

We collected the 8 conversations between February 22 and 28, 2025, using 21-24 questions modified from VCBS items [45] and Google Trends queries [46]. Numbers following AI chatbot names (eg, Claude_1 and Claude_2) indicate dataset identifiers used to distinguish different responses from the same AI chatbots.

### Structure and Pattern

In structure and pattern of the responses, we observed organization format, logical reasoning, information relevance, details and length, and conclusion styles of each response.

#### *Organization*

In terms of the sentence organization format when answering one question, all AI chatbots responded more often using bulleted or numbered lists, or a combination of both, instead of paragraph-style responses. ChatGPT more frequently used bulleted points nested under a numbered list than other formatting styles. Claude more often used bulleted points but sometimes responded using only numbered lists or bullet points under numbered lists. DeepSeek typically used an organization of bulleted points under a numbered list, and at times used bulleted points nested within other bulleted points under a numbered list:

> *1. For Individuals Aged 9-14 Years*
>
> - Number of Doses: 2 doses
> - Schedule:
>   - First Dose: Given at the start of the series. Second Dose: Given 6-12 months after the first dose.
>
> *This age group has a stronger immune response to the vaccine, so only two doses are needed for full protection.* [DeepSeek_2]

Docus more frequently presented responses with bullets nested under other bullets or under numbers, but it also occasionally provided responses in paragraph style:

> *Individuals who experience a life-threatening allergic reaction, such as anaphylaxis, after receiving an HPV vaccine should not continue with the vaccine series. It is crucial to consult a healthcare provider for personalized guidance and to discuss alternative options for protection against HPV-related diseases. Your healthcare provider can assess the situation and provide the best advice tailored to your specific medical needs.* [Docus_1]

#### *Logic and Relevance of Information*

All AI chatbots provided logical reasoning to support their answers, often using phrases such as “Here’s why:” [Claude_1, ChatGPT_1, DeepSeek_2, and Docus_1], “Why trust this information?” [ChatGPT_2], and “Why the difference in doses?” [DeepSeek_1]. These explanations were followed with relevant, evidence-based information to justify their responses. For example, when a user asked, “Is the info about the HPV vaccine’s safety even real, or is it just fake?,” AI chatbots offered a clear rationale grounded in scientific research:

> *7. Why Trust This Information?*
>
> *The evidence supporting the HPV vaccine’s safety comes from scientific consensus, not just anecdotal reports or single studies. The vaccine has been in use since 2006, and the data from over a decade of global use demonstrates its positive impact on public health.* [ChatGPT_2]
>
> *The HPV vaccine underwent rigorous clinical trials before approval, involving thousands of participants to ensure its safety and efficacy.* [Docus_2]

#### *Details and Length*

Some AI chatbots included additional details that, while related, were not directly relevant to the question asked, making their responses unnecessarily long. For instance, when DeepSeek was asked, “Why is the HPV vaccine not recommended after 26 years old?,” it not only explained the main reason but also introduced a new topic: “What Does ‘Shared Clinical Decision-Making’ Mean?” [DeepSeek_2]. Similarly, when asked, “Does the HPV vaccine also protect against other STDs like HIV or chlamydia?,” Docus veered into broader prevention advice, stating: “To reduce the risk of other STDs, including HIV and chlamydia, it’s important to practice safe sexual behaviors, such as...” [Docus_2].

On the other hand, we identified instances where AI chatbot responses did not provide sufficient detail. For example, ChatGPT stated, “Early safety reviews identified rare instances of anaphylaxis, approximately 1.7 cases per million doses, and episodes of syncope (fainting), often related to anxiety” [ChatGPT_1], without clarifying what was meant by “anxiety,” such as fear of needles or an underlying anxiety disorder which could be important for user understanding. Similarly, Claude mentioned, “There’s no evidence of systematic deception about HPV vaccine effectiveness” [Claude_1] but did not provide an explanation of what systematic deception means.

In our sample of 4 AI chatbots, we found that ChatGPT and DeepSeek tended to provide longer and more superfluous responses to questions than Claude and Docus. In this context, superfluous refers to answers that included excessive or unnecessary details and lacked straightforwardness. DeepSeek (510.0 words) had the highest mean word count for responses to each question, while Docus (159.4 words) had the lowest.

XSL•FO
RenderX

### *Conclusion Styles*

To conclude their responses to a question, AI chatbots included a summary, follow-up question, further direction, or a combination of these. All AI chatbots frequently provided summaries and often used starting phrases like "The bottom line:" [ChatGPT_1], "In summary" [ChatGPT_2], or "Key takeaways" [DeepSeek_2]. We did not find any responses from DeepSeek or Docus that concluded only with a follow-up question, while ChatGPT and Claude occasionally ended their responses with follow-up questions, such as:

> *Would you like to dive deeper into any specific studies or concerns about the vaccine?* [ChatGPT_1]
>
> *Would you like more specific information about any of these side effects?* [Claude_2]

AI chatbots often provided further directions that typically encouraged users to consult a "healthcare provider" [ChatGPT_2, Claude_2, DeepSeek_1, and Docus_2] or refer to trusted sources like the "CDC or WHO" [DeepSeek_1 and Docus_1] to confirm users' understanding or if users would like to look for further information.

## Linguistic Features

The AI chatbots exhibited diverse linguistic features, from the use of jargon or complex medical terms to providing sentences to foster users' emotional validation. Not all AI chatbots provided responses tailored to individual users, and emotional validation varied. Some AI chatbots had more understandable responses than others, as evidenced by Flesch-Kincaid scores.

### *Terminology*

All AI chatbots occasionally used jargon or medical vocabulary that was infrequently used in lay audience's everyday speech. Lay users would need to seek out the definitions in order to fully comprehend the provided sentences. Uncommon terminology used included "cervical epithelial neoplasia" and "primary ovarian insufficiency" [ChatGPT_1], "immunosuppressive medications" and "post-market surveillance" [ChatGPT_2], "precancerous lesion" [Claude_1], "vertical transmission" [Claude_2], "salicylic acid or cryotherapy kits" [DeepSeek_1], "fomite transmission" [DeepSeek_2], "anaphylaxis" [Docus_1], and "oropharynx" [Docus_2]. Furthermore, all 4 AI chatbots used the term "gender" when addressing questions on the recipients of the HPV vaccine, despite "sex" being the more precise term in this context, as it pertains to biological distinctions. For instance, Docus remarked:

> *HPV also affects males and can lead to other types of cancers and genital warts. Therefore, the vaccination recommendations have expanded to include both genders.* [Docus_2]

### *User Centric and Emotional Validation*

DeepSeek and Docus did not provide a user-centric experience, indicated by not incorporating essential users' personal information in their responses such as age or sex when applicable. Conversely, ChatGPT and Claude incorporated this contextual information. In response to the question, "How many shots do I need to get for the HPV vaccine?," DeepSeek and Docus offered a broad explanation in correspondence to the age of HPV vaccine initiation and did not provide a personalized reference. ChatGPT provided a specialized segment, "Is it too late to receive the HPV vaccine at 22?" [ChatGPT_1], and Claude stated, "Since you're 22, you would follow the 3-dose schedule" [Claude_2]. Related to emotional validation, all AI chatbots offered a degree of emotional affirmation, particularly when addressing apprehension around vaccine safety and efficacy. Docus exhibited the least affirming tone for emotional validation, providing only the short "Certainly!" [Docus_1]. Conversely, ChatGPT, Claude, and DeepSeek used more detail and affirming language, likely fostering a sense of acknowledgment among users, for instance:

> *That's a great question, and it's totally understandable to want to be sure about the safety of any vaccine.* [ChatGPT_2]
>
> *It's normal to have questions about vaccine safety.* [Claude_2]
>
> *It's understandable why some people might feel like they've been lied to about HPV vaccine safety.* [DeepSeek_2]

Additional quotes related to emotional validation can be found in Multimedia Appendix 3.

### *Relative vs Numeric*

All AI chatbots used either relative or exact numerical statistics depending on whether precision was necessary. For instance, when citing specific studies, ChatGPT presented comprehensive numerical data:

> *Research published in The BMJ highlighted that women vaccinated between ages 12 and 13 showed an 83.9% decrease in cervical cancer rates and a 94.3% reduction in cervical intraepithelial neoplasia grade 3.* [ChatGPT_1]

In a similar vein, when addressing HPV vaccine recommendations, AI chatbots used precise age ranges and dosage quantities instead of ambiguous phrases such as "teens" or "some doses." For example:

> *Two doses: for those starting the vaccine series at age 9-14.* [ChatGPT_2]
>
> *Ages 9-14: Recommended for routine vaccination (2-dose series).* [Claude_1]
>
> *For those aged 9-14: Two doses are recommended, with the second dose given 6-12 months after the first.* [DeepSeek_2]
>
> *For those starting the vaccine series before age 15, two doses are recommended.* [Docus_1]

Conversely, when precise numbers were unnecessary to understand the context, AI chatbots used relative terminology, such as "nearly," "some," or "hundreds," exemplified by statements like:

> *In clinical trials, the vaccine was nearly 100% effective at preventing precancerous cervical lesions.* [DeepSeek_2]

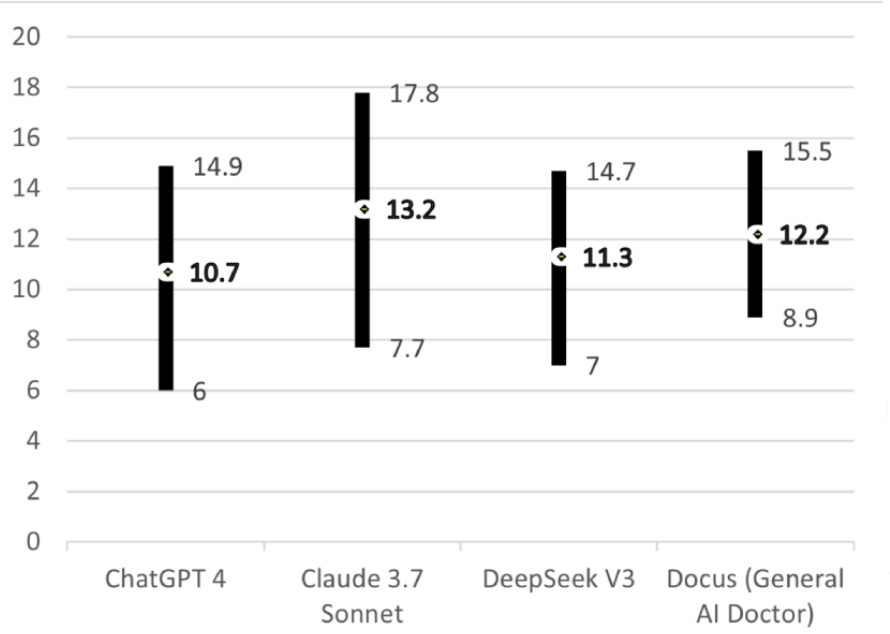
XSL•FO
RenderX

> *The HPV vaccine has been the subject of hundreds of independent studies from universities, research hospitals, and international health organization.* [ChatGPT_1]

### *Flesch-Kincaid Scores*

Overall, ChatGPT provided responses with the lowest mean Grade Level and the highest Reading Ease Score among the 4 AI chatbots. In contrast, Claude's scores had the highest mean Grade Level and lowest mean Reading Ease Score, suggesting that its responses may be more complex than those of the other AI chatbots and potentially less accessible to a lay audience (Figures 1 and 2).

**Figure 1.** Artificial intelligence chatbots' Flesch-Kincaid Grade Level (range and mean).



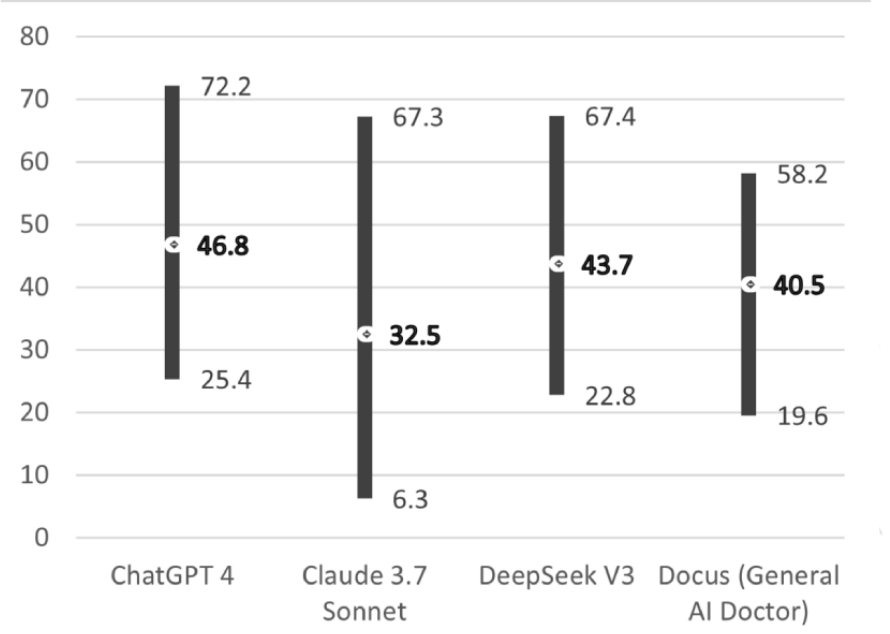


**Figure 2.** Artificial intelligence chatbots' Flesch-Kincaid Reading Ease Score (range and mean).

## Accuracy

To examine accuracy, we observed the credibility of links provided in the responses, data accuracy, and intersentence coherence.

### *Information Credibility*

When citing links, all AI chatbots included functional links to real, existing websites from reputable organizations, such as the WHO [ChatGPT_1], the American College of Obstetricians and Gynecologists [Claude_1], the European Medicines Agency [DeepSeek_2], and the Centers for Disease Control and

XSL•FO
RenderX

Prevention (CDC) [Docus_2]. We found no fabricated or nonexistent links, with no fake studies, fact sheets, or infographics generated. All linked studies were from peer-reviewed academic journals, including the *BMJ* [ChatGPT_1] and the *New England Journal of Medicine* [Docus_1]. However, some of the links provided, particularly those from CDC, were no longer functional at the time of data analysis and led to broken pages displaying "Page Not Found" errors. Furthermore, in a few instances, the AI chatbot responses included links unrelated to the topic asked. For example, when a user requested information about HPV vaccine safety, ChatGPT provided a link to a page on feminizing hormone therapy [70], which contained no information about the HPV vaccine. Similarly, when asked for a study on HPV vaccine safety, Docus linked to a measles vaccine study [71], which also had no relevance to the HPV vaccine (Table 2).

**Table 2.** Comparison of 4 artificial intelligence (AI) chatbot responses based on selected measurements.

| Chatbots | ChatGPT 4 | Claude 3.7 Sonnet | DeepSeek V3 | Docus (General AI Doctor) |
|---|---|---|---|---|
| **Structure and pattern** | | | | |
| Organization format[a] | Bulleted points nested under numbered list | Bulleted points | Bulleted points nested under numbered list | Bulleted points nested under bulleted points |
| Word counts per question, mean (range) | 436.4 (218-954) | 188.0 (138-255) | 510.0 (325-735) | 159.4 (61-200) |
| Conclusion styles[b] | Summary and further direction | Summary and further direction | Summary and further direction | Further direction |
| **Linguistic features** | | | | |
| Jargon/medical terminology[c] | Immunosuppressive medications, postmarket surveillance | Precancerous lesion prevention, vertical transmission | Cryotherapy kits, fomite transmission | Anaphylaxis, oropharynx |
| Personalization[d] | Yes | Yes | No | No |
| Emotional validation[e] | "That's a great question, and it's totally understandable to want to be sure about the safety of any vaccine." | "It's normal to have questions about vaccine safety." | "It's understandable why some people might feel like they've been lied to about HPV vaccine safety." | "Certainly!" |
| **Accuracy** | | | | |
| Links credibility[f] | Yes | Yes | Yes | Yes |
| Fabricated sources[g] | No | No | No | No |
| Incorrect links[h] | Yes | No | No | Yes |
| Statistics accuracy[i] | Yes | Yes | Yes | Yes |
| Currency[j] | No | Yes | Yes | Yes |
| Vaccination stance[k] | Pro | Neutral | Pro | Pro |

[a]Most frequently used response structure to a question (eg, using bullet points, numbered lists, paragraphs, or combinations).

[b]Most frequent way responses ended to each question (eg, with summary, follow-up questions, further suggestion, or combinations).

[c]Example of jargon/medical terminology used.

[d]Referenced user's sex and ages when necessary.

[e]Example of affirming language used to acknowledge user's feeling.

[f]Always provided real link from reputable organization or peer-reviewed journal.

[g]Ever provided link/information that are made up or nonexistent.

[h]Ever provided links that are not related to the discussed topic.

[i]Always provided/cited accurate statistic numbers based on scientific evidence.

[j]Always provided information or fact sheets that were not older than 12 months or studies not older than 5 years.

[k]Most frequent stance on HPV vaccination per question (eg, contra, neutral, or pro).

### *Data Accuracy and Coherence*

We found no inaccuracies in the numerical data or statistics provided by the AI chatbots in our sample. Additionally, when responses included links to studies, the statistical values cited in the responses matched those in the referenced sources. However, we did identify an instance of internal inconsistency in Claude's and DeepSeek's responses. Claude initially stated, "Based on extensive safety monitoring and research, there aren't specific demographic groups who systematically experience

XSL•FO
RenderX

significantly more problems with HPV vaccines" [Claude_2]. Yet, it immediately followed with, "However, there are a few considerations worth noting:" and listed groups who should avoid the vaccine, such as individuals with yeast allergies. Similarly, DeepSeek mentioned, "There are currently three vaccines available: 1. Gardasil 9: Protects against 9 types of HPV (6, 11, 16, 18, 31, 33, 45, 52, and 58). It is the most commonly used vaccine in many countries" [DeepSeek_2], but only mentioned Gardasil 9 and failed to elaborate on the other two vaccines referenced in the previous sentence or specify that they are not all available worldwide. For example, only Gardasil 9 is currently available in the United States.

### Currency

Some of the studies cited by ChatGPT were more than 5 years old when addressing whether the HPV vaccine affects fertility. While these studies were not outdated, we applied a 5-year cutoff as a point of comparison to assess the currency. For example, ChatGPT referenced, "A 2018 study in Pediatrics" and "a 2019 Australian study" [ChatGPT_1]. However, we did not find any information or fact sheets that were older than 12 months or studies older than 5 years in responses from the other AI chatbots.

### HPV Vaccination Stance

Across all responses, none of the AI chatbots expressed opposition to HPV vaccination, as the tone remained either neutral or supportive. Even when asked whether individuals with a history of life-threatening allergic reactions to the HPV vaccine should get vaccinated, none of the AI chatbots directly advised against it. Instead, they consistently recommended consulting health care professionals. Examples include:

> *Talk to an allergist or immunologist before getting vaccinated.* [ChatGPT_1]
>
> *Your healthcare provider can help assess the specific situation and determine whether it was truly a severe allergic reaction or another type of side effect that might not prevent further vaccination.* [Claude_1]
>
> *...the decision to receive the HPV vaccine requires careful consideration and consultation with a healthcare provider.* [DeepSeek_1]
>
> *Your healthcare provider can assess the situation and provide the best advice tailored to your specific medical needs.* [Docus_1]

## Discussion

### Principal Findings

Our study examined the response of 4 AI chatbots (ChatGPT 4, Claude 3.7 Sonnet, DeepSeek V3, and Docus [General AI Doctor]) in answering HPV vaccine–related questions, with an emphasis on structure and patterns, linguistic features, accuracy, information currency, and stance on HPV vaccination. Our results showed that while all AI chatbots responded based on scientific research and reputable websites, there were some variations in response length, details, readability, and personalization. All of the AI chatbots presented valid scientific references without fabrication of sources, but there were instances of AI chatbots providing broken or irrelevant links. While statistical data were accurate for all AI chatbots, several showed inconsistencies across sentences and lack of informational completeness. Although the AI chatbots did not disseminate incorrect information, their utility in public health communication is still mixed in effectively providing information about HPV vaccination in a young adult population.

Our AI chatbots sample provided responses based on scientific data, cited websites of reputable organizations, and displayed no evidence of falsification of sources. These findings imply that AI chatbots can offer factually accurate information on the HPV vaccine, similar to recent studies that discussed AI chatbots' inclusion of accurate medical information in their responses [43,72]. A systematic review also highlighted that AI chatbots have primarily been used to deliver factual information in response to users' vaccine-related questions [73]. However, when we verified the links provided in the responses, we occasionally discovered broken or irrelevant links. The majority of the broken links came from the CDC website, which may have been restructured in accordance with directives from the current administration [74,75]. Consequently, certain links that were operational at the time of data collection may have become unreachable during later analysis. As public health information is often shaped by political leadership, static AI chatbot content may quickly become outdated if it is not updated rapidly. Despite finding fewer than 5 irrelevant links, this instance may increase apprehension regarding the credibility of these AI chatbots as a medium to disseminate health information. Although these irrelevant links were not fabricated, as is often a concern in studies examining AI chatbot "hallucination" where responses contain made-up references that do not correspond to any existing studies [76,77], they still pose challenges. Users who attempt to verify information through these links may experience reduced trust or increased frustration when attempting to make informed health decisions.

The readability of AI chatbot responses in our sample, assessed using Flesch-Kincaid's Grade Level and Ease Score, would be challenging for a lay audience to comprehend. The mean Grade Level scores for each AI chatbot ranged from 10.7 to 13.2 (ChatGPT: 10.7; Claude: 13.2; DeepSeek: 11.3; and Docus: 12.2). The Reading Ease Score was 32.5 to 46.8 (ChatGPT: 46.8; Claude: 32.5; DeepSeek: 43.7; and Docus: 40.5). Therefore, ChatGPT was the most comprehensible and Claude the least comprehensible in each Flesch-Kincaid measure. Nevertheless, all AI chatbot means of Grade Level were beyond 8 and the Reading Ease Scores were below 50, indicating that all AI chatbots in our sample were deemed difficult for a lay audience to comprehend [49]. A recent study on AI chatbots also reported a high mean of Grade level score and a low mean of Reading Ease score [51]. This is concerning, as health information that exceeded suggested readability levels may create barriers to comprehension for persons with lower health literacy [78]. Additionally, the prevalent use of medical jargon among all AI chatbots in our sample may exacerbate the readability issue. Many lay audiences without medical backgrounds may not be familiar with medical terminologies such as "cervical epithelial neoplasia" and "immunosuppressive medications." Without providing definitions or further

XSL•FO
RenderX

explanation of these terminologies, it could further impede understanding. Moreover, the excessive length of responses from ChatGPT and DeepSeek may overwhelm users. Recent studies indicated that information overload, described as a condition in which an individual is unable to comprehend or respond to stimuli due to excessive information [79], may counterproductively reduce the ability to process information [80] and eventually affect HPV vaccination decision-making. In light of these challenges revealed by our study, AI developers should explore AI chatbot optimization approaches to improve readability for lay audiences, by implementing features like real-time readability adjustment, automatic jargon detection, and using summary-first formats that provide essential points up front, with optional details available on demand.

The degree of personalized responses varied across AI chatbots in our sample, with ChatGPT and Claude often referencing user characteristics such as age and sex in their responses, while DeepSeek and Docus did not, despite these user characteristics being provided at the beginning of the conversation. Personalization in health communication has been shown to enhance user experience by increasing perceived benefits and self-efficacy [81]. When AI chatbots did not include personalization, they may have missed opportunities to deliver tailored information that could have enhanced the uptake of HPV vaccination. In addition to personalization, using affirming language that acknowledges user concerns or feelings can further improve user experience and eventually improve engagement, particularly when discussing stigmatized topics like sexually transmitted infections caused by HPV [82]. However, it is important to note that implementing personalization and affirming language may require AI chatbots to retain user information, sometimes without the user's explicit consent, which in turn raises concerns about data privacy and security [83,84]. A study found that 47% of the respondents were concerned about the security of information entered into AI chatbots, which may reduce AI chatbots' acceptability in health care services [27]. To minimize these risks, robust data protection protocols are essential to safeguard user privacy when interacting with AI chatbots [83].

The uniformly neutral or provaccine stance exhibited by all AI chatbots in our sample corresponds with the scientific consensus, even when asked questions rooted in vaccination conspiracy beliefs. We found that AI chatbots maintained evidence-based stances without embracing antivaccine rhetoric. If AI chatbots take an antivaccine stance, it can fuel misinformation, such as antivaccine statements are scientifically unconfirmed and often rooted in personal stories [10,85]. While neutrality may not directly challenge misinformation, it offers an opportunity to present information in a nonjudgmental manner without using strongly persuasive messaging, helping to build trust among vaccine-hesitant individuals [86,87]. In challenging questions where AI chatbots were questioned about obtaining a vaccine despite potential life-threatening reactions, AI chatbots typically deferred to health care providers for evaluation rather than becoming the decision maker. By guiding users to health care professionals, AI chatbots effectively position themselves as supportive tools rather than substitutes for health care providers [88]. Chatbots can enhance online interactions between patients and health care professionals, especially when navigating complex medical questions [89].

## Limitations

This study has multiple limitations. First, our data collection was performed during a defined period (February 22-28, 2025), documenting AI chatbot responses at a singular timeframe of their evolution. Due to the rapid advancement of AI technology, these findings may not accurately represent the current capabilities of these platforms. Second, our analysis focused on text-based responses and did not assess multimedia components that could support information dissemination on certain AI chatbots. Third, there was a time lapse of several weeks between data collection and data analysis, during which some of the links provided in AI chatbot responses were no longer available due to shifts in political leadership. Fourth, while we simulated young adult users, actual interactions may differ based on user's specific characteristics and differences in query formulation. Furthermore, it may not fully capture the diversity and natural language patterns seen in actual queries from young adults. Our question set may also not fully capture the breadth of real-world HPV-related concerns among young adults, although its development based on Google Trends data may reflect what users are commonly searching for in an online space. Furthermore, we did not measure actual user comprehension or behavioral outcomes following interactions with these AI chatbots, limiting our ability to assess their real-world relationship on HPV vaccination decisions. Fifth, we used AI chatbots with different update methods (static and dynamic) that may partially explain why some AI chatbots provided less relevant information. Finally, the generalizability of our findings may be limited as our sample focused on a subset of AI chatbots mimicking young adult users in the United States. We analyzed 2 queries per AI chatbot, which limits the ability to fully assess response variability and consistency within each platform. We focused on a select group of AI chatbots based on some sets of criteria, not comprehensively including more AI chatbots. Therefore, results may not extend to other populations, age groups, or other AI chatbots not assessed in this study.

## Conclusions and Recommendations

Our study highlights the potential of AI chatbots as sources of generally accurate HPV vaccine information for young adults, potentially serving as alternatives to the misinformation-rich health content often found online. However, challenges remain in verifying the sources or links provided, ensuring readability, and maintaining personalization. These challenges underscore the urgent need for the development and adoption of standardized evaluation tools to ensure the efficacy of AI chatbots when they are used to supply health information to lay audiences. Such standardized tools would enable consistent benchmarking of AI chatbots' performance and facilitate meaningful comparisons in their ability to deliver reliable health information to lay audiences. In addition, standardized tools could help identify gaps in AI chatbot knowledge and functionality, guiding developers in refining these systems. To ensure information remains current and reliable, AI chatbots should implement regular knowledge updates and systematic checks for source accuracy. To improve readability, AI chatbots

XSL•FO
RenderX

should explore optimization approaches such as real-time readability adjustment. To enhance personalization, developers should design AI chatbot responses that are tailored to users while safeguarding their data privacy and security.

Our findings also signal the emergence of fostering "AI health literacy," which refers to the ability of individuals to understand and verify health information generated by AI tools. Moving forward, public health interventions must focus not only on the supply side by improving AI chatbots technology, but also on the demand side by equipping users with skills to verify AI-generated content to mitigate the overreliance on misinformation. We also recommend that users appropriately position AI chatbots as complements to, rather than replacements for, health care professionals' guidance. Given that AI chatbots sometimes adopt a neutral stance when discussing HPV vaccination, understanding the implications of this neutrality for combating misinformation and promoting vaccine confidence remains an important direction for future research.

Finally, moving forward, health policies should focus on partnering with technology firms to establish a systematic process for AI chatbots to help users distinguish high-quality and low-quality AI chatbots used in health care services. By addressing these considerations, AI chatbots could become accessible and valuable tools for improving HPV vaccine knowledge and potentially increasing vaccination rates among young adults.

## Acknowledgments

No generative artificial intelligence (AI) was used to create the content of this manuscript. AI tools were only used to enhance grammar and readability before submission.

## Funding

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

## Data Availability

The datasets used and analyzed during the study are available from the corresponding author on reasonable request.

The JMIR Publications Editorial Office is retracting the article "Secular Trends in Gastric and Esophageal Cancer Attributable to Dietary Carcinogens From 1990 to 2019 and Projections Until 2044 in China: Population-Based Study" [1].

This action is being taken due to identified concerns regarding the integrity of the peer-review process for this article. Following investigation, an author disclosed to the Editorial Office that they had impersonated an appointed reviewer for this article and fabricated a review.

Following this disclosure, the corresponding author Bing Hua Yin requested retraction of the article. This matter has since been referred to the institute for further investigation.

All of the authors agree with the decision to retract the article.

The JMIR Publications Editorial Office is retracting the article "Arterial Stiffness and Obesity as Predictors of Diabetes: Longitudinal Cohort Study" [1] due to concerns regarding the integrity of the peer review process.

Author Lin Liu responded to the concerns, stating that there were undisclosed conflicts of interest with the reviewers but asserted these did not impact the peer review process for the article.

However, the Editorial Office and editor in chief have determined that there is sufficient evidence indicating that the peer review process for this article was compromised.

The authors did not respond to the decision to retract the article.
