# JMIR Public Health and Surveillance

Impact Factor (2023): 3.5
Volume 12 (2026) ISSN 2369-2960 Editor in Chief: Travis Sanchez, PhD, MPH

## Contents

### Viewpoints

Reframing Pandemic Preparedness: Why Positive-Pressure Exposure Control Merits Formal Public Health Evaluation (e90211)
Yusaku Fujii. . . . 16

Reimagining Data for Equity: Reaching the Unreached Map Explorer for Localized Public Health Intelligence in the Western Pacific Region (e93324)
Sumbul Hashmi, Anne-Laure Budts, Vincent Meurrens, Jessica Stow, Fukushi Morishita, Rajendra-Prasad Yadav. . . . 23

Beyond Training: Systems Framework for Sustainable Health Informatics Investment in Africa (e89482)
Eric Ikoona, Lucy Namulemo, Ronald Kaluya, Rebecca Ikoona, Foday Sahr. . . . 32

Integrating AI Into Governmental Public Health Decision Making: Challenges, Considerations, and a Path Forward (e88470)
Elizabeth Campbell, Oluremilekun Oyefolu, Sarah Gillani, Hannah Goodtree, Alison Kelly, Caitlin Rivers, Crystal Watson. . . . 42

Bias-Mitigated AI as a Foundation for Resilient and Effective Health Systems (e88457)
Jarbas Barbosa da Silva Jr, Maureen Birminghamm, Ana Rivière Cinnamond, Eldonna Boisson, Mary Valdez, Sebastian Garcia Saiso, Joao Souza, Myrna Marti, Leah-Marie Richards, Javier Guzman, Jennifer Nelson, Karina Pesce, Ana Haddad, James Fitzgerald, Ernesto Bascolo, Marcelo D'Agostino. . . . 53

The 100-Miles for QVOICES (Queer Voices in Oncology Igniting Change Through Empowered Stories of Survivorship) Campaign: Overview of the Benefits and Costs of Crowdfunding as a Funding Mechanism for Research (e80079)
Viktor Clark, Milena Insalaco, Charles Kamen, Lauren Ghazal. . . . 59

### Reviews

Everyday Digital Technology Use and Youth Health: Scoping Review of Longitudinal Studies (e85094)
Preetika Banerjee, Louise Holly. . . . 68

Digital Tools' Effectiveness on Physical Activity Outcomes in Children and Adolescents: Umbrella Review (e75769)
Garden Tabacchi, Antonino Scardina, Antonella Amato, Marta Giardina, Giulia Accardi, Valentina Di Liberto, Giuseppe Giglia, Sonya Vasto, Monica Frinchi, Paolo Boffetta, Walter Mazzucco, Marianna Bellafiore. . . . 86

XSL•FO

The Effectiveness of Contact Tracing to Reduce Transmission of Infectious Diseases During Epidemic or Pandemic Response: Rapid Systematic Review (e84805)
Michael Nunns, Samantha Febrey, Kieran Becker, Morgan Weiland, Jill Buckland, Rebecca Abbott, Rebecca Whear, Alison Bethel, Liz Shaw, Kate Boddy, Serena Carville, Tamsyn Harris, Jo Thompson Coon, G Melendez-Torres. . . . . 114

Mapping Movement Behaviors and Mental Health Among Frontline Workers: Scoping Review (e106002)
Amalie Skovgaard, Alison Kirk, Ellie Campbell, Gabrielle Horan-Buchanan, Nicola Cogan. . . . . 492

## Original Papers

Examining the Factor Structure of Objective Health Literacy and Numeracy Scales: Large-Scale Cross-Sectional Study (e71701)
Chihiro Moriishi, Keisuke Takano, Takeyuki Oba, Naoki Konishi, Kentaro Katahira, Kenta Kimura. . . . . 135

Data Completeness and Acceptability of Annual Feedback Reports and Tuberculosis Surveillance in Spain, 2018-2024: Mixed Methods Analysis (e93719)
Allegra Chatterjee, Alvaro Roy, Rocio Amillategui, María Sastre, Christine Schwarz, Rosa Cano, Laura Herrera-León, Zaida Herrador, Spanish Working Group on Tuberculosis. . . . . 150

Evaluating Tuberculosis Surveillance Using Global Standards and Benchmarks in the Philippines: Mixed Methods Study (e77058)
Minal Ahson, Donna Gaviola, Stephanie O'Connor, Andro Gutierrez, Marvin Apas, Maria Eguia, Devon Pacial, Arianne Zamora, Romel Lacson, Alethea De Guzman, Patrick Moonan. . . . . 162

Global Heated Tobacco Product User Estimates, 2014-2024: Descriptive Surveillance Study Using Manufacturer Disclosures (e88761)
Giorgi Mzhavanadze, Gerry Stimson, Tomasz Jerzy ski. . . . . 169

Systematic Assessment of Flavor Cues and Additives in Cigarettes and Heated Tobacco Products in Korea: Cross-Sectional Surveillance Study (e87537)
Geon Heo, Doyoon Kim, Yehyun Kim, Ara Kim, Nagyeong Cho, Naeun Kang, Jungmi Park, Eunsil Cheon, Seulgi Kim, Susan Park, Sungmin Park, Sung-il Cho, Heewon Kang. . . . . 184

Epidemiological Shifts and Trends From 2009 to 2023 in Hospital Admissions for Ruptured Aortic Aneurysms and Aortic Dissections in Austria: Retrospective, Population-Wide Study (e81702)
Fadi Taher, Maria Leinweber, Afshin Assadian, Amun Hofmann. . . . . 203

Twenty-Five Years of Firearm Homicides and Suicides Among US Children and Young Adults, 1999 to 2024: Intersectional Surveillance Analysis (e96931)
Chuka Emezue, Tipparat Udmuangpia. . . . . 214

Temporal Trends in Type 2 Diabetes Burden and Care Outcomes in Taiwan From 2012 to 2021: Nationwide Population-Based Cohort Study (e86356)
Ming-Yen Lin, Yi-Ling Wu, Hsiaoting Wu, Chih-Cheng Hsu, iH3 Research Group. . . . . 233

Temporal Trends in Lung Cancer and Histological Subtype Incidence and Bayesian Projections to 2030 in China: Population-Based Quantitative Study (e98324)
Xing Su, Jing Li, Xiaowei Hu. . . . . 243

Epidemiological Characteristics and Incidence Trends of Hemorrhagic Fever With Renal Syndrome in Shandong Province, China: Retrospective Observational Study With Forecasting (e99524)
Qing Duan, Ti Liu, Yinlong Li, Suying Guo, Shiyi Huang, Jing Xu, Ruixiao Li, Zengqiang Kou. . . . . 254

XSL•FO

Broadband Access and Ophthalmologist Density in the United States: Cross-Sectional Questionnaire Study (e88473)
Patrick Akarapimand, John Lin, Ingrid Scott, Sally Baxter. . . . 298

Health Care Providers' Perspectives on Early Warning Systems for Acute Respiratory Infections in Canada: Qualitative Study (e85244)
Jinfan Qiang, Kevin Maruthananth, Maaha Farrukh, Andrew Pinto, Banafshe Hosseini. . . . 308

Digital Health Center App for Community and National Malaria Surveillance in Cambodia: Implementation Case Study (e85881)
Pengby Ngor, Huy Rekol, Eng Thyda, Ry Rith, Sok Kimleng, Yoem Rattana, Ou Vunsokserey, Hem Vanna, Chang Pumeoung, Pascal Ringwald, Richard Maude, Lisa White, Siv Sovannaroth. . . . 321

The Barcelona Injury Surveillance System (BISS) for Safer Cities: Observational, Descriptive Study Using Routine Health and Police Information Databases (e82079)
Katherine Pérez, Elena Santamariña-Rubio, Mònica Cortés-Albaladejo, Lucía Artazcoz, Adnan Hyder, Carme Borrell. . . . 342

Requirements and Implementation Challenges of Automated Outbreak Detection Systems in the European Union: Mixed Methods Study (e96576)
Paulina vom Felde genannt Imbusch, Ann Vietor, Inessa Markus, Michaela Diercke, Alexander Ullrich. . . . 401

Temporal Patterns of Multimorbidity Progression Among Inpatients With a Recorded Hypertension Diagnosis Across Three Counties in Rural Henan, China: Retrospective Cohort Study Using Temporal Network Analysis (e93217)
Yifei Wang, Yanna Mao, Xi Wang, Rongmei Liu, Manman Cui, Ruihua Feng. . . . 412

Establishing One Health Surveillance Platform for Electronic Integrated Disease Surveillance and Response in Malawi: Action Design Research Study (e72029)
Tsung-Shu Wu, Matthew Mvula, Edward Chado, Blessings Kamanga, Daniel Mapemba, Rajab Billy, Louis Nyirongo, Annie Mwale, Evelyn Banda, Matthew Kagoli, Tiwonge Manda, Gunnar Bjune, Jens Kaasbøll. . . . 426

Sustaining Public Health Surveillance Systems in Thailand: Comparative Qualitative Case Study of 2 National Platforms (e106399)
Weerapat Pipithruengkrai, Saranath Lawpoolsri, Chawarat Rotejanaprasert, Peter Haddawy, Thomas Barkowsky. . . . 444

Interactive Digital Visualization Counseling for Lifestyle Change in Patients at Risk of Cardiovascular Diseases: Randomized Controlled Trial (e83488)
Adrijana Svenšek, Mateja Lorber, Zalika Klemenc-Ketiš, Lucija Gosak, Dominika Muršec, Gregor Štiglic. . . . 458

Using Natural Language Processing to Examine State Child Maltreatment Policies and Associations With Outcomes: Multistate Cross-Sectional Study (e99643)
Zhidi Luo, Richard Epstein, Nethra Sambamoorthi, Lutfiyya Muhammad, Neil Jordan. . . . 475

Healthy Lifestyle Score and the Risk of Cardiovascular Disease, Cancer, and Mortality in an Asian Population: Prospective Cohort Study (e95237)
Su Park, Peh Ho, Xuan Liang, Rob van Dam, Mary Chong, Charlie Lim, Xueling Sim, Airu Chia. . . . 511

Effectiveness of Online Training on Cardiopulmonary Resuscitation and Automated External Defibrillator Use in Simulations With Rural Populations: Quasi-Experimental Community Intervention Study (e80359)
Elena Taverna-Llauradó, Sara Martinez-Torres, Alba Roca-Biosca, Meritxell Pallejà-Millán, Francisco Martín-Luján, Cristina Rey-Reñones. . . 5 2 4

Occupational Fatigue and Multidimensional Traffic Risk Outcomes Among Motorcycle-Based Food Delivery Workers: Cross-Sectional Study (e92667)
Sookyung Kim, Chang Park, Mi-So Shim. . . . 534

XSL•FO
RenderX

Population-Level Impact of the Enterovirus A71 Vaccination Program on Hand, Foot, and Mouth Disease: Ecological Time-Series Study (e85604)
Ye Tong, Huan Fan, Jing Wang, Xinru Zeng, Xiaoqing Cheng, Changjun Bao, Liguo Zhu, Hong Ji, Xiang Huo. . . . 548

The Impact of US Food and Drug Administration's Advisory and Enforcement Actions on US Sales of Esco Bars Products in 2023: Synthetic Control Approach (e81033)
Hyungsik Shin, Jonathan Hannings, Zachary Cahn, Xin Xu, Robin Toblin, Matthew Farrelly, Brian King. . . . 557

Uncovering the Reasons Behind Maternal Care Dropout in Bangladesh: Cross-Sectional Study (e85875)
Syeda Alam, Plabon Sarkar, M Rifat, Sumaiya Jahan, Rokibul Islam, Israt Jahan, Sanjib Saha. . . . 569

Exploring Motives for Reducing Alcohol Consumption Among Users of an Alcohol Reduction App: Content Analysis (e88992)
Lucille Seppi, Olivia Maynard, Dimitra Kale, John Cunningham, Claire Garnett. . . . 584

Mediation Analysis of the Relationship Between Health Literacy and the French General Population's Opinions on Hepatitis B Vaccination: Representative Cross-Sectional Survey of the SLAVACO Project (e82496)
Bakary Cissé, Sylvie Boyer, Jeremy Ward, Julien Mancini. . . . 598

Association Between Gestational Blood Pressure Trajectories and Postpartum Normotension Recovery in Hypertensive Disorders: Retrospective Cohort Study (e89295)
Zhijiang Liang, Huili Wei, Xiaojun Xu, Rong Xu, Xinyue Yang, Jinlian Dong, Xiaoyan Fan, Yukun Chen, Meiling Feng, Xin Zhou, Yijun Cai, Lijuan Lv. . . . 614

Assessment of Knowledge, Attitudes, and Behaviors Toward Others' Mental Disorders to Improve Mental Health First Aid: Cross-Sectional Study in a French Workplace (e93207)
Matthieu Lebrat, Florence Carrouel, Benjamin du Sartz de Vigneulles, Michel Lamure, Corélie Salque, Roger Salamon, Catherine Massoubre, Nicolas Franck, Claude Dussart. . . . 630

Psychosocial Correlates of Sedentary Behavior Reduction Readiness Relevant to Zero-Time Exercise Among Chinese Adults in Sedentary Occupations: Cross-Sectional Study (e95707)
Ziyan Xiong, Xiangyuan Li, Lu Chai, Xiongqiang Duan, Xiang Hu, Yuan Xie, Li Cong. . . . 649

Clinical Epidemiology of Cancer in People Living With HIV in Germany: Retrospective, Observational, Multicenter Federated Claims Data Analysis (e81092)
Bastian Reiter, Stefanie Andreas, Linnea Schumann, Bernd Bender, Isabel Schnorr, Andreas Heidenreich, Christoph Stephan, Andrea Prunotto, Andrea Laukhuf, Julius Wehrle, Matthias Müller, Fabio Aubele, Marlien Hagedorn, Fady Albashiti, Ulrich Seybold, Julia Roider, Melanie Stecher, Daniel Maier, Jörg Vehreschild. . . . 666

Acceptability and Feasibility of Longitudinal Sampling for Sexually Transmitted Enteric Infections in Gay, Bisexual, and Other Men Who Have Sex With Men (GBMSM): Prospective Cohort Pilot Study Conducted in 2022 in South East England (e73762)
Holly Fountain, Katie Thorley, David Reid, Dana Ogaz, Daniel Richardson, Hannah Charles, Kate Baker, Claire Jenkins, Caisey Pulford, Gwenda Hughes, Nigel Field, Catherine Mercer, Xavier Didelot, Noel McCarthy, Hamish Mohammed, Holly Mitchell. . . . 678

Moderating Role of Condom-Use Inertia on the Association Between Status Quo Bias and Pre-Exposure Prophylaxis Resistance Intention Among Chinese Men Who Have Sex With Men: Cross-Sectional Study (e88806)
Min Zhao, Shanshan Li, Xiang Zhao, Jincheng Hu, Zhuoheng Yin, Fanpu Ji, Weiming Tang, Lei Zhang. . . . 695

Stigma, Food Insecurity, and Limited Social Support as Psychosocial Correlates of Antiretroviral Therapy Adherence Among Pregnant Women Living With HIV: Cross-Sectional Study (e84914)
Setor Sorkpor, Ibrahim Yigit, Rachel Thompson, Brittany Lane, Geoffrey Anguyo, Jerry Ouner. . . . 711

XSL•FO

Preferences for mHealth Features to Support Engagement in the HIV Preexposure Prophylaxis Cascade Among Men Who Have Sex With Men in Peru: Cross-Sectional Online Survey (e84982)
Jorge Gallardo-Cartagena, Dora German-Quiñones, Kelika Konda, Susan Buchbinder, Jorge Sanchez, Frederick Altice. . . . . 723

Profiles of Willingness to Use Pre-Exposure Prophylaxis Modalities and an HIV Vaccine Among Sexual and Gender Minority Individuals in Brazil, Mexico, and Peru: Cross-Sectional Online Survey (e75753)
Jazmin Qquellon, Kelika Konda, Oliver Elorreaga, Hamid Vega-Ramirez, Centli Guillén-Díaz-Barriga, Dulce Díaz-Sosa, Brenda Hoagland, Juan Guanira, Marcos Benedetti, Cristina Pimenta, Beatriz Grinsztejn, Carlos Caceres, Valdilea Veloso, Thiago Torres. . . . . 743

Impact of a Culturally Tailored Educational Intervention on Human Papillomavirus Knowledge and Vaccination Intentions Among Women in Saudi Arabia: Quasi-Experimental Study (e104529)
Ebtesam Elsayed, Fathia Mersal, Heba Mohamed, Ala Aljehani, Najla Aljehani. . . . . 758

Prevalence, Trends, and Associated Factors of HIV, Syphilis, and Anti–Hepatitis C Virus Seropositivity Among Attendees at Voluntary Counseling and Testing Clinics in Zhejiang Province, China, From 2022 to 2024: Retrospective Quantitative Study (e96584)
Jinlei Zheng, Lin Chen, Lin He, Tingting Jiang, Hui Wang, Wanjun Chen, Yapin Yao. . . . . 777

A Critical Health Literacy Podcast to Counter Health Misinformation at Scale: Randomized Controlled Trial (e78003)
Vanesa Mora Ringle, Amanda Jensen-Doss. . . . . 791

Legal Infoveillance of Unlicensed Medical Practices in South Korea Through Criminal Court Decisions Using Machine Learning: Retrospective Observational Study (e92591)
Min Kim, Min Choi. . . . . 806

Encouraging Adults at Risk for Type 2 Diabetes to Enroll in Diabetes Prevention Programs Through a Media Campaign in Hawai'i: Cross-Sectional Study (e90880)
Kara Saiki, Eunjung Lim, Blythe Nett, Gail Ogawa, Lance Ching, Riana Kawasaki, Nianest Barreto, Katherine Inoue, Lola Irvin, Kiana Kaupiko, L Keliikoa, Meghan McGurk. . . . . 817

The Impact on Audience Engagement of Coordinating a Public Health Campaign on Antimicrobial Resistance Through a Network of Health Content Creators: Longitudinal Observational Study (e86587)
Fangyue Chen, Jack Cooper, Amish Acharya, Simon Dryden, Ara Darzi, Kate Grailey. . . . . 836

A Social Media Campaign to Promote COVID-19 Vaccination: Cost-Effectiveness Analysis (e84540)
Michael Long, Jeffrey Bingenheimer, Khadidiatou Ndiaye, Dante Donati, Nandan Rao, Selinam Akaba, Sohail Agha, William Evans. . . . . 846

Physical Activity Indicators Among Children and Adolescents in Lebanon, Qatar, and the United Arab Emirates: Comparative Synthesis of Active Healthy Kids Report Card Data From 1998 to 2022 (e85998)
Ameneh Baghestani, Lina Majed, Merilyn Lock, Ali Alrahma, Patrick Abi Nader, Suzan Sayegh, Abdulla Al-Mohannadi, Javaid Nauman, Salomé Aubert, Mark Tremblay, Tom Loney. . . . . 856

Assessing the Willingness of Future Health Care Providers to Participate in Vaccine Trials: Cross-Sectional VACCELERATE European Study (e84952)
Andreas Yiallouris, Charalampos Filippou, Christina Merakou, Christos Argyropoulos, Sophia Themistocleous, George Shiamakkides, Andreas Sarantopoulos, Ahmed Shaikh, Evgenia Noula, Andria Nearchou, Elizabeth Johnson, Maria Papaconstantinou-Leontidou, Charis Armeftis, George Astras, Fiona Stewart, Kerstin Albus, Jon Salmanton-García, Janina Leckler, Anna Azzini, Ruth Davis, Lenka Sou ková, Helena Askling, Tobias Battle, Elena Álvarez-Barco, Augustina Mozeryte, Dimitrios Poulimeneas, Ioannis Kopsidas, Jana Prellezo, Olena Valdenmaiier, Stine Jakobsen, Rebecca Cox, Margot Hellemans, Greet Hendrickx, Pierre van Damme, Jordi Ochando, Theoklis Zaoutis, Ligita Jancoriene, Patrick Mallon, Pontus Nauclér, Petr Husa, Evelina Tacconelli, Oliver Cornely, Zoi-Dorothea Pana. . . . . 871

Association of Noise Exposure, Perceived Noise Impact, and BMI on Nonalcoholic Fatty Liver Disease Among Chinese Seafarers: Nationwide Population-Based Survey (e57844)
Ruizi Shi, Shuai Zhou, Zhitao Yang, Erzhen Chen, Hanbing Shang, Ying Zhou. . . . . 882

XSL•FO

Public Awareness, Attitudes, and Practices Toward Digital Health Surveillance in Malawi: Cross-Sectional Study (e91033)
Patricia Kamanga, Jeremot Masoambeta, Vincent Kamforzi, Bertha Kayuni, Isaach Ndemera, Chriswell Nkoloma, Lusungu Chisesa, Atusaye Mwalwanda, Selemani Ngwira, Hope Kalichero, Alex Thawani, Robina Vokhiwa, Dzinkambani Kambalame, Hamdan Saidi, Peter Salilika, Tsung-Shu Wu . . . . . 899

Molecular Transmission Clustering and Pretreatment Drug Resistance Among Men Infected With HIV-1 Who Have Sex With Men in Baotou, China: A Cross-Sectional Subgroup Analysis (e82208)
Hanping Li, Yu Liu, Hong Yang, Jiao Wu, Ziwei Liu, Baobao Bai, Yongjian Liu, Lei Jia, Jingwan Han, Bohan Zhang, Xiaolin Wang, Xiangchun Li, Lin Li . . . . . 911

Social Determinants of Health Associated With Unhealthy Weight Management Behaviors Among Emerging Adult Women: Nationwide Cross-Sectional Study (e95474)
Jisu Lee, Hyeonkyeong Lee, Hyemi Sun, Chaehyeon Kang, Sun Shim . . . . . 930

The Association Between Family Health and Proactive Health Risk Management With the Mediating Role of Health Literacy: Nationwide Cross-Sectional Study (e73659)
Shangfeng Tang, Yilin Wei, Heng Dong, Kangkang Zhang, Chunying Wang, Jia Song, Hua Qing, Yibo Wu . . . . . 945

Adolescent Self-Reported Recovery for Substance Use in Illinois: Statewide Representative Epidemiological Study (e82792)
Douglas Smith, Crystal Reinhart, Shahana Begum, Tarjani Bhatt . . . . . 960

Determinants of Willingness to Receive Health Information From Neighborhood Food and Beauty Establishments: Cross-Sectional Study (e86435)
Seema Aithal, Huiling Guo, Zoe Hildon, May Lwin, Angela Chow . . . . . 968

Willingness to Undergo Human Papillomavirus Testing Among Men Who Have Sex With Men in China Based on the Information-Motivation-Behavioral Skills Model: Online Cross-Sectional Study (e85543)
Xin Liu, Xuelin Yang, Mohan Lyu, Zhenwei Dai, Shu Jing, You Xin, Fei Yu, Shenglan Tang, Xiaoyou Su . . . . . 982

Associations of Health Care System Deficiency–Related Patient Deterioration With Burnout, Depressive Symptoms, and Sleep Problems Among Emergency Medical Service Providers: Cross-Sectional Study (e90130)
Min Choi, Soo Kim, Yonghwan Moon, Hyekyung Woo . . . . . 998

Impact of Different COVID-19 Pandemic Phases on Emergency Department Length of Stay and Intensive Care Unit Admission Risk: Single-Center Retrospective Cohort Study (e87597)
Zehua Wang, Xiangmei Zhao . . . . . 1012

Antimicrobial Resistance Across Four Iraqi Governorates: A Multicenter Cross-Sectional Surveillance Analysis With Implications for Antimicrobial Stewardship Policy and WHO AWaRe–Aligned Public Health Strategies (e94436)
Hemn Omer, Omeed Darweesh, Gulbahar Karim, Baref Rashid, Rozhgar Ahmed, Andrew Seaton, Brian Godman, Amanj Kurdi . . . . . 1024

Depressive and Anxiety Symptoms and Their Comorbidity Across Industries: Multi-Industry Cross-Sectional Study in China (e91782)
Lei Cao, Ruihong Ran, Huadong Zhang, Heling Bao . . . . . 1041

Crimean-Congo Hemorrhagic Fever Disease Awareness Scale: Scale Development, Validity, and Reliability Study (e93724)
Gülay Yilmazel, Ay e Çalmaz, Emre Kele . . . . . 1056

XSL•FO
RenderX

Genetic Subtypes, Pretreatment Drug Resistance, and Associated Factors Among Individuals Newly Diagnosed With HIV-1 in Zhejiang Province From 2022 to 2024: Cross-Sectional Study (e96139)
Wei Cheng, Qin Fan, Jiafeng Zhang, Jun Jiang, Jiezhe Yang, Yun Xu, Lin Chen, Chengliang Chai, Xiaohong Pan. . . . . 1077

Prevalence and Associated Factors of Renal Disease in Saudi Residents Attending Primary Health Care Centers in Riyadh, Saudi Arabia: Cross-Sectional Study (e81849)
Saad Alshahrani, Ashraf El-Metwally, Awad Alshahrani, Badr Al-Khateeb, Aljohrah Aldubikhi, Khadijah Angawi, Amani Alharthy, Lubna Alnaim, Amal Zaidan, Raed Aldahash. . . . . 1091

Trends and Core Competence Shifts in Nurses' Infectious Disease Emergency Response Competence Across COVID-19 Pandemic Phases: Repeated Cross-Sectional Survey and Network Analysis (e83281)
Jiagen Xiang, Qiuxia Liang, Yufei Lu, Meizhen Lin, Juan Liu, Hongman Li, Jingjing Cai, Yan Wu, Bingbing Li, Wenting Liu, Ming Yang, Xiaoning Sun, Yan Luo, Yibing Tan, Hairun Liu, Jiaying Li, Liming Lu, Zengjie Ye. . . . . 1105

Gestational Diabetes Mellitus and Associated Factors in Rural Areas of Northern Vietnam: Cross-Sectional Survey (e79688)
Duc Le, Thi Nguyen, Thi Nguyen, Thi Tran, Xuan Luong, Thi Do, Xuan Tran, Van Ngo, Thi Bui, Tien Nguyen, Van Hoang, Thanh Vu. . . . . 1117

Factors Affecting Acceptance of Life Education in Mainland China: National Cross-Sectional Study (e78844)
Xinyue Zhang, Nana Huang, Yuyang Yi, Yinlin Wang, Wai-Kit Ming, Yibo Wu, Xiaohong Ning, Chen Wang. . . . . 1128

Prevalence and Factors Associated With Acute Stress Disorder Among Adults Ever Infected With COVID-19 During the Ending Phase of the Pandemic in 7 Chinese Cities: Cross-Sectional Study (e73002)
Ziying Yang, Yanqiu Yu, Hui Lu, Xu Wang, Yong Xu, Junqiang Ying, Xianying Wen, Lei Luo, Meng Wang, Muwen Liu, Xingyi Geng, Xuchong Zhao, Biyu He, Tao Liu, Remina Maimaitijiang, Jing Gu, Joseph Lau. . . . . 1154

Regional Disparities in Factors Associated With Subjective Health Among Older Adults in Aging and Super-Aged Areas of Korea: Nationwide Cross-Sectional Study (e80189)
Gi-Moon Nam, Ye-Rin Lee, Ji-Hye Mun, Su-Hyeun Cho, Hee-Sook Lim. . . . . 1171

HIV Risk Profiles and Pre-Exposure Prophylaxis and Postexposure Prophylaxis Uptake Among Men Who Have Sex With Men in China: Cross-Sectional Latent Class Analysis (e81405)
Ziwei Wu, Xinrui Zhang, Xingliang Zhang, Junfang Xu. . . . . 1186

Association Between Health Literacy and Prehypertension in South Korean Adults: Cross-Sectional Study Using the 2023 Korea National Health and Nutrition Examination Survey (e82684)
Jiyeon Chun, Dan Kim, Suk-Yong Jang, Eun-Cheol Park. . . . . 1204

The Gendered Mediation Effects of Social Support on Fertility Intentions Among Childless Adults of Reproductive Age in China: National Cross-Sectional Study (e77484)
Xinyu Xu, Peiyu Liu, Peihua Ren, Wenyan Shi, Sha Lai. . . . . 1222

Survey Modalities and COVID-19 Vaccine Uptake in Vietnamese Americans: Cross-Sectional Study (e77520)
Celine Nguyen, Alexander Le, Paul Yeh, Ben King, Angelica Nguyen, Jannette Diep, Bich-May Nguyen. . . . . 1238

Knowledge, Attitudes, Practices, and Vaccination Willingness Toward Mpox (Monkeypox) Among Chinese Medical Students: Cross-Sectional Study (e86981)
Yang Liu, Yuehui Jia, Honglong Li, Jie Ge, Yunfeng Han, Zhiping Xie, Jiaxin Chen. . . . . 1251

Digital Exclusion Among People Experiencing Homelessness and Residents of Urban Communities in Brazil: Cross-Sectional Study (e77124)
Ariela Tártaro, Dulce Gomes, Thaís Berra, Reginaldo Tavares, Yan Alves, Letícia Ferezin, Antônio Ramos, Nathalia Zini, Maria Pelodan, Marcela Popolin, Ricardo Arcêncio. . . . . 1263

Drug-Facilitated Sexual Assault Pornography and Sexual Violence While Partying: Cross-Sectional Study (e80110)
Pablo Prego-Meleiro, Guadalupe Pastor-Moreno, Irantzu Recalde-Esnoz, Luis Sordo. . . . 1276

Problematic Alcohol Use Among Adolescents in Germany: Representative Cross-Sectional Study (e87800)
Rebekka Schröder, Tim Hamer, Ralf Suhr, Lars König. . . . 1288

Association of Vitamin D and Weight Status With Neurodevelopmental Outcomes in a Large Pediatric Population: Cross-Sectional Study (e89756)
Ying Shen, Meiying Gao, Lejing Guan, Lidan Sun, Yanfen Xu, Bethel Daniel, Kyla Zhang, Guannan Bai. . . . 1302

Social Networks and Their Influence on the Choice of Unassisted Smoking Cessation: Cross-Sectional Study in Six Cities in China (e74147)
Sihui Peng, Tingzhong Yang, Lijing Li, Weifang Zhang, Randall Cottrell. . . . 1314

Urinary Sodium Excretion and the Risk of Prevalent Anemia: Nationwide Population-Based Cross-Sectional Study (e88408)
Sang Suh, Dohyeon Lee, Seong Ma, Sunyong Yoo, Soo Kim. . . . 1330

Prevalence of Rest Intolerance and Its Associations With Mental Health and Quality of Life Among Adults in China: Cross-Sectional Study (e100611)
Fei Wang, Xuanjing Ji, Xin Guan, Ting Wang, Rui Zhong, Yibo Wu, Tingshao Zhu. . . . 1342

Longitudinal Population-Level Shifts in Infectious Disease–Specific Health Literacy During and After the COVID-19 Pandemic in Zhejiang, China: Six-Round Cross-Sectional Study (e89958)
Zhao Yusui, Dingming Yao, Yue Xu, Xiujing Hu, Qingqing Wu, Lei Wang, Xuehai Zhang, Zhen Jiang. . . . 1355

Socioeconomic and Regional Disparities in Long-Term Mortality Among Intensive Care Unit Survivors in South Korea: Nationwide Cohort Study (e89127)
Nayeon Choi, Jaehoon Oh, Kyung Yoo, Juncheol Lee, Sang Lee. . . . 1372

Long-Term Exposure to Particulate Matter 2.5 and Ozone and the Risk of Acute Respiratory Infections: Community-Based Prospective Cohort Study (e88045)
Xiaolei Duan, Xiao Yu, Hongyu Liang, Zexuan Wen, Wenyong Zhou, Ying Ma, Weibing Wang, Yaxu Zheng, Huanyu Wu. . . . 1389

Triglyceride-Glucose Index and Risk of End-Stage Kidney Disease in Young Adults: National Population-Based Cohort Study (e73750)
Jin Kim, Yu Lee, Sungjin Chung, Hyeon Hwang, Kyungdo Han, Hye Yoon. . . . 1402

Alcohol Consumption and Age-Specific Risk of Esophageal Cancer: Prospective Cohort Study (e92949)
Yongbo Yang, Xing Xing, Zhen Qin, Chunyang Han, He Zhu. . . . 1421

Determining the Association Between Hearing Disability and Injury Risk in Older Adults Using Propensity Score Matching: Quasi-Experimental Study (e78826)
Woo-Ri Lee, Sungyoun Chun, Youyoung An, Hyun Choi. . . . 1435

Association Between Low Chinese Visceral Adiposity Index Values and Chronic Lung Disease in Older Adults: Cohort Study (e78627)
Xiaorong Zhu, Hui Tian, Zhi Liu, Zhoubin Huang, Miaomiao Yuan, Zhangshun Tu, Kaiwang Cui, Jianping Liu, Xiangwen Gong. . . . 1450

## Abstract

Powered air-purifying respirators (PAPRs) are respiratory protective devices that actively supply filtered air and maintain positive pressure in the breathing zone, thereby limiting the inward leakage of unfiltered ambient air through gaps. Their principles and technology are already established. Positive-pressure PAPRs have primarily been used by health care workers in high-risk environments. However, their potential as an individual-level infection-control measure applicable to the general public has not been formally positioned for evaluation within the context of pandemic preparedness. This viewpoint aims to demonstrate the rationale for and need to position exposure control using positive-pressure PAPRs designed for the general public as a subject of systematic public health evaluation. Unlike existing measures that depend primarily on behavioral change, spatial separation, or acquisition of immunity, this intervention directly reduces aerosol inhalation exposure in an individual's breathing zone—the physical process that precedes airborne infection. Existing engineering studies increasingly make it possible to consider a public-oriented positive-pressure PAPR not merely as an idea but as a concrete intervention model with the potential for manufacture and implementation. However, the extent to which engineering measures of aerosol protection translate into individual-level prevention of infection and population-level infection control under real-world conditions must be established empirically. Individual-level preventive effectiveness, population-level infection-control effectiveness, engineering performance, feasibility of implementation, sustained use, social acceptability, cost, and equity must therefore be evaluated comprehensively by integrating medical and engineering assessments within a public health framework. This article does not advocate the immediate introduction of positive-pressure PAPRs for the general public. Rather, it identifies an institutional gap: established principles and technologies have not been incorporated into formal public health evaluation as a population-level infection-control measure. Evaluating positive-pressure exposure control for the general public is necessary to determine whether it could broaden policy options in future respiratory infectious disease pandemics and reduce excessive reliance on measures with major societal consequences.

**KEYWORDS**

pandemic preparedness; powered air-purifying respirator; PAPR; positive-pressure exposure control; population-level intervention; public health evaluation; privacy-preserving governance

## Introduction

Two broad strategies played major roles in the global response to the COVID-19 pandemic [1]. The first combined behavioral interventions, such as mask mandates and physical distancing [2], with mass vaccination intended to establish population immunity [3]. The second was lockdown—the broad restriction of social and economic activity when health systems faced the threat of collapse [4].

Although lockdowns helped curb the spread of infection [4], the COVID-19 pandemic and the accompanying broad societal restrictions placed severe burdens on economies, education, and social life [5,6]. Lessons from the COVID-19 pandemic have reaffirmed the importance of infection surveillance, early-response systems, international cooperation frameworks, and national pandemic preparedness plans [7,8]. At the same time, reconciling epidemic control with the continuation of social activity requires not only the continued improvement of existing measures but also the exploration and evaluation, during nonemergency periods, of new interventions that could complement them.

Existing measures include means of physically reducing inhalation exposure, such as masks. However, measures intended for the general public that actively supply filtered air, maintain positive pressure in the breathing zone, limit the inward leakage of unfiltered ambient air, and control inhalation exposure with a high protection factor have not been established as formal public health options. During respiratory infectious disease pandemics, inhalation of infectious aerosols can be a major route of transmission [9,10]. Because infection is influenced by the infectious dose reaching the respiratory tract, substantially reducing that dose below the threshold could, in theory, prevent infection regardless of the ambient pathogen concentration [11].

XSL•FO
RenderX

A potential third axis is an engineering intervention that directly and physically reduces inhalation exposure. One concrete means is the powered air-purifying respirator (PAPR). A positive-pressure PAPR actively supplies filtered air and maintains positive pressure in the breathing zone, thereby limiting the inward leakage of unfiltered ambient air through gaps. Its principles and technology are already established, and PAPRs have primarily been used in high-risk clinical settings, such as intensive care units and infectious disease isolation environments. However, their potential as an individual-level infection-control measure applicable to the general public has not been formally evaluated as a public health option for pandemic preparedness [12].

The author has named the concept of exposure control using positive-pressure PAPRs for the general public "PAPR for Everyone" (PFE). The concept was proposed at the beginning of the pandemic in 2020 [13], after which the engineering and epidemiological evidence underlying it was accumulated in stages [14-18]. Since 2024, findings concerning manufacturability and ease of implementation, required use rates, respiratory-state estimation, real-time leak detection, and time-managed use have been published in journals including *JMIR Biomedical Engineering* and *Scientific Reports*. These engineering and theoretical studies have brought positive-pressure PAPRs for the general public to a stage at which they can be considered a concrete, testable intervention rather than merely a conceptual proposal.

This article aims to demonstrate the rationale and need for positioning exposure control using positive-pressure PAPRs for the general public as a subject of formal public health evaluation in pandemic preparedness. It summarizes the engineering and theoretical evidence accumulated for PFE and examines why this option has been overlooked. Rather than calling for its immediate introduction, we propose beginning with field studies during seasonal influenza epidemics and systematically evaluating individual-level preventive effectiveness, population-level infection-control effectiveness, engineering performance, feasibility of implementation, sustained use, social acceptability, cost, and equity by integrating medical and engineering assessments within a public health framework.

## Current Evidence

### Dose-Based Infection Control and the Significance of PAPRs

Infection by airborne pathogens requires inhalation of a sufficient quantity of viable pathogens—an infectious dose [11,19]. Interventions that reduce this dose below the relevant threshold reduce the probability of infection [11,19]. Accordingly, a means of directly and reliably reducing inhalation exposure could, in principle, be a highly powerful infection-control intervention [11,19].

High-efficiency particulate air (HEPA) filters have a collection efficiency of at least 99.9% for 0.3 µm test particles, while the most penetrating particle size (MPPS) varies around 0.3 µm depending on the filter medium, flow rate, and other conditions [20]. A PAPR uses a blower to actively supply air cleaned through a HEPA filter to the breathing zone and prevents the ingress of unfiltered ambient air by maintaining positive pressure in that zone [14,21]. The assigned protection factor (APF) for a helmet- or hood-type PAPR is generally 25; however, an APF of 1000 may be applied to models for which the manufacturer demonstrates performance of at least 1000 based on a workplace protection factor (WPF), simulated workplace protection factor (SWPF), or equivalent test [22]. This article focuses on positive-pressure PAPRs with an APF of 1000 that meet these testing requirements. Under specified conditions of fit and operation, they are expected to reduce the concentration of inhaled aerosols to approximately one-thousandth of the ambient concentration [22]. A reduction in inhaled infectious dose of this magnitude would be expected to substantially reduce the probability of infection in ordinary living environments [11,19].

This protective mechanism differs fundamentally from that of passive masks and negative-pressure respirators. In such devices, inhalation creates negative pressure inside the device, and inadequate facial sealing may allow unfiltered ambient air to enter through gaps. By contrast, a PAPR actively maintains positive pressure in the breathing zone and therefore limits inward leakage through gaps in principle. Comparing an APF of 10 for a negative-pressure respirator with an APF of 1000 for a positive-pressure PAPR, inhalation exposure under specified conditions of fit and operation differs by approximately 100-fold, or about 2 orders of magnitude [22]. This substantial reduction in inhaled infectious dose could be expected to have a decisive effect, bringing the probability of infection close to zero in ordinary living environments.

Cost is one barrier to widespread use. Medical-grade PAPRs are expensive, although their basic structure consists only of a nonwoven filter, pump, and battery [21,23]. The author demonstrated that a prototype providing equivalent performance could be assembled from commercially available components costing approximately US $40 in total [14]. Mass production is highly likely to reduce costs to a level suitable for public health procurement.

### Findings From the Author's Research Group

The author's research group has progressively developed the engineering and epidemiological foundations of PFE. Four studies make important contributions.

First, the rate of PAPR use required for it to function as an alternative to lockdown was quantified using an epidemiological mathematical model based on the effective reproduction number [15]. Simulations showed that continuous use by approximately 55% or more of the population could reduce the effective reproduction number from 2 to <0.9. They also showed that, if everyone used a PAPR, an approximately 55% reduction in each individual's probability of infection would produce an equivalent population-level infection-control effect ($R_t$).

Second, a detailed fluid-flow model of airflow inside a PAPR was developed [16]. A method was proposed for estimating respiratory state from a differential-pressure sensor and a pulse-width modulation (PWM) control signal, enabling

XSL•FO
RenderX

respiratory-phase-adaptive control intended to provide pressure-supported breathing through reverse-pressure control.

Third, validation with a physical prototype demonstrated that the wearer's respiratory flow could be estimated accurately in real time and that leakage associated with improper fit could be detected using only 1 differential-pressure sensor and the pump drive signal [17]. These findings established a technical basis for respiratory-state-responsive airflow control and the implementation of pressure-supported breathing.

Finally, the PAPR Wear-Rate Management System Network (PWS-NET) was proposed and prototyped [18]. This system combines real-time use and leak detection using a differential-pressure sensor, GPS location reporting through a smartphone, and a rule-based web server. It introduces the concept of saved allowable time (SAT), defined as the amount of time during which an individual is permitted to remove the PAPR. Prototype validation confirmed that SAT updating, violation detection, and real-time feedback to users functioned as intended.

PWS-NET is a framework that simultaneously enables population-wide monitoring of use rates and individual selection of SAT [18]. In this context, an AI-output governance framework comprising the Guide to the Expression of Legitimacy of Output (GLO) and the Verifiable Record of AI Output (VRAIO) becomes important [24]. GLO is a common language that treats an output candidate generated by an AI system as a "claim" and uses structured metadata to express whether its purpose and content comply with publicly disclosed rules. In this article, the same concept is envisaged as applying to the use of information and system decisions in PWS-NET. VRAIO provides the institutional and technical infrastructure needed to ensure the authenticity and verifiability of GLO declarations through compliance verification by an independent recorder, tamper-resistant records, and subsequent independent audits [24].

The more effective PWS-NET becomes, the greater its capacity to collect and use personal information. The GLO-VRAIO framework could impose verifiable institutional constraints on that capacity and offer a promising governance option for implementing PFE not as an instrument of intensified surveillance, but as public health infrastructure premised on privacy protection. In other words, a 3-layer structure—physical protection by PAPRs, use-rate management by PWS-NET, and governance of information use and system outputs through GLO-VRAIO—would seek to reconcile effective infection control with a high level of protection for citizens' rights.

### Logical Implications of the Current Evidence

Four implications follow from the aforementioned analysis. First, during pandemics dominated by airborne transmission, PAPRs could partially substitute for lockdown and may make it possible to manage infection risk without halting societal functions. Second, positive-pressure exposure control using PAPRs directly controls the physical process of inhalation exposure to infectious aerosols, irrespective of pathogen type. It may therefore be available immediately after the emergence of a new respiratory pathogen, without waiting for pathogen-specific vaccines or therapeutics. If inhalation exposure can be reduced sufficiently, it may be possible to control transmission without relying solely on acquisition of immunity and to secure time for pathogen identification, characterization of transmission, and development of vaccines and therapeutics. Third, PAPRs give individuals the option to reduce their risk of infection, and voluntary uptake could contribute to society-wide epidemic control. Finally, combining PWS-NET with the GLO-VRAIO framework may enable the information needed for infection control to be used while making it possible to verify the purposes for which information on use status, movement histories, and biometric information is collected and analyzed, as well as compliance with privacy protection rules [18,24]. This could provide an institutional basis for reconciling infection control grounded in the principle that "what cannot be measured cannot be controlled" with the protection of citizens' privacy and rights.

These implications indicate that PFE could become an additional axis of pandemic response, linking individual-level inhalation-exposure control to population-level infection control [14,15,18].

## Scope for Improvement: PAPR Technology Has Yet to Be Fully Optimized

Current PAPRs are used primarily in specialized hazardous environments in medical and industrial settings. They are produced in small quantities for limited markets and are subject to rigorous performance testing, quality assurance, and certification. Consequently, they tend to be expensive, and there has been little product-development competition concerning the lightness, comfort, functionality, design, and affordability required for routine use by the general public [23,25]. At the same time, their basic functional components are a nonwoven filter, an electric fan, and a battery, while their hoods or helmets are composed mainly of plastic, fabric, or nonwoven materials [14,21,23]. Current prices and forms therefore partly reflect conventional applications and market structures rather than inherent technological limitations.

Because an integrated helmet-type PAPR contains a battery, electric fan, control circuitry, and supporting structure, it also offers a suitable platform for integrating sensors that measure respiratory state and leakage, communication functions, augmented-reality displays, and smartphone functions. However, the required protective performance and comfort must be reconciled while evaluating the effects of added functions on weight, power consumption, heat generation, safety, and privacy. In addition to helmet-type devices, possible implementations of positive-pressure exposure control include personal booth systems for offices and restaurants [14,15] and ventilation-unit replacement systems that cover entire interiors of homes, offices, hotels, and other buildings.

This article has focused primarily on positive-pressure PAPRs with an APF of 1000 as a benchmark for high individual protection. However, the performance required of PAPRs for the general public need not uniformly be an APF of 1000. A

XSL•FO
RenderX

lower protection factor may suffice if it can achieve the individual-level objective of keeping the inhaled infectious dose below the level required to establish infection or the public health objective of maintaining the effective reproduction number below 1 across the population. The required performance level will vary with the pathogen's infectious dose, environmental concentration, duration of exposure, rate of PAPR use, and continuity of use. Future empirical studies should therefore verify the performance of APF 1000-class devices while also identifying the protection level that is necessary and sufficient to achieve individual- and population-level infection-control objectives.

PFE can be deployed without PWS-NET; PWS-NET is a future option intended to reconcile use-rate management with individual choice of SAT [18]. However, the use of wearing histories, location information, proximity information, and biometric data could permit inferences about an individual's patterns of daily life. By using GLO to make structured declarations of the purposes of data acquisition and analysis and VRAIO to verify, record, and audit compliance with privacy protection rules, information use by PWS-NET could be handled as a verifiable institutional procedure [24].

If positive-pressure PAPRs for the general public become a formal subject of public health evaluation and future demand becomes clear, mass production, component standardization, and competition among products may advance, promoting lower prices and designs suitable for daily use. The present generation of prototypes is a starting point, not a finished product. By continuously incorporating public health needs and evaluation results into engineering development, PAPRs must evolve into lighter, more comfortable, and safer devices while maintaining the required protective performance.

In the longer term, if PAPRs become sufficiently comfortable and convenient, people may voluntarily choose them to breathe purified air regardless of whether governments request their use. Just as people routinely use hygienically managed water, this concept envisages a future in which individuals can also choose purified air to breathe. When PAPRs shift from specialized protective equipment for emergencies to routine devices for controlling inhalation exposure, control of airborne infectious diseases may reach a major turning point—from a framework dependent on behavioral restrictions and requests to wear protective devices to 1 grounded in voluntary control of individual exposure.

## A Structural Oversight: Why Has an Apparently Obvious Option Never Been Evaluated?

The filtration performance of HEPA filters, the prevention of ambient-air ingress through positive pressure, and the dose-based understanding of infection described here are not new principles; each is grounded in existing research and standards [11,20,22].

No controlled trial has measured the effect of population-level PAPR use on infection rates, and prospective studies evaluating real-world effectiveness, adherence, and adverse events are scarce [12]. World Health Organization (WHO) preparedness and resilience for emerging threats (PRET) module 1 provides an integrated planning framework for respiratory pathogen pandemics [26]. However, positive-pressure exposure control for the general public is not explicitly identified as an independent candidate intervention. The absence of an institutional conceptual category may help explain why the option has not been evaluated despite the existence of its underlying principles and technology.

PAPRs have primarily been studied and used as respiratory protection for health care workers exposed to highly infectious diseases. The systematic review by Licina et al [12] found that existing PAPR research mainly addressed the protection of health care workers from highly infectious viral diseases and identified the higher cost of PAPRs relative to N95 respirators as an implementation disadvantage. A narrative review by the same research group showed that PAPRs have been considered protective equipment for health care workers performing high-risk procedures—particularly aerosol-generating procedures (AGPs)—on patients with suspected or confirmed COVID-19 pandemic [27]. Elkington et al [28] further reported that existing certified PAPRs typically cost £600 to £1100 (GBP £1=US $1.35, as of August 14, 2026) and explicitly identified this high price as one of the main reasons why PAPRs were not widely adopted worldwide during the COVID-19 pandemic, even among health care workers.

Thus, PAPRs were developed within the conceptual category of high-performance, expensive, specialized protective equipment for health care workers facing a high risk of infection. Face masks, by contrast, were treated as an adjunctive behavioral intervention [29]. The idea of redesigning and evaluating PAPRs—which were not widely adopted even among health care workers—as a population-level infection-control measure for routine use by the general public therefore appears to have remained effectively outside conventional research and institutional assumptions. The concept of a full-fledged engineering exposure-control device worn routinely by the general public fit none of the conventional categories and occupied an academic and institutional no-man's-land. Without a category, a concept cannot even be placed on the agenda for evaluation.

The cost of this structural omission became real during the COVID-19 pandemic. When an unknown pathogen emerged, rapidly deployable options were effectively limited to behavioral interventions plus vaccination, or lockdown. A third option—one with the potential to reduce inhalation exposure by orders of magnitude regardless of pathogen type—existed in principle but was absent in practice. Closing this gap is precisely what should be done now to prepare for the next pandemic.

PFE should therefore be examined by combining medical and engineering assessments within a public health framework. Engineering assessment should use an APF of 1000 as a high-performance benchmark and establish aerosol-protection performance, maintenance of positive pressure, removal of exhaled carbon dioxide, stability of device performance, and applicable conditions of use in ordinary daily life. Medical

XSL•FO
RenderX

assessment should determine how an engineering-measured reduction in exposure translates into inhaled infectious dose and individual-level prevention of infection, while also evaluating the safety of prolonged use. Public health assessment should determine how individual-level preventive effectiveness, use rates, and fit or use status translate into population-level infection-control effectiveness and identify the protection levels and use rates necessary and sufficient to achieve infection-control objectives. Feasibility of implementation, social acceptability, cost, and equity should also be evaluated comprehensively. If networking through PWS-NET or a similar system is used, the effect of the PAPR alone should be distinguished from the additional effect of networking, and the effects on privacy and citizens' rights should be treated as independent evaluation outcomes.

To translate the rapid deployment feasibility of PAPRs into an actual pandemic response, beginning development only after a crisis occurs would be insufficient. During nonemergency periods, performance requirements, safety, sustained use, and conditions of use for public-oriented models should be evaluated, while the number of units required, manufacturing capacity, standardization of components and consumables, and systems for procurement, stockpiling, and distribution should be considered in advance. Current PAPRs are bulky and may appear excessive in daily life; nevertheless, models certified with an APF of 1000 can provide high aerosol-protection performance under specified conditions of fit and operation. A realistic approach is to prepare practicable models first and then progressively reduce weight and noise and ensure adequate airflow during physical activity on the basis of evaluation and operational experience.

## Conclusions

Another respiratory infectious disease pandemic is likely to occur in the future. The question is whether we will search for new countermeasures only after the next crisis begins or evaluate concrete, testable candidate interventions in advance during the current nonemergency period.

Exposure control using positive-pressure PAPRs for the general public directly reduces aerosol inhalation exposure in the individual breathing zone—the process that precedes airborne infection—regardless of pathogen type. Its principles and technology are already established, and existing engineering and theoretical research has brought it to a stage at which it can be considered a candidate intervention with the potential for manufacture and implementation. Nevertheless, it has not been positioned as a subject of formal public health evaluation as a population-level infection-control measure.

This viewpoint does not advocate the immediate introduction of PFE or a universal mandate for its use. Existing engineering and theoretical evidence does not establish the effectiveness of PFE; rather, it justifies beginning its formal evaluation. Although the roles of engineering, medicine, and public health overlap in practice, engineering assessment should verify aerosol-protection performance, maintenance of positive pressure, removal of exhaled carbon dioxide, and stability of device performance in ordinary daily life conditions. Medical assessment must determine how engineering-measured reductions in exposure translate into individual-level prevention of infection and safety during prolonged use. Public health assessment must examine how individual-level preventive effectiveness, population use rates, and continuous and proper use at the necessary times and locations translate into population-level infection-control effectiveness. Feasibility of implementation, social acceptability, cost, and equity must also be evaluated comprehensively.

An APF of 1000 provides a benchmark for evaluating high individual protection, but the performance required of PAPRs for the general public need not uniformly be an APF of 1000. The protection level that is necessary and sufficient to achieve individual- and population-level infection-control objectives should be determined through public health evaluation incorporating medical and engineering evidence. Networking through PWS-NET or similar systems should also be distinguished from evaluation of the PAPR alone; its additional infection-control effect and its implications for privacy and citizens' rights must be evaluated independently.

To advance this evaluation institutionally, we propose that WHO and national pandemic preparedness plans explicitly position positive-pressure exposure control for the general public as a "candidate intervention for which evidence of effectiveness needs to be accumulated." Field studies should begin during nonemergency periods to evaluate engineering performance, individual-level preventive effectiveness, population-level infection-control effectiveness, and implementation conditions in stages, while examining the feasibility of manufacturing, procurement, stockpiling, and distribution. Positive-pressure exposure control for the general public should be added to the scope of formal public health evaluation before the next pandemic arrives.

## Abstract

Geographic information systems (GISs) and digital dashboards have become central to epidemic monitoring and crisis response, yet their broader potential for routine, equity-focused public health decision-making remains underused. As health systems increasingly prioritize reaching underserved and vulnerable populations, mapping platforms must evolve from static visualization tools to dynamic decision-support systems. This paper reflects on the development and strategic role of the Reaching the Unreached (RTU) map explorer, a regional geospatial decision-intelligence platform developed in collaboration with the World Health Organization Regional Office for the Western Pacific. The RTU map explorer integrates high-resolution subnational data across 36 countries and areas in the Western Pacific Region. It consolidates demographic, socioeconomic, health access, and vulnerability indicators into a unified geoportal that enables visualization at resolutions ranging from the national level to the village level. Drawing on open-access spatial repositories and modeled datasets, the platform applies population-based spatial clustering methods to settings where administrative units are too large to capture meaningful local variation. Built using an open-source architecture, the platform offers interactive functionalities, including layer activation, filtering, prioritization tools, and location-specific mapping, to support localized planning and resource allocation. By combining contextual and health-related data within a single interface, the RTU map explorer facilitates a shift from reactive surveillance to proactive, equity-oriented decision-making. Policymakers can compare vulnerabilities across regions, program managers can prioritize high-need districts or communities, and local implementers can identify specific locations for targeted interventions. Although challenges remain, including data recency, modeled data uncertainty, and the need for field validation, the platform illustrates how integrated geospatial intelligence can move public health beyond documenting disparities to actively addressing them through localized, data-driven action.

geospatial intelligence; digital health; vulnerability mapping; public health surveillance; health equity

## Introduction

Geographic information systems (GISs) and mapping platforms have long been used in public health, with the most frequent application being epidemic monitoring and disease surveillance [1,2]. A near-global use of such tools was observed during the COVID-19 pandemic, during which mapping platforms and live dashboards provided intuitive outputs and were extensively leveraged [3]. However, as the epidemic curve plateaus, the use of these highly valuable applications also tends to diminish [4]. Such solutions possess considerable potential to address numerous public health questions and support routine decision-making when properly implemented [3]. These tools are beneficial for a range of stakeholders, including policymakers, program managers, and local implementers such as community-based organizations.

To ensure a map's utility for all stakeholders and its relevance to routine decision-making, the required spatial resolution must transcend the national or district level [5]. A well-designed visualization can address critical questions such as the following: "Which villages lack basic Water, Sanitation, and Hygiene (WASH) services?" "Where are pregnant women least likely to deliver in a maternity facility?" "Where are children dropping out of school?" "Where do children require additional nutritional assistance?" "Which areas have poor connectivity to primary healthcare?" or "Which communities are lagging in childhood

XSL•FO
RenderX

immunization coverage?" [6]. Answering these questions requires a comprehensive understanding of the local context; therefore, integrating this information into a single platform is a logical approach [7].

## The Map Explorer for Reaching the Unreached: A Regional Decision-Intelligence Platform

One such platform, the Reaching the Unreached (RTU) map explorer for the Western Pacific Region, encompasses 36 countries and areas within the World Health Organization (WHO) Western Pacific Region. Indonesia, which transitioned from the WHO South-East Asia Region to the Western Pacific Region in May 2025, was not included because all analyses were completed prior to this reassignment. The Pitcairn Islands were also excluded due to their small population size. This paper reflects on our experience developing the platform, which is a regional initiative by the WHO to strengthen data-driven decision-making. We discuss its evolution as a regional intelligence tool and how it can support the transition toward localized, equitable, and continuous decision-support systems in public health. The platform was designed for use by regional, national, and subnational public health decision-makers, including WHO teams, ministries of health, program managers, funding partners, and nongovernmental or community-based implementers seeking to identify underserved populations and guide more localized, equitable action.

The platform was developed by EPCON in September 2024 in collaboration with the WHO Regional Office for the Western Pacific to support the implementation of the WHO Regional Framework for RTU [8]. The overarching goal of this project was to develop a platform capable of supporting data-driven decision-making for common public health concerns and of assisting in the identification of vulnerable populations at scales extending down to the village or community level.

The RTU map explorer hosts high-resolution, subnational data spanning a range of indicators, including demographic characteristics, socioeconomic development, overall human development, health care access, and population vulnerability. The data are available across all administrative levels, from the national level down to a resolution of a few kilometers (village or neighborhood level). This granular data make the platform suitable for diverse public health programs, such as those focused on disease control (eg, tuberculosis [TB], HIV, malaria, and other epidemics) as well as programs related to population welfare, education, immunization, WASH, and health promotion, with a focus on underserved or unreached populations [9,10]. Given the constraints of limited resources and a high vulnerability burden, the efficient use of resources is paramount [11]. Investing in advanced tools that facilitate context-driven decision-making can ensure that interventions reach the populations most in need and optimize intervention implementation [12].

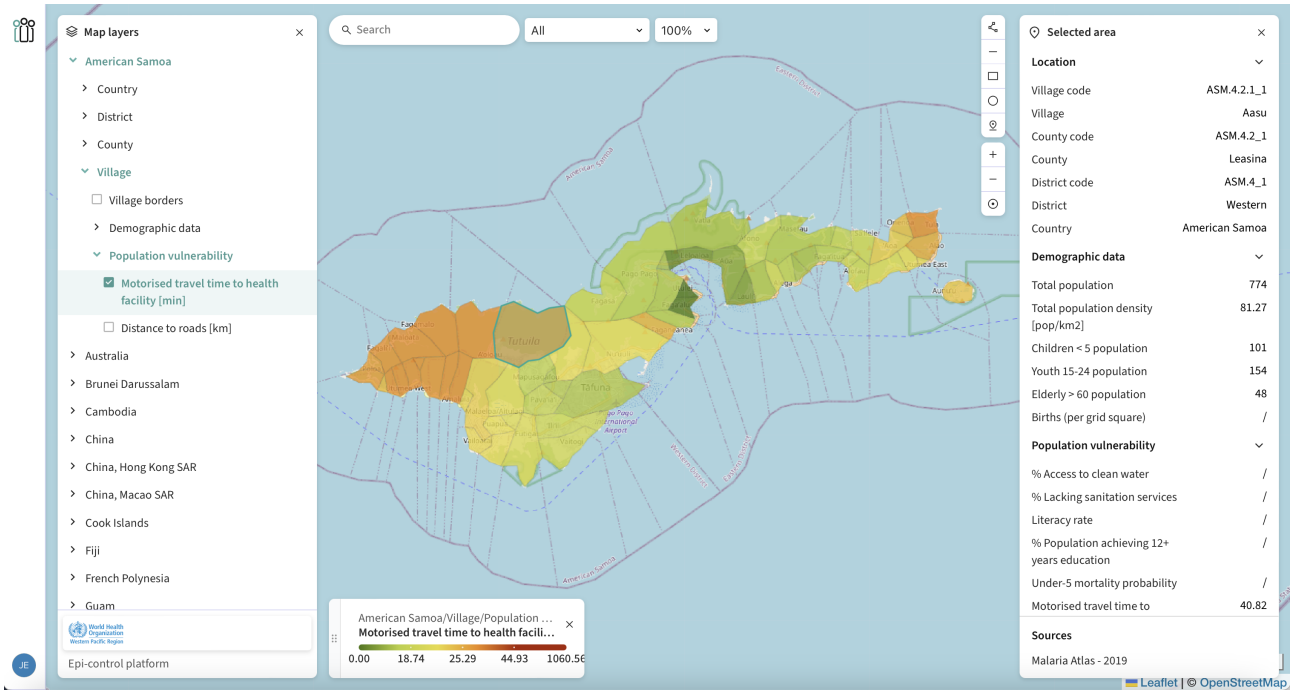
The RTU map explorer is built on a geoportal, the web-based mapping component of the Epi-control platform (EPCON). The Epi-control platform is an AI-driven "digital twin" that is deployed in several countries to support specific disease control programs, primarily TB and HIV [13,14]. Within the Epi-control platform, data from health programs can be augmented with high-resolution subnational contextual data to train predictive models that identify high-transmission areas or disease "hotspots." The "digital twin" is a dynamic model that updates in near real-time, or as required, to forecast new hot spots based on programmatic progress and planning. Community-based interventions are guided by a comprehensive, data-driven process, moving beyond sole reliance on case notification rates. This approach has yielded improved intervention outcomes and helped direct resources to priority areas, thereby maximizing program impact [14,15]. However, the implementation of this approach and its outcome evaluation in the Western Pacific Region have yet to be evaluated. The RTU map explorer functions as a data integration and visualization platform, providing the static contextual intelligence layer upon which, when combined with programmatic or case notification data, programmatic decision-making can be grounded.

## Transforming the Role of Maps

The first step was a thorough search for subnational high-resolution data. Relevant data sources were identified from open online repositories that host survey or modeled indicators, including the Demographic and Health Surveys (DHS) spatial repository, the Institute for Health Metrics and Evaluation (IHME), WorldPop, the Humanitarian Data Exchange (HDX), and country government websites. The data sources were selected based on the criteria of resolution, recency, and extent; a complete inventory is provided in Multimedia Appendix 1. Such high-resolution raster data were extracted and aggregated within each administrative boundary using zonal statistics. Pixel values were either summed (for count-based data, eg, population counts) or averaged (for continuous or rate-based data, eg, prevalence data). To aggregate values up the administrative hierarchy, population-weighted averages were used for indicators that vary with population size (eg, vaccination coverage), and mean values were used for those that do not vary with population size (eg, distance to the nearest health care facility).

On the basis of the availability of high-resolution data and high population density, the smallest administrative units in some countries were further subdivided into smaller units. This was achieved using a recursive weighted k-means clustering algorithm [16]. For each administrative unit, the algorithm iteratively assigned population-weighted centroids using k-means clustering, from which "Thiessen" (Voronoi) polygons were constructed and their populations computed [17]. If the population of a generated polygon exceeded a target threshold of approximately 10,000 individuals, the unit was iteratively subdivided. The 10,000-person population threshold was determined in collaboration with project stakeholders to make administrative units comparable across the 36 countries and areas of the Western Pacific Region.

The weighted k-means algorithm partitioned the population into clusters, after which new Voronoi polygons were generated around the resulting cluster centroids, and oversized polygons

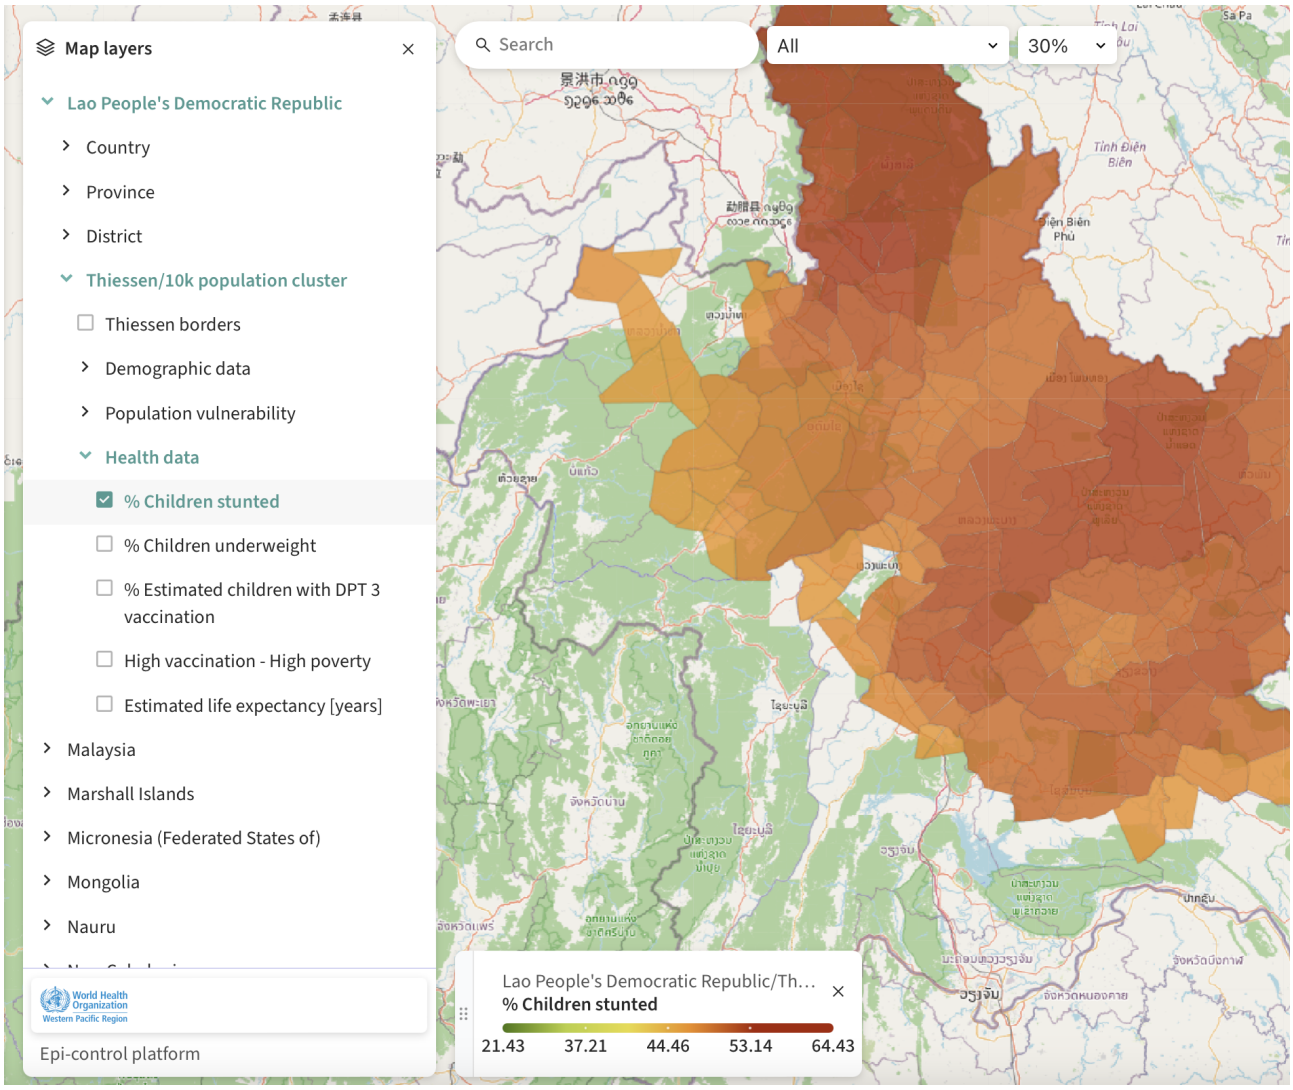


XSL•FO
RenderX

were replaced with these smaller units. This process was repeated recursively until all polygons fell within the target population range. Each polygon was then spatially clipped to fit within its original administrative boundary. The final output comprised a table of Thiessen polygons, each associated with a population count and clipped geometry. The map explorer is implemented using proprietary Python code (version 3.12.3; Python Software Foundation) and leverages open-source software components.

The data layers are organized separately for each of the 36 countries and areas, followed by a comprehensive "Western Pacific Region" tab that visualizes all countries simultaneously for intercountry comparisons. For each country, the data layers are subdivided based on the respective administrative levels, commencing at the national level, followed by district, county, and village levels. Figure 1 demonstrates the selection of a layer to visualize data at the highest available resolution for American Samoa (village).

**Figure 1.** Arrangement of data layers for American Samoa, showing motorized travel time to health facilities at the village level. The color scale ranges from green (low travel time to health facilities) to orange red (high travel time to health facilities).



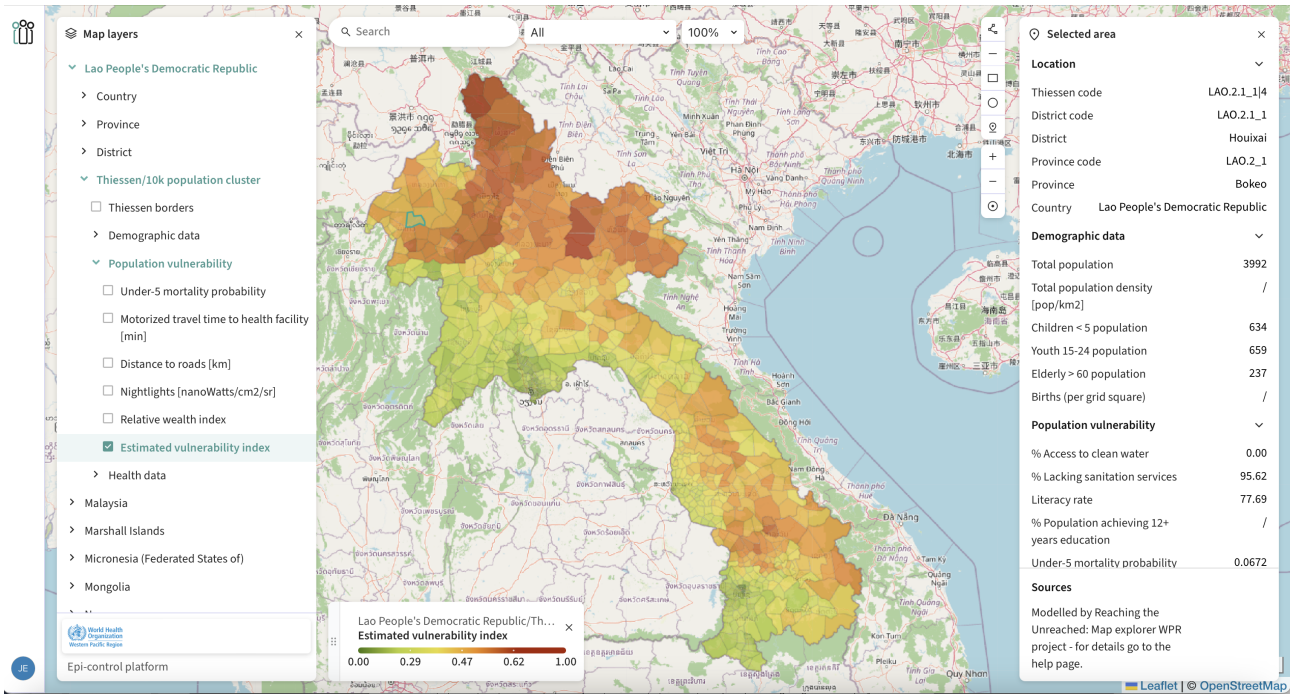
The map explorer provides several functionalities for seamless exploration of data layers. To commence exploration of a particular country, a data layer must be selected to activate the map. The "focus" tool facilitates direct zooming onto the country whose layer has been activated. The "location pointer" tool allows users to place a "pin" directly on the map and provides a Google Maps link to that specific location. This link can be shared or used to explore the neighborhood within the village or community, proving particularly useful for local implementers or nongovernmental organizations (NGOs) working closely with communities. It aids in identifying a specific landmark or village community for outreach purposes. The "filter" option enables the shortlisting of priority locations for targeted interventions. Figure 2 demonstrates the filtering capability of the platform to identify at-risk communities with high prevalence of child stunting. This is valuable for both program management and community-based organizations, allowing users to filter priority districts, wards, villages, or communes for specific resource allocation or intervention planning.

XSL•FO
RenderX

**Figure 2.** Enlarged view of the data layers available under different categories at the Thiessen-level (subdistrict-level) visualization of children stunting prevalence in the Lao People's Democratic Republic. The values are filtered to display the top 30% Thiessens with the highest prevalence of child stunting. The color scale ranges from green (low percentage of children stunted) to orange red (high percentage of children stunted). Thiessen borders are shown in lighter lines, and active layers are displayed in green on the left-side layer panel.

## Bridging the Gap Between Data and Decision

The platform is designed to support public health decision-making, the planning of local programs, and disease surveillance. The extensive data library can facilitate horizontal program integration. Sociodemographic conditions and local context are determinants not only of health and disease conditions but also of human behavior, local practices, and the design of interventions [18]. The platform offers an opportunity to gain a comprehensive understanding of the local context from the national to the village level, making it suitable for designing integrated programs such as TB and nutritional support interventions, maternal and child health (MCH) and immunization programs, and education and financial support initiatives.



To further support decision-making across multiple administrative units, an estimated vulnerability index was constructed using 11 indicators spanning 3 domains: health access (travel time to the nearest health center, distance to roads, and vaccination coverage), demographic and health outcomes (population density, elderly population aged ≥60 years, child mortality, and the prevalence of underweight children), and socioeconomic conditions (male and female literacy, nightlight intensity, access to water, and the prevalence of open defecation). For each indicator, spatial units were ranked relative to one another, with the direction of ranking assigned so that a higher rank consistently represented greater vulnerability. Each unit's rank was then normalized by dividing it by the maximum rank observed for that indicator, producing a score between 0 and 1 for every indicator across all spatial units. The vulnerability index for each spatial unit was computed as the mean of its normalized ranks across all available indicators. This formulation treats each indicator with equal weight and accommodates spatial units with missing data by computing the mean over observed indicators only, ensuring that partial data does not systematically bias the index. Figures 3 and 4 demonstrate the visualization of the vulnerability index at high resolution (Thiessen). For visualization at less granular administrative levels, unit-level index scores were spatially aggregated using the median to ensure robustness to outlying

XSL•FO
RenderX

values within administrative units. The resulting index is a relative measure of estimated vulnerability, situating each administrative unit within the national distribution of vulnerability across all 3 domains simultaneously. The index is intended to support exploratory prioritization and dialogue with countries, not as a resource-allocation tool.

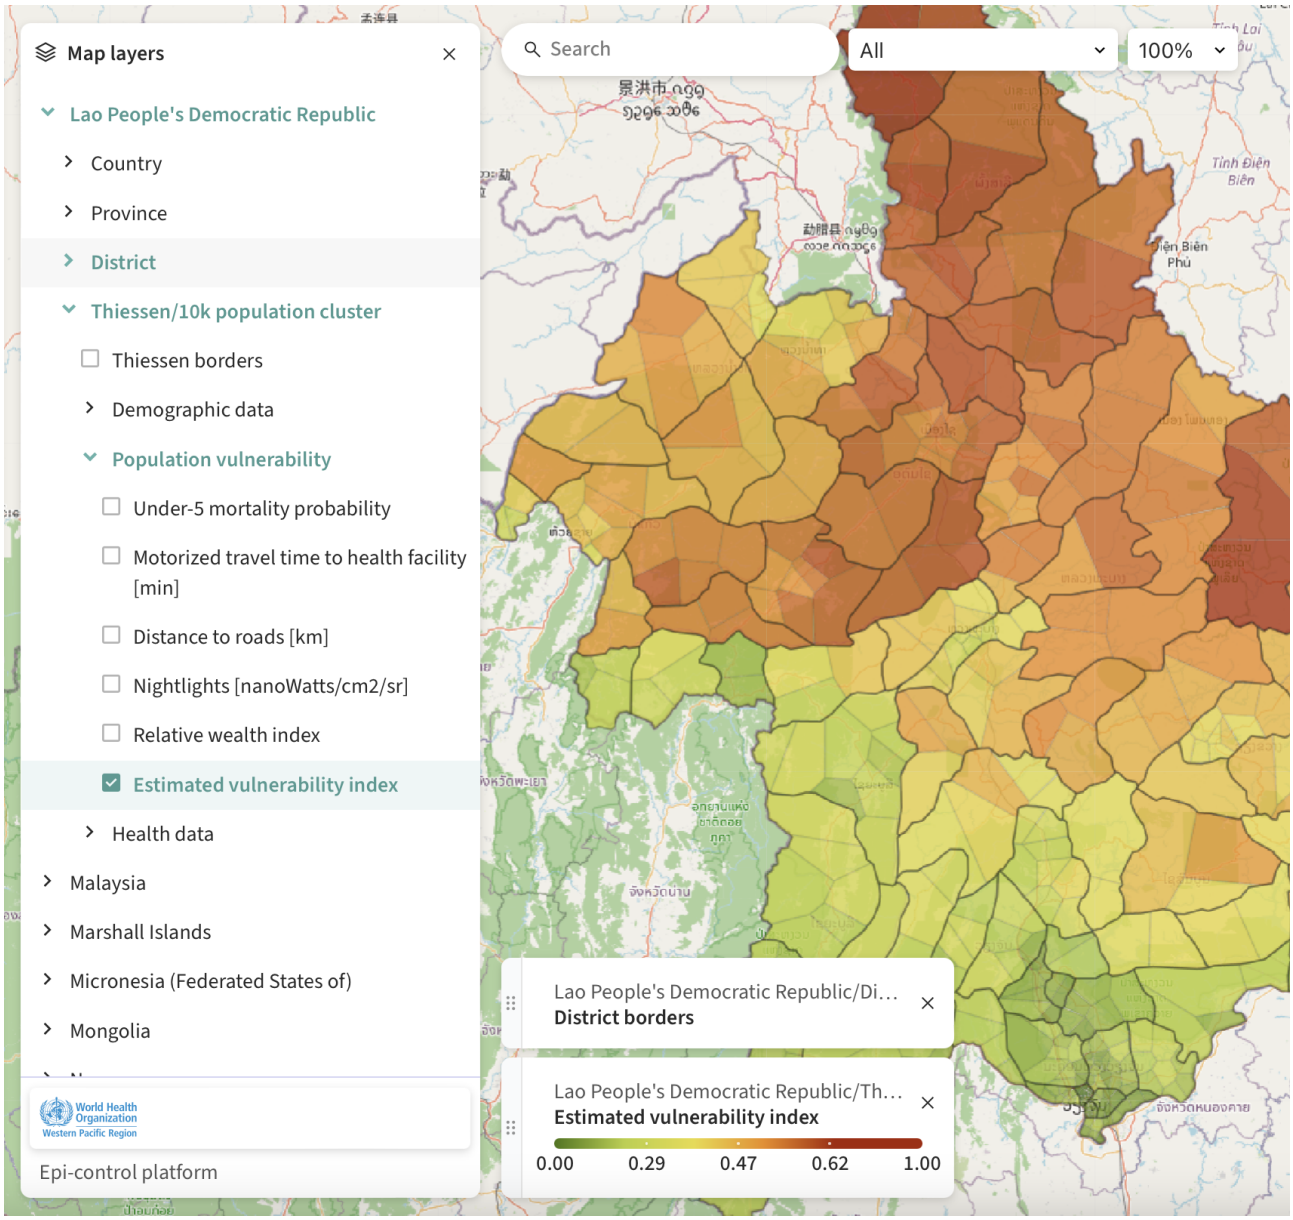


**Figure 3.** Thiessen-level (subdistrict-level) visualization of estimated vulnerability in the Lao People's Democratic Republic. The color scale ranges from green (low vulnerability) to orange red (high vulnerability).

XSL•FO
RenderX

**Figure 4.** Enlarged view of the Thiessen-level (subdistrict-level) visualization of estimated vulnerability in the Lao People's Democratic Republic. The color scale ranges from green (low vulnerability) to orange red (high vulnerability). District borders are shown in dark lines, and Thiessen borders are shown in lighter lines.

The mapping of data across all administrative levels ensures the platform's suitability for stakeholders across multiple professional cadres. Policy-level stakeholders may require a high-level overview, program implementers may need more granular information at the community level, and the scientific community may require both. Access levels and the scope of data can be customized based on local requirements, balancing comprehensiveness with simplicity.

## Toward a More Equitable Data Future

The RTU map explorer is designed to support near real-time data updates when linked to a country's data platform or disease notification system, allowing new cases, interventions, or planned activities to be dynamically mapped on the platform. This integration is facilitated on a case-by-case basis according to country needs and data infrastructure. This also supports monitoring and evaluation efforts and contributes to pandemic preparedness strategies. As new survey data or modeled estimates become available, the data sources can be refreshed. For instance, the platform is currently being used in other countries, such as Nigeria [15], Pakistan [14], Uganda [19], and the Philippines, for planning community-based TB active case-finding interventions. Program stakeholders are able to track progress and plan interventions based on their access level.

Although the RTU map explorer platform has yet to achieve full uptake in the region, it has been integrated in other countries with mobile apps, diagnostic tools [20], X-ray equipment, and District Health Information Software 2 (DHIS2) platforms to access and map health-related data in real-time or to transmit notifications and data to other dashboards or devices.

Although various open-source platforms make subnational high-resolution data publicly available, this map explorer is unique in integrating data from different domains into a single platform, thereby maximizing its potential for scientific,

XSL•FO
RenderX

policy-level, and programmatic decision-making. Mapping and granular visualizations illuminate details that would remain obscured within aggregated numbers in tables and graphs, which is particularly crucial when attempting to reach underserved, remote, and vulnerable population groups [21]. The mapping of the local context enhances data intuitiveness and fosters opportunities for new ideas, approaches, and discussions [22].

In its current form, the platform is beneficial for government agencies, funding organizations, and local implementers. Funding agencies can use it to compare vulnerable regions both across and within countries to identify resource needs. Program planners and ministries can use it to identify high-priority regions within their respective countries. Local organizations can pinpoint communities or neighborhoods for targeted interventions, informed by the backdrop of local contextual data.

However, maintaining contextual and demographic data sources on such a platform comes with certain challenges. Reliable estimates and granular data may not be available for all countries and regions. These estimates are not updated on fixed timelines; therefore, the most recent granular estimates can be ≥5 years old for some countries. Second, most granular estimates are modeled datasets, which can inherently have large uncertainties. The platform in its current state is unable to visualize the associated CIs or uncertainties for these modeled estimates. The platform is not currently open source and comes with a licensing fee. The governance framework for platform adoption, including country-specific data-sharing, access, and stewardship arrangements, will be an important consideration when nonpublicly available data are incorporated into the platform. For a more tailored experience and to facilitate joint efforts in programmatic decision-making, the subsequent phase would involve the creation of individual mapping portals for specific countries. There is also a need for field validation and evaluation of the feasibility and uptake of the platform in the Western Pacific Region.

Data can generate greater impact when they empower those closest to the problem. Public health systems need to look beyond documenting inequality; there is a need for active tools that help make decisions. The progress of public health intelligence will depend not only on accumulating more data but also on transforming existing data into meaningful, local, relevant, and equitable insights. The RTU map explorer exemplifies technology that supports decision-making that is not just more intelligent, but also fairer.

## Acknowledgments

No generative AI or AI-assisted technologies were used in the drafting, preparation, or analysis of this manuscript.

## Funding

The World Health Organization Regional Office for the Western Pacific contracted EPCON for the implementation of the platform in support of its mandate to reach the most underserved populations in the region. EPCON did not receive any funding for the preparation of this manuscript.

## Disclaimer

## Abstract

Across Africa, substantial investment has built national health information systems (HISs), including the surveillance platforms, reporting tools, and digital infrastructure through which health data flow. However, the health informatics capacity needed to sustain those systems remains fragile: trained health informaticians leave for better-resourced organizations, platforms fall into disrepair when donor funding ends, and data systems multiply without connecting. Health informatics is the discipline that designs, governs, and sustains HISs; the two are inseparable, and investment that builds one while neglecting the other cannot produce durable results. This viewpoint, grounded in the authors' direct implementation experience across sub-Saharan Africa and informed by published literature, argues that the cause is a structurally misaligned investment logic: resources concentrate on training health informaticians while the institutional, governance, and infrastructure conditions that determine whether those informaticians can perform are chronically underfunded. We propose that sustainable health informatics capacity requires a functioning HIS ecosystem and that this ecosystem rests on four interdependent pillars: (1) workforce development beyond training; (2) institutional strengthening; (3) governance and data standards; and (4) interoperable infrastructure, including the national HIS platforms, such as the District Health Information Software 2, through which health informatics practice operates. The pillars are interdependent: weakness in any one undermines the others in specific, predictable ways. The framework makes 3 contributions beyond existing World Health Organization (WHO) and Africa Centers for Disease Control and Prevention frameworks: it shows how weakness in one pillar actively undermines the others; it focuses specifically on health informatics and national HISs as the primary investment domain rather than as components of a broader digital health agenda; and it treats the enabling environment, specifically civil service structures, domestic financing, data sovereignty, and artificial intelligence governance, as core investment requirements rather than background conditions. Drawing on illustrative experiences from Ethiopia, Kenya, and Sierra Leone, we show how health informatics capacity succeeds or fails depending on the strength of all 4 conditions. A practical readiness checklist and audience-specific policy recommendations are provided for national health ministries, national public health institutes, regional bodies, and development partners.

## Introduction

Over the past decade, African governments and development partners have invested substantially in digital health. More than 40 nations reportedly use the District Health Information Software 2 (DHIS2) for routine health information management [1,2], and health workers—from rural facilities to national disease control centers—now use digital platforms such as DHIS2-based surveillance modules, electronic disease notification systems, and mobile reporting tools to track outbreaks, monitor immunization coverage, and coordinate emergency responses [3,4]. The infrastructure investment is real and significant, but the capacity to sustain and use it effectively has not kept pace. This gap, between platforms built and platforms functioning, is the problem this paper addresses.

Understanding why requires a precise distinction between 2 related but different concepts. A health information system (HIS) is the operational infrastructure of a health system—the surveillance platforms, electronic health records, reporting tools, registries, and dataflows through which health data are

XSL•FO
RenderX

generated, managed, and used. DHIS2, the most widely deployed HIS platform in Africa, is an example. Health informatics is the discipline that designs, governs, and continuously improves those systems—the trained workforce, institutional arrangements, data standards, interoperability frameworks, and governance rules that determine whether an HIS functions well or poorly. An HIS is the system. Health informatics is what makes the system work. The relationship between them is the paper's central concern: health informatics capacity must be embedded within a functioning HIS ecosystem, and a functioning HIS ecosystem requires health informatics capacity to sustain it. Investment that treats them as separate problems produces neither.

However, the dominant investment logic does not reflect this relationship. Across Africa, health informatics investment concentrates on training: initiatives such as Africa Centers for Disease Control and Prevention's (CDC's) Africa Epidemic Services-Public Health Informatics (AES-PHI) fellowship produce competency-trained graduates and directly address workforce shortages [5,6]. This is necessary, but training produces individuals, not systems. A trained informatician placed in an institution without a funded post, a governance mandate, or functional HIS infrastructure cannot perform. The informatician and the system each need the other, and investment that builds one while neglecting the other cannot produce sustainable health informatics capacity. Existing frameworks recognize that workforce, governance, and infrastructure are all important: the World Health Organization (WHO), the World Bank, and Africa CDC have consistently identified them as interdependent requirements for sustainable health system performance [2,5,7-9], but they treat these elements as parallel components rather than as interdependent conditions whose misalignment is itself the cause of failure. What has been missing is a framework that explains, specifically for health informatics, how misalignment across these conditions limits the translation of training investment into functioning national HISs.

We therefore propose a 4-pillar systems framework for sustainable health informatics investment in Africa, one that goes beyond training to address the full set of conditions a health informatician needs to perform. The 4 pillars are workforce development beyond training, institutional strengthening, governance and data standards, and interoperable infrastructure. The framework is designed for 4 audiences: national health ministries responsible for health informatics investment decisions, national public health institutes (NPHIs) that serve as institutional anchors for surveillance and health informatics practice, regional bodies such as Africa CDC that set standards and coordinate capacity, and development partners whose financing decisions shape what gets built and what gets sustained.

## From Paper to Platform: The African Digital Health Journey

### Overview

For decades, African health systems ran on paper, with data arriving late, incomplete, and largely unused. The 2014 to 2016 Ebola outbreak exposed these gaps and accelerated investment in HISs across the region [1,2]. DHIS2, developed by the Health Information Systems Program at the University of Oslo, became the platform of choice: by 2020, over 40 African countries reportedly had national DHIS2 platforms supporting routine health information, surveillance, or both [1,10,11].

The country experiences mentioned under the *Ethiopia*, *Kenya*, and *Sierra Leone* sections are illustrative, not a systematic review. Their purpose is to show how the relative strength or weakness of specific enabling conditions shapes health informatics capacity. Those conditions map to the 4 pillars of the framework presented in the section that follows.

### Ethiopia

Ethiopia's nationwide DHIS2 rollout, combined with the electronic community HIS, formed part of a sustained federal investment in digital health embedded in successive national health sector transformation plans [12]. An interrupted time series study subsequently reported improvements in maternal and child health indicators, documenting gains in data completeness and reporting timeliness [13]. In the authors' assessment, Ethiopia's trajectory illustrates an uneven pillar profile. Pillars 1 and 4 were relatively strong: the country built substantial informatics workforce capacity and invested in interoperable infrastructure. Pillars 2 and 3 lagged: harmonizing parallel vertical systems required cross-ministry mandates and consolidated data standards that took much longer to establish. The result was a system where skills and infrastructure existed but institutional coordination and governance frameworks were absent. This constrained comprehensive integration. It is a direct illustration of why pillar 4 investment alone cannot compensate for weak pillars 2 and 3.

### Kenya

Kenya offers a contrasting trajectory. The 2011 to 2012 national DHIS2 rollout documented investment across all 4 enabling conditions: informatics workforce with defined institutional roles (pillar 1), coordination structures linking district and national health system levels (pillar 2), frameworks governing data access and use (pillar 3), and the technical infrastructure to connect them (pillar 4) [14]. The result was a more integrated national platform than comparator settings where investment was concentrated on a single domain [14,15]. The contrast with Ethiopia is not about resources, it is about alignment: investing across all 4 conditions simultaneously produced better integration than concentrating on 1 or 2 conditions.

### Sierra Leone: Crisis-Driven Innovation and Systems Learning

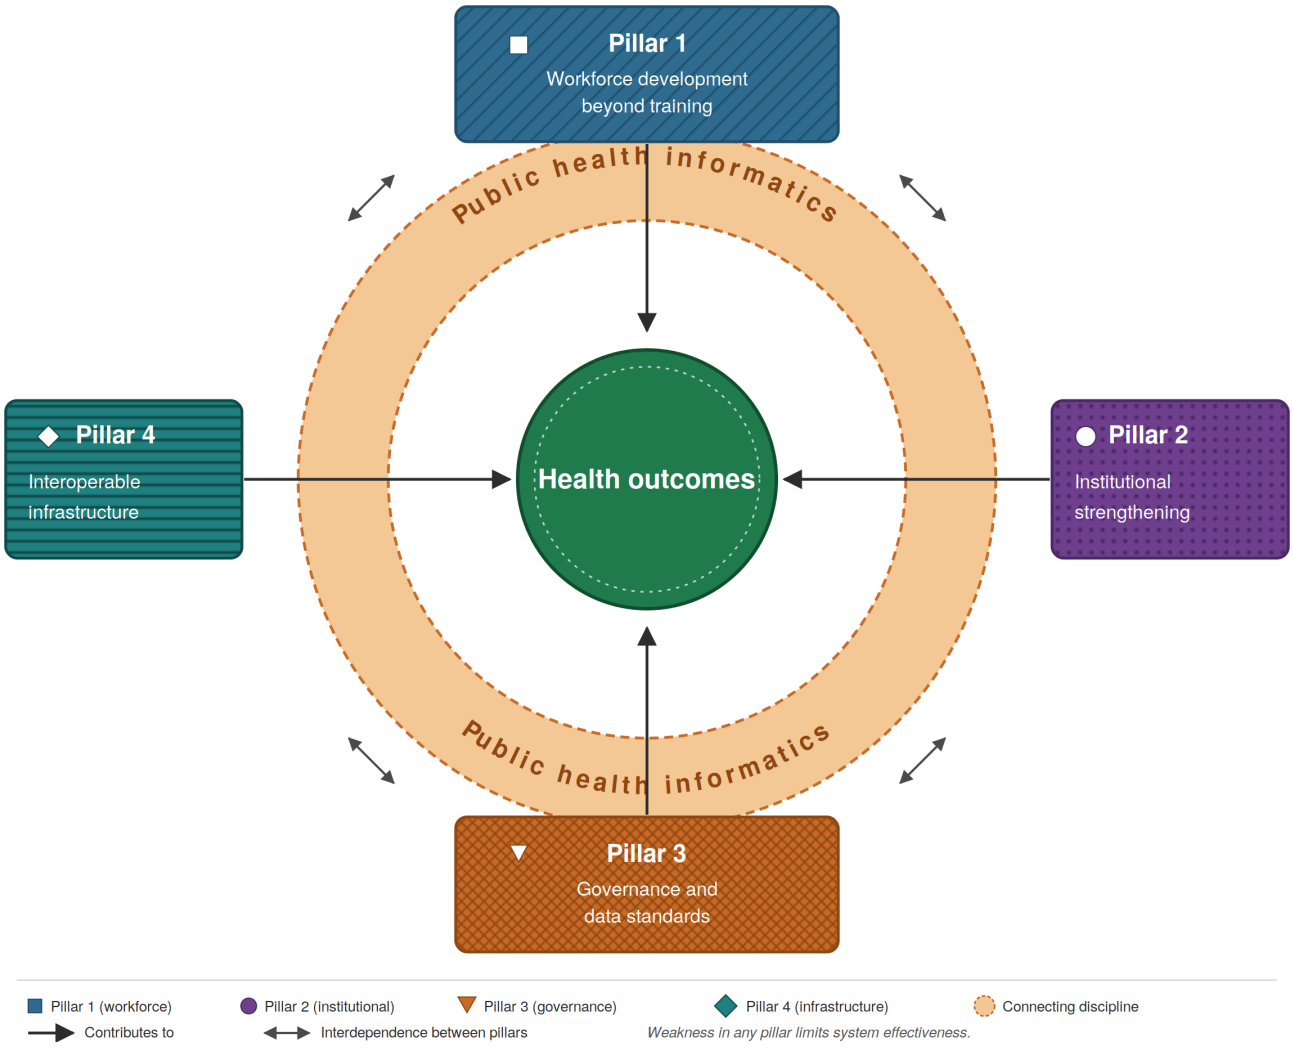
Sierra Leone did not plan its way to building health informatics capacity; crisis forced it. The 2014 to 2016 Ebola epidemic exposed acute gaps in surveillance and coordination. It drove

XSL•FO
RenderX

rapid investment from the Ministry of Health and Sanitation, the US CDC, WHO, and partners [16,17]. In 2019, Sierra Leone became the first country in the WHO African region to achieve nationwide electronic health facility reporting of surveillance data [16].

The electronic Integrated Disease Surveillance and Response system, built on DHIS2, now operates across all 16 districts and more than 1500 health facilities [16,17]. Completeness of weekly IDSR reports rose from 68% in 2015 to above 98% in 2023, according to national DHIS2 data in the peer-reviewed literature [18]; these figures reflect reported national routine data and should be interpreted accordingly. Four enabling conditions drove this improvement: a trained surveillance workforce, a strengthened National Public Health Agency with a statutory mandate, standardized data definitions and reporting protocols, and a hybrid infrastructure combining SMS text messaging, mobile data entry, and web interfaces to accommodate varied connectivity [16,19].

When the COVID-19 pandemic arrived, Sierra Leone did not build new systems. National teams adapted the existing DHIS2-based platform for surveillance, contact tracing, and laboratory modules [11]. Precrisis investment in platforms and workforce enabled a faster, more coordinated response than would otherwise have been possible.



Two subsequent emergencies further tested this infrastructure. A synthetic cannabinoid crisis (locally called Kush) and concurrent mpox outbreaks [19,20] required rapid multisectoral coordination for which no dedicated parallel system existed. The National Public Health Agency coordinated responses using real-time DHIS2 data [19,20]—no new system was built. This is the clearest demonstration the Sierra Leone experience offers: when all 4 pillars are in place, routine HIS infrastructure can absorb novel threats without emergency workarounds.

## A Systems Framework for Sustainable Health Informatics Investment

### Overview

The country experiences above illustrate what happens when some of these conditions are in place and others are not. The framework shown in Figure 1 makes those conditions explicit and maps their interdependencies. Each pillar is addressed in the subsections below; the failure mechanisms linking them are addressed in the following section.

**Figure 1.** A systems framework for sustainable public health informatics investment in Africa. Four interdependent pillars (workforce development, institutional strengthening, governance and data standards, and interoperable infrastructure) converge on health outcomes. Public health informatics (orange ring) is the connecting discipline. Bidirectional arrows denote interdependence; weakness in any pillar limits system effectiveness.

XSL•FO
RenderX

### Pillar 1: Workforce Development Beyond Training

Health informatics cannot function without trained practitioners. Africa CDC's workforce framework identifies health informatics as a priority domain [5], and the AES-PHI fellowship is one of the most important mechanisms for building this cadre [6]. However, training is the starting point, not the destination.

A stable workforce requires more than a training certificate. It requires formal civil service career pathways within ministries of health and NPHIs, salary structures that reduce attrition to the private sector and international organizations, structured mentoring, continuing professional development programs, and cross-border learning networks [21].

When these conditions are absent, fellowship graduates can migrate to better-resourced organizations, leaving the institutions that trained them without the human capital required to execute their mandates. This dynamic directly undermines pillar 2: institutions lose their most capable staff before those staff can build the routines and practices that make the institution function.

### Pillar 2: Institutional Strengthening

Trained individuals cannot act without institutions that give them authority, resources, and a mandate. The gap between institutional presence and institutional capacity is well documented. Eighty percent of African countries have established a public health emergency operations center (PHEOC). However, fewer than one-third meet most core functionality criteria [22]. A structure on paper and a functioning institution are not the same thing.

The WHO–Africa CDC PHEOC framework establishes that functional operations centers require coherent policies, defined data systems, and stable skilled staffing working together—not physical infrastructure alone [23]. Clear mandates, standard operating procedures, and stable funding are the conditions under which data and skills can translate into coordinated action. Without them, neither does.

NPHIs are the natural institutional anchors for health informatics practice. They combine a statutory public health mandate with technical independence from line ministries, and can host surveillance systems, PHEOCs, and analytic units under a single roof [21,24]. In many settings, the binding constraint is not talent but the absence of a dedicated domestic budget line. Health informatics work that depends on donor funding cycles rarely aligns with national planning horizons. When grants end, the capacity they supported is at risk.

When institutional strengthening is weak, informaticians trained under pillar 1 can lack the resource authority, legal mandate, and budget to act. Their technical skills risk being stranded. Without an institutional anchor, governance frameworks and data-sharing agreements may remain aspirational: rules without the authority to enforce them.

### Pillar 3: Governance and Data Standards

Data without governance are a liability, not an asset. Across Africa, many countries lack enforceable rules for cross-program data access, data-sharing agreements, and privacy protections [25]. Fragmented vertical systems, each funded by a separate donor project, complicate data harmonization and increase reporting burden on health workers. The WHO Regional Office for Africa identifies governance as a core HIS building block, and these gaps remain pervasive across the region [7]. When standards are absent and governance is unenforced, pillar 4 infrastructure defaults to program-specific specifications. Those specifications cannot be shared across systems, reproducing exactly the fragmentation that coordinated investment was intended to resolve.

The governance imperative extends to artificial intelligence (AI). AI tools for outbreak detection, clinical decision support, and resource allocation are being deployed across African health systems—in many cases ahead of the governance frameworks needed to guide them [26,27]. Without proactive national policies, the risks are concrete: AI data stewardship roles go undefined, consent requirements remain unspecified, and parameters for cross-border data sharing are left to external actors. These tools can then encode existing biases and concentrate analytical control outside the continent. Governance is not a constraint on informatics development. It is what makes that development safe, equitable, and nationally accountable.

### Pillar 4: Interoperable Infrastructure

Infrastructure is not a background condition. It is an active determinant of whether the other three pillars can function. The Open Health Information Exchange architecture provides a widely adopted blueprint, defining components for client registries, facility registries, terminology services, and interoperability layers [28]. Sierra Leone's Integrated Disease Surveillance and Response experience illustrates how hybrid infrastructure design can accommodate real-world connectivity constraints while feeding a single national platform, combining SMS text messaging, offline data entry, and web interfaces.

Infrastructure investments must address reliable power and connectivity for rural facilities, hardware procurement and maintenance plans, interoperability layers connecting DHIS2 with laboratory and logistics systems, and cybersecurity protections. When infrastructure is unreliable or noninteroperable, health workers can revert to paper, data gaps accumulate, and rural facilities may effectively drop out of national surveillance and resource allocation. The professional confidence of the informatics workforce can erode, reinforcing the attrition that pillar 1 works to prevent.

## Relation to Existing Frameworks and New Contribution

This framework builds on an established conceptual lineage. The WHO health systems building blocks [29] identified six interdependent foundations of functioning health systems: health workforce, health information, financing, medical products, leadership and governance, and service delivery. It has shaped health systems discourse for nearly two decades [29]. The Africa CDC workforce framework [5] and the WHO framework for implementing the global strategy on digital health [7] apply that logic to workforce development and digital health ecosystems respectively. These frameworks establish the consensus that no

XSL•FO
RenderX

single investment domain is sufficient. The contribution of this paper is not to identify new components of digital health systems. It is to explain how misalignment across these components limits the translation of health informatics investment into functioning national HISs. None of the existing frameworks specifies how weakness in one domain actively undermines investment in another or which direction that failure travels. None is scoped specifically to health informatics as the primary investment domain, and none treats the enabling environment, specifically civil service structures, domestic funding models, data sovereignty, and AI governance, as core investment requirements rather than supplementary considerations.

Against those three gaps, this framework makes three specific advances. First, it frames health informatics as the primary investment domain and treats HIS platforms as the core infrastructure through which that discipline operates, rather than as one component among many in a broader digital health agenda. Second, it explains how weakness in one pillar undermines the others: an informatician placed in an institution without a mandate, budget, or functional infrastructure cannot perform, regardless of the quality of their training; failure pathways run in both directions and explain why single-pillar investments so frequently underperform. Third, it treats the enabling environment, specifically civil service structures, domestic financing, data sovereignty, and AI governance, as core investment requirements rather than background conditions. Existing frameworks name these as context. This framework treats them as investment objects without which the other pillars cannot be sustained. Table 1 maps these gaps and contributions systematically.

**Table .** Comparison of this framework with existing Africa Centers for Disease Control and Prevention (CDC) and World Health Organization (WHO) frameworks.

| Feature | WHO building blocks [29]; Africa CDC and WHO digital health frameworks [5,7] | This framework |
|---|---|---|
| Core domains identified | Six building blocks: health workforce, health information, financing, medical products, leadership or governance, and service delivery [29]; adapted to digital health as workforce, governance, infrastructure, and human resources [5,7] | Same 4 domains, explicitly named as pillars with defined interdependencies |
| Failure mechanisms | Building blocks note interdependence but do not map failure pathways; digital health frameworks list domains without interaction logic or sequencing guidance | Bidirectional failure pathways mapped (eg, weak pillar 2 strands pillar 1 investment, and absent pillar 3 fragments pillar 4) |
| Focus object | Broad digital health ecosystem | HIS[a] and public health informatics as primary investment objects; interoperability as shared national asset |
| Political economy | Not addressed | Civil service career pathways, domestic budget lines, and donor-dependency cycles |
| Data sovereignty and AI[b] governance | Mentioned generically or absent | Treated as core governance requirements with operational implications for platform hosting and policy review cycles |
| Equity dimensions | Not systematically addressed | Urban-rural connectivity gaps, gender-stratified access, and frontline worker inclusion in governance |
| Investment sequencing guidance | Not provided | Readiness checklist enables pillar-by-pillar gap assessment and prioritization |

[a]HIS: health information system.

[b]AI: artificial intelligence.

How the pillars undermine each other follows predictable patterns. Weak institutional mandates (pillar 2) strand trained informaticians (pillar 1): without a funded post or decision-making authority, a fellowship graduate has no mechanism through which to act. Fragmented data governance (pillar 3) compounds this: absent standards mean workforce competencies trained for one program cannot transfer across systems. Absent governance also fragments infrastructure (pillar 4): platforms built without enforced interoperability standards cannot be connected, reproducing the vertical silos investment was meant to resolve. Moreover, as infrastructure scales, governance must keep pace: AI tools and cross-border dataflows that go unaddressed convert new technical capacity into new institutional risk. The failure runs in reverse too: unreliable infrastructure erodes the working environment of the informatics workforce, reinforcing the attrition that pillar 1 investment works to prevent. These are the patterns through which single-pillar investments so frequently underperform.

As the pillars depend on each other, the order in which they are strengthened matters. When a country trains health informaticians before establishing the institutional structures that give them a post and a mandate, the graduates leave. When it builds HIS infrastructure before putting governance and data standards in place, platforms become program-specific silos that cannot communicate. In low-baseline settings, pillar 2 must

XSL•FO
RenderX

come first: without a mandated institution with a budget and defined governance roles, neither workforce retention nor data governance enforcement is achievable. Pillar 3 should precede major pillar 4 investment for the same reason. In higher-baseline settings where pillars 2 and 3 are functional, pillars 1 and 4 can advance together. No sequence is universal: the readiness checklist in Table 2 provides a tool for identifying which pillar is the binding constraint in a given country context.

**Table .** Minimum enabling conditions, example indicators, and sequencing priority by pillar. Sequencing priority indicates whether a pillar is a prerequisite for others (must be established first), concurrent (can be developed in parallel), or dependent (requires other pillars to be functional first).

| Pillar | Minimum enabling conditions | Example indicators | Sequencing priority |
|---|---|---|---|
| Pillar 1: workforce development | Civil service posts for informaticians; retention incentives; CPD[a] programs; structured mentoring | Vacancy rate; turnover rate; CPD completion rate; fellowship-to-post conversion rate | Concurrent in high-baseline settings; dependent on pillar 2 in low-baseline settings (no post=no retention) |
| Pillar 2: institutional strengthening | NPHI[b] or PHEOC[c] with statutory mandate; dedicated domestic budget line; clear HIS[d] governance roles | PHEOC functionality score; budget share for digital health; SOP[e] coverage for core functions | Prerequisite in most settings. Without mandate and budget, pillars 1, 3, and 4 lack an authorizing home |
| Pillar 3: governance and data standards | Approved national digital health policy; DSAs[f]; AI[g] governance principles; interoperability standards | Number of signed DSAs; data breach response time; AI use case registry; proportion of systems using national standards | Prerequisite before major pillar 4 investment. Infrastructure without governance defaults to vertical silos |
| Pillar 4: interoperable infrastructure | National HIS platform; interoperability layer connecting DHIS2, laboratory, and logistics systems; backup and uptime plan; cybersecurity protections | System uptime (%); API[h] transactions per month; facility connectivity rate; backup test success rate | Dependent on pillars 2 and 3. In high-baseline settings, simultaneous investment with pillar 1 retention pathways is optimal |

[a]CPD: continuing professional development.

[b]NPHI: national public health institute.

[c]PHEOC: public health emergency operations center.

[d]HIS: health information system.

[e]SOP: standard operating procedure.

[f]DSA: data-sharing agreement.

[g]AI: artificial intelligence.

[h]API: application programming interface.

## Practical Checklist: Minimum Enabling Conditions by Pillar

Table 2 provides indicative minimum enabling conditions, example indicators, and sequencing priority for each pillar. These are intended as a starting point for government and partner readiness assessments, not as a prescriptive checklist.

## Implementation Challenges, Counterarguments, and Scope

This framework is analytically coherent. Implementing it is another matter. Politically, health ministries and development partners favor visible, countable outputs: training certificates and installed hardware. Systemic investments such as civil service reform and interoperability standards are harder to measure and harder to fund. Financially, sustaining recurring platform costs remains a persistent challenge: the funding landscape for disease surveillance digitalization in Africa is fragmented and predominantly externally driven [30]. Logistically, coordinating across ministries, regulatory bodies, and donor programs demands sustained political will and a named institutional owner with authority to enforce standards.

None of these obstacles is insurmountable. Ministries can build the political case for systemic investments by linking them to outcomes that are already valued: demonstrating that interoperable platforms reduced outbreak response times, for instance, makes the case for infrastructure investment in terms that existing accountability frameworks can register. Governments can pool regional resources to distribute platform maintenance costs and establish domestic budget lines to cofinance core infrastructure, reducing donor dependency over time.

The framework carries inherent limitations. It is grounded in published literature and the authors' direct implementation experience in a limited set of East and West African countries. Evidence for specific interventions is uneven, implementation contexts vary substantially across the continent, and the framework has not been prospectively validated. Country examples are illustrative; causal claims should not be drawn from them. Future empirical work could test and refine the framework through comparative implementation studies, workforce retention analyses linking civil service post availability to fellowship graduate outcomes, and validation of the pillar-based readiness indicators in Table 2.

A genuine counterargument deserves acknowledgment. Technology-first approaches have achieved real gains: rapid DHIS2 deployment during the Ebola response created

XSL•FO
RenderX

surveillance infrastructure that proved adaptable to subsequent crises [11,16,17]. There are settings where building the platform first was more pragmatic than waiting for all enabling conditions to be in place. This framework does not argue against emergency or opportunistic investment. It argues that such investment must be followed, as rapidly as possible, by the institutional and governance conditions that prevent the gains from remaining fragile. Sierra Leone's experience is illustrative precisely because the crisis-driven infrastructure investment was followed by deliberate strengthening of all 4 pillars.

## Equity and Political-Economy Considerations

Digital health transformation does not occur in a neutral space. Within countries, urban facilities are typically connected before rural and remote clinics, compounding existing inequities in health system access [30,31]. Language barriers and gender norms shape who is recruited into informatics training programs and who benefits from digital tools [2,31]. Without deliberate corrective investment, digital health rollout can widen rather than narrow health system inequity. A system optimized purely for efficiency, connecting well-resourced facilities and training the most accessible graduates, will generate impressive aggregate indicators while leaving the most vulnerable populations underserved.

At the global level, data ownership and sovereignty are actively contested. External partners frequently host data or analytic platforms in servers outside the country, limiting national autonomy and generating well-founded concerns about data extraction [30,31]. Funding patterns that favor short-term pilots over sustained system investment perpetuate fragmentation and external dependency. Treating data sovereignty as a core pillar 3 governance requirement means mandating local hosting, national data stewardship roles, and African-led AI oversight. Development partners committed to African health security should align their platform-hosting and financing decisions accordingly.

## Regional Integration and Cross-Border Collaboration

Infectious diseases do not respect national borders, and neither can HISs. Africa CDC's coordinating role during the COVID-19 pandemic demonstrated the value of shared platforms and regional institutional capacity [24], and the agency continues to support PHEOC development, cross-border surveillance networks, and common standards for laboratory and surveillance systems [5,21]. Each pillar has a cross-border dimension: regionally coordinated workforce development reduces brain-drain from smaller countries, harmonized governance and data standards lower the costs of cross-border data exchange, and common infrastructure standards allow national platforms to communicate during outbreaks without bespoke interoperability work for each event. These regional dimensions are not optional extensions of the framework. They are the conditions under which the framework can operate at the scale that continental health security requires.

## Policy Implications and Recommendations

Translating the framework into action requires coordinated steps from governments, regional bodies, and development partners.

*National governments* have 4 priority actions. First, establish civil service career tracks for health informaticians with defined job descriptions, promotion pathways, and competitive salaries, as the primary mechanism for reducing postfellowship attrition [5,6,21]. Second, strengthen NPHIs and PHEOCs as institutional anchors for surveillance and digital health coordination, with investment in mandate, budget, and staffing capacity, not structure alone [22]. Third, establish dedicated domestic budget lines for national HIS platforms and infrastructure maintenance, treating interoperability as a shared public good [30]. Fourth, develop or update national digital health strategies to integrate HIS governance, AI oversight, equity indicators, and data sovereignty provisions, reviewed at least every 3 to 5 years [7,8,25].

*Regional bodies* have three priority actions. First, expand training programs in public health informatics with strong placement linkages to NPHIs and PHEOCs, building on the AES-PHI model to ensure graduates enter funded posts rather than unfilled institutional vacancies [5,6,21]. Second, promote harmonized standards for cross-border data exchange, privacy protection, and AI ethics, building on WHO and Open Health Information Exchange guidance [7,25,28]. Third, create peer-learning networks for technical platform maintenance, allowing countries to share infrastructure expertise and avoid duplicating the fixed costs of building national platform capacity independently.

*Development partners* have 4 priority actions. First, shift financing from parallel, program-specific information systems toward long-term support for national platforms and the interoperability standards that connect them [1,11,30]. Second, fund civil service post creation and workforce retention incentives alongside fellowship training. The return on training investment depends entirely on the institutional conditions that allow graduates to remain and act [5,6]. Third, condition infrastructure grants on the prior existence of a governance framework and a named institutional owner, so that pillar 4 investment does not precede the pillar 2 and pillar 3 conditions required to sustain it [23,25]. Fourth, adopt multipillar readiness assessments before designing new digital health programs; the checklist in Table 2 provides a starting framework for identifying which enabling conditions are weakest and sequencing investments accordingly.

## Conclusions

Africa has built something real. Post-Ebola and post–COVID-19 pandemic investments have created a foundation of surveillance systems, PHEOCs, and digital platforms that did not exist a decade ago. The gains are documented and significant, but they are also fragile. Sustaining and expanding them requires a shift not in effort but in logic: the goal is not to produce trained

XSL•FO
RenderX

individuals but to build the enabling ecosystems in which those individuals can act.

What makes the framework useful is not the list of pillars but the logic connecting them. Each pillar creates the conditions the next one requires: workforce development produces the capacity, institutional strengthening gives it authority and resources, governance and data standards direct how that capacity is used, and interoperable infrastructure ensures it operates within a connected, nationally owned system. When any one is missing, the system does not merely underperform: it generates a category of failure that investment in the remaining pillars cannot compensate for. That is the core analytical insight this paper advances.

Empirical validation is the essential next step. Longitudinal studies tracking the retention and system-level impact of health informatics fellowship graduates would test the core pillar 1–pillar 2 interdependency. Multicountry comparisons of divergent pillar-investment trajectories would assess whether coordinated multipillar investment produces better outcomes than single-pillar approaches. Implementation research should examine whether the readiness checklist in Table 2 predicts health informatics system performance across diverse country contexts.

Public health informatics in Africa is not merely a technical enterprise; it is the information infrastructure on which evidence-based health governance depends. African institutions that own their data, have the workforce to analyze them, and operate within governance frameworks that protect and direct their use are better positioned to set their own health priorities and hold their own systems accountable. The 4-pillar framework is offered as a practical tool for building that capacity systematically, equitably, and durably.

## Acknowledgments

All authors declared that they had insufficient funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article. Generative artificial intelligence was not used in any portion of the drafting or generation of this manuscript.

## Funding

No funding was received for this viewpoint paper.

## Data Availability

No datasets were generated or analyzed for this viewpoint paper.

## Authors' Contributions

ENI conceptualized the manuscript, wrote the original draft, and led revisions. LN, RK, and RI provided critical review and contributed to drafting sections. FS contributed to conceptualization, critical review, and contextualization for Sierra Leone and African regional structures. All authors reviewed and approved the final manuscript.

## Abstract

Public health emergencies such as pandemics, natural disasters, and epidemics may require rapid, high-stakes decisions often made by elected officials with limited public health training. Artificial intelligence (AI) holds significant promise to enhance the quality, transparency, and timeliness of governmental decision-making during such crises. This paper examines the potential of AI as a decision-support tool for elected officials while identifying key technical, logistical, ethical, and policy challenges. Technical considerations include model accuracy, data representativeness, and privacy protection, while ethical imperatives center on fairness, transparency, and accountability to prevent amplification of existing health disparities. The paper further explores workforce development needs, emphasizing AI literacy and cross-sector collaboration to enable informed use of AI insights. This viewpoint presents a novel AI Decision Support Lifecycle framework specifically designed for governmental public health emergency response, mapping six phases from problem definition through post-emergency evaluation. We provide stakeholder-specific recommendations for model developers, health agencies, and elected officials, and illustrate practical application through a detailed case example and use cases. Drawing on empirical evidence regarding digital health technologies and AI governance, we emphasize that technology deployment alone is insufficient. Successful implementation requires complementary investments in organizational capacity, data infrastructure, workforce training, community engagement, and continuous evaluation. AI integration also requires robust governance frameworks, continuous model evaluation, and alignment with existing crisis management structures. Policy recommendations highlight the importance of ethical AI frameworks, risk assessments, and public engagement to foster trust. Ultimately, AI can strengthen public health decision-making if developed and implemented responsibly within transparent and equitable systems.

## Introduction

Public health emergencies, such as the COVID-19 pandemic, the 2014‐2016 West Africa Ebola epidemic, and natural disasters such as floods or hurricanes, pose serious and pressing individual and population health threats. Depending on the size and scope of these emergencies, they can require urgent and harmonized responses from governmental decision makers and public health systems at the local/tribal, state/territorial, and even national levels [1,2]. Sometimes, when an emergency is of significant size and scope, or is highly visible or consequential, decisions that are typically made by public health or emergency management experts shift to, or at least involve, elected officials, such as state governors [3]. This shift might be made because elected officials are politically responsible for the outcome of a response, or the shift might happen because only elected officials can exercise the legal powers necessary to respond. For example, in all states and territories, governors can issue emergency declarations to enact measures such as accessing and reallocating funds or suspending laws and regulations that may impede response efforts [4-6].

Regardless of the inciting event, when elected officials or other leaders are thrust into a public health decision-making role, often without formal public health or crisis response training, they may need additional support to ensure that decisions are well-considered. While public health and emergency management experts can, and should, play a significant supporting role in decision-making, leaders without good decision-making processes in place can easily fall victim to so-called decision-derailers–common biases, traps, and heuristics that can make decisions less-than sound [7].

## Challenges to Decision Making During Public Health Emergencies

A hallmark of public health emergencies is an initial severe information deficit, while many competing voices clamor for

XSL•FO
RenderX

urgent action. There is also inevitably a tug-of-war between health and safety priorities and other societal imperatives such as economic stability. Further, the broad categories of "health," "economic," and "societal" impacts must themselves be unpacked; choices about how to respond, what measures and recommendations should be put in place, must consider and involve diverse populations who are affected in very different ways and to different degrees.

So, what can leaders do to ensure that their decision-making process has systematically identified and considered a full range of actions that could effectively address fundamental goals; carefully considered and balanced all the values at stake; incorporated the information available while hedging against the remaining uncertainties; and has built public support through its transparency and thoroughness?

## Operationalizing Effective Decision Making During Public Health Emergencies

First, policymakers should clearly define, justify, and articulate the strategic goals that they aim to achieve and then share this information with the public. Next, it is critical to identify what principles leaders want to uphold in an emergency response. Protecting the health of the public is a general principle that most leaders identify with. Are there other important principles that should not be forgotten, like ensuring the consequences of interventions are fair across populations? As decisions are not made in a vacuum, the voices of diverse experts help to consider a variety of angles to a problem.

Once the goals, principles, and structure for decision-making are in place, an assessment process for identifying and evaluating options for action is needed. Evaluating the possible downstream impacts of options (both positive and negative), comparing options against one another, and assessing the logistical feasibility of the range of options. Finally, in addition to a continual updating as new evidence and information emerges, well-documented communication practices highlight the importance of telling the public that information may change and foreshadowing how new information can change plans.

In a crisis, these structures and processes are very difficult to implement, especially under time pressure and without prior planning. Developing plans ahead of a crisis is optimal, but limited time and resources make this rare, and leaders will still face an information deficit difficult to overcome with legacy approaches to data gathering.

## AI for Public Health Decision-Making

Artificial intelligence holds considerable promise to help decision-makers gather data to inform decisions and implement decision-making processes to systematically consider options and undertake tradeoff analyses. Ultimately, AI has the potential to greatly enhance the quality of public health decision-making in these emergencies. However, while the potential for decision support is significant, numerous challenges persist in developing and operationalizing AI for public health crisis decision making.

While digital health technologies and information and communication technology (ICT) infrastructure have expanded rapidly, empirical evidence regarding their impact on population health outcomes remains mixed [8-12]. Studies show that ICT adoption does not automatically translate into measurable health improvements, particularly when institutional capacity, governance quality, workforce skills, and implementation fidelity are insufficient. Previous digital health initiatives often showed weak or context-dependent effects due to inadequate organizational readiness, data quality issues, and a lack of complementary investments in regulatory frameworks and human capital.

The following viewpoint considers technical, logistical, and ethical challenges in developing AI tools to support elected officials in public health decision making and describes important considerations when addressing AI applications to optimize system use in the public health domain.

### Aim and Scope

This viewpoint article aims to: (1) examine the potential role of AI as a decision-support tool for elected officials during public health emergencies and (2) identify key technical, ethical, and governance challenges that must be addressed.

This viewpoint focuses specifically on US federal, state, and local governmental public health decision-making contexts. While many principles may apply internationally, our discussion of policy frameworks, legal requirements, and organizational structures reflects the US governance system. Jurisdictions with different regulatory environments, data infrastructure capacity, or political structures may face distinct challenges requiring adaptation of these recommendations.

### Target Audience

This viewpoint is written for three primary audiences: (1) state and local public health leaders and emergency management officials who must integrate AI tools into decision-making workflows; (2) AI developers and data scientists working with governmental agencies on public health applications; and (3) elected officials and policymakers who oversee public health emergency response and must understand both the potential benefits and risks of AI-supported decision making.

### Methodological Approach

This is a viewpoint article that synthesizes insights from the emerging interdisciplinary literature on AI in public health, governmental AI governance, and algorithmic fairness. Literature was identified through targeted searches of key databases (PubMed, Web of Science, OAISTER) and policy sources (federal and state government websites, Office of Management and Budget [OMB] guidance, state legislative databases), focusing on AI applications in governmental public health decision-making, with particular attention to recent publications (2020 - 2025) addressing COVID-19 response and other public health emergencies.

While existing AI governance frameworks (eg, the National Institute of Standards and Technology (NIST) AI Risk Management Framework, Organisation for Economic Co-operation and Development (OECD) AI Principles) offer

XSL•FO
RenderX

domain-general guidance, and crisis management models address emergency decision structures, neither adequately addresses the intersection of AI-specific technical challenges and the distinctive governance realities of public health emergency response [1,13]. This includes the shift of decision authority to elected officials with limited technical training, political accountability pressures, and the need for real-time model adaptation. The AI Decision Support Lifecycle framework presented here is designed to fill this gap by providing phase-specific, stakeholder-differentiated guidance tailored to this context.

## Technical Challenges in Model Development

Machine learning (ML) models that support public health decision-making are subject to technical challenges in their development pipeline prior to being scaled for public health response efforts. Underfitting and overfitting are two of the most common challenges in the model development process, which limit a model's utility. Models are sensitive to quality and representativeness in the data used to train them.

Overfitting occurs when a model becomes too specialized in its training data and fails to perform well on new, unseen data. Overfitting limits a model's generalizability on test or real-world data and leads to high variance in model performance based on changes to input data. For example, a forecasting model trained on historical influenza data that captures every nuance of past flu seasons may perform poorly during a novel pandemic like COVID-19, where transmission dynamics, public behavior, and health care utilization patterns differ substantially from historical precedent. Overfitting may be addressed by collecting more data to create a more robust training set, reducing the model parameters or undertaking feature selection, and using cross-validation. Underfitting occurs when a model is too simplistic and fails to capture underlying patterns in data. This leads to missed patterns and inaccurate predictions, even for training data. In emergency contexts, this might manifest as a basic model that predicts hospital admissions using only a single variable (eg, previous d's case count) while ignoring critical factors like vaccination rates, demographic composition, or seasonal patterns. Such models provide unreliable guidance and may lead decision-makers to underestimate resource needs. Increasing the number of model parameters or features and reducing regularization may help to reduce underfitting.

## Ethical Considerations for AI in Public Health

### Bias and Fairness in AI Algorithms for Public Health Decision Making

Ensuring algorithmic fairness and minimizing potential algorithmic biases is a key goal for successfully implementing AI into public health decision-making processes. Data used for developing AI models for public health practice may come from a variety of sources, including electronic health records, governmental data on demographic, socioeconomic, and environmental indicators, social media, and genomic data. These models are trained on vast amounts of data, which may inadvertently contain bias. Without actively and adequately addressing these biases, AI models for public health decision making may amplify and perpetuate existing health disparities.

Bias in public health AI models may come from a variety of sources. If training data is not representative of all subpopulations (eg, age, race/ethnicity, gender), this leads to sampling bias and may cause inaccurate model predictions for members of underrepresented groups [14-16]. Furthermore, AI models trained on past health care data may learn historical biases embedded in these data [17]. For example, Obermeyer et al identified bias in model performance against Black patients for a commercial algorithm used to predict population health risk. The model used health care costs as a proxy for health (ie, lower health care costs equating to better health). However, in the US health care system, less money is spent caring for Black patients compared to White patients, and Black patients are less likely to seek out and obtain medical care [18]. Health care data is also subject to measurement bias, which occurs when there are systemic errors in how health outcomes are measured and recorded (eg, misdiagnosis or underreporting) [19]. Finally, bias may be introduced algorithmically (eg, feature selection bias) or in model design processes [20-22]. AI algorithms also often work as black boxes, which further complicates their deployment in public health decision making efforts since it is difficult for both government officials and constituents to understand how a decision was reached. This lack of transparency and explainability can reduce trust in AI-driven policies, cause concerns about accountability, and create complex ethical and legal challenges should AI-driven recommendations lead to harm [23]. Should AI solutions produce incorrect, harmful, or misleading recommendations, this leads to public mistrust and decreased likelihood of buy-in for public health measures that require community-wide support (eg, social distancing).

### Equity in Practice

To mitigate some of these potential risks, organizations responsible for developing and scaling public health AI models and governmental decision makers may undertake several actions. First, model designers should carefully curate large, representative datasets that reflect the diverse populations that public health decisions will impact. When models are developed, it is also critical that designers assess models for performance disparities, identify fairness metrics, and undertake careful documentation of model development processes to ensure transparency and accountability. Furthermore, it is essential that decision makers receive thorough training so that they are able to understand and interpret AI system recommendations to promote trust, accountability, and transparency. To operationalize equity in public health AI systems, organizations must implement concrete safeguards throughout the AI lifecycle, including: establishing compensated community advisory boards with decision-making authority from historically marginalized populations; engaging diverse stakeholders through participatory design processes to identify potential harms and validate outputs; conducting formal equity impact assessments before and during deployment with transparent public reporting; evaluating and reporting model performance metrics separately for demographic

XSL•FO
RenderX

and geographic subgroups (race/ethnicity, age, gender, socioeconomic status, disability, language, geography) with minimum performance thresholds for all groups rather than population averages alone; developing culturally appropriate communication strategies that provide plain language, multilingual explanations of AI use through trusted community channels with clear feedback and recourse mechanisms; and implementing continuous bias auditing through both internal reviews and independent third-party assessments with public documentation of findings and remediation steps. Finally, model development teams and government organizations should work together to regularly monitor and evaluate AI models to identify and correct potential biases, update and retrain models as new data becomes available, and ensure that models continue to adhere to existing legal and ethical standards [24].

### Privacy and Data Security

AI and ML programs and utilization can both enhance data security or generate issues related to privacy, confidentiality breaches, and data security [25]. There are opportunities for both malicious and accidental incidents that can result in confidence reduction, misclassification of data, or misclassification of outputs, all with the potential for severe downstream effects [26]. AI and ML models require the collection, storage, and analysis of vast quantities of data, including health data, personal identifying information, and confidential information. Security risks are a huge concern for these models and should be a priority when developing and using AI or ML tools. Opportunities for data breaches or loss of security could occur at an individual level, including someone with authorized access using data maliciously, it could occur accidentally through non-secure networks, or it could occur through organized and intentional breaches into private systems [27].

The vast number of systems that may interact with an individual's personal data also increases the risk of privacy concerns, since more systems translates to more opportunities for risk [28]. It is essential that developers, researchers, and institutions develop, test, and continue to improve and invest in safeguards for data access, use, and control. These safeguards can include privacy risk mitigation strategies and privacy-enhancing technologies [29], including de-identifying data, safeguarding physical access to systems, and strong encryption and protection of cloud-based systems [28]. There are also ethical considerations for inadequate data privacy protections, including data breaches or unauthorized access. Individuals who have personal or confidential data used in these models should have provided fully informed consent [30], be updated in the event of a security compromise, and have the option to withdraw their data from the model. There are ongoing discussions on data ownership and profit from individual data as well [31]. Finally, regulatory bodies should exist that can enforce privacy protections and provide recourse when entities fail to protect sensitive data or violate consent for data use [30].

## Implementation: Organizational Readiness

### Integrating AI Into Education and Government Workforce Development

Successful AI deployment in the public sector hinges not only on technological capabilities but equally on organizational readiness and workforce expertise. Evidence from previous digital health initiatives demonstrates that technology alone is insufficient; effective implementation requires complementary investments in organizational capacity, data infrastructure, and workforce skills [8-12].

The G7 Toolkit for Artificial Intelligence in the Public Sector identifies workforce digital skills as a foundational requirement for effective and responsible AI deployment in government contexts. A multi-layered approach is essential to building this capacity. Foundational AI literacy programs can equip public officials with an understanding of both AI's potential and its inherent limitations. Expert workshops utilizing scenario-based exercises represent another valuable resource that could help decision-makers navigate the complex trade-offs between privacy protection, equity considerations, and operational efficiency. Historical analysis also offers great learning opportunities. By examining case studies demonstrating predictive disease surveillance and resource allocation during past emergencies, officials can visualize concrete applications of AI and develop strategies to manage implementation challenges as they arise.

### Considerations for Implementation Into Workflows, Policy Formulation, Program Planning, and Resource Allocation

A successful deployment of artificial intelligence during public health emergencies extends well beyond technological considerations, requiring robust institutional frameworks and operational adaptations. Historically, expert consensus functioned as a governance mechanism through which policy alternatives were prioritized. The absence of a standardized governance framework for AI implementation may create significant hesitation among elected officials to support AI-derived recommendations, particularly in situations when actions are under public scrutiny [32].

AI integration into public health decision-making would also require a seamless alignment with existing processes and adaptive governance structures. The fragmentation of data across multiple stakeholders and information systems could result in delayed or incompatible information transfer, compromising model accuracy when rapid analytical insights are most critical [33]. At the operational level, AI outputs must be integrated directly into existing crisis-management dashboards and consoles so that public health officials can obtain timely and actionable insights without redundant data entry or additional interfaces [34].

The implementation of AI tools during a public health emergency involves significant resource considerations beyond software licensing and hardware acquisition. Investments in

XSL•FO
RenderX

data management infrastructure, cybersecurity protections, and dedicated personnel are also essential. Additionally, ongoing model retraining and impact assessments are required to maintain relevance as conditions evolve [35]. The resource allocation challenge is further complicated in emergency settings, where bandwidth and computational resources face competition from numerous concurrent priorities such as other critical emergency response functions.

Artificial intelligence systems can function as decision support mechanisms that enhance rather than supplant the judgment of elected officials and their technical advisors when designed with appropriate architectural safeguards. The safeguard features could include human validation functions that allow flagging specific output for expert review at key decision points [36], an iterative feedback loop function to allow officials to log disagreements with model outputs and feed these back into model retraining [33], an ensemble function that can combine model predictions with expert systems to ensure known constraints are reinforced alongside data-driven insights [37].

**Case Study:** To illustrate how these implementation considerations manifest in practice, we present a detailed case example:

### Hospital Surge Prediction During Influenza Season

A state health department seeks to deploy an AI forecasting model to predict hospital bed needs 2 - 4 weeks ahead during the influenza season, allowing proactive resource mobilization.

*Problem Definition*: The health department, in consultation with hospital associations and emergency management, identifies specific decision needs: estimating intensive care unit (ICU) bed demand, identifying which geographic regions will face capacity constraints, and determining timing for activating surge capacity plans.

*Model Development*: Data scientists develop an ensemble forecasting model using historical hospitalization data, influenza surveillance data, and demographic information. The model undergoes rigorous validation using holdout data from previous flu seasons, with performance assessed overall and for relevant subgroups (age categories, urban vs rural regions).

*Integration*: The model is integrated into the state's existing emergency operations center dashboard, providing daily updated forecasts with clear uncertainty ranges. Training is provided to epidemiologists and emergency coordinators on interpreting forecasts and understanding uncertainty.

*Deployment*: During flu season, forecasts inform daily situation reports to the governor's office. When the model predicts ICU capacity concerns in the jurisdiction's northern region, officials activate surge plans, coordinate patient transfers, and deploy mobile medical units. Importantly, epidemiologists review each forecast before distribution, flagging any predictions that seem inconsistent with other data sources.

*Failure Mode*: Mid-season, a new influenza strain emerges with higher severity. The model, trained on previous seasons' severity patterns, initially underestimates hospitalization demand. Human validation catches this discrepancy within 48 hours, prompting manual adjustments and communication to decision-makers about model limitations.

*Mitigation*: The incident illustrates the importance of human oversight, ensemble modeling (the team supplements the AI forecast with expert judgment and alternative models), and clear uncertainty communication (decision-makers understand that forecasts carry substantial uncertainty during novel epidemiological situations).

## Evaluation and Continuous Learning

Systematic evaluation is essential for responsible AI deployment in public health emergencies. Agencies should conduct pre-deployment testing through prospective validation using historical emergency data, simulation exercises, and tabletop drills to assess accuracy, identify failure modes, and evaluate integration with decision workflows before operational use. Performance benchmarking should establish baseline accuracy metrics, track performance over time, and, where possible compare AI-supported versus non-AI-supported decision outcomes to assess actual impact on decision quality. Real-time monitoring requires dashboards that track model performance during deployment with automated alerts for degradation, supplemented by regular expert review to identify issues not captured by automated metrics. Agencies must establish adverse event reporting mechanisms similar to health care systems, with clear protocols for investigating suspected AI-related errors or harms and implementing corrective actions. Post-emergency after-action reviews should systematically assess whether AI tools were useful, what worked well, what failed, how tools should be modified, and whether unintended consequences or equity impacts occurred. Finally, agencies should define clear decommissioning criteria and transition plans for retiring models when they exhibit poor performance, conditions change, or better alternatives become available.

## Policy Implications of AI in Public Health Decision Making

State-level legislative activity around governmental AI use has accelerated rapidly, with more than 150 bills introduced in 2024 and at least 30 states issuing formal guidance on AI use by state agencies. For example, Connecticut has implemented the AI Responsible Use Framework (Policy AI-01), which promotes ethical AI use, fairness, privacy, and transparency across all state agencies. Maryland enacted the Artificial Intelligence Governance Act of 2024, requiring each unit of state government to conduct inventories and assessments of systems that employ high-risk AI, and providing for the Department of Information Technology to develop policies and procedures concerning the development, procurement, deployment, use, and assessment of such systems [38]. Vermont established the Division of Artificial Intelligence within the Agency of Digital Services to review all aspects of AI systems developed, employed, or procured in state government [38].

At the federal level, several policies regulate the use of AI in governmental decision-making. The AI in Government Act of 2020 facilitates the adoption of AI technologies in the federal

XSL•FO
RenderX

government, aiming to improve cohesion and competency in the adoption and use of AI within federal agencies. Executive Order 13960, titled "Promoting the Use of Trustworthy Artificial Intelligence in the Federal Government," establishes the policy of the United States to promote the innovation and use of AI to improve government operations and services in a manner that fosters public trust and confidence while protecting privacy, civil rights, civil liberties, and American values. Additionally, the Office of Management and Budget (OMB) issued Memorandum M-25‐21, "Accelerating Federal Use of AI through Innovation, Governance, and Public Trust," which provides guidance for federal agencies to enhance their AI governance and risk management practices [39-41]. More recently, Executive Order 14,319 (July 2025), titled "Preventing Woke AI in the Federal Government," required federal agencies to procure only AI models that prioritize truth-seeking and ideological neutrality, restricting the incorporation of diversity, equity, and inclusion frameworks into AI outputs [42]. This policy places constraints on public health AI decision-making by limiting the use of equity-informed analytic approaches that are commonly used to identify health disparities and guide targeted interventions. In December 2025, Executive Order 14365, titled "Ensuring a National Policy Framework for Artificial Intelligence," established a uniform national AI framework intended to preempt state regulations deemed burdensome to innovation. By authorizing federal challenges to inconsistent state laws and allowing the withholding of federal funding from non-compliant states, the order reshapes public health AI governance by centralizing oversight, potentially reducing states' ability to tailor AI safeguards, transparency standards, and equity protections to local public health needs [43].

[38]To strengthen AI regulations in government, several policies should be implemented. Governments should establish ethical AI frameworks that operationalize the fairness and bias mitigation principles discussed earlier, with continuous assessments to identify biases, ensure privacy protection, and evaluate AI system reliability. More states should implement policies like Connecticut, Maryland, and Vermont to regulate AI use within state agencies to ensure the ethical use of AI systems in government operations [38]. Additionally, mandatory impact assessments should be conducted before deploying AI systems, ensuring that risks, including bias and discrimination, are mitigated and disclosed publicly. Governments should also require AI systems to be explainable, allowing the public to understand the decision-making logic behind AI outcomes. For instance, New York has required state agencies to publicly disclose detailed information about their automated decision systems [44]. Public oversight should be ensured through independent governance structures, such as Chief AI Officers, who would be responsible for ensuring AI deployment aligns with ethical standards and transparency.

Building public trust in AI use requires active engagement with stakeholders, including community leaders, ethicists, and public health experts, to ensure AI applications meet the needs and values of the community. Governments must prioritize clear and accessible communication about how AI is used in decision-making, including detailed reports on AI system performance, challenges, and successes. Regular audits should be conducted to address potential biases, ensuring AI systems are fair and inclusive. Furthermore, ethical AI governance structures should be implemented, including ethics boards and external reviews, to monitor and guide responsible AI use. Creating avenues for public feedback, such as town halls or online platforms, will allow communities to voice concerns and provide input on improving AI systems. Strong privacy protections should be enacted to safeguard citizens' data, ensuring AI systems are compliant with privacy standards. Lastly, ongoing public education and training on AI literacy will help demystify AI and foster confidence in its use, ultimately increasing public trust in governmental AI decision-making.

However, even with emerging governance frameworks, empirical evidence suggests that formal governance structures do not automatically translate into improved outcomes [45-48]. Cross-country studies find that standard governance indicators (government effectiveness, rule of law, transparency) show weak or inconsistent relationships with population health outcomes once other factors are controlled. Similarly, AI governance arrangements (such as ethical guidelines, transparency principles, and oversight bodies) do not necessarily translate into effective implementation at the operational level. This disconnect occurs because high-level institutional indicators may fail to capture sector-specific capacities essential for public health emergency response: data quality, frontline health system integration, decision-maker competence, organizational culture, and implementation fidelity. Successful AI governance requires attention to these operational realities, not just policy documents.

## The AI Decision Support Lifecycle for Public Health Emergencies

Drawing on the technical, ethical, organizational, and policy considerations discussed above, we propose an AI Decision Support Lifecycle framework specifically designed for governmental public health emergency response (Figure 1).

XSL•FO
RenderX

**Figure 1.** AI decision supported lifecycle in public health emergencies.

*Phase 1* consists of defining the problem at hand and conducting a needs assessment. Stakeholders must clarify the decisions that will be made, the information that is required to help decision makers, the end users of AI outputs, and the consequences of wrong decisions. This phase involves engaging elected officials, public health leaders, emergency managers, and community representatives to ensure AI development targets genuine decision needs.

*Phase 2* consists of equity-driven, technically robust model development and validation. Key details and steps include using representative data, evaluating performance across demographic and geographic subgroups, and documenting model limitations and uncertainty. Additional safeguards include independent expert review prior to operational deployment.

*Phase 3* includes integrating AI models into workflows and pre-deployment testing. AI tools must be integrated into existing workflows and information systems. Steps include but are not limited to developing user interfaces compatible with incident command structures, training end users on interpretation and appropriate use, and establishing clear protocols for human validation and override of AI recommendations.

In *Phase 4*, a model is ready for deployment during an emergency. During an emergency, AI tools provide decision support while human officials retain ultimate authority. When AI is being deployed during an emergency, model performance must be monitored in real time, validating outputs using expert evaluation before high-stakes decisions, and clear communication of uncertainty to decision makers.

Monitoring and adaptation comprise *Phase 5*, which includes tracking accuracy metrics, comparing predictions to observed outcomes, and adjusting models as new data becomes available.

Finally, in *Phase 6*, models are evaluated after emergency deployment, and lessons learned are gleaned. Evaluation includes understanding the model's usefulness for decision making, identifying what worked well and what didn't as well as any unintended consequences, and understanding how the tool may be used or modified for future emergencies.

A number of critical principles apply throughout the phases of the AI Decision Support Lifecycle for Public Health Emergencies. First, it is vital that there are robust privacy and confidentiality protections in place and that there is limited data use for limited and specific purposes. Next, equity principles should be positioned as a key priority in model development and implementation. Similarly, there must be clear documentation for model development and use, explainability for model outputs, and public accountability for the use of AI in public health decision-making. Finally, human authority must remain the centerpiece of public health emergency decision-making. AI can only serve as decision support, never an autonomous decision-maker.

XSL•FO
RenderX

Table 1 organizes and synthesizes technical, ethical, organizational, and policy challenges that occur throughout the lifecycle, with specific actionable recommendations for model developers, health agencies, and elected officials.

**Table .** Key challenges and stakeholder actions for AI integration in public health emergency decision-making.

| Challenge area | Model developers | Health agencies & officials | Policymakers & elected officials |
|---|---|---|---|
| Technical challenges | | | |
| Model Development (underfitting, overfitting, data quality) | Ensure models are sensitive to data quality and representativeness; avoid over-specialization to training data | Work with modelers to validate models before deployment; establish validation processes for AI outputs | Understand model limitations; ensure AI enhances rather than supplants judgment |
| Ethical challenges | | | |
| Bias & Fairness | Curate representative datasets; assess for performance disparities across subgroups; document model development transparently | Continuously evaluate models for bias; implement continuous monitoring and regular auditing of AI systems | Ensure decisions account for diverse communities; conduct regular audits for fairness and inclusiveness |
| Privacy & Data Security | Design models with privacy protections; maintain confidentiality of training and testing data | Implement robust data management infrastructure and cybersecurity protections | Enforce transparent risk management and privacy protection policies; ensure civil rights protections |
| Organizational challenges | | | |
| Workforce Development & AI Literacy | Design user-friendly interfaces; provide training resources for end users | Implement foundational AI literacy programs; provide expert workshops using scenario-based training | Understand AI's potential and limitations; receive training to interpret and implement AI outputs |
| Workflow Integration & Implementation | Include human validation functions, feedback loops, and ensemble functions combining model predictions with expert systems | Integrate AI outputs into crisis-management dashboards; ensure seamless alignment with existing processes | Establish governance frameworks to reduce hesitation in supporting AI-derived recommendations |
| Resource Allocation & Infrastructure | Plan for ongoing maintenance and model updates beyond initial development | Invest in data management infrastructure, cybersecurity, and dedicated personnel | Allocate resources beyond software licensing and hardware acquisition |
| Policy & governance challenges | | | |
| Governance Frameworks & Standards | Follow ethical AI principles prioritizing fairness, transparency, and accountability | Develop adaptive governance structures; implement continuous risk assessments | Establish ethical AI frameworks at federal and state levels; implement mandatory impact assessments |
| Public Trust & Stakeholder Engagement | Design transparent systems that enable public understanding of AI decision-making processes | Engage with community leaders, ethicists, and public health experts; provide detailed performance reports | Ensure AI applications meet community needs and values; prioritize clear communication about AI use |

## Conclusion

Artificial intelligence holds substantial promise for supporting governmental public health emergency response, but responsible implementation requires adherence to core ethical principles rather than simply deploying technology. First, AI must function strictly as decision-support tools while preserving human authority. Elected officials and public health leaders retain ultimate accountability for decisions, with clear protocols for validating and overriding AI recommendations. Second, equity must be designed into AI systems from inception, not treated as an afterthought, through representative data, subgroup performance evaluation, community advisory boards, and transparent equity impact reporting. Third, successful AI deployment demands comprehensive organizational readiness, including workforce capacity (data scientists working collaboratively with epidemiologists and communication specialists), robust data infrastructure, governance structures, and sustained funding beyond initial acquisition costs.

Fourth, transparency and accountability mechanisms are non-negotiable, requiring public disclosure of when AI informs decisions, comprehensive model documentation, explainable outputs, and clear processes for challenging AI-informed decisions. Finally, continuous monitoring, evaluation, and adaptation throughout the AI lifecycle ensures systems remain reliable as conditions change, with pre-deployment testing, real-time performance monitoring, adverse event reporting, and willingness to decommission underperforming models. Achieving AI's potential requires genuine collaboration between technical developers, public health agencies, and elected officials, with each stakeholder group taking specific, complementary actions to ensure models meet legal and ethical standards while meaningfully supporting evidence-based decision-making that reduces rather than exacerbates health inequities.

## Abstract

Artificial intelligence (AI) is rapidly reshaping the landscape of health care, from clinical diagnostics and disease surveillance to the prediction of individual health risks. Yet, its immense promise will only materialize if the tools we deploy work for everyone. Algorithms trained on incomplete or biased datasets risk embedding historical health disparities and can replicate patterns of uneven data representation, thereby limiting accuracy and generalizability across population groups. Addressing algorithmic bias should be treated as a core health quality standard, comparable in importance to safety and efficacy evaluations, to ensure consistent performance across all segments of the population. This paper aims to frame algorithmic bias in health-related AI as a quality, safety, and governance challenge for health systems rather than solely a technical problem for developers. It aims to inform policymakers, regulators, health system leaders, and developers by translating existing scientific evidence and regulatory guidance into operational governance considerations, with particular attention to the realities of low- and middle-income settings in the region of the Americas. This paper synthesizes existing knowledge and institutional experience into a practical, regionally grounded policy perspective. To operationalize this perspective, this paper first outlines the main forms of algorithmic bias relevant to health systems—including representation, measurement, aggregation, and deployment biases—and illustrates how each can emerge across the AI lifecycle. It then situates these technical challenges within the broader digital health context, where structural, commercial, and social dynamics may amplify inequities. This paper discusses the implications of biased data for emerging areas such as precision medicine before proposing a governance-oriented framework for bias mitigation that spans design, validation, deployment, and postmarket monitoring. It concludes with priority governance actions for policymakers, regulators, and health system leaders to embed fairness as a measurable component of health system performance.

## When Data Exclude, Health Follows: The Manifestations of Algorithmic Bias

The problem of bias is not one of malicious intent but of deep-seated scientific and structural oversight. While some of the examples discussed below originate in data collection practices or medical device calibration rather than in artificial intelligence (AI) models themselves, these upstream measurement biases are critical to understanding algorithmic bias in health. In practice, biased measurements and nonrepresentative clinical data are often used as training inputs for AI systems, allowing inequities embedded in devices or data standards to be inherited, amplified, and scaled through algorithmic decision-making. When data are nonrepresentative, bias often follows. Algorithms are only as sound as the data they are trained on, and when datasets fail to represent the full diversity of our populations across ancestry, gender, geography, and socioeconomic status, the resulting tools may perform well on average but systematically fail for underrepresented groups. This challenge has been documented in clinical settings and, in some cases, addressed, underscoring the need for improved model generalizability and data representation. The sources of bias are varied and can emerge at any stage of the AI lifecycle

XSL•FO
RenderX

[1,2]. To strengthen the analytical structure, bias can be grouped into four main categories: representation bias, measurement bias, aggregation bias, and deployment bias. This taxonomy helps identify specific interventions at each stage.

A clear example is representation bias, where training data does not reflect the target population. An AI system designed to detect skin cancer, for instance, achieved high accuracy when trained predominantly on images of light-skinned individuals. However, its diagnostic accuracy was nearly halved when applied to lesions on Black patients, reducing diagnostic performance in populations where early detection is already more difficult due to historical underrepresentation in medical datasets [3]. The result is an algorithm that may systematically discount reported symptoms or predict poor adherence, automating and scaling existing disparities, including in areas such as pain management and diagnostic triage decisions [1,4]. These examples illustrate that even well-established clinical language can reflect historical assumptions, an important consideration for developers of data-driven tools. Similar lifecycle-based taxonomies have been proposed in the broader machine learning literature, which consistently identify data collection and representation as primary sources of algorithmic unfairness, alongside proxy feature selection, model training, and deployment-related feedback effects [5].

Measurement bias can be embedded in the very tools we use to collect data. The pulse oximeter, a ubiquitous medical device, has been shown to overestimate blood oxygen levels in individuals with darker skin tones, a flaw rooted in the device's initial calibration on insufficiently diverse populations [1,6]. Although pulse oximetry bias is not, in itself, an AI-specific phenomenon, its relevance to this discussion lies in the fact that oxygen saturation data are frequently used in clinical datasets and predictive models, including AI-based risk stratification and decision support tools. When such measurements are systematically skewed for certain population groups, downstream algorithms trained on these data may reproduce or intensify these inaccuracies at scale. During the COVID-19 pandemic, this technical inaccuracy had profound implications, potentially delaying the recognition of severe hypoxemia and the delivery of critical care to already hard-hit communities [7]. Similar biases are found in clinical tools like spirometry equations that apply race-based "corrections" that may not be scientifically sound [6]. Similar considerations apply to race-based spirometry equations, where historically embedded assumptions in measurement standards can shape clinical datasets and, if left unexamined, be incorporated into AI-enabled models that rely on pulmonary function data for prediction or triage. In the Latin American and Caribbean region, where most medical devices are imported and not locally calibrated, this type of bias may be amplified, affecting vulnerable and remote populations that already face different barriers of access to specialized care.

Aggregation and deployment biases can emerge even with good data. Aggregation bias occurs when a single model is applied to a diverse population, ignoring crucial differences between subgroups. For years, cardiovascular risk models built predominantly on male data underdiagnosed heart attacks in women, whose symptoms can differ significantly [8]. Deployment bias arises when a tool developed in one context is applied to another without adaptation. Deployment bias can also appear in the prioritization of AI applications, where tools developed predominantly for specialized or hospital-based clinical contexts may inadvertently overshadow the needs of primary care and essential public health services, areas where data availability and research output are more limited. An algorithm trained in a high-resource tertiary hospital may perform poorly in a rural clinic with different patient demographics and resources [9]. This was also evident in the global response to COVID-19, where digital contact-tracing apps requiring modern smartphones and reliable internet inadvertently excluded older, poorer, and rural populations, the very groups most vulnerable to the pandemic's impact [10,11].

It is important to note that many of the well-documented empirical examples of algorithmic and measurement bias cited in the literature originate from high-income settings, reflecting where AI evaluation and postmarket surveillance mechanisms are most established. This does not imply that such biases are less relevant in Latin America and the Caribbean. On the contrary, health systems in the region frequently rely on imported medical devices, digital tools, and AI-enabled applications developed and validated elsewhere, often without systematic local calibration or performance assessment across diverse populations. The relative scarcity of region-specific evidence therefore represents a structural evidence gap rather than an absence of risk, underscoring the need for stronger regional capacity in evaluation, governance, and postdeployment monitoring of AI-enabled health technologies.

## The Digital Context of Health

These technical biases do not exist in a vacuum. They are magnified by the emerging digital landscape, where structural forces, such as commercial and social ones, can shape and/or exacerbate existing disparities in health outcomes [12]. The same platforms that could deliver critical health information can also be vectors for dangerous misinformation or be used to market unhealthy products that may be particularly detrimental to vulnerable populations. Moreover, the vast datasets collected by technology companies, often without transparent consent, may be used in ways that deepen existing patterns of exclusion and social stratification. Addressing algorithmic bias in clinical tools is a critical first step, while also encouraging a digital ecosystem that balances innovation with transparent, responsible use of data in support of health objectives. Building institutional public-sector capacity for AI governance, including regulatory oversight, audit mechanisms, and digital literacy among health professionals, is essential to address health population needs, especially for low- and middle-income countries that face financial and human resource constraints.

## Precision Medicine Demands Precision in Data

These biases extend to the most advanced frontiers of medicine. Precision medicine, which aims to tailor care to an individual's unique genetic, environmental, and lifestyle profile, is severely

XSL•FO
RenderX

hampered by a profound lack of diversity in the foundational data. An estimated 80% of participants in genome-wide association studies—the research that underpins many genetic tests—have been of European descent, a group that comprises just 16% of the world's population [13]. The consequences are alarming. The resulting genetic risk scores, used to predict the likelihood of developing diseases like cancer or heart disease, are most accurate for this single, well-studied group. For individuals of African, Asian, or Indigenous ancestry, these scores can be uninformative or, worse, misleading, limiting their clinical utility and the clinical relevance of advanced medical tools for diverse populations and reducing the full potential of precision medicine [12,14]. In Latin America, where more than half of the population identifies as Indigenous, Afro-descendant, or of mixed ancestry, underrepresentation in genomic research limits the accuracy and fairness of emerging AI-based diagnostic tools.

Expanding ancestral diversity in datasets is a critical prerequisite for making precision medicine more accurate, equitable, and clinically relevant across populations. Furthermore, investing in robust, representative data is a catalyst for discovery. Calls for increased diversity in precision medicine research often conflate multiple meanings of representation, spanning genetic ancestry, social identity, and inclusion objectives, which can lead to ambiguity in how datasets are constructed and interpreted [15]. Collecting pharmacogenomic data across diverse populations can prevent one-size-fits-all dosing errors and reveal novel population-specific genetic variants that could inspire new, targeted treatments [16,17]. For companies developing clinical AI tools and medical devices, ensuring reliable performance across all population groups reduces liability risks and facilitates regulatory approval, factors that support broader adoption and market sustainability. Establishing regional genomic research networks and public–private partnerships can help ensure that Latin America and the Caribbean are included in this new frontier of data-driven medicine.

## A Framework for Fairness: Bias Mitigation Across the Algorithm Lifecycle

Achieving bias-mitigated AI requires vigilance and intentionality at every stage. A proactive, sociotechnical approach is needed. First, the process must begin with inclusive design and data collection. This means moving beyond convenience sampling to deliberately curate datasets that represent the full spectrum of the target population. Health-related institutions and developers should partner with minority-serving clinics and community organizations to fill critical data gaps. Where data are scarce, techniques like synthetic data augmentation may be carefully explored as a temporary bridge, but they are no substitute for real-world representation [18]. In the region of the Americas, countries can leverage the Information Systems for Health Framework and the Pan American Highway for Digital Health Initiative to establish secure, interoperable, and bias-aware data ecosystems that enable such inclusivity.

Second, it is critical to implement rigorous bias checks and fairness metrics during model building and validation. It is not enough to measure overall accuracy. Performance must be audited by subgroup to identify any significant disparities in error rates. A model that is 95% accurate for one group but only 80% for another is not a sign of robustness; it highlights the need for improved performance across diverse population segments to ensure reliability and impact in health. These audits should be a standard requirement before any algorithm is deployed in a clinical setting [19].

Strengthening algorithm performance across population subgroups also supports domestic preparedness by cultivating a digitally competent, bias-aware health workforce. These efforts align with voluntary standards such as the AI Risk Management Framework developed by the National Institute of Standards and Technology and the Good Machine Learning Practice principles issued by the US Food and Drug Administration, ensuring that AI in health care is both innovative and reliable. Collaborative partnerships between industry, regulators, and health care providers are essential to ensure that these tools are not only clinically sound but widely accessible. Expanding population representation in health datasets is a prerequisite for scientific accuracy, improved generalizability, and reduced liability across AI-enabled medical systems. To operationalize fairness, governments could adopt measurable indicators such as subgroup parity rates, demographic calibration metrics, and public reporting of bias audit results as part of AI system certification or procurement. Fairness metrics are inherently context-dependent and may involve trade-offs between competing objectives such as sensitivity, specificity, and equity across population groups. No single metric or threshold is universally applicable across all clinical or public health use cases. As a result, the selection and interpretation of fairness measures should be informed by clinical context, population characteristics, and local health system priorities and should be complemented by human oversight and local validation.

Third, regulatory agencies should take the lead in advancing transparency and explainability in health AI systems. While voluntary frameworks, such as the Good Machine Learning Practices and the AI Risk Management Framework, are important early steps, they can lay the groundwork for future formal regulations with enforceable requirements and mandatory mechanisms. Developers should be required to provide clear documentation on data sources, demographic representation, and known limitations, often referred to as "datasheets for datasets." This transparency will allow clinical institutions and oversight bodies to better evaluate algorithmic recommendations, ensuring these tools support, rather than replace, sound medical judgment. These actions align with global regulatory trends, including the EU AI Act, which mandates oversight for high-risk AI systems [20]. Regional adaptation of these principles through national AI oversight committees would promote harmonized, context-appropriate governance across the Americas.

Fourth, diverse multidisciplinary teams, including clinicians, data scientists, bioethicists, and representatives of affected communities, are essential to uncovering blind spots that homogeneous teams might miss. Engaging patients and community members can reveal contextual factors and potential harm that are not apparent from a purely technical perspective. Including gender experts, disability advocates, and Indigenous

XSL•FO
RenderX

community representatives in these teams ensures an intersectional approach to fairness.

Finally, strengthening health authority stewardship with clear and strong governance capacities, supported by accountability mechanisms, is essential. Regulatory agencies should define enforceable requirements for algorithmic performance, transparency, and postmarket monitoring. In parallel, institutional review bodies, such as algorithm bias–resistant committees, can play a complementary role within health systems or clinical institutions by independently evaluating tools for bias, transparency, and contextual fit before implementation. Once deployed, ongoing monitoring through real-world bias audits is necessary to detect performance drift and emerging disparities over time. To maintain trust, there must also be well-defined pathways for redress when AI tools are found to cause harm. Governments can also establish national registries of AI systems in health, linking performance data, fairness audits, and postmarket surveillance to ensure accountability and transparency.

To move from principles to practice, governance-oriented actions are needed that can be realistically implemented across diverse health system contexts. Table 1 summarizes a set of priority governance actions that health authorities and regulators can use to operationalize bias mitigation across the AI lifecycle. These actions are intended to be a flexible policy toolbox that can be adapted to different levels of regulatory maturity and resource availability, with particular relevance for low- and middle-income settings. The table summarizes governance-oriented actions proposed in this policy perspective to support bias mitigation in AI-enabled health tools across design, validation, deployment, and postmarket monitoring stages. The actions are intended for health policymakers, regulators, and health system leaders, with particular relevance for low- and middle-income settings in the region of the Americas.

**Table .** Priority governance actions to mitigate algorithmic bias across the artificial intelligence (AI) lifecycle in health systems.

| Governance lever | Priority action | Primary actors | Policy rationale |
|---|---|---|---|
| Transparency and disclosure | Require population-representativeness disclosures for AI-enabled health tools, including data sources, demographic coverage, and known performance limitations. | Regulators, ministries of health. | Enables informed decision-making, reduces hidden bias risks, and supports accountability in procurement and deployment. |
| Performance assessment | Mandate subgroup-level performance reporting for high-risk AI applications rather than reliance on aggregate accuracy metrics. | Regulators, health technology assessment bodies. | Identifies differential impacts across population groups and prevents masking of inequities. |
| Predeployment review | Establish multidisciplinary review mechanisms within health authorities to assess bias, transparency, and contextual fit prior to deployment. | Ministries of health, regulatory agencies, ethics committees. | Leverages existing institutional structures to identify risks before scale-up. |
| Local validation | Promote context-specific validation of AI tools, particularly when systems are imported or adapted from other countries. | Health institutions, regulators, implementers. | Reduces deployment bias and ensures relevance to local populations and care pathways. |
| Postmarket monitoring | Integrate bias considerations into postmarket surveillance using routine health data and real-world evidence. | Regulators, health system operators. | Detects performance drift and emerging disparities after implementation. |
| Data governance | Strengthen data governance and interoperability frameworks to improve data quality, disaggregation, and representativeness. | Governments, digital health authorities. | Creates the foundational conditions for equitable AI development over time. |
| Workforce capacity | Invest in digital literacy and AI governance competencies for regulators, clinicians, and public health professionals. | Ministries of health, academic institutions. | Enables informed oversight and responsible adoption of AI tools. |
| Procurement and financing | Link fairness, transparency, and accountability criteria to public procurement and funding decisions. | Governments, public purchasers, donors. | Institutionalizes equity as a measurable component of health system quality. |

## From Ethical Mandate to a Health Standard

Addressing algorithmic bias should not be seen as a barrier to innovation. On the contrary, addressing such bias should be considered a catalyst for better science. An algorithm rigorously tested and validated to perform equally across diverse populations is inherently more robust, reliable, and effective. Confronting and correcting these biases allows AI to serve a dual purpose: improving health outcomes and exposing the

XSL•FO
RenderX

hidden disparities within health systems, using technology as a mirror to reveal where actions, applications, and policies must improve. Embedding bias detection into national quality standards and linking fairness to funding eligibility can institutionalize fairness as a measurable component of health system performance.

## Conclusion and Call to Action

As the region of the Americas advances its digital transformation, the Pan American Health Organization urges countries, developers, and regulators to treat algorithmic fairness not as a technical afterthought but as a foundational element of resilient and inclusive health systems. This imperative aligns directly with the Pan American Health Organization's *Eight Guiding Principles of the Digital Transformation of the Health Sector,* notably Principle 2: Equity and Inclusion, which emphasizes the need to ensure that digital health benefits reach all population groups, and Principle 5: Ethical Use of Technology, which calls for the responsible and transparent design of digital tools [21]. Addressing algorithmic bias, from data collection to real-world deployment, is an ethical and health mandate that underpins scientific reliability, system trustworthiness, and equitable health outcomes.

Ensuring fairness also means that AI strengthens primary health care and essential public health functions, not only specialized clinical services, and future work should continue to explore how AI can be developed and deployed in ways that reinforce these levels of care, where evidence generation and data availability have historically been more limited.

AI holds extraordinary potential to enhance early detection, optimize resources, and extend care to underserved populations. But if left unchecked, it risks reinforcing the same data-driven health disparities that public health aims to dismantle. Ensuring that AI systems are designed to recognize and counter bias from the start will help create health technologies that are not only more accurate and reliable, but also truly reflective of the populations they aim to serve.

### Acknowledgments

Disclosure of delegation to generative artificial intelligence (AI): The authors declare the use of generative AI tools during the research and manuscript preparation process, under full human supervision. The original concept, analytical framing, and initial draft of this editorial were developed by the authors, informed by institutional experience and discussions grounded in real-world public health cases. Generative AI–enabled tools, including NotebookLM and Gemini Pro (Deep Research), were used to support the identification, retrieval, and systematization of relevant peer-reviewed literature, as well as to cross-check cited evidence against published sources. Subsequently, a generative language model (ChatGPT, version 5.2) was used in a limited manner to support editorial language refinement and clarity. These tools were not used to generate scientific content, interpret data, or formulate conclusions. Responsibility for the final manuscript rests entirely with the authors.

### Funding

No external funding was received for the preparation of this manuscript. The views expressed are those of the authors and do not necessarily reflect the official positions of their affiliated institutions.

### Conflicts of Interest

None declared.

## Abstract

In today's unstable funding climate, alternative research funding mechanisms are essential. Investigators are facing novel barriers to acquiring funding for their research. Early-stage investigators, in particular those who are beginning their careers in research, are especially vulnerable to these funding disruptions. Currently, finding alternative funding is especially relevant for scientists studying historically and intentionally excluded communities, such as lesbian, gay, bisexual, transgender, queer, or other sexual and/or gender expansive (LGBTQ+) populations, as many investigators have had their LGBTQ+ grants revoked by the Trump administration. Crowdfunding for research studies is a potential funding avenue that has grown in popularity, with more than US $12 million raised since 2012. This Viewpoint highlights crowdfunding as a potential funding model for LGBTQ+ cancer research, specifically to support the collection of preliminary data for predoctoral students and early-stage investigators. We describe the benefits and challenges of using crowdfunding as the sole funding mechanism for a mixed methods observational study among LGBTQ+ survivors of cancer. Despite challenges, crowdfunding can fund rigorous research on health disparities, notably in historically and intentionally excluded communities.

crowdfunding; early-stage investigators; LGBTQ+; cancer; survivorship

## Background

### Predoctoral Students and Early-Stage Investigators

Predoctoral students are currently enrolled in a doctoral program and eligible to conduct research [1], whereas early-stage investigators are defined as researchers in the early years (typically within 10 years) of their terminal degree who have not yet received a substantial independent research award (eg, R00 and R01) [2]. As of 2022, there were more than 250,000 full-time doctoral students in the fields of science, engineering, and health [3]; more than 55,000 doctoral degrees were awarded, more than 34,000 medical students were matched, and more than 62,000 postdoctoral trainees began their careers in the United States, representing a combined generation of early-stage investigators and predoctoral students [4]. As required by many independent research awards, predoctoral students and early-stage investigators must acquire preliminary data to achieve a successful funding application [5]. However, there are limited government-supported funding mechanisms that

XSL•FO
RenderX

provide resources to develop such preliminary data (eg, small R03s, R21s, and R15s) [6], and these have recently become even more restricted for research investigating historically and intentionally excluded communities [7]. Determining innovative strategies for collecting preliminary data among historically and intentionally excluded communities is necessary to ensure that researchers focusing on these disparities can progress in their careers and that the health disparities faced by these communities continue to be studied to work toward amelioration.

### Crowdfunding

Crowdfunding (ie, the raising of money, capital, or other resources from a large number of people to support a project or venture) [8] is an innovative strategy that has been used to assist in funding for-profit business ventures, nonprofit social entrepreneurship projects, and even to offset medical expenses [9]. Since 2012, crowdfunding has grown, even within the scientific community, especially on platforms such as Experiment.com, which has been used to help fund more than 3000 research projects and raise more than US $12 million [10]. Crowdfunding has emerged as a notable phenomenon that researchers are examining to identify which types of projects are best supported by this financing model [11]. The growth of crowdfunding has been particularly notable among students and early-stage investigators who may require alternative funding pathways beyond traditional government-based models [12]. Crowdfunding may be particularly salient in light of the current funding crisis as a result of numerous executive orders signed by President Donald Trump [13].

### Current Status of Research for Lesbian, Gay, Bisexual, Transgender, Queer, or Other Sexual and/or Gender Expansive Communities

Even before the executive orders implemented by President Trump, funding for research focused on some specific minoritized communities has been bleak, specifically among lesbian, gay, bisexual, transgender, queer, or other sexual and/or gender expansive (LGBTQ+) research efforts. Between 1989 and 2014, the National Institutes of Health (NIH) allocated 0.1% of its total budget toward LGBTQ+ research that was not related to HIV [14]. In 2020, this increased to 0.8%, when NIH funded 500 non–HIV-related projects pertaining to LGBTQ+ individuals (US $284,051,683) [15]. In 2015, NIH developed the Office of Sexual and Gender Minority Research, which helped support leading efforts to collect sexual orientation and gender identity data to determine the extent of health disparities between LGBTQ+ and cisgender heterosexual individuals [16]. With the support of the Office of Sexual and Gender Minority Research, longitudinal studies have been conducted that have revealed substantive disparities in health care for LGBTQ+ individuals. Examples of these disparities include higher rates of drug, alcohol, and tobacco use; greater mental health concerns, especially regarding aging; and a higher risk of several cancers (eg, skin, cervical, and anal) among LGBTQ+ individuals compared with cisgender heterosexual individuals [17,18]. In early 2025, the Office of Sexual and Gender Minority Research was dismantled through executive orders issued by President Trump [19]. Furthermore, in these executive orders, LGBTQ+ research has been deemed superfluous, leading to significant gaps in governmental funding [20]. As of 2025, nearly 10% (1 in 10) of the US adult population identifies as LGBTQ+ [21]. This proportion is even higher among younger generations, with nearly 30% (1 in 3) identifying as LGBTQ+ [22]. Consequently, health care systems are now tasked with providing care to LGBTQ+ individuals, yet many remain ill-equipped to do so [23]. However, disparities faced by LGBTQ+ people and gaps in knowledge regarding their experiences, particularly across the cancer control continuum, persist [24].

### Viewpoint Aim

As these disparities persist and government funding becomes more restricted, the need for alternative funding for LGBTQ+ cancer research remains a high priority. In this Viewpoint, we highlight crowdfunding as a potential funding model for LGBTQ+ cancer research as an alternative to government-funded research for the collection of preliminary data, particularly for predoctoral students and early-stage investigators. We describe how crowdfunding was used for the QVOICES (Queer Voices in Oncology Igniting Change through Empowered stories of Survivorship) study, a mixed methods observational study among LGBTQ+ survivors of cancer.

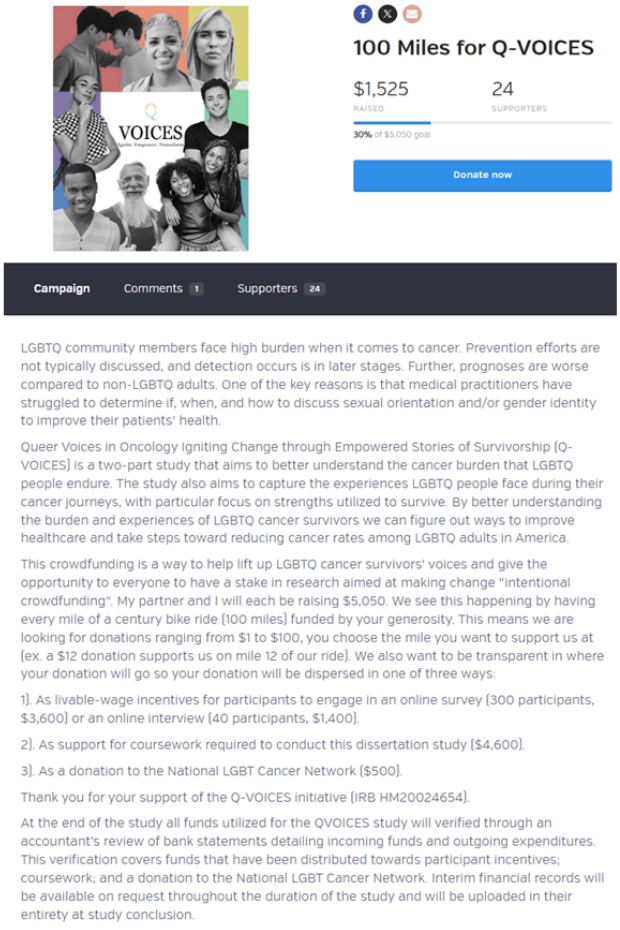
## Study Overview

### Crowdfunding for QVOICES

In 2022, the QVOICES study was launched [25]. QVOICES was a mixed methods dissertation led by the first author (VC) and used crowdfunding to provide livable wage incentives for participants in the study. The QVOICES crowdfunding campaign was titled “100 Miles for QVOICES.” The first author (VC) engaged in a 100-mile (160-km) bike ride in support of this campaign. Donors to the crowdfunding campaign were encouraged to make donations ranging from US $1 to US $100. The campaign was shared across social media platforms (ie, Instagram [Meta Platforms, Inc] and Facebook [Meta Platforms, Inc]) and through email. Both social media ads and emails provided links that directed potential donors to a main crowdfunding webpage hosted on BetterWorld, a fundraising and crowdfunding platform focused mainly on nonprofit, charitable, and social impact initiatives [26]. BetterWorld was chosen due to its elimination of hosting fees, unlike other crowdfunding platforms such as GoFundMe or Kickstarter [26]. The main crowdfunding webpage had details about the QVOICES project and a self-created video that gave an overview of how donors’ funds would be used (Figure 1).

Funds were split into 3 intentions. First, funds were allocated to participant incentives. Second, funds were applied to offset study costs. Third, any remaining funds were donated to the National LGBT Cancer Network [27].

To reach key stakeholders, crowdfunding campaign materials were distributed in several ways. First, texts and emails were sent to the social networks of the first author (VC), including friends and family (Figure 2). Second, emails with an electronic flyer (Figure 3) were sent to (1) diversity, equity, and inclusion offices; (2) faculty engaged in LGBTQ+ research efforts, identified through faculty biographies, publication histories,



XSL•FO
RenderX

and abstracts; (3) National Cancer Institute–designated cancer centers determined to be LGBTQ+ inclusive, identified using the National LGBT Cancer Network "LGBT Welcoming Treatment Providers" tool [28]; and (4) LGBTQ+ affinity groups at various universities. At each National Cancer Institute–designated cancer center, faculty listed as LGBT-friendly providers by the National LGBT Cancer Network tool were specifically contacted. Within the LGBTQ+ affinity groups, the president or vice president was contacted if their information was available; if not, the general information email was used. Finally, the campaign was also posted in LGBTQ+ Facebook groups and on Instagram using Instagram carousels (Figure 4), with numerous hashtags (eg, #QVOICES, #crowdfunding, #LGBTQ, #cancer, #research, #donate, #ignite, #empower, and #transform).

The 100 Miles for QVOICES crowdfunding campaign ran from March 1, 2022, to June 30, 2022. Approximately 500 emails and texts were distributed, and Facebook ads were run daily during this period. An estimated US $150 was spent on Facebook ads. For marketing efforts, Instagram stories were also created every other day on a QVOICES-specific account between March 1, 2022, and June 30, 2022. QVOICES was approved by the Virginia Commonwealth University institutional review board (IRB) as an exempt study for all participant engagement. Funding initiatives through crowdsourcing were outside the scope of IRB jurisdiction.

### Crowdfunding Results and Benefits

#### *Overview*

Crowdfunding efforts resulted in a total of US $2218 from 26 donors. Of these donations, the majority (n=24, 92%) were acquired through text messages from friends and family or through word-of-mouth referrals from friends and family. Two donations were received from faculty at institutions engaged in LGBTQ+ research.

#### *Benefits*

A crowdfunding approach to the QVOICES project led to several benefits. First, researchers were able to engage with community stakeholders and other scientists [29]. Second, branding around QVOICES established a means for all project-related materials to be interconnected [30]. Third, there was validation that LGBTQ+ focused cancer research was a priority, as evidenced by funding support [31]. Finally, maintaining autonomy in all funding decisions allowed for the use of innovative and attractive incentives (eg, participants were able to select their own gift cards [1 of 75 different types]) as compensation for engagement in the study [32].

## Lessons Learned

### Engaging With Community Stakeholders and Scientists

Throughout the distribution of crowdfunding materials, community stakeholders and scientists came together to help spread the word about the 100 Miles for QVOICES campaign. LGBTQ+ community members and scientists were often not direct sources of donations but instead served as champions by sharing information with allies who ultimately contributed. This was an interesting phenomenon and may be explained by LGBTQ+ community members historically being tasked with raising funds for their own initiatives and a new mentality shift toward collaborating with those in privileged positions to make change for marginalized communities [33].

Regarding engaging with scientists, past research has argued that those with postgraduate degrees have been found to be one of the lowest groups to contribute to crowdfunding efforts [29]. However, although their contributions to crowdfunding have been low, academic scientists over the past decade have been more accepting of using crowdfunding as a practical way to offset funding shortages and continue research initiatives [34].

### Ethics of Crowdfunding

As noted, QVOICES being funded through crowdfunding efforts meant that the materials we disseminated to donors were not subject to IRB oversight. However, we carefully maneuvered how to engage with our donors and demonstrate tangible results from their contributions. On our donation page, we had a disclaimer stating that donating to the QVOICES project did not provide donors with rights to individual participant data; rather, the data would be reported as summative data in accordance with the IRB.

It was also important for us to be as transparent as possible with the use of funds that we were raising; therefore, we had detailed information on fund allocation laid out in a three-item financial budget: (1) livable wage participant incentives (US $8 per 15-minute survey and US $40 per hour interview), (2) research costs (ie, transcription software), and (3) a donation to the National LGBT Cancer Network if goal of US $5000 was met. We also informed donors that QVOICES had specific branding and that, in accordance with this branding, donors could search for and find any publications or conference proceedings connected to the QVOICES study. Donors' names, should they want them to appear in any disseminated materials, would be included on all manuscripts and conference proceedings, similar to that of a funding agency. All these efforts were to enhance the ethics of keeping the robustness and high quality of data collection at a peak, to keep the confidentiality of our participants safe, and to have our donors stay engaged and recognize that we were devoted to using their funds in a meaningful way.

### Branding

Due to the increasing number of crowdfunding efforts, branding has become even more essential. Branding is defined as a means to differentiate oneself from competitors [35] and can include logos, messaging, and calls to action [36]. Successful branding has been determined to be instrumental in crowdfunding decision-making [37]. During the process of developing the 100-Miles QVOICES campaign, branding was an essential target in our development.

This was achieved through several means. First, QVOICES developed a distinct logo that was applied to all materials distributed for the campaign and the study (Figure 5). The pastel rainbow coloring of the "Q" in the logo intentionally established the LGBTQ+ community as the target audience. We also used

XSL•FO
RenderX

a simple 3-word tagline, “Ignite. Empower. Transform,” which summarized our intention across all QVOICES efforts to use LGBTQ+ voices to *ignite* change, *empower* individuals, and *transform* cancer outcomes for these communities. Now, at the dissemination phase of QVOICES, this logo is placed on all posters, oral presentations, and manuscripts to recognize the crowdfunding donors and research participants who similarly supported the brand and research efforts of QVOICES.

**Figure 5.** QVOICES logo.

### Validation and Prioritization of LGBTQ+ Cancer Research Among Donors

One of the most important aspects of crowdfunding is that financial support validates a crowd’s belief in an effort [38]. We were able to achieve somewhat of a local validation. Our initial goal was US $5000, and we were successful in funding US $2218 (44.4%). We also had a <5% of response rate, resulting in 26 individual donations. Among these donors, LGBTQ+ cancer research was seen as a priority. This was reflected in our study, requesting donations ranging from US $1 to $100 to represent the 100 miles that would be biked throughout the campaign and achieving an average of US $88 (SD US $68.68) per donation.

### Financial Autonomy

Finally, due to our funding resulting from crowdfunding, there were many aspects of the government-required financial process that we were able to avoid. One such process was the collection of social security numbers. Due to our community of interest (LGBTQ+ individuals), many participants were concerned about providing their social security numbers; therefore, reducing this barrier to participation was essential. In addition, often incentives need to be distributed at the conclusion of interviews or a few days later due to the processing of funds through systems. However, due to having autonomy in our funds, we were able to distribute our interview incentives at the beginning of the interview, allowing participants the autonomy to discontinue their participation at any point without penalty. We believe this approach led to more engagement, retention, and transparency throughout the interviews.

## Barriers to Crowdfunding

Although there were many benefits to crowdfunding, there were also some costs that came with using crowdfunding, both in our marketing stream of the 100-Miles for QVOICES campaign and in using crowdfunding as our sole source of funding.

### Mistrust or Stigma of the LGBTQ+ Topic Area

Because our campaign was run through the site BetterWorld, which is a newer platform and not as popular as Kickstarter or GoFundMe, this may have impacted donors’ trust in the campaign. Additionally, because the majority of emails sent were “cold” emails (ie, initial contact made with the individual by our study team) and social media posts were cast to a large network, acquiring trust that we were going to use donations toward the promised efforts may have been difficult to obtain. Furthermore, because the emails were sent cold, many administrators, faculty, affinity officers, social media users, and text recipients were unfamiliar with our principal investigator (VC), which may have also caused some hesitation in donating toward the 100-Miles for QVOICES efforts.

Additionally, a complex stigma has been established for LGBTQ+ academicians regarding whether to engage in or even endorse LGBTQ+ research [39]. This complexity has only grown due to the politically hostile environment created by various executive orders under the Trump presidency [13]. QVOICES data were collected from June 2020 to January 2021 (during the first Trump presidency). Within this time, more than 150 anti-LGBTQ+ bills were introduced into state legislation [40]. This politically hostile environment may have further dissuaded people from donating due to concerns regarding their academic standings, even if they were interested in supporting the findings of the QVOICES dissertation work. Future studies should examine how trust in the campaign, trust in the sponsor of the campaign, and trust in the project topic impact intent to donate and conversion to actual donation from key stakeholders.

### Lack of Sense of Urgency

In our campaign materials distributed through emails, texts, Facebook ads, and Instagram posts, we included (1) a blurb with a hyperlink to the BetterWorld crowdfunding site; (2) a video describing both the QVOICES study and the 100-mile campaign, with the website to the BetterWorld crowdfunding site included at the end; and (3) a PDF flyer for the 100-mile campaign with a call-to-action for how donors could get involved with a clickable hyperlink to the BetterWorld crowdfunding site. We felt that providing all 3 mediums maximized the potential for donations.

However, a more iterative and interactive modality may have resulted in better crowdfunding donation reactions [37]. This may have included developing Instagram posts with open comments, sending materials out in iterative waves (eg, first with blurbs about the study, then a flyer, and then a video) to

XSL•FO
RenderX

keep the crowdfunding materials accessible to potential donors, and using daily updates and discussions through the "BetterWorld" campaign page. Overall, while we had many well-developed marketing materials, the implementation of these materials could have been improved.

Additionally, providing an option for participants to opt out of iterative marketing materials, with a reason (eg, not interested in the project or have received too many funding requests about the topic area), may help to establish if saturation among key stakeholders on the topic area has been reached and whether an expansion of stakeholders is necessary.

### Nuance

Crowdfunding has typically been used to fund business ventures and nonprofit social entrepreneurship projects and even to offset medical expenses [9]. Due to the nuance of crowdfunding being used within the research sector, this may have created some hesitation to engage in donation. According to the theory of Diffusion of Innovations [41], often with innovations, only 2.5% of individuals are seen as innovators or the first individuals to adopt an innovation, which is consistent with our low rate of return, as indicated by individuals who actually donated to our campaign.

If crowdfunding is to remain a permanent means of funding research, this rate should grow to approximately 13.4% of individuals, representing early adopters [41], followed by another 34% as the early majority, another 34% as the late majority [41], and finally 16% representing individuals who are the last to adopt crowdfunding as a reasonable means to fund research [41]. In alignment with the theory of Diffusion of Innovations, our goal of US $5000 was not met, and we had a <5% return rate. However, we see the 100-Miles for QVOICES campaign as the cutting edge of this innovation curve and anticipate crowdfunding to become more widely adopted as funding options shift.

### Future Directions

From the 100-Miles for QVOICES campaign and the QVOICES study, we have learned many fundamental lessons to carry out other successful crowdfunding campaigns for research in the future. One of the biggest takeaways from this campaign was that when given the opportunity, donors—if interested and if barriers to donation are overcome—will rise to support the efforts of researchers, when they trust the effort, know that the research will be carried out, and know that their funds will be used in an effective and transparent way.

Our biggest lesson learned is that having a brand is only one step of the solution toward a successful campaign. Additionally, ensuring that the brand is backed by a strong marketing strategy, that there are large audiences to pivot toward, and that techniques exist to overcome barriers such as stigma are all essential to reaching the overarching goal of a campaign—particularly when conducting LGBTQ+ research. Future directions should apply these strategies to (1) various funding initiatives to enable comparative metrics to determine if topic area matters and (2) expand funding initiatives beyond solely participant incentives (eg, study materials, personnel, and salary support).

### Conclusions

Crowdfunding can be a functional method for funding research that may need minimal support from nontraditional avenues (eg, outside of government funding or foundational grants), such as that of preliminary data collection among early-stage investigators. As government funding becomes more constrained and foundational grants become more saturated, crowdfunding provides an additional alternative for financial support [42]. Through the 100-Miles of QVOICES campaign, we have seen a glimpse of success that a crowdfunding campaign can bring in ensuring that high-quality research can be conducted and disseminated. Although crowdfunding can come with various challenges, with thoughtful planning, branding, marketing, and support, the possibilities of using crowdfunding as an innovative strategy to conduct research addressing health disparities is achievable.

## Funding

No external funding was provided for the development of this project; all funding was provided through generous donations collected via the 100-Miles for QVOICES crowdfunding campaign.

## Conflicts of Interest

None declared.

## Abstract

**Background:** Everyday digital technologies such as social media, gaming, and internet use are deeply integrated into the lives of children, adolescents, and young adults. While these platforms can foster connection, learning, and entertainment, concerns have grown about their potential to influence mental, physical, and social well-being. Research on this topic has expanded rapidly over the past decade, yet much of it remains cross-sectional, limiting insights into long-term outcomes. Longitudinal studies are essential to capture evolving patterns of digital engagement, identify causal relationships, and guide effective policies and interventions that support youth in navigating digital environments. In particular, evidence is needed to distinguish between beneficial and harmful forms of digital engagement, such as social connection versus problematic use, and to understand how these impacts differ across diverse populations and contexts. The COVID-19 pandemic further accelerated young people's technology use, underscoring the urgency of examining both risks and opportunities. This review, therefore, synthesizes longitudinal research to map trends, identify knowledge gaps, and inform future directions.

**Objective:** The study aimed to systematically identify and map longitudinal studies examining associations between everyday digital technology use (eg, social media, gaming, and internet use) and the health and well-being of youth (25 years or younger) and to chart the types of evidence available by technology category, outcomes, and geographical setting in order to highlight key gaps for future research.

**Methods:** A systematic search of PubMed, Embase, and PsycArticles (2014‐2024) was conducted and reported in accordance with PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews). Data extraction covered demographics, digital technology categories, and health outcomes. Studies were grouped into 6 key themes: social media use and mental health, digital addiction and behavioral outcomes, physical activity and digital technology, digital health technologies and cognitive development, parental influence and digital technology, and digital well-being and risk behaviors.

**Results:** Of the 456 studies identified, 267 were longitudinal studies relevant to our research aims. Internet use (n=201 studies), social media (n=140 studies), and gaming (n=83 studies) dominated the themes. Mental health was the most frequently assessed outcome, with a focus on anxiety and depression. Geographically, 15% (40/267) of studies originated from low- and middle-income countries, with the majority from high-income settings such as the United States (n=76 studies) and Australia (n=15 studies). Nearly half (131/267, 49%) were published post 2020, reflecting heightened interest during the COVID-19 pandemic.

**Conclusions:** Longitudinal evidence on everyday digital technology use and youth health is growing but remains concentrated in mental health outcomes and high-income settings, with notable gaps in physical health, educational outcomes, and equity-focused research. These findings highlight the need for more diverse, methodologically robust longitudinal studies to inform context-sensitive policies and interventions that balance the risks and benefits of digital engagement for young people.

## Introduction

### Digital Technology Use and Youth Health

The rapid expansion of digital technologies has profoundly shaped young people's lives, introducing both opportunities and risks for their health and well-being [1]. Over the past decade, everyday digital technologies such as smartphones, social media platforms, and online games have become nearly ubiquitous in the lives of children and adolescents, with many young people spending several hours per day online across multiple devices [2]. Recent national and international reports indicate that a large proportion of adolescents exceed recommended daily screen-time limits and engage with multiple platforms concurrently, raising concerns about potential impacts on sleep, physical activity, and mental health [3]. At the same time, digital environments also provide opportunities for social connection, health information seeking, and access to mental health resources, underscoring the need to understand both the potential benefits and harms of digital engagement for youth well-being [4]

A growing body of empirical research has examined associations between social media use and adolescent mental health, with mixed but increasingly nuanced findings [5]. Several recent studies suggest that intensive or heavy use of social media is associated with higher levels of depressive symptoms, anxiety, and poor sleep, particularly among girls and young people with pre-existing vulnerabilities, although effect sizes are generally small to moderate [6,7]. Other work highlights that online social support, positive interactions, and access to digital mental health resources can mitigate some risks and, in some cases, promote improved well-being, illustrating the complex and bidirectional nature of these relationships [8,9].

Beyond social media, concerns about problematic or addictive patterns of digital technology use have intensified, with recent systematic reviews linking digital addiction, including problematic internet use, smartphone overuse, and gaming disorder, to poorer mental health, academic difficulties, and impaired social functioning in young people [10]. Emerging evidence also associates high levels of screen time and sedentary digital behaviors with higher risk of obesity, reduced physical activity, and disrupted sleep, although findings vary by age, sex, and type of digital activity [11]. At the same time, digital health technologies and serious games have shown promise for promoting physical activity, cognitive skills, and emotional regulation, suggesting that the health impacts of digital technologies depend on how, why, and in what contexts they are used [11].

### Evidence Gaps and the Need for Longitudinal Research

Despite rapid growth in the literature, the current body of evidence is dominated by studies that are cross-sectional, focus on single platforms or outcomes, or are conducted in high-income countries, limiting understanding of causal pathways, developmental trajectories, and contextual factors such as socioeconomic position and digital literacy. Recent protocols and initiatives have called for more comprehensive approaches that examine diverse forms of digital technology use, multiple health domains, and inequities in access and risks, highlighting the need for syntheses that map this emerging evidence base [11]. Several reviews and expert statements emphasize that strong longitudinal evidence on the long-term health consequences of digital engagement in young people remains limited, particularly in low- and middle-income settings. In 2021, a joint commission of *The Lancet* and *Financial Times* called for more longitudinal studies to be conducted with young people, particularly in low- and middle-income countries (LMICs) to understand the impact of different digital determinants of young people's health [12]. Subsequent expert work has echoed these concerns, noting that current studies are often short term, rely heavily on self-reported screen use, and provide only fragmented evidence on mechanisms. Consequently, new longitudinal research agendas have been recommended [11,13]. Researchers, policymakers, and educators continue to grapple with understanding the effects of digital technology use on youth health, development, and education [13]. Longitudinal studies like Young Lives provide critical insights into how digital access, skills, and youth outcomes evolve over time, particularly in LMICs. Their findings underscore the importance of digital literacy and equitable access, highlighting how digital inclusion—or lack thereof—affects health and educational disparities [14]. Similarly, the Global Kids Online initiative explores how children's digital engagement influences their social, emotional, and cognitive development, emphasizing how unequal access to technology can deepen existing inequalities [15].

The Health Behavior in School-Aged Children (HBSC) study has also been instrumental in tracking the impact of digital technologies on youth well-being. By examining digital device usage and its correlation with mental and physical health, HBSC data reveal growing concerns over social media's influence on mental health, particularly in the wake of COVID-19, when digital communication became a crucial social lifeline [16]. These studies collectively illustrate the multifaceted relationship between digital engagement and youth outcomes, reinforcing the need for continued research to address the evolving challenges and opportunities presented by digital technologies.

While long-term research projects such as Young Lives, Global Kids Online, and HBSC offer important insights into how young people's use of digital technologies is evolving, significant evidence gaps exist regarding the long-term effects of digital technology use on different aspects of young people's health and well-being.

### Objectives of This Scoping Review

The purpose of scoping reviews is to synthesize evidence and assess the scope of existing literature on a topic. The objective of this scoping review is to systematically identify and map the breadth of longitudinal evidence on the relationships between everyday digital technology use and the health and well-being of young people under the age of 25 years. For the purposes of this review, we define longitudinal studies as empirical studies that collected data from the same participants at 2 or more time points separated by at least 3 months, allowing examination of changes in digital technology exposure and health outcomes over time. Specifically, the review seeks to inform future research directions by (1) charting the characteristics of existing

XSL•FO
RenderX

longitudinal studies (including populations, types of digital technologies, outcomes, and settings), (2) summarizing how these studies conceptualize and measure digital engagement and health outcomes, and (3) identifying gaps and priorities for future longitudinal research.

Conceptually, this review is informed by emerging work on digital determinants of health, which examines how the various characteristics, features, uses, and governance of digital technologies and digital ecosystems influence health-related behaviors, health outcomes, and health care delivery [17]. For example, platform design, accessibility, data practices, and digital literacy have been identified as interacting with traditional social determinants to produce unequal risks and benefits of digital technologies across youth populations [18,19]. In addition, we draw on Bronfenbrenner ecological systems theory, which views young people's development as shaped by interacting influences at multiple levels, from family and peers to schools, communities, and broader sociotechnical and policy environments [20]. Everyday digital engagement can be understood as a proximal process embedded within these nested systems, with bidirectional influences whereby youth both shape and are shaped by their use of digital technologies.

## Methods

### Search Strategy

This scoping review was conducted and reported in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) [21]. A comprehensive literature search was conducted in PubMed, Embase, and PsycArticles to identify relevant studies published between 2014 and 2024. Search strategies were developed using the PICOTS (Patient Population, Intervention, Comparator, Outcomes, Timing, Setting) framework (Table 1). These 3 databases were chosen because they collectively cover a wide range of biomedical, psychological, and public health research on digital technologies and youth health and were fully accessible within our institutional subscriptions. Keywords related to the specified population and technologies were used to refine searches across databases. Boolean operators were employed to combine terms such as "youth," "adolescent," "digital technology," and "longitudinal study" to target relevant research. Database-specific search strings for PubMed, Embase, and PsycArticles, including all search terms, field tags, and limits, are provided in Multimedia Appendix 1.

**Table .** PICOTS (patient population, intervention, comparator, outcomes, timing, setting) framework used to structure the search strategy for this scoping review of longitudinal studies examining associations between everyday digital technology use and health and well-being outcomes among young people aged 25 years or younger (2014 - 2024).

| Question | Keywords |
|---|---|
| P (patient or population) | Youth, adolescent, child, childhood |
| I (intervention) | Digital technology, social media, video games, internet use |
| C (comparator) | Not applicable for this study |
| O (outcomes) | No keywords applied to enable broad inclusion of different health and well-being outcomes |
| T (timing) | 2014 - 2024 |
| S (study type) | Longitudinal |

The reporting of the search strategy follows key elements of the PRISMA-ScR checklist (Checklist 1). Search results from all databases were imported into Rayyan for reference management; Rayyan's deduplication function was used to identify duplicate records, which were then reviewed and confirmed by the first author before screening [22].

Given the exploratory nature of this scoping review, formal preregistration was not performed; however, a documented protocol was established and shared to enhance rigor and transparency. Quality appraisal was not conducted as the objective of the review was to map the literature and not assess quality of evidence. For similar reasons, no attempt was made to estimate pooled effect sizes or formally assess risk of bias.

Search strategies were developed using the PICOTS framework as a guide and tailored to each database, combining controlled vocabulary (eg, MeSH, Emtree) and free-text terms for youth (child, adolescent, young adult), digital technologies (digital technology, internet use, social media, video games, digital health, mobile apps, telemedicine, wearable electronic devices), and longitudinal study designs [23, 24]. Detailed search strings for each database and aim are provided in Multimedia Appendix 1 to enable replication.

### Selection of Sources of Evidence

A total of 456 studies were initially identified in the screening process. After applying the inclusion and exclusion criteria detailed in Table 2, 267 studies were deemed relevant to the research question, focusing on longitudinal studies that examine the impact of digital technologies on youth well-being. The remaining 189 studies were excluded due to irrelevance, as they did not meet the criteria for exploring the relationship between everyday digital technology use and youth health outcomes in a longitudinal framework. This rigorous screening process ensured that only studies directly aligned with the research objectives were included for synthesis and analysis.

XSL•FO
RenderX

**Table .** Inclusion and exclusion criteria applied during screening of longitudinal empirical studies examining associations between everyday digital technology use and health or well-being outcomes among children, adolescents, and young adults (≤25 y) published between 2014 and 2024.

| Category | Inclusion criteria | Exclusion criteria |
|---|---|---|
| Article type | Longitudinal empirical studies (cohort, panel, or repeated-measures designs) examining associations between everyday digital technology use and health or well-being outcomes in youth | Cross-sectional studies, case reports, qualitative-only studies, reviews, commentaries, editorials, conference abstracts without full data, and nonempirical papers |
| Population | Children, adolescents, and young adults aged ≤25 years (or samples with a mean age ≤25, SD 5 y) from any country or setting | Studies focusing exclusively on adults >25 years or mixed-age samples where data for participants ≤25 years cannot be disaggregated |
| Digital technology exposure | Everyday digital technologies such as internet use, social media, online gaming, smartphones, and other general digital media exposures | Studies focusing solely on highly specialized clinical technologies (eg, neurosurgical devices) or nondigital interventions; technology not related to personal digital media use |
| Outcomes | Health and well-being outcomes, including mental, physical, behavioral, social, or cognitive outcomes assessed at follow-up | Studies without health or well-being outcomes (eg, usability only) or outcomes unrelated to youth health (eg, purely technical performance metrics) |
| Study design and timeframe | Longitudinal design with at least 2 time points; published between 2014 and 2024 in peer-reviewed journals | Single time point (cross-sectional) designs; studies outside the 2014 - 2024 window or not peer reviewed |
| Language | Articles published in English | Articles published in languages other than English |

Titles and abstracts were screened by the first author using predefined inclusion and exclusion criteria developed together with the second author. Any uncertainties were discussed with the second author before making final eligibility decisions. Full texts of potentially eligible articles were then assessed against the same criteria.

## Data Extraction

Data from all included studies were extracted by the first author, with methodological guidance and spot checks provided by the second author to ensure accuracy and consistency. The form was piloted on a sample of studies and refined prior to full data charting. Data charting was conducted using a standardized Microsoft Excel form developed specifically for this review. The first author initially charted data from a small sample of eligible studies to pilot the form, after which the structure and definitions of each field were refined in consultation with the second author to improve clarity and consistency. The first author then charted data from all included studies, and the second author performed targeted checks of randomly selected entries to verify accuracy and resolve any uncertainties.

For each study, we extracted key data to organize and analyze the findings effectively. The following variables were recorded:

1. *Title:* The full title of the study for accurate identification
2. *Abstract:* A summary outlining the study's aims, methods, and results
3. *Journal:* The journal in which the study was published
4. *Volume, issue, pages:* Journal volume, issue number, and page range for citation purposes
5. *Authors:* The research team behind the study
6. *DOI:* The Digital Object Identifier (DOI) for easy access to study
7. *Theme:* The main research focus (eg, social media, video games, mobile applications)
8. *Subtheme:* A more specific focus within the theme (eg, for social media—"Impact on mental health")
9. *Age group:* The age category of the participants (eg, child, adolescent, young adult)
10. *Study type:* The design of the study (eg, longitudinal, cross-sectional)
11. *Outcome type:* The health or well-being outcome being assessed (eg, mental health, cognitive development)
12. *Gender:* The gender breakdown of the study population (eg, male, female, mixed)
13. *Geographical focus:* The region or country where the study took place
14. *Study name:* The official name of the study, if available
15. *Leading institution:* The institution responsible for the research

## Themes Identified

Data charted from individual studies were synthesized using an inductive-deductive thematic approach appropriate for scoping reviews. Study aims and prior conceptual work informed an initial set of themes, which was then refined as new themes and insights emerged from the data. After familiarization with the charted data, the first author grouped studies according to similarities in digital technology type, health or well-being outcomes, and study aims. These preliminary groupings and definitions were then reviewed with the second author, who suggested refinements until consensus was reached on 6 overarching themes. Each included study was assigned to 1 primary theme based on its main focus; when a study spanned multiple topics, the dominant exposure-outcome relationship was used to guide classification. Within each theme, findings were synthesized descriptively, focusing on patterns in study designs, measures of digital engagement and outcomes, direction and consistency of reported associations, and notable gaps in populations or contexts. No meta-analysis or quantitative

XSL•FO
RenderX

pooling of effect estimates was performed, in line with the objectives of a scoping review.

The following 6 key themes were assigned to the studies based on their content and focus:

1. *Social media use and mental health:* Studies exploring the relationship between social media engagement and various mental health outcomes, including anxiety, depression, and social well-being
2. *Digital addiction and behavioral outcomes*: Research investigating the addictive potential of digital technologies and their effects on behavior, such as compulsive use of social media or video games
3. *Physical activity and digital technology:* Studies examining the interaction between physical activity levels and digital technology use, including how digital technologies may influence exercise behaviors
4. *Digital health technologies and cognitive development:* Research focused on the use of digital tools, such as mobile apps and telemedicine, to enhance cognitive development and support educational outcomes in young people
5. *Parental influence and digital technology:* Studies exploring the role of parents in shaping their children's use of digital technologies, including the impact of parental guidance on digital behaviors
6. *Digital well-being and risk behaviors:* Research addressing how digital technology use impacts risk behaviors such as substance abuse, risky sexual behavior, and online safety concerns

To facilitate reproducibility, the full search strategies, screening decision rules, and data-extraction template are available in Multimedia Appendix 1 and from the corresponding author upon reasonable request. The completed PRISMA-ScR checklist is provided in Checklist 1.

## Results

### Study Selection and Overview of Included Studies

The scoping review encompassed a total of 267 studies, which provided insight into various aspects of digital technology use and its impact on the health and well-being of young people over time. Internet use (n=201 studies), social media (n=140 studies), and gaming (n=83 studies) dominated the themes. Mental health was the most frequently assessed outcome, with a focus on anxiety and depression. Figure 1 presents the PRISMA-ScR flow of records through identification, screening, eligibility assessment, and inclusion. Across databases, 913 records were retrieved (PubMed n=518, Embase n=370, and PsycArticles n=25), of which 457 duplicates were removed before screening, leaving 456 unique records for title and abstract review. Of these, 190 records were excluded (wrong article type n=50, wrong population n=47, wrong outcome n=63, outside of date range n=30), with 266 studies remaining. One additional report was identified and retreived outside the initial screening process, resulting in 267 studies being included in the review.

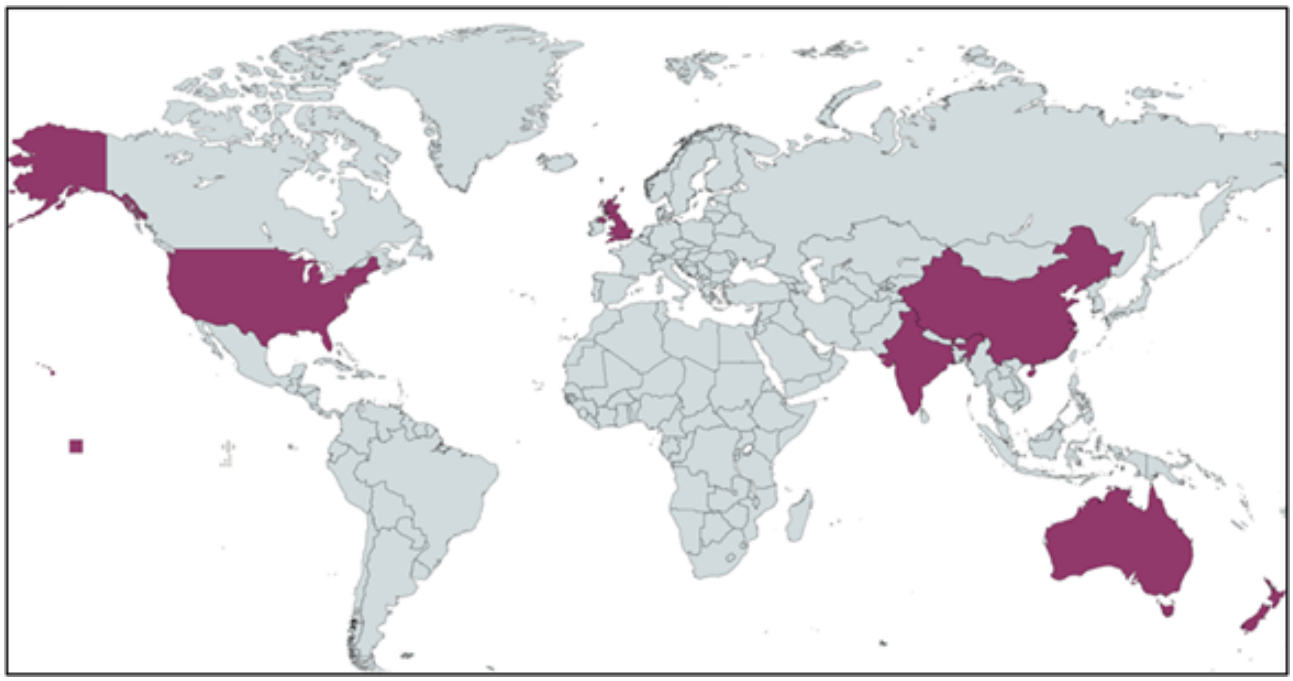

**Figure 1.** PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) flow diagram illustrating identification, screening, eligibility assessment, and inclusion of longitudinal studies examining everyday digital technology use and health or well-being outcomes among young people aged 25 years or younger (2014 - 2024).

XSL•FO
RenderX

Geographically, 15% (40/267) of studies originated from LMICs, with the majority coming from high-income settings such as the United States (n=76 studies) and Australia (n=15 studies; Figure 2). Nearly half (131/267, 49%) were published post 2020, reflecting heightened interest during the COVID-19 pandemic.

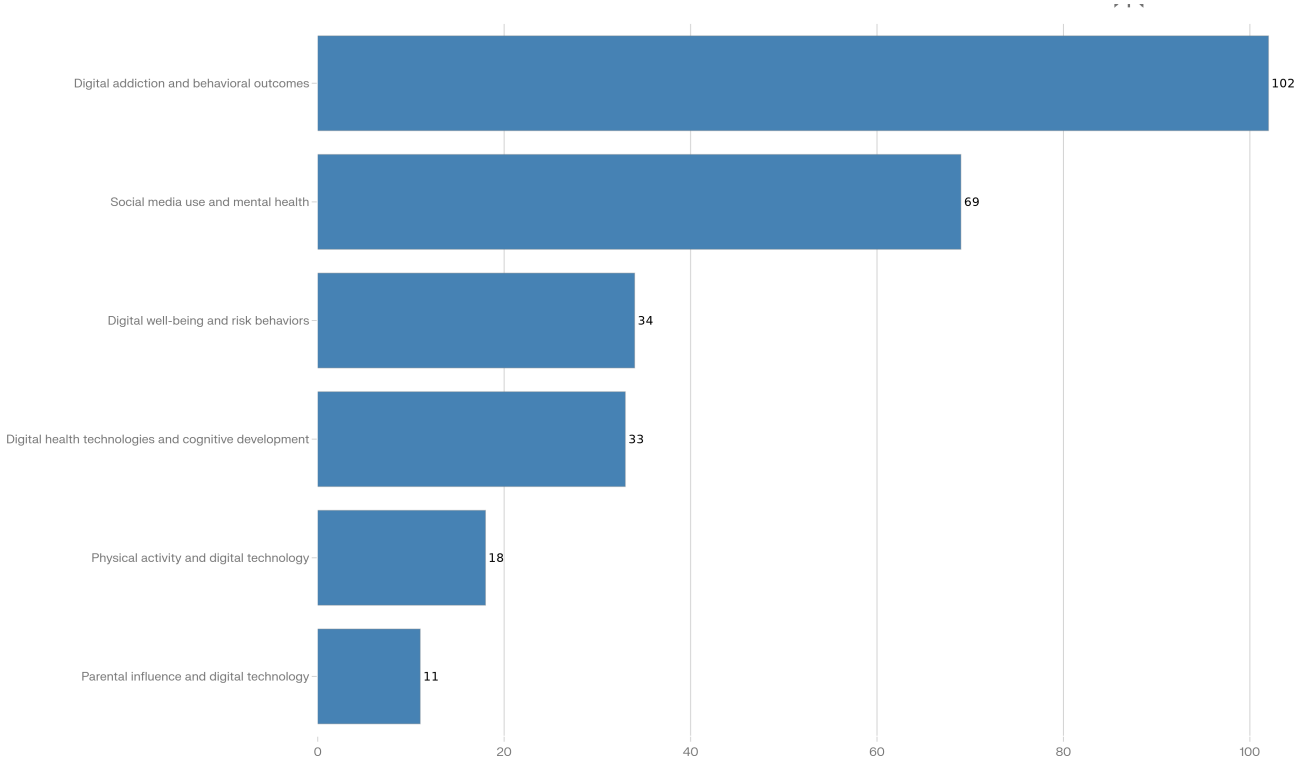
**Figure 2.** Geographic distribution of the 267 longitudinal studies included in the scoping review examining digital technology use and youth health outcomes, highlighting the predominance of studies conducted in high-income countries.

The analysis of these longitudinal studies revealed 6 key themes: social media use and mental health; digital addiction and behavioral outcomes; physical activity and digital technology; digital health technologies and cognitive development; parental influence and digital technology; and digital well-being and risk factors. Each theme highlights important findings related to the impact of digital technologies on health outcomes for youth. Table 3 summarizes the number of included studies by thematic category, country income group, and predominant age group, illustrating the concentration of research in high-income settings and among adolescents and young adults.

**Table .** Distribution of 267 longitudinal studies included in the scoping review examining digital technology use and youth health outcomes, categorized by thematic focus, country income group, and predominant participant age group.

| Theme | Studies (N=267), n | Main country income groups[a] | Predominant age groups[b] |
|---|---|---|---|
| Social media use and mental health | 69 | Mostly high-income; some upper-middle-income | Adolescents, young adults |
| Digital addiction and behavioral outcomes | 102 | High-income and upper-middle-income | Adolescents, young adults |
| Physical activity and digital technology | 18 | Mostly high-income | Children, adolescents |
| Digital health technologies and cognitive development | 33 | Mostly high-income | Children, adolescents |
| Parental influence and digital technology | 11 | Mostly high-income | Children, adolescents |
| Digital well-being and risk behaviors | 34 | High-income and upper-middle-income | Adolescents, young adults |

[a]Income groups classified according to the World Bank categories reported for study countries.



[b]Age groups as charted during data extraction: children (<12 y), adolescents (12 - 17 y), and young adults (18 - 25 y).

The distribution of longitudinal studies across the 6 thematic categories is presented in Figure 3. This visualization highlights the predominance of research on digital addiction and mental health outcomes compared to a relative scarcity of longitudinal studies on physical health and cognitive development impacts.

XSL•FO
RenderX

**Figure 3.** Number of longitudinal studies included in the scoping review by thematic category of digital technology use and youth health outcomes.

## Theme 1: Social Media Use and Mental Health

A total of 69 longitudinal studies focused on the effects of social media on adolescent mental health. Of these, 45 studies examined depression and anxiety, showing a strong association between increased social media use and negative mental health outcomes, particularly depression and anxiety. Six studies explored the influence of social media on self-esteem and body image, indicating that social media can exacerbate body dissatisfaction, especially among adolescent girls [25-30]. Nine studies addressed the issue of cyberbullying, which was found to significantly affect mental health, with higher risks of depression, anxiety, and suicidal ideation [31-39]. Nine studies also highlighted positive aspects of social media use, such as online support groups and mental health resources [34,40-48]. Overall, the studies suggest that social media use has a complex, bidirectional relationship with mental health, with both positive and negative outcomes.

These studies reveal an important distinction between intensive and problematic social media use among adolescents. Intensive use, defined as high frequency or duration of engagement, was not consistently associated with adverse mental health outcomes, with several studies reporting no significant correlation between frequency of social media use and measures such as depression, anxiety, or stress [16,49]. In contrast, problematic social media use, characterized by addiction-like symptoms such as compulsive engagement, withdrawal, and loss of control, was moderately and consistently linked to increased symptoms of depression, anxiety, stress, and loneliness [16,50]. For example, meta-analytic and longitudinal studies reported that increases in problematic social media use are significantly associated with heightened depressive symptoms and loneliness over time, while intensive use alone does not show these associations [49,50]. These findings underscored the importance of differentiating between patterns of social media engagement, as problematic use appeared to pose a greater risk to adolescent mental health than high-frequency use alone.

Of the 69 studies in this theme, roughly two-thirds reported predominantly adverse associations between problematic or intensive social media use and later mental health outcomes, around one-quarter reported mixed or null findings, and a small minority emphasized mainly positive or buffering effects of online engagement. Taken together, the longitudinal evidence suggested that how adolescents use social media matters more than how much they use it, with addiction-like, emotionally dysregulated engagement aligning more closely with stress-generation and differential-susceptibility models than simple “screen-time” explanations. This theme highlighted the need for future studies to explicitly test mechanisms such as social comparison, sleep disruption, and online victimization as pathways linking problematic use to later depressive and anxiety symptoms.

## Theme 2: Digital Addiction and Behavioral Outcomes

This theme addressed longitudinal studies of addictive-like behaviors fostered by everyday technology use (eg, internet, gaming, smartphone addiction) and their associations with mental health and behavioral functioning.

This review incorporated 102 studies on the impact of digital addiction. The majority of the studies (n=56 observational) demonstrated a link between excessive or compulsive digital technology use, particularly internet and gaming addiction, and behavioral issues like anxiety, depression, and poor social functioning. Notably, internet addiction (n=39 studies) and gaming addiction (n=38 studies) were strongly correlated with poor mental health and academic performance, while smartphone dependency (n=4 studies) and behavioral disorders

XSL•FO
RenderX

(n=20 studies) further exacerbated existing mental health issues [51-57]. Among 36 intervention studies, 54% (144/267) reported positive outcomes in terms of digital addiction treatment and management. However, a significant portion of studies revealed harmful effects of excessive digital use, which included disrupted sleep, increased mental health symptoms, and social isolation. Longitudinal research emphasized the long-term psychological consequences, such as increased depression and anxiety, associated with digital addiction [58-60].

Across the 102 digital addiction studies, most observational studies found that higher levels of internet or gaming addiction predicted worsening mood or functioning over time, whereas only a minority of intervention trials demonstrated sustained reductions in both addictive use and mental health symptoms. Overall, findings in this theme support conceptualizing digital addiction as part of a broader cluster of self-regulation and impulse-control difficulties, rather than as an isolated problem of device use. Several studies and reviews also highlighted how specific design features of social media platforms and games, such as variable and unpredictable rewards and always-on social notifications, were intended to maximize engagement and could reinforce compulsive checking and prolonged use, particularly among adolescents [61,62]. Longitudinal patterns linking persistent addiction-like use with worsening mood, school functioning, and social withdrawal pointed to the importance of interventions that targeted underlying regulatory skills and family or school contexts alongside usage reduction.

### Theme 3: Physical Activity and Digital Technology

A total of 18 longitudinal studies were analyzed under this theme. A total of 13 studies explored the relationship between sedentary screen time and reduced physical activity. Two studies researched the effectiveness of digital tools, including fitness apps and activity trackers, in increasing physical activity levels. A further 3 studies focused on digital gamification or exergames designed to increase movement. Studies on sedentary screen time pointed to the negative effects of excessive screen time, which were associated with physically inactive lifestyles and an increased risk of obesity, particularly among girls. A bidirectional relationship was observed, with excessive screen time negatively impacting physical activity, while physical inactivity also exacerbated screen time use [63,64]. Only a small subset of intervention and gamification studies found sustained increases in physical activity linked to digital tools.

Across studies, digital technologies emerged as a double-edged tool for youth physical health: design features that scaffolded motivation and feedback could nudge activity, while unstructured screen use reinforced sedentary routines and obesogenic environments. These findings underscored the value of moving beyond total “screen time” metrics toward frameworks that differentiate health-promoting, deliberately designed movement-supporting tools from passive, displacement-oriented digital use. Future research should focus on long-term interventions to increase physical activity and reduce sedentary behavior across diverse youth populations.

### Theme 4: Digital Health Technologies and Cognitive Development

A total of 33 longitudinal studies focused on the relationship between digital technology use and cognitive development. Fifteen studies evaluated deliberately designed digital health or educational tools to support cognitive outcomes (mobile health or training apps, n=10; telemedicine or telehealth for cognitive disorders, n=2; e-learning or serious game platforms, n=3), while 18 studies examined everyday digital media use (eg, overall screen time, general device or internet use) in relation to cognitive development. These studies generally indicated positive effects of digital health technologies on cognitive and behavioral outcomes, including attention improvement and executive function through exergames and mobile applications [65-76]. However, concerns regarding the long-term effectiveness of these technologies were prevalent, with many showing only short-term improvements or mixed results in sustained behavior change.

Eighteen studies explored the impact of everyday digital technology use on cognitive development. Across these studies of everyday digital technology use, higher overall screen time and background television exposure were frequently associated with weaker performance or slower gains in language, executive function, or school readiness, especially in younger children, although effect sizes were generally small. These patterns reinforced concerns about heavy, nonstructured screen use and support calls for more balanced, developmentally appropriate digital engagement

Of the 33 studies in this theme, around two-thirds documented short-term improvements in at least 1 cognitive or learning outcome following exposure to digital health or educational technologies (eg, training apps, exergames, e-learning platforms), whereas approximately one-third reported mixed, null, or unsustained effects, particularly at longer follow-up or in relation to more diffuse measures of everyday screen use.

Evidence in this theme suggested that digital health technologies are promising but not yet consistently transformative tools for youth cognitive development, with many benefits appearing short-term or context-dependent. Conceptually, this suggests that technology functions as an amplifier of existing learning environments and supports, rather than a stand-alone solution, and that sustained gains likely require integration with offline pedagogy, family engagement, and broader educational resources. At the same time, findings from observational studies in this theme underscored the importance of actively mitigating potential harms from heavy, nonstructured or background screen exposure, through limits on overall screen time, attention to content quality, and alignment of digital use with age-appropriate, offline learning and caregiving routines

### Theme 5: Parental Influence and Digital Technology

A total of 11 longitudinal studies analyzed parental influence on children’s digital behaviors and online safety. The studies revealed that parental monitoring and control of screen time positively influenced youth behavior, with several studies showing improved outcomes in mental health and behavioral issues. However, some studies highlighted the challenges of

XSL•FO
RenderX

treatment adherence and the need for refinement in interventions aimed at parental involvement. Parental education about digital literacy and online safety was also shown to have a beneficial impact, although the effects were small and varied depending on the type of screen activity [76-80]. Future research should refine interventions to better support family dynamics and address treatment attrition.

Among the 11 studies examining parental influence, most found that some form of active monitoring, co-use, or guidance was linked to modest improvements in mental health, behavior, or online safety indicators, whereas purely restrictive strategies showed smaller and less consistent benefits and occasionally coincided with more conflictual digital use.

Collectively, these studies reinforce models of "co-regulation," in which parents shape not only how much time children spend online but also the meanings and risks attached to that time. Modest but consistent benefits of warm, structured guidance, compared with either lax or highly controlling approaches, highlighted the need for interventions that bolster parents' digital literacy and relational engagement rather than focusing solely on restrictive screen-time limits.

### Theme 6: Digital Risk Factors

This theme focused on digital risk behaviors (eg, cyberbullying, sexting, exposure to harmful content) and how they co-occurred with and predict substance use, aggression, and other offline risks. This theme covered 34 longitudinal studies on risky digital behaviors—such as cyberbullying, sexting, and exposure to harmful content—and their relationship with other risk factors that influence young people's well-being, including substance abuse and aggressive behavior. Studies indicated that increased social media exposure and engagement in online activities such as cyberbullying, sexting, and online grooming correlated with higher risks of substance abuse and aggressive behaviors [30,81]. Furthermore, substance abuse was found to be linked to digital media use, particularly in adolescents, with frequent social media users reporting higher rates of alcohol, tobacco, and drug use compared to their peers [82-95]. The studies underlined the need for better regulation and monitoring of digital content to mitigate these risks [96]. Studies suggested that early media exposure could influence long-term risky behaviors, and intervention strategies focusing on media literacy and parental monitoring were highlighted as effective approaches [97-99].

Findings in this theme suggested that risky online behaviors often co-occurred with broader clusters of offline vulnerability, supporting syndemic and developmental-cascade perspectives in which digital and offline risks reinforced one another over time. Interventions that combine media literacy, skills for navigating online social pressures, and targeted support for substance use and aggression appeared more theoretically justified than approaches that address digital and offline risks in isolation.

Overall, the findings from these 6 themes underscored the complexity of digital technology's influence on youth health, with both positive and negative outcomes depending on usage patterns and the context of engagement. Across all 6 themes, the evidence depicted everyday digital technology use as a contextual, socially embedded determinant of youth health, with risks and benefits shaped by prior vulnerabilities, family and school environments, and the specific functions that digital tools serve in young people's lives.

## Discussion

### Principal Findings

The aim of this scoping review was to systematically identify and map the breadth of longitudinal evidence on the relationships between everyday digital technology use and the health and well-being of young people under the age of 25 years. The review sought to (1) chart the characteristics of existing longitudinal studies, (2) summarize how these studies conceptualize and measure digital engagement and health outcomes, and (3) identify gaps and priorities for future longitudinal research.

The review found that most longitudinal studies published between 2014 and 2024 focused on 3 aspects of technology use: internet browsing (n=201), social media (n=140), and gaming (n=83). Digital addiction and mental health, particularly anxiety and depression, were the dominant health outcomes studied. A major gap in the geographical scope of studies was identified: only 15% (40/267) of the included studies originated from LMICs.

### Conceptual Implications

Taken together, the 6 dominant themes identified within the longitudinal studies support an ecological view of digital engagement and youth health, in which associations are rarely linear or uniform but instead depend on who is using which technologies, in what social and structural contexts, and for what purposes. For example, problematic, dysregulated use in the context of family conflict and offline adversity appears more strongly linked to subsequent internalizing symptoms and risky behaviors than similar levels of use in supportive environments, consistent with ecological and digital-determinants perspectives. Social media use was linked to increased loneliness and distress, especially during the COVID-19 pandemic. At the same time, positive uses, such as accessing health information or supportive communities, illustrate how digital spaces can also function as protective resources when embedded within enabling microsystems and macrosystems [18,20].

By combining thematic synthesis with simple frequency counts across technologies, outcomes, age groups, and regions, this review functions as an evidence map that highlights both densely studied areas (eg, social media and internalizing symptoms) and important gaps (eg, physical health, cognitive development outcomes, and research in low- and middle-income settings).

### Cross-Cutting Patterns

Across themes, several cross-cutting patterns emerge from the longitudinal evidence. First, associations between digital engagement and youth health are generally small in magnitude, often contingent on baseline vulnerabilities, offline context, and the quality rather than the quantity of engagement, which aligns with differential susceptibility and person-by-context interaction

XSL•FO
RenderX

models. Second, studies that distinguish between specific modes of use (eg, passive vs active social media use, recreational vs problematic gaming) more consistently report directional relationships than those that rely on global screen-time measures, suggesting that conceptual models focused on "time displacement" alone are insufficient. Third, very few longitudinal studies explicitly test mediating pathways (eg, sleep disruption, social comparison, cyberbullying), limiting the ability to draw firm causal conclusions even when temporal ordering is clear. Digital addiction and digital risk behaviors represent related but distinct pathways through which online engagement influences youth health; these themes are therefore discussed separately but cross-referenced where studies span both domains.

### Implications for Theory and Methods

Taken together, the mapped evidence supports a shift away from simple "screen-time" narratives toward frameworks that emphasize conditional and pathway-specific effects of digital engagement on youth health, for example, models in which digital experiences amplify existing mental health risks for some young people while offering compensatory social support or health information for others. Longitudinal designs that incorporate repeated measures of context, mediators, and offline supports are needed to move from description toward testing such conceptual models.

### Implications for Public Health and Policy

From a public health perspective, these findings support a shift from individual responsibility narratives toward policies that address the digital environments in which young people spend time [100]. First, educators and health systems can use this evidence to develop age-appropriate digital literacy and mental health literacy programs that help young people recognize harmful content, manage problematic use, and leverage supportive online spaces, particularly for those already facing offline vulnerabilities [101]. Second, the concentration of harms around specific platform features, such as algorithmic amplification of extreme content and design elements that encourage compulsive engagement, underscores the need for regulation that embeds "safety-by-design" principles, transparency, and accountability for industry actors [102]. Third, inequities in who benefits from digital health technologies point to the importance of treating digital connectivity, skills, and protections as digital determinants of health and of integrating these into broader strategies to reduce mental health and well-being disparities among young people [103].

Our analysis reveals a marked increase in publications addressing digital technology and youth health since 2020. Most studies focus on mental health, particularly the effects of social media use, while fewer address physical health, educational outcomes, or equity considerations. Notably, there is a paucity of research from LMICs and limited longitudinal evidence on the long-term impacts of digital technology use. Given that 15% (40/267) of the included studies originated from LMICs, our conclusions about global patterns of digital engagement and health should be interpreted cautiously and viewed as more representative of high-income settings. Expanding research in these settings is crucial to understanding disparities in access and digital literacy. These gaps underscore the need for future research in underrepresented areas and populations. Additionally, the diversity of study designs reflects the evolving nature of this field, with a trend toward more sophisticated methodologies in recent years.

### Strengths and Limitations

This review has several strengths, including the systematic mapping of longitudinal evidence across multiple domains of digital technology use and youth health outcomes. This scoping review synthesizes available longitudinal evidence on everyday digital technology use and youth well-being, highlighting predominant research foci and key gaps rather than providing a definitive assessment of effects. The findings point to priorities for future longitudinal research and for the careful design and evaluation of digital policies and interventions, particularly in underrepresented regions and populations.

This scoping review has several limitations that should be considered when interpreting the findings. First, the search was restricted to 3 databases (PubMed, Embase, and PsycArticles), to articles published in English, and to studies from 2014 to 2024, which means that relevant longitudinal research indexed elsewhere, published in other languages, or outside this time window may have been missed. The search was limited to PubMed, Embase, and PsycArticles; other multidisciplinary databases such as Scopus or Web of Science were not searched, which means that some relevant longitudinal studies indexed elsewhere may have been omitted.

Second, consistent with the aims and methodology of a scoping review, we did not conduct a formal meta-analysis, and the synthesis is descriptive rather than quantitative; therefore, the review cannot determine the direction or magnitude of causal effects. Third, most included studies were conducted in high-income countries, so the patterns summarized here may not be generalizable to low- and middle-income settings or to underrepresented youth populations.

Although a formal quality assessment or risk-of-bias appraisal was not undertaken in line with scoping review guidance, several recurrent methodological limitations should be noted at the level of the primary studies. Many relied on self-reported digital use and health outcomes, which are vulnerable to recall and social desirability biases, and follow-up periods were often relatively short, limiting inferences about long-term trajectories. Residual confounding is also likely, as few studies used repeated measures, time-varying covariates, or strong causal designs. Additionally, most samples were drawn from high-income countries and school- or clinic-based populations, which constrain generalizability. Taken together, these patterns suggest that both harmful and beneficial associations between digital engagement and youth health may be misestimated in the existing longitudinal evidence base and point to the need for more rigorous and diverse designs in future work.

### Directions for Future Research

The findings from this study reinforce the call from the *Lancet* and *Financial Times* Commission for more longitudinal research on the digital determinants of young people's health and well-being. Future longitudinal research should examine the

XSL•FO
RenderX

long-term effects of everyday technology use and other forms of digital engagement on different dimensions of youth physical health, mental health, and well-being, including emerging technologies like virtual reality and artificial intelligence. Important objectives of these studies should be to increase our collective understanding of which features of digital technologies and platforms are most likely to promote or undermine health outcomes and why some young people are more vulnerable to the negative impacts of digital technology use than others. Greater effort is needed to generate evidence from LMICs to understand how sociocultural and economic contexts shape the impacts of technology use. Additionally, studies should examine the role of digital literacy in mitigating risks and tailoring interventions to diverse populations. Exploring digital interventions—such as literacy programs, online support communities, and mental health resources—will be essential in maximizing benefits while minimizing risks, ultimately fostering youth resilience and well-being.

## Conclusions

This scoping review highlights the rapid expansion of longitudinal research examining digital technology use and youth health, while also revealing important conceptual and geographical gaps in the evidence base. Most existing studies focus on mental health outcomes in high-income settings, with far fewer investigating physical health, cognitive development, or youth populations in LMICs. Future research should prioritize more diverse populations, stronger longitudinal designs, and clearer conceptual models to better understand how different forms of digital engagement shape young people's health and well-being over time. Strengthening this evidence base will be essential for informing policies and interventions that maximize the benefits of digital technologies while mitigating potential harms.

## Acknowledgments

The authors extend their sincere thanks to Aferdita Bytyqi for providing the opportunity to pursue this project and for her continued support throughout its development. Appreciation is further extended to the Digital Transformations for Health Lab for their support, which made the completion of this work possible. The authors declare the use of generative artificial intelligence (AI) tools during manuscript preparation. According to the GAIDeT (Generative AI Delegation Taxonomy; 2025), generative AI was used under full human supervision for proofreading and editing, summarizing text, and reformatting content, but not for data generation, analysis, or interpretation of results. The tools used were ChatGPT (GPT-4.5) and Perplexity. Responsibility for the integrity and accuracy of all content rests entirely with the human authors. Generative AI tools are not listed as authors and do not bear responsibility for the final manuscript.

## Funding

This work was supported by the Digital Transformations for Health Lab as part of its research fellowship program. This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors. All work was undertaken as part of the authors' institutional roles.

## Data Availability

The data that support the findings of this study are available from the corresponding author upon reasonable request. The datasets generated and analyzed during this scoping review (including study-level extraction sheets and the coding framework for thematic classification) are available from the corresponding author upon reasonable request. All data are derived from previously published studies and do not include any individual-level participant information.

## Authors' Contributions

PB served as the lead on data collection, analysis, and drafting of the manuscript. LH provided supervision, guidance on conceptualization, study design and methodology, and critical revisions of the manuscript. Both authors reviewed and approved the final version of the manuscript.

## Conflicts of Interest

None declared.

## Abstract

**Background:** A substantial proportion of children and adolescents worldwide do not meet current physical activity (PA) guidelines. So digital tools interventions have been implemented worldwide. However, evidence regarding the effectiveness of these remains inconsistent, underscoring the need for a comprehensive synthesis of the available literature.

**Objective:** This umbrella review aimed to summarize and critically evaluate the characteristics and effectiveness of digital interventions designed to increase PA in children and adolescents.

**Methods:** An overview of systematic reviews (SRs) and meta-analyses of randomized controlled trials (RCTs) was conducted in accordance with the PRIOR (Preferred Reporting Items for Overviews of Reviews) and the PRISMA-S (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Literature Search Extension) checklists. Reviews published between 2018 and 2025 were searched in SCOPUS, PubMed or MEDLINE, Web of Science, Cochrane Database of Systematic Reviews, and SPORTDiscus or EBSCO, using a combination of terms addressing the type of digital tool (eg, apps, wearables, etc) and device-based PA outcomes. Eligible SRs and meta-analyses focused on populations aged 6 - 17 years and evaluated digital interventions aimed at increasing PA. Methodological quality was assessed using AMSTAR 2 (A Measurement Tool to Assess Systematic Reviews) for SRs and meta-analyses, and Risk of Bias 2 for RCTs. Intervention characteristics and effectiveness outcomes were summarized as frequencies, and chi-square tests were applied to explore differences in effectiveness across study features.

**Results:** Forty-eight SRs or meta-analyses comprising 62 RCTs were included. The reviews' quality was moderate to poor, and 7/62 (11.3%) of RCTs were judged to have a high risk of bias. The mainly addressed PA outcomes were moderate-to-vigorous PA and step counts, commonly measured using accelerometers and pedometers. Overall, 45.2% of interventions demonstrated effectiveness for at least 1 PA outcome. Higher effectiveness rates were observed in RCTs that targeted PA as the sole primary outcome (19/32, 59.4%), used wearables as both the digital intervention component (7/11, 63.6%) and delivery device (8/12, 66.7%), and used pedometers for PA outcome measurement (13/16, 81.3%). Significant differences in effectiveness were found for the type of PA assessment device ($P$=.003) and for interventions targeting low-income populations, which showed lower effectiveness ($P$=.01). Additional trends were identified for geographic region ($P$=.06), intervention setting ($P$=.09), baseline activity level ($P$=.06), intervention focus ($P$=.09), and device brand ($P$=.09).

**Conclusions:** This novel umbrella review provides a comprehensive synthesis of digital PA interventions in youth, foreseeing potential factors that may influence their effectiveness, and highlighting methodological limitations. It offers evidence-based insights for practitioners, educators, and policymakers, helping to identify digital tools most likely to successfully increase PA in youth. Future research should prioritize stronger methodological rigor and more precise intervention designs. This has clear value for the public health practice to reduce long-term disease risk.

## Introduction

Physical activity (PA) is an important determinant of health status. Nearly a third of the population in the world does not meet the PA recommended levels [1], and this can be observed already in young ages, with 80% of adolescents aged 11 - 17 years not meeting the current PA guidelines [2]. This low PA level in children and adolescents may lead to obesity, poor cardiometabolic health, low fitness levels, sleep disturbances, and other diseases in adulthood.

Continuous monitoring of PA is thus needed to identify trends and priorities in public health, and effective interventions are mandatory to improve PA in youngsters and prevent future health status impairment. Among the most common actions, increasing evidence outlines the use of digital interventions in youth to improve PA and reduce sedentary behaviors (SBs), beyond addressing other health-related attitudes such as eating, tobacco smoking, or alcohol drinking.

Recently, the Global Action Plan on Physical Activity 2018 - 2030 of the World Health Organization underlined the need to increase PA by 15% by 2030, through different policy actions that also include digital approaches such as apps, wearables, or virtual coaching [3,4].

Digital technologies are particularly appealing to children and adolescents, and this is supported by recent data indicating that among those aged 15 years, more than 50% spent 30+ hours/week using digital devices, and in some countries up to 43% spent 60+ hours/week [5]. The main used technology is the internet, with 1 in 3 internet users in the world being children and adolescents [6], and 98% of those aged 15 years having a smartphone with internet connection [5]. The main digital devices used are smartphones, with the rate of adoption having increased particularly in those of young ages; 95% of teens from the US and 86% of European adolescents use smartphones and social media every day [5,7]. Other digital devices used in this age can be PCs, tablets, smartwatches, activity trackers, virtual reality headsets, and other wearables, and digital components can include websites, apps, text messages, voice messages, gamification components, virtual coaching, virtual reality, etc.

As all these tools can offer effective ways to improve and promote PA in youth, they have been increasingly included in tailored interventions in recent years [8,9]. These interventions were conducted in different settings, including education contexts such as schools, although only 40% of primary schools, 50% of lower secondary schools, and 65% of upper secondary schools were connected to the internet for pedagogical purposes [10]. Several studies were found on behavior change techniques (ie, activity monitoring with feedback, goal setting, graded tasks, or social incentives) [11-13], which are supposed to be effective for initiating and maintaining active behaviors over time by enhancing motivation and accountability.

Nonetheless, still clearer information is needed on the effectiveness of digital approaches in modifying PA behaviors of young populations. Literature shows that interventions aimed at increasing PA have been performed in different ways, with different designs and digital tools [14]. Thus, the main objective of this umbrella review is to systematically summarize and critically evaluate the characteristics and effectiveness of digital interventions aimed at increasing PA in children and adolescents, with particular attention to intervention components, determinants of effectiveness, and methodological limitations.

## Methods

### Protocol and Registration

This umbrella review was registered in the PROSPERO (International Prospective Register of Systematic Reviews; CRD42024510602). The search strategy was amended from what was originally specified at registration and in the protocol. The search was performed by following the PRIOR (Preferred Reporting Items for Overviews of Reviews) [15] and the PRISMA-S (Preferred Reporting Items for Systematic Review and Meta-Analyses Literature Search Extension) [16] checklists (Checklists 1 and 2).

### Study Design

The present review is part of a larger systematic review (SR) protocol, which includes studies identifying digital interventions aimed to improve different lifestyles, such as PA, dietary behaviors, migraine, or sleep patterns, within the DARE (Digital Lifelong Prevention) Project. The DARE Project is an initiative funded by the Italian Ministry of Universities and Research within the National Recovery and Resilience Plan, aimed at using digital technologies to create a data-driven health care ecosystem that can contribute to promoting healthy lifestyles and disease prevention and cure.

A systematically conducted overview of reviews and meta-analyses was chosen as the best design for the search and is hereafter referred to as an umbrella review. An umbrella review can be viewed as a way to obtain evidence from different existing reviews that address a broader question and can be useful for comparing interventions and developing guidelines, thus providing a very high level of evidence [17,18]. As a huge number of studies have been conducted and published in the literature on this topic, most of them lacking methodological rigor, the present search was limited to capturing SRs and meta-analyses that collected experimental studies, that is, randomized controlled trials (RCTs). SRs included by the authors followed a strict, peer-reviewed protocol to ensure all available evidence was considered impartially, involving a comprehensive literature search, critical appraisal of study quality, and statistical synthesis of results to provide a clear, evidence-based answer.

### Search Strategy

The review was conducted on 5 databases: Scopus, PubMed or MEDLINE, Web of Science, the Cochrane Database of Systematic Reviews via the Cochrane Library, and SPORTDiscus via EBSCOhost. The search was conducted in

XSL•FO
RenderX

November 2025, with record publication dates restricted to the years 2018 - 2025, informed by evidence that research on second-generation technologies (such as smartphones and wearables) has risen sharply since 2013 [19]; a 2018 review would therefore be expected to encompass a larger set of previously used tools.

A manual search was conducted in parallel by browsing the reference lists of all included reviews, by searching for information on the websites, and from gray literature. For papers not freely available on the internet, the authors were contacted and asked to provide the full-text versions.

Keywords used for the search included a combination of terms addressing the type of digital tool and the main PA outcomes (Multimedia Appendix 1). In detail, the type of digital tools searched included apps, wearables, social media, messaging, exergames, digital assistants, and different devices such as pedometers or accelerometers (Multimedia Appendix 1). No language restrictions were applied to the search strategy. Filters used were the range publication year from 2018 to 2025, the study design being an SR or meta-analysis, and the age range between 6 and 65 years. With regard to age, a comprehensive search for the age ranges 6 - 65 years was performed first, as this was the target of the authors' pilot study within the DARE Project, and afterward, studies targeting only children and adolescents (6 - 17 y) were selected for the purposes of this study. The decision to conduct separate analyses for younger populations and adults was motivated by important age-related differences in the use of digital technologies. Young people tend to engage with digital tools that are distinct from those commonly used by adults. Moreover, these tools may influence behaviors in different ways across age groups. In particular, the impact of digital technologies on PA practice may vary according to developmental stage. For these reasons, age-specific analyses were considered necessary to ensure a more accurate interpretation of the findings.

References were managed and duplicates removed using Zotero (version 6.0.37, Corporation for Digital Scholarship). The selection process, with a first screening of titles and abstracts and a second screening of full texts, was conducted by 2 independent reviewers. Possible divergences were solved by discussion between the two reviewers or with the intervention of a third reviewer.

## Eligibility Criteria

The PICOS (Population, Intervention, Comparison, Outcome, and Study Type) criteria were used to derive the eligibility of the studies.

For the population, we selected healthy human participants in the age range of 6 - 17 years. Healthy participants are those who are not diagnosed with any disease or who do not have disabilities that could affect PA outcome assessment. Reviews targeted to overweight or obese participants without another declared disease were retained. Moreover, populations aged 6 - 65 years were initially included in the review, based on the needs of the project; afterward, studies targeting only populations aged between 6 and 17 years were selected for the present review.

For intervention, we had interventions using digital approaches to increase PA. Such digital approaches should have included the use of one or a combination of the following: IT devices (eg, smartphone, tablet, and PC); wearable activity trackers (eg, accelerometers and pedometers); applications (eg, stand-alone apps or apps associated with wearable devices); social media tools (eg, chatbots or conversational agents, and social networks); messaging tools (eg, email, SMS text messages, and podcasts); web-based tools (eg, websites, and video chats or video sharing); exergames, active video games, or gamification approaches; and synchronous or nonsynchronous PA coaching or training.

For comparison, we use any other intervention or no intervention.

For the outcome, we used PA as the primary or secondary outcome.

For study type, we used SRs and meta-analyses including RCTs. The following reviews were excluded: reviews of reviews or meta-analyses; scoping or narrative reviews; those not reporting PA-specific outcomes (eg, those reporting only SBs, only dietary or nutrition outcomes, or only weight-related outcomes); those focusing only on wearables that cannot be applied to huge populations for economical or organizational reasons (eg, virtual reality); those focusing on individuals (telemedicine); studies where the intervention was not delivered by at least 1 digital tool; papers where the digital component was used only to "measure" PA and not as a means to increase PA; those reporting only nondigital self-reported tools (such as paper questionnaires) for the assessment of PA; interventions for secondary or tertiary prevention (eg, targeted to individuals with preclinical signs); studies targeted to specific groups, such as smokers or pregnant women.

## Data Extraction

The data from the selected reviews were extracted by the same 2 independent reviewers that conducted the selection process, and the following information was reported: first author and year of publication; document type; design of studies included in the review; country; age group; special population; date range of the search; number of databases searched; digital device for intervention delivery; digital component for intervention delivery; focus of intervention or digital tool; outcomes; number of total studies included in the review; number of total RCTs in all reviews; number of RCTs of interest; and inclusion criteria, first author, and publication date of RCTs describing tools of interest.

For the primary studies identified within each review, the following information was extracted: first author and year of publication; country; age group; special population; school attendance; sample dimension and type; intervention duration, arms, or name; setting; focus task; theoretical foundation; digital component or components of intervention; nondigital component or components; digital device for intervention delivery; intervention group (IG) and control group (CG); device-based or self-reported PA measure; PA objective measurement tool; fitness tests assessed; other assessed measures; and effectiveness on PA or SB outcomes. Regarding outcome effectiveness, an

XSL•FO
RenderX

intervention was classified as partially effective when positive effects were observed for some, but not all, PA outcomes.

### Data Synthesis Methods

Data regarding the characteristics of the different reviews and of the RCTs selected are presented as numbers and percentage frequencies. Effectiveness data were stratified by the type of device-based PA outcome and by the characteristics of the interventions. Differences between groups in relation to their effectiveness have been estimated through the Pearson chi-square test. All statistical estimates were conducted using STATA MP (version 12.1, StataCorp, 2011) software. As a meta-analysis was not feasible given the design of this review, heterogeneity between studies was explored using qualitative and descriptive methods combined with narrative synthesis. Sensitivity analyses were qualitatively performed as well to understand differences in populations, interventions, and outcomes that may explain variability in findings. Considered factors for sensitivity analyses were the quality of included reviews and RCTs, the study population characteristics, the intervention features, and the outcome measurement.

### Degree of Overlap

The extent of overlap of RCTs across the included SRs and meta-analyses was examined using the corrected covered area (CCA) approach [20]. As STATA does not provide a dedicated command for computing the CCA, a citation matrix was constructed, with primary studies listed in rows and the different SRs or meta-analyses in columns. A custom STATA script was developed to automate the calculation according to the formula: $CCA = (N - r) / (r \times c - r)$, where *N* represents the total number of publications, *r* the number of unique studies, and *c* the number of reviews or meta-analyses. The resulting values were converted to percentages by multiplying by 100. A CCA of 0% indicates no overlap (each review or meta-analysis includes only unique RCT); 0% - 5% reflects slight overlap; 6% - 10% moderate overlap; 11% - 15% high overlap; and values above 15% indicate very high overlap. A value of 100% denotes complete overlap, meaning that all reviews or meta-analyses include the same primary studies.

### Quality Assessment of the Reviews or Meta-Analyses

The methodological quality of included reviews and meta-analyses reporting randomized controlled interventions was assessed using the AMSTAR 2 (A Measurement Tool to Assess Systematic Reviews) tool [21]. This tool allows a quality assessment based on 7 critical and 9 noncritical domains, rather than a total score, generating an overall rating of “high” quality (those reviews or meta-analyses that meet 7/7 critical domains), “moderate” (6/7), “low” (those meeting all but one critical domain and missing few noncritical domains), and “critically low” (not meeting multiple critical domains).

### Quality Assessment of the RCTs

The methodological quality of each included RCT was evaluated using the 5 domains of the revised Cochrane Risk of Bias 2 (RoB 2) tool for RCTs [22]. Overall judgments for individual studies were derived according to the RoB 2 algorithm, categorizing studies as having a low risk of bias, some concerns, or a high risk of bias. A total of 2 reviewers conducted the assessments independently, and any discrepancies were resolved through consultation with a third reviewer.

## Results

### Search Flow Results

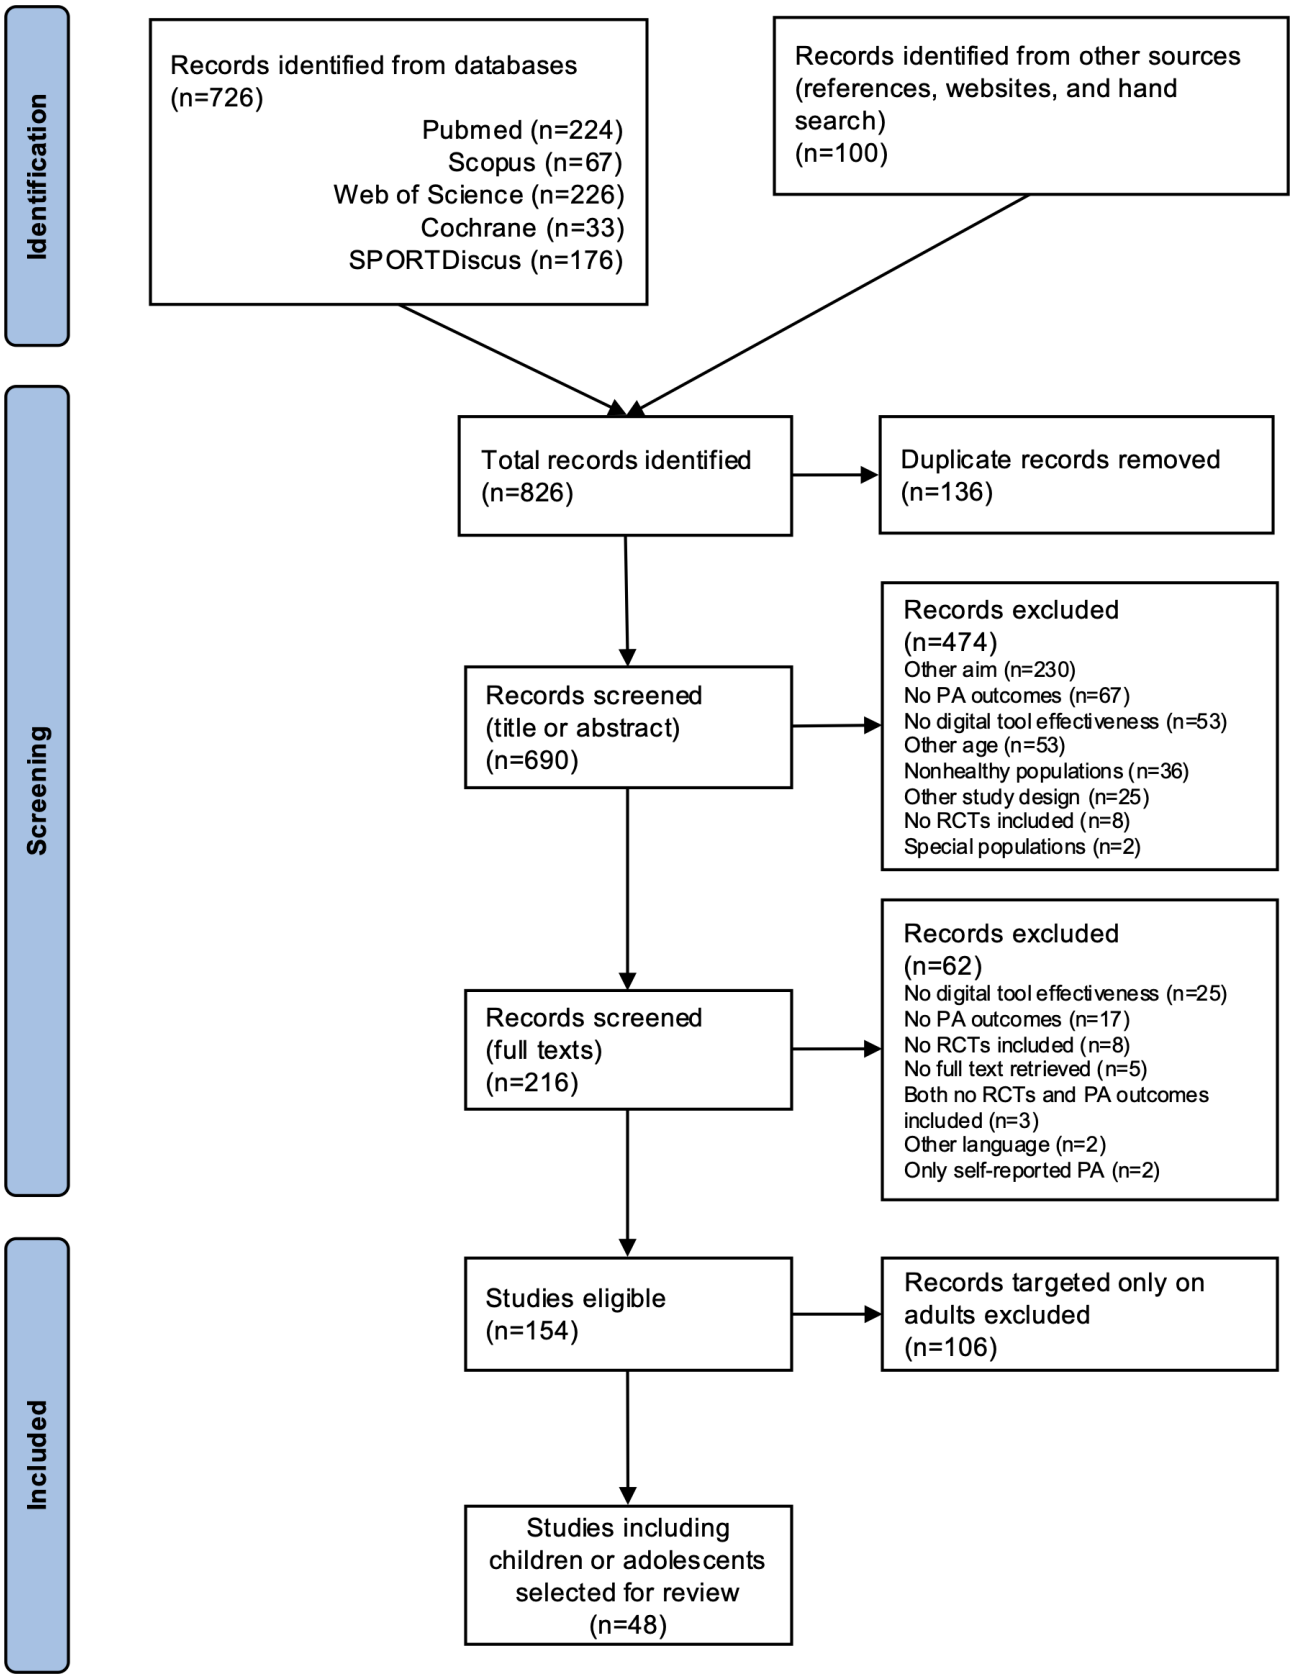

Figure 1 shows the flow diagram of the search.

The database search included a total of 726 records, which were added to the 100 records identified by the manual search. After excluding 136 duplicates, a total of 690 reviews were screened by title and abstract, and subsequently, the full texts of the selected 216 records were examined. A total of 154 studies were eligible, but they included all-age populations. A further selection finally included a total of 48 SRs and meta-analyses targeted specifically to children and adolescents [23-70].

## Description of the SRs or Meta-Analyses

### *Characteristics of the SRs or Meta-Analyses*

The characteristics of the included SRs or meta-analyses are shown in Multimedia Appendix 2, while Figure S1 Multimedia Appendix 3 provides a summary of the percentage frequencies of the different characteristics.

As shown in Figure S1 Multimedia Appendix 3, in 43.8% of the reviews, a meta-analysis was added to the SR [23,26,27,31,32,40,42,43,46,47,50,52,54,58,60,61,63,66-69]. The considered SRs or meta-analyses included any kind of study, both experimental and observational. The major part of SRs or meta-analyses was published by European research groups, mainly from the United Kingdom [28,29,32,34,39,41,45,59,61], Germany [23,24,33,47,50], Italy [25,38,55], and Spain [26,43,63]. The other European SRs or meta-analyses were published by research groups from Portugal [35,56], France [40], the Netherlands [44], and Denmark [65]. Less than one-third of the reviews were from research groups based in different Asian countries, such as China [31,49,53,54,60,66-69], Hong Kong [52], Korea [52], Malaysia [58,62], Iran [36], Singapore [37], and Qatar [41]. Most American SRs or meta-analyses were from the United States [30,47,48,57,71-75], and the others from Canada [51] and Brazil [42,64]. Only 2 reviews were published by Australian research groups [27,70].

Most reviews included studies using a miscellaneous assortment of device types [24,27,29,32-35,37,38,40-42,45,48,53,56,57,59,61,63,68-71] including mobiles, computers, tablets, and wearables, or mobiles and wearables, followed by only mobiles or smartphones [23,25,30,31,36,39,44,46,47,49-51,55,66] or only wearables [26,28,43,52,54,58,67], or consoles as devices for their gamification tools [60,62,64,65].

Parallelly, most SRs or meta-analyses searched for a miscellaneous assortment of different components for the intervention delivery [23,24,27,29-34,37,38,41,46,55-59,61,63,70], while a lower number searched only for gamification tools, including exergames, serious games, or games in devices [35,40,42,45,48,49,60,62,64,65,68,71], and in one case the exergame use was associated with coaching or telehealth [45]. Some reviews examined apps [25,36,44,47,50,51,66], and some investigated wearables [26,28,43,52,54,67]; 2 reviews were focused on chatbots [53,69] and only 1 on text messaging [39].

The focus task comprised exclusively of PAs in less than half of the reviews [24,28,30,31,33,37,40,41,44,45,47-50,52,54,57,58,60,61,63,76]; in the other reviews, the main outcomes were PAs associated with SB [23,26,38,39,43,67-69], with weight, obesity, or body composition [29,42,64,65], with diet [35] or physical fitness [66]; other reviews were focused on weight or obesity management [25,32,34,36,62,70], and on multiple health behaviors such as alcohol consumption, tobacco smoking, or diet and sleep, beyond PA and SB [27,46,51,53,55,56,59,71].

The selected reviews included an average of 19 (SD 12.2) experimental studies each for a total of 1023 studies. An average of 3.7 (SD 2.9) RCTs was present in each review. A total of 165 primary RCTs were identified across the 48 SRs or meta-analyses, according to the inclusion criteria (RCTs, healthy populations, PA outcomes present, ages between 6 and 17 years, published in the last 15 years, and effectiveness of digital tools assessed). The resulting CCA was 3.5%, indicating a slight degree of overlap. The 62 unique component studies identified were included in the final analysis [77-138].

### *Quality of the SRs or Meta-Analyses*

The schematic results of the SRs' and meta-analyses' quality are shown in Multimedia Appendix 4. A high percentage of the reviews was rated as critically low (43.8%) [24-30,33-39,41,44,45,48,49,51,70], a rating that was often attributed to authors' failure to address one of the critical criteria, namely providing a list of excluded studies along with justifications for their exclusion.

## Description of RCTs

### *General Characteristics*

All extracted data from RCTs are shown in Multimedia Appendix 5. A total of 22 interventions did not have a specific name. The same intervention was described in 2 papers as follows: Active Teen Leaders Avoiding Screen-Time obesity prevention program [110,128], Dads and Daughters Exercising and Empowered intervention [115,116], Diab and Nano study [80,82], Girls on the Move intervention [120,124], MyMovez project [135,136], and the Raising Awareness of PA study [123,137]. The Nutrition and Enjoyable Activity for Teen Girls intervention was described in 3 papers [88,89,109].

Considerable heterogeneity was found for the sample dimension that was included between a minimum of 10 and a maximum of 1519 schoolchildren, and for intervention duration, which ranged between 2 weeks and 24 months.

In Figure S2 Multimedia Appendix 3, a summary of the main characteristics of the interventions, divided by general RCT aspects, is presented. The included RCTs were published between 2010 and 2025, mostly in America, and were primarily conducted in school settings, with others in home or community environments. Most interventions targeted middle school children, followed by primary school children and adolescents, with some focusing on overweight or obese students, and 11.3% conducted in low-income areas. The majority used a 2-arm design with IGs and CGs and mainly focused on PA alone, followed by PA combined with other behaviors or obesity-related outcomes.

A total of 38 interventions were based on different theories for behavioral changes. The most used theoretical models were the following: the self-determination theory by Deci and Ryan [139] and Ryan and Deci [140] was used in 16 RCTs [78,81,95-97,99,100,120,121,124,127,128,132,135,136,138]; the social cognitive theory by Bandura [141] was used in 15 RCTs [86,88,89,101,102,108,114,121,123,125,128,130,131,134,137]; 5 interventions [94,102,122,135,136] were based on the theory of planned behavior by Aizen [142]; the transtheoretical model

XSL•FO
RenderX

of behavior change that was suggested by Prochaska and Velicer [143] was applied in 2 interventions [86,107].

### Digital Aspects

Figure S3 Multimedia Appendix 3 shows a summary of the main characteristics of the trials related to the digital aspects of the intervention delivery. Most interventions included a wearable as a digital component of the intervention; in some cases, the wearable was a unique, tested digital tool [77,79,92,103,105,106,108,113,114,117,118,129], in some other trials, it was included in a multicomponent intervention [84,86,88,89,99,100,102,107,109,110,114-116,126,128,132,135-137]. Several RCTs used gamification, apps, web-based technologies, and text messaging; few interventions used social media, live coaching, or intelligent personal assistants. The most used digital devices were mobile phones or smartphones or wearables; 19.4% of interventions used the console or arcade machine and the computer, laptop, or tablet.

Around half of the RCTs used nondigital components for the intervention delivery, such as goals, rewards, incentives, advice, diaries, school programs, face-to-face educational sessions, lessons, or booklets (Multimedia Appendix 5).

A total of 53.2% of interventions used device-based measures only to evaluate PA outcomes, while the rest used device-based measures together with self-report measures, such as data from questionnaires or step diaries (Figure S3 Multimedia Appendix 3).

Device-based measurement tools were mainly accelerometers or activity trackers, that is, ActiGraph (Ametris, LLC) [80-83,85,86,88-90,92,93,98,99,101,102,104,109-112,117,120,123,124,128,130-133,137], Fitbit Flex or Fitbit Zip (Fitbit, Inc) [121,123,131,134-136], GENEActiv (ActivInsights Ltd) accelerometers [78,84,87] and Polar Active (Polar Products Inc) sensors [103,107,126,144]. Around one-third of the interventions used pedometers for step count, mainly Yamax (Polygon Direct [UK] Ltd) [77,79,94,108,113-116,129], Tractivity (Tractivity Ltd) [95-97], and Omron (OMRON Healthcare Co, Ltd) [106,118]. In 5 RCTs, other device-based measurement tools were embedded, for example, in the game machines such as the PlayStation (Sony Interactive Entertainment LLC) memory cards [82,93,111,112,122].

Device-based measures consisted mostly of moderate-to-vigorous physical activity (MVPA) or other PA outcomes such as vigorous physical activity (VPA), moderate PA, light physical activity (LPA), and total PA [80-82,85-88,89,92,93,95-98,101,103,104,109-112,117,119,121,122,126-128,130,131,133,137]; step counts were evaluated in half of the interventions [77,79,84,91,92,94-99,102,106,108,113-116,118,121,123,125,127,129-132,134-136,138].

A total of 19 RCTs also assessed physical fitness abilities through fitness tests; for example, cardiorespiratory fitness through the 20 m shuttle test [84,104,111,120], the 1-mile walk or run test [90,113], or the grip strength through the dynamometer [84,103,107,128]. A total of 86.9% of the interventions collected other outcomes, including anthropometry or body composition, cognitive or psychosocial aspects, dietary outcomes, clinical biomarkers, smoking, alcohol, sleep, and media use.

### Effectiveness

As reported in Table 1 and Multimedia Appendix 5, a total of 54.8% of the interventions were not effective on the considered device-based PA outcomes [78,80-82,85,88-90,92,93,98,99,102,108-113,120-126,128-130,134-138]. The other RCTs showed effectiveness (37.1%) [77,79,83,84,86,94-97,100,101,104-107,114-116,118,127,131-133] or partial effectiveness (8.1%) [87,91,103,117,119] on one or more PA outcomes, meaning that the digital intervention had positive effects on some PA outcomes and not on other PA outcomes; for example, in the intervention of Comeras-Chueca et al [87], the Active video game increased the LPA, but not moderate PA, VPA, or total PA; or in the RCT from Petrušič et al [119], the digital placebo video games contributed to increasing the level of LPA but not of the VPA.

XSL•FO

**Table .** Frequencies (in number and percentage) of the RCTs[a] effectiveness overall and by specific device-based outcome.[b]

| Device-based outcomes | Total | Effective | Ineffective |
|---|---|---|---|
| Total RCTs, n (%) | 62 (100) | 28[c] (45.2) | 34 (54.8) |
| Total outcomes, n (%) | 122 (100) | 40 (32.8) | 82 (67.2) |
| Steps, n (%) | 31 (50) | 16 (25.8) | 15 (24.2) |
| MVPA[d], n (%) | 38 (61.3) | 12 (19.4) | 26 (41.9) |
| LPA[e], n (%) | 13 (21) | 4 (6.5) | 9 (14.5) |
| MPA[f], n (%) | 6 (9.7) | 1 (1.6) | 5 (8.1) |
| VPA[g], n (%) | 9 (14.5) | 1 (1.6) | 8 (12.9) |
| TPA[h], n (%) | 7 (11.3) | 1 (1.6) | 6 (9.7) |
| LVPA[i], n (%) | 1 (1.6) | 0 (0) | 1 (1.6) |
| CPM[j], n (%) | 12 (19.4) | 2 (3.2) | 10 (16.1) |
| Active minutes, n (%) | 5 (8.1) | 3 (4.8) | 2 (3.2) |

[a]RCT: randomized controlled trial.

[b]Referred to the 62 randomized controlled trials.

[c]A total of 5 of 28 interventions were partially effective, that is, effectiveness was demonstrated for some physical activity outcomes of the intervention.

[d]MVPA: moderate-to-vigorous physical activity.

[e]LPA: light physical activity.

[f]MPA: moderate physical activity.

[g]VPA: vigorous physical activity.

[h]TPA: total physical activity.

[i]LVPA: light-to-vigorous physical activity.

[j]CPM: counts per minute.

Moreover, some interventions demonstrated stronger effects when implemented over shorter durations or when assessed at short-term follow-up, typically within 3 to 6 months [91,103,118].

When stratifying RCTs' effectiveness by the type of device-based outcomes, a total of 25.8% of the RCTs were effective in increasing the number of steps, while a similar percentage demonstrated no effectiveness (Table 1). The major part of the RCTs assessing MVPA was not effective in this increase; all the other device-based PA outcomes mostly did not increase after the digital intervention (Table 1). Totally, 67.2% of the PA outcomes were not positively affected by the intervention.

Stratified analyses of intervention characteristics (Table 2) showed higher proportions of effective interventions in trials conducted in Asian populations; those targeting PA as the sole primary outcome; interventions using wearables as the digital component or delivery device; trials measuring PA with pedometers; and interventions using specific devices (Tractivity, Omron, Polar Active, and Yamax) rather than ActiGraph or other accelerometers.

[h]MVPA: moderate-to-vigorous physical activity.

[i]CPM: counts per minute; LPA: light physical activity; LVPA: light-to-vigorous physical activity; VPA: vigorous physical activity; active minutes.

Examining in detail, the results on the digital components for intervention delivery, the gamification tools that were efficacious or partially efficacious on the device-based PA outcomes were the MobileKids Monster Manor installed on iPhone (Apple Inc); Xbox 360 (Microsoft Corp); games of the Nintendo Wii, such as Wii Sports-Tennis, Sonic and Mario at the Olympics or Celebrity Sports Showdown-Horse Racing, Just Dance 3; games from Kinect (Microsoft Corp), such as Kinect Your Shape: Fitness Evolved 2012, Disneyland Adventures and Kinect Sports Season 2, and Kinetic Adventures! Some games from Xbox 360 were efficacious in 2 interventions [104,131], and nonefficacious in 1 intervention from Staiano et al [130]. The game Dance Dance Revolution was efficacious when it was used in the intervention from Maloney et al [112], while in the intervention from Errickson et al [93], it did not show any effect on PA outcomes. The ineffective games were Diab and Nano, as well as active video games such as PlayStation or Sports and Dance Factory, Sport Champions, Move Fitness, Start the Party and Medieval Moves, Dance Star Party and Sorcery, Camp Conquer, a FitQuest smartphone exergame, and Dance Central.

Effective apps in increasing schoolchildren's PA were the Dads and Daughters Exercising and Empowered app [115] and the mobile app MapMyFitness [127]; they both were developed quite recently and targeted to primary and secondary schoolchildren, respectively. The smartphone app "Eat Wisely and Move Happily" used in the Diet, Exercise and Cardiovascular Health–Children [145] was partially effective, while 3 apps were ineffective in increasing PA, such as the immersive app "Zombies Run! 5K training" and the nonimmersive app "Get Running-Couch to 5K" from the AIMFIT (Apps for Improving Fitness) [90], the app from the Active Teen Leaders Avoiding Screen-Time obesity prevention program [110], and from MyMovez project [135,136].

Conversely, higher proportions of ineffective interventions were observed in RCTs conducted in Australia or New Zealand; home-based trials; interventions targeting individuals at risk for obesity, overweight or obese participants, or mixed populations including overweight youth; and trials focused on low-income or insufficiently active children and adolescents. Interventions lasting longer than 3 months and those targeting PA alongside other behaviors or obesity-related outcomes were mostly ineffective (Table 2). App-based and mixed digital interventions also showed limited effectiveness. Trials using multiple delivery devices were largely ineffective, whereas combining accelerometers with exergame or pedometer devices, or using exergame-only devices, was associated with higher effectiveness.

Nearly 70% of the interventions using ActiGraph accelerometers were not effective, all interventions using Fitbit Flex were ineffective, and ineffectiveness increased to 75% when 2 devices were used. Overall, 68.4% of interventions did not increase MVPA, and 64.5% did not improve other PA outcomes. Chi-square analyses showed significant associations for low-income populations (*P*=.01) and outcome measurement device (*P*=.003), with additional trends for country of origin, setting, baseline PA level, intervention focus, and sensor brand (Table 2).

### *Quality of the RCTs*

A total of 11.3% of the RCTs showed a high risk of bias, while the 48.4% had some concern (Multimedia Appendix 6). One of the critical points regards the "deviations from the intended interventions" (33.9% of the interventions) and "measurement of the outcome" (19.4%).

## Discussion

### Principal Findings

The present umbrella review provides an overview of SRs and meta-analyses that collected RCTs aimed at evaluating the effectiveness of digital approaches to increase PA in healthy children and adolescents. It summarizes and critically evaluates the digital intervention components, as well as the possible determinants and methodological limitations of their effectiveness.

XSL•FO
RenderX

Slightly less than half of the interventions reported either total or partial effectiveness of the digital tools in increasing device-based PA outcomes. A wide variation in study designs, target age groups, intervention objectives, digital devices, and intervention components was identified across the reviews and trials.

Effectiveness over the population target of the present review appears to be influenced by multiple factors, including the focus task of the intervention, the type of digital component used to deliver the intervention and its delivery device, the device used for the objective measurement of PA, some specific population target, and other characteristics such as the geographic region, the intervention setting, and the device brand.

## Country

### *Overview*

A first observation concerns the underrepresentation of certain countries in the implementation of the included trials, particularly when considered in relation to the population size of countries with advanced economies across continents. Most interventions were conducted in North America, predominantly in the United States; however, this concentration does not adequately reflect the size and diversity of the North American population, because when compared with the approximately 380 million inhabitants of the United States and Canada [146], the number of interventions remains relatively limited. Around one quarter of the included RCTs were conducted in Europe, mainly in the United Kingdom, while another quarter originated from Australia and New Zealand; the latter proportion appears comparatively high given the much smaller population size of these countries (approximately 31 million) compared with Europe (approximately 744 million) [146]. In contrast, Asian countries with advanced economies were notably underrepresented despite their large combined population (approximately 206 million) [146].

Moreover, the influence of the country on the effectiveness of digital tools is confirmed by the trend observed after the nonparametric association analyses. Several factors may plausibly explain why digital tools appear to be more effective in increasing PA among children in Asian populations. Higher levels of digital literacy and early exposure to technology in many Asian countries (especially in the economically advanced regions) may facilitate greater engagement with apps, wearables, and gamified platforms. In several Asian contexts, structured educational systems, strong acceptance of technology, and high parental support may enhance adherence and implementation fidelity. Additionally, school curricula may better integrate digital health tools into daily routines, increasing consistency of exposure. Urban environments, limited outdoor spaces, and academic pressures may further increase the appeal of digital interventions, helping to explain regional differences in their effectiveness for promoting PA in children. Future research should aim to address this imbalance by promoting RCTs in underrepresented regions and deeply investigating the differences in the effectiveness between the different countries. Expanding the geographical diversity of intervention settings would improve the generalizability of findings and provide a more comprehensive understanding of the effectiveness of digital interventions across different cultural and socioeconomic contexts.

### *Age and Special Population Groups*

This review identified a tendency for RCTs to collect fewer data on high school students compared with those in primary and middle school, suggesting a need for increased research focused on this age group. Furthermore, specific population subgroups, such as students who are overweight or obese, or those from low socioeconomic backgrounds, were rarely included in the reviewed trials. This finding is consistent with the observations reported by Kracht et al [14]. All the interventions conducted to low-income populations were significantly ineffective, which suggests that it would be urgent to plan digital interventions that can positively affect PA also in children and adolescents from low-income families. Similar results were observed for subpopulations of insufficiently active children and adolescents, for whom all digital interventions did not result in effectiveness. Accordingly, future intervention studies should place greater emphasis on the inclusion of these underrepresented subgroups when designing and evaluating digital interventions.

### *Setting*

With regard to the intervention setting, community-based environments, including schools, were substantially more prevalent than home-based settings, and a significant trend of difference in effectiveness for increasing PA was observed between these 2 contexts. As demonstrated in previous studies, social support, together with parental involvement and responsibility in implementing interventions with their children, plays a crucial role in facilitating behavior change [147,148]. Moreover, the ecological model of health and disease highlights how the onset of chronic conditions is influenced by environmental factors, beginning within the family context and extending to schools and the broader community [149]. Accordingly, both school and home environments are essential for the development of interventions aimed at modifying lifestyle behaviors [150,151]. Future research should therefore take greater consideration in conducting RCTs within home-based settings.

### *Focus Task*

PA was a primary focus in most reviews, followed by the weight or obesity management tasks, and this was also reflected in the RCTs extracted by the reviews. Those interventions that had only PA as an outcome were apparently more effective than those focusing primarily on weight or obesity or PA together with other variables. Even though the explanation for this effect is not clear, it could be hypothesized that closer and more specific attention to a topic could improve the intervention procedure to then obtain more effective results. From a theoretical perspective, behavior change frameworks such as the self-determination theory [139] (which has been used in several RCTs of the present overview) suggest that interventions targeting clearly defined mechanisms (eg, motivation, capability, and opportunity) are more likely to be implemented with fidelity and evaluated appropriately. Narrowly focused interventions allow for clearer operationalization of outcomes and improved

XSL•FO
RenderX

alignment between intervention components and measurement strategies. Empirically, previous SRs of digital PA interventions in children and adolescents have shown that interventions with clearly specified objectives and well-defined outcomes tend to report more consistent and interpretable effects compared with broadly defined or multicomponent interventions [66,152,153]. Moreover, methodological guidance for complex interventions (eg, the Medical Research Council framework [154]) emphasizes that precise intervention focus facilitates better study design, implementation, and evaluation.

### *Theoretical Foundation*

This review revealed that studies including a theoretical foundation in the trial procedure seemed to be less effective than those that did not report any theory. This result is not in line with the literature reporting that the behavior change techniques and theoretical frameworks represent the core mechanisms through which interventions exert their effects. Although the most widely adopted standardized taxonomy of behavior change techniques was introduced only in 2013 [14], potentially constraining its use in earlier primary studies and reviews, the RCTs included in the present review that incorporated theoretical frameworks were predominantly conducted and published after this date. This advocates the need for reviewing and specifically addressing target populations with all the behavior change techniques and theories on the basis of digital tools interventions.

### *Digital Components for the Intervention Delivery*

#### Gamification

The gamification was a digital component frequently investigated in the reviews and a commonly used tool in the retrieved RCTs. This is expected when we consider the target age of the populations under study; gamification tools such as exergames, serious games, or games embedded in devices are commonly used in this age as they are more appealing than other digital intervention tools. Gamification is intended as the use of suggestive digital games and game elements such as points or reward systems in nongame contexts, to influence users' behavior and motivation [155]; gamification targeting PA is specifically designed to involve children in movement-based gameplay, encouraging them to be more active, as many common exergames (also called active video games) do. Recently, the concept of serious games has been of great interest, as they are designed for a primary purpose other than pure entertainment, thus having mainly an educational aim. However, there is often misleading information in the literature about the use of the term "serious game" because some authors define a serious game as any game used for an intervention study; that is, Liu et al [145] in their meta-analysis included different games that showed a significant effect of serious games on the increase of PA in children. In our work, there was no intervention reporting the term serious games, but only "exergames," "role-playing videogames," "active video games," or "arcade machines," which could be considered as serious games because they were designed or used for the purpose of the intervention. The term "serious game" should then be clarified in future publications to shed light on an agreement between the results of the different interventions.

In summary, it was expected that interventions using gamification and apps as digital components could be more effective than other tools in increasing the PA of young populations, but this was not found out in this umbrella review. The explanation is not so easy because different factors can influence the effectiveness of digital interventions, but it would be useful to explore in detail the single intervention, which is not the purpose of this review. Our recommendation, therefore, is that future studies should plan interventions using accurate gamification tools and apps that could be more effective for schoolchildren's PA.

#### Wearables

The major part of interventions testing a wearable as a unique delivery tool and component reported effective results on increasing PA. These results are in line with the literature stating that wearable technologies have emerged as important digital tools for promoting PA among children and adolescents [156-158]. By providing real-time feedback, goal setting, and self-monitoring features, wearables can enhance awareness of movement behaviors and motivate users to increase daily activity levels. In younger populations, these devices support the development of self-regulation skills and reinforce positive behavior through immediate reinforcement and gamified elements. Moreover, wearable-based interventions can be integrated with mobile apps and social features, facilitating parental involvement, peer support, and structured activity challenges. Importantly, wearables also enable objective assessment of activity patterns, improving the accuracy of outcome measurement in intervention studies. Collectively, these features position wearable technologies as effective and scalable tools for supporting PA promotion in pediatric populations. It is suggested that these devices should be prioritized in future RCTs as intervention delivery tools.

#### Web-Based Tools, Apps, and Text Messages

Very few interventions examined the effects of web-based tools, mobile apps, and text messaging as unique components of the interventions, as these tools were generally included in a multicomponent intervention. Similar proportions of effective and ineffective outcomes between these 3 tools were observed in this review. In particular, RCTs that used web-based components were mainly addressed to older children attending middle or high schools, in contrast with gamification approaches that were targeted principally to schoolchildren from elementary schools, which is consistent with findings from the international literature [159-162]. Overall, these digital approaches demonstrate potential but yield inconsistent effects on PA promotion in schoolchildren [163].

### Nondigital Components

Nondigital components were used in slightly more than half of the interventions, and they were mostly goals, rewards, and incentives. Previous works have shown that multicomponent interventions, including nondigital components such as counseling for children and parents, class seminars, and health promotion curricula, could have a positive impact on PA outcomes [159]. Therefore, different communication channels should be combined with digital tools because they are based on the possible behavior change [164].

XSL•FO
RenderX

### Digital Device for Intervention Delivery and for PA Outcome Assessment

Most SRs or meta-analyses and RCTs included studies that used smartphones as devices for the intervention delivery, and this is consistent with the fact that they are the most common devices used to access the internet games, apps, or other digital components [165]. Effectiveness was not likely to be affected by the specific device. The same could be stated for the use of devices such as console or arcade machines, computers, tablets, or iPod touch in relation to the increase in PA outcomes. The use of a miscellaneous array of devices, instead, revealed a major proportion of ineffective interventions.

Other frequently used devices were the wearables, in most cases overlapping with the wearable that was used as a component of the digital intervention delivered. The main used wearables were accelerometers and pedometers, such as ActiGraph, Polar Active, or Tractivity, all tools that have been widely validated and broadly used [166-168]. Additionally, Yamax or Omron pedometers were mainly used for the step count measurement. The same type of device was used within the intervention for the assessment of PA outcomes. Greater significant effectiveness was found for the use of pedometers, compared for example to the accelerometers. Pedometers may be more effective than accelerometers in increasing PA among children and adolescents because they provide simple, easily interpretable feedback, such as step counts, that is readily understood by young users. This immediacy can enhance motivation and goal setting, particularly when daily step targets are used. Pedometers are also less complex and often more user-friendly, which may promote consistent wear and engagement. In contrast, accelerometers are typically designed primarily for measurement rather than behavior change and often provide limited or delayed feedback to participants [67,77,169]. The visibility of step counts can encourage self-monitoring and reinforce active behaviors throughout the day. As a result, pedometers may better support behavior change processes in youth populations.

### Device-Based PA Outcomes

Some considerations have to be made about the specific outcomes that were assessed through the devices. Step count was positively affected by the digital intervention in half of the considered interventions, while MVPA or other PA outcomes, such as light-to-vigorous PA, LPA, MVPA, VPA, counts per minute, and active minutes, did not increase in the majority of the interventions. The failure in increasing step or other PA outcomes could be explained by supposing that engagement with the technology declined over time, reducing sustained behavior change. Some interventions relied primarily on monitoring without incorporating sufficient behavior change techniques such as goal setting, feedback, or rewards.

Limited integration of social support from parents, peers, or schools may also have weakened intervention effects [170]. In addition, interventions of short duration may have been insufficient to produce measurable increases in habitual PA, or those that were too long may have led to a loss of interest [171]. Technical issues, poor usability, or lack of age-appropriate design could have further limited children's and adolescents' motivation to increase daily steps and other PA outcomes [44]. Finally, measurement challenges and high baseline MVPA levels in some samples may have limited the capacity to observe significant increases [172].

### Overlapping

The observed slight degree of overlap indicates that most SRs and meta-analyses include different primary studies. This statement supports more robust and balanced conclusions in this umbrella review, as the risk of double-counting evidence is reduced, and the independence of findings across reviews is strengthened. Although a slight overlap enhances the credibility of the overall synthesis by ensuring that conclusions are not driven by a small number of repeated trials, it may also increase heterogeneity, as findings are drawn from diverse interventions and populations [173]. Interpretation, therefore, requires careful consideration of contextual differences.

### Quality of the Studies

The critically low rating of the major part of the SRs and meta-analyses was frequently due to the omission of a key methodological requirement, specifically the reporting of excluded reviews and the reasons for their exclusion. The lack of transparency regarding excluded reviews could limit the completeness of the evidence base and the potential for selection bias.

With regard to the quality assessment of the RCTs, the domain of the RoB 2 tool "deviations from the intended interventions" was particularly critical. Digital interventions strongly depend on user engagement, adherence, and correct use of the technology, which are often inconsistent in younger populations. Children and adolescents may discontinue use, use the tools incorrectly, or engage at varying intensities. When participants deviate from the assigned intervention, the estimated intervention effect may be biased, especially if these deviations differ systematically between IG and CGs [174]. When not properly addressed analytically, they may lead to overestimation or underestimation of intervention effects or heterogeneity in reported outcomes.

### Limitations

A limitation of the present umbrella review is that several included SRs and meta-analyses were of critically low methodological quality; however, excluding all such reviews would have resulted in the omission of a substantial proportion of relevant evidence. This implies a potential and substantial influence on the interpretation of evidence of the digital tools' effectiveness on increasing PA in children and adolescents. For example, methodological weaknesses, such as unclear inclusion criteria, incomplete search strategies, poor transparency in data extraction and synthesis, may reduce reproducibility and confidence in findings; inadequate assessment of risk of bias can result in overestimation or underestimation of intervention effects; insufficiently explored heterogeneity may mask important differences between intervention types or populations; inconsistent outcome definitions and measurement methods further limit comparability across reviews [175]. Therefore, the findings of this umbrella review should be interpreted with caution.

XSL•FO
RenderX

Similarly, RCTs assessed as having a high risk of bias constituted a substantial portion of the evidence base; therefore, excluding them would have been detrimental to the review. This could have influenced the results of this umbrella review, in the sense of overestimating the effectiveness of interventions, masking real differences between types of digital tools, such as mobile apps, wearable devices, or exergames. Common sources of bias, including inadequate randomization, lack of blinding, and high attrition, can systematically skew outcomes. Overall, the presence of high-risk trials weakens the ability to grade the certainty of evidence and may ultimately lead to inappropriate or poorly informed recommendations for practice and policy. Moreover, the lack of certainty of assessment (eg, through the GRADE [Grading of Recommendations, Assessment, Development, and Evaluation] tool) was a deliberate choice; it is a common and currently recognized practice in the field that a significant portion of published umbrella reviews do not assess the certainty of evidence, particularly when authors focus instead on the methodological quality of the included reviews using the AMSTAR 2 tool [176,177].

Another limit of this review is that it did not quantitatively synthesize through a meta-analytical approach (meta-meta-analyses or meta-analysis of the RCTs) the overall effectiveness, the heterogeneity, and the effects obtained after stratification and sensitivity analyses. Digital tools such as apps, wearables, exergames, and gamified platforms often differ in content, intensity, duration, and implementation context, making direct comparisons challenging. This variability limits the ability to synthesize findings quantitatively and reduces confidence in pooled effect estimates. In this overview, heterogeneity was explored through qualitative methods combined with narrative synthesis, and this approach helped in the identification of patterns and potential moderators even when quantitative pooling is not possible. Heterogeneity may obscure true intervention effects, as positive outcomes observed in some interventions may not be generalizable across different settings or age groups [178]. It also complicates the identification of which specific digital components or delivery strategies are most effective for schoolchildren. Consequently, conclusions must be framed more descriptively, and recommendations for practice and policy should emphasize context-specific effectiveness rather than universal applicability. Therefore, the authors envisage that the next step is to conduct a meta-analysis of RCTs to more robustly assess the effects of digital approaches on increases in PA. Such analyses should be complemented by sensitivity analyses, for example, excluding interventions of lower methodological quality, to enhance the robustness and interpretability of the findings.

As some of the included RCTs were conducted during the COVID-19 pandemic (2020 - 2022) or in the postpandemic period, changes in PA patterns and digital tool use during these years may have influenced the observed outcomes [179], and this should be considered for the interpretation of results.

### Strengths

This umbrella review was based on rigorous and systematic methodology, relying on reviews that collected RCTs and that used objective device-based measures of PA. These measures improve the reliability of the review by providing more accurate and unbiased outcome assessment than self-reported data. Moreover, they reduce recall and social desirability bias, enhance comparability across studies, and allow more precise detection of changes in activity levels. As a result, they strengthen the quality of the evidence base, reduce heterogeneity related to outcome measurement, and increase confidence in conclusions regarding the effectiveness of digital interventions [180,181].

Risk of bias was evaluated at both the review and primary study levels, given that only a small subset of interventions from each review met the inclusion criteria for inclusion in this umbrella review. As a result, assessing risk of bias exclusively at the review level may have led to misleading conclusions, because the original reviews incorporated a broader evidence base.

Another strength of this review is its innovative character, as it is among the first umbrella reviews to comprehensively synthesize evidence from recent SRs and meta-analyses on digital PA interventions in children and adolescents. It provides novel comparative insights into methodological features and population subgroups that may drive or limit the success of digital approaches.

The findings of this work have several important real-world implications and contributions. They provide evidence-based guidance for practitioners, schools, and policymakers on which digital tools are more likely to effectively increase PA in children and adolescents, supporting more informed decision-making. The results highlight the importance of selecting appropriate devices, outcome measures, and intervention designs to maximize impact in real-world settings. This work also identifies gaps in equity and population coverage, informing future interventions aimed at reducing disparities in PA. Finally, the findings contribute to the optimization and scaling of digital health interventions by clarifying which approaches are most promising for practical implementation.

### Recommendations for Future Research and Implications

While the authors envisage quantitatively analyzing the effect of the interventions on the specific PA outcomes in children and adolescents in a future study through meta-analytic procedures, they wish to guide the strengthening of rigor for future SRs and interventions and support greater engagement in PA during childhood and adolescence.

First of all, the selection of device-based measures, which are able to provide reliable and comparable data, should be stressed. A clarification on the way to use gamification should be provided, together with a clearer explanation of the term “serious game” when it is used within the interventions. The importance of incorporating gamification tools, wearables, and/or apps as integral components of interventions should be highlighted, as they may be particularly effective for school-aged children [74,163].

Future interventions should place greater emphasis on conducting RCTs within home-based settings [150]. PA management should be the primary aim of the intervention; limiting the focus of the RCT to PA, without going too far into

XSL•FO
RenderX

other outcomes that may cause a loss of the focus, could help in obtaining accurate data and effective outcomes [182]. There is a need to intensify RCTs targeted at high school populations, also considering that this age range is particularly engaged with digital technologies. Sustaining engagement over time remains a key challenge [183], highlighting the importance of developing and evaluating strategies that support long-term participation and adherence to digital interventions.

Better planning of interventions targeted to low-income and to insufficiently active subpopulations of children and adolescents represents a key aspect [184]. Future research should aim to promote and support RCTs in underrepresented regions, particularly in Asian and other non-Western high-income countries.

A greater emphasis on methodological transparency throughout the review and intervention selection process is suggested; in particular, clear and explicit criteria for study inclusion and exclusion should be reported. Transparency is needed in quality assessment procedures, including the rationale for quality scoring and study weighting; in addition, future reviews should clearly describe how methodological quality influences the interpretation of findings. The need for systematic evaluation and deliberate selection of behavior change techniques and theoretical models that are explicitly tailored to specific target populations within digital intervention contexts is underscored [185].

The results of this umbrella review can suggest practical actions both to schools and policymakers. Schools should avoid embedding PA as a minor component within broad well-being or educational programs; can integrate wearable-based programs (eg, step challenges and activity feedback) into physical education or daily routines; should favor pedometers or basic wearables over self-report tools to monitor student activity; and should accurately choose the type of device when implementing digital PA programs. Schools in disadvantaged areas may require additional support, such as teacher training, parental engagement strategies, or longer intervention duration.

Policymakers should prioritize funding and endorsement of interventions where PA improvement is explicitly defined, measured, and prioritized; can justify investments in wearable technologies as scalable and effective tools for youth PA promotion; can recommend objective PA monitoring standards in school-based programs to improve evaluation quality and accountability; can develop guidelines specifying preferred assessment tools to improve program effectiveness and comparability; should avoid one-size-fits-all approaches and allocate additional resources to adapt digital interventions to low-income contexts.

## Conclusions

This innovative study represents one of the first umbrella reviews describing digital PA interventions in youth, determinants of effectiveness, and methodological gaps. It provides evidence-based guidance for practitioners, schools, and policymakers on which features of the interventions are more likely to effectively increase PA in children and adolescents, supporting more informed decision-making. Interventions appear to be most effective when they prioritize focused PA objectives, incorporate wearables as both the core digital intervention component and the delivery device, use pedometers to measure PA outcomes, and choose accurately the device to assess PA as a quality criterion in program selection.

All these adaptations in future studies could be of great importance to generating high-quality primary RCTs and provide consistent conclusions about the usefulness of digital approaches to increase PA. The findings of this umbrella review have important implications for public health practice and policy. Digital PA interventions represent a scalable, cost-effective approach to addressing low PA levels among children and adolescents, a key modifiable risk factor for noncommunicable diseases across the life course. By identifying which types of digital tools show the greatest potential and which design and contextual factors influence effectiveness, this review supports more strategic investment in evidence-based digital solutions within schools, communities, and health care systems. The results also underscore the need for public health stakeholders to move beyond one-size-fits-all approaches and to ensure that digital interventions are developmentally appropriate, engaging, and equitably accessible, particularly for underserved populations. Strengthening methodological rigor in future research will improve the reliability of evidence used to guide policy decisions and large-scale implementation.

Collectively, these insights can help inform integrated public health strategies that leverage digital innovation to promote lifelong PA habits, reduce health inequalities among youth, and the burden of chronic diseases in adulthood.

## Acknowledgments

The authors declare the use of generative artificial intelligence (GenAI) in the research and writing process. According to the GAIDeT (Generative Artificial Intelligence Delegation Taxonomy, 2025), the following tasks were delegated to GenAI tools under full human supervision: (1) proofreading and editing, (2) summarizing text, and (3) translation. The GenAI tool used was ChatGPT-3.5 (OpenAI). The responsibility for the final paper lies entirely with the authors. GenAI tools are not listed as authors and do not bear responsibility for the outcomes. This declaration was submitted by collective responsibility.

## Abstract

**Background:** Contact tracing (CT), the process of identifying and managing contacts of infected cases, is one public health and social measure that may reduce the spread of infectious diseases. While previous systematic reviews of CT exist, a comprehensive review of both the effectiveness and potential unintended consequences has not been undertaken to our knowledge. Understanding effective CT strategies could help governments and health authorities prepare effectively for emergency epidemic or pandemic situations.

**Objective:** This study aims to systematically review the evidence on the effectiveness of CT across infectious diseases with epidemic or pandemic potential. Effectiveness is measured in terms of impacts on disease transmission, health care use, mortality, or unintended consequences.

**Methods:** We searched 6 bibliographic databases (MEDLINE, Embase, Global Health, CINAHL Ultimate, Cochrane, and Scopus) between November 29 and December 3, 2024, with supplementary citation searching. We sought human studies comparing CT with interventions with no CT or other forms of CT, delivered in the community, in prespecified diseases of epidemic or pandemic potential. We included studies with any measure of disease transmission, related health care use, or unintended consequences of CT and prioritized studies with concurrent comparators. Screening, data extraction, and critical appraisal were performed in duplicate. Due to substantial heterogeneity, a narrative synthesis was performed. This review was informed by meetings with a patient and public involvement and engagement group.

**Results:** After deduplication, a total of 12,816 titles and abstracts were screened, with 198 records assessed for eligibility at full text. Five additional studies were found through supplementary searching. Finally, 88 reports (of 86 studies) were included, of which 57 reports (of 55 studies) were prioritized. Two main routes of transmission were represented: respiratory (tuberculosis [TB], 15 studies; COVID-19, 5 studies) and blood-borne or sexually transmitted infections (STIs; 35 studies, of which 13 were in HIV, and 22 were bacterial or parasitic infections). No evidence was found on vector-borne, direct contact, or food- or water-borne routes of transmission. Evidence was highly heterogeneous, and more than half of the studies had notable methodological limitations. While there was no difference between CT and comparator interventions for most outcomes, there

XSL•FO
RenderX

was some evidence of reductions in disease prevalence in TB and for provider-initiated CT to be superior to patient-led approaches in STIs. Only 2 studies reported measures of unintended consequences.

**Conclusions:** We found inconsistent evidence for the effectiveness of CT, focused primarily on TB and on contrasts between provider-initiated CT and patient-led referral in STIs and HIV. High heterogeneity in study design precluded clear assertions regarding optimal strategies for CT, including with respect to relevant subgroups. Future work should consider generalizability of CT mechanisms across contexts, including by route of transmission and from the Global South, and a more thorough account of unintended consequences.

## Introduction

### Overview

The term Public Health and Social Measures (PHSMs) describes a range of nonpharmaceutical interventions implemented by individuals, communities, and governments to reduce the risk and scale of infection during a health emergency such as an epidemic or pandemic [1]. PHSMs play a role through all phases of such emergencies, especially while clinical countermeasures (vaccines and therapeutics) are being developed and deployed. It is therefore important to understand the effectiveness of PHSMs and their potential unintended consequences to allow governments and public health organizations to prepare for epidemics and pandemics.

Contact tracing (CT) is one important PHSM, defined by the World Health Organization (WHO) as the process of identifying, assessing, and managing people who have been exposed to someone who has been infected with the infection of interest [1]. CT may take many forms or be a component of multicomponent interventions and is an important element of organizational responses to any infectious disease. This review focused on CT, as well as innovations linked to CT that are generalizable across a range of infectious diseases.

One systematic review of CT in the control of infectious diseases from 2022 found that provider-initiated CT can be effective in managing infectious diseases but that evidence was relatively scarce outside of tuberculosis (TB), highly heterogeneous, and of mixed quality [2]. Similar reviews of CT have been published in relation to COVID-19 [3-8]. These reviews either included modeling or simulation studies, used broader definitions of CT that included human resource–intensive strategies such as active case finding, CT in combination with other measures, or included aspects of CT that are not generalizable to pathogens that spread by other routes of transmission (such as partner-delivered treatment for sexually transmitted infections [STIs]). Given the variability in the existing review evidence, and our research aim to have a comprehensive review of CT in the context of epidemic or pandemic response, a de novo systematic review examining the effectiveness of CT for different pathogens and routes of transmission is warranted.

### Research Question

What is the effectiveness of CT in reducing transmission of infectious disease as part of an epidemic or pandemic response?

## Methods

### Overview

The protocol for this review was drafted in conjunction with key interest holders at the UK Health Security Agency and a patient and public involvement and engagement group (described below). It was prospectively registered on PROSPERO (International Prospective Register of Systematic Reviews) prior to commencement of the review (CRD42025628278). The review was reported following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [9] (see checklist in Multimedia Appendix 1). This was a rapid review conducted between November 2024 and April 2025. Full methodological details are available in the protocol and full report [10].

### Identification of Studies

The search strategy was developed in MEDLINE by an information specialist (JB), peer reviewed by a second information specialist (AB), and translated for the other databases. Validated search filters for randomized controlled trials (RCTs) were obtained via the InterTASC Information Specialists' Sub-Group (ISSG) Filters Resource [11] for searching MEDLINE [12], Embase [12], and CINAHL Ultimate [13] and nonvalidated search filters for observational studies [14], evaluation studies, and nonrandomized trials or quasi-experimental studies [15].

The list of diseases was developed and validated with subject matter experts as a pragmatic list of representative diseases of each of the 5 routes of transmission (respiratory, vector-borne, direct contact, blood-borne, food-borne, and water-borne [ingestion]). The searches used a combination of relevant controlled vocabulary terms (eg, MeSH [Medical Subject]) and free-text terms.

A total of 6 bibliographic databases were searched between November 29 and December 3, 2024: MEDLINE (1946-current), Embase (1974-current), and Global Health (1973-current) via Ovid; CINAHL Ultimate (1937-current) via EBSCOhost; Cochrane Central via Cochrane; and Scopus (1788-current) via Elsevier. No date or language restrictions were used. Results

XSL•FO
RenderX

were downloaded into EndNote (version 20; Clarivate Analytics), which was used for finding and removing duplicates.

Supplementary searching involved forward and backward citation searching of included references using Scopus. After deduplication using EndNote, the remaining 1996 records were single screened. Search strategies are available in Multimedia Appendix 2.

## Inclusion and Exclusion Criteria

The inclusion and exclusion criteria were defined in consultation with interest holders and are summarized below. A more detailed description is provided in Multimedia Appendix 3.

### *Participants or Population*

Include: all humans in the context of an outbreak, epidemic, or pandemic of one of the prespecified infectious diseases of interest (full list provided in Multimedia Appendix 3), using WHO definitions for an outbreak, epidemic, or pandemic [16]. We focused on conditions with the potential to reach epidemic or pandemic status, as it was considered that this could help inform the use of CT to prevent an outbreak from escalating.

### *Intervention*

The inclusion criteria were as follows: interventions that incorporate CT, defined as the process of starting from a confirmed case diagnosed with an infectious disease (index case), identifying who the index case may have come into contact with, and attempting to communicate with the contacts. CT may be a stand-alone intervention or part of a multicomponent intervention that may involve further management of contacts (eg, treatment or quarantine) or other activities to improve infection detection (eg, education and training of health care staff). Interventions should take place in a community setting (including CT that is led by a health care setting but not limited to that health care setting).

Exclusion criteria were as follows: any other form of PHSMs or intervention to reduce transmission that does not incorporate CT; studies in health care settings where the goal was control of nosocomial outbreaks.

### *Comparator*

Different CT approaches compared with each other or compared with no CT were included.

Other PHSMs as comparators where these were not part of background measures in both arms were excluded.

### *Outcomes*

Studies with at least 1 measure of effectiveness (ie, measures of transmission of the focal disease, health care use, or mortality) or unintended consequences were included, as detailed in Multimedia Appendix 3.

### *Study Design*

Experimental studies with a control group, including RCTs, quasi-experimental studies, and before-and-after studies, and observational studies with a control group, including cross-sectional and case-control cohorts were included.

Studies without control groups, reviews of any type, crossover study designs, modeling studies, case series, case reports, and qualitative studies were excluded.

We included only peer-reviewed research published in English, with no restriction on date of publication or setting.

## Selection of Evidence

After piloting, the title and abstract of each record retrieved by the search were screened by 2 independent reviewers (MN, SF, MW, K Becker, RA, JTC, GJMT, and JB). The full text of each remaining record was then screened by 2 independent reviewers (MN, SF, MW, and K Becker). Disagreements at each stage were resolved through discussion. Articles excluded at full text were coded to indicate the first reason for exclusion. Several additional clarifications to the inclusion criteria were needed as study selection progressed due to the complex nature of interventions:

- Testing interventions were included if testing (ie, partner-delivered testing kits) was part of the CT process.
- Treatment interventions were excluded if there was no difference in CT activity between arms.
- Community-led surveillance interventions (where "community hot spots" with high disease prevalence were actively targeted for screening) were excluded.
- Any paper in which only proxy measures for a relevant outcome were presented was excluded.
- Active case finding or intensified active case finding was included if the process began from a known index case, rather than indiscriminate case finding based on location, for example.

## Prioritization

Because of the volume of evidence identified, we prioritized the most robust evidence (studies with concurrent control). This was a protocol deviation and was registered on PROSPERO. Top-level data were extracted from nonprioritized studies, tabulated, and briefly narratively described.

## Critical Appraisal

After piloting, each included trial was critically appraised using a modified version of the Effective Public Health Practice Project Quality Assessment Tool for Quantitative Studies, a validated tool suitable for multiple study designs [17]. Each study was rated either "strong," "moderate," or "weak" in 6 domains, with the number of "weak" scores given per study used to determine its overall score: studies were rated as "strong" if they had no "weak" scores, "moderate" with 1 "weak" score, and "weak" if they had 2 or more "weak" scores. Modifications and interpretations established during critical appraisal are described in the full report [10].

Appraisal was independently conducted by 2 reviewers (K Becker, MW, SF, LS, and RW), with disagreements resolved through discussion. The findings of critical appraisal informed the interpretation of results and did not influence the inclusion of studies in the review or the synthesis.

XSL•FO
RenderX

### Data Extraction

After piloting, key information was extracted from included trials by 1 reviewer and checked by a second (K Becker, MW, SF, and RA). Discrepancies were resolved through discussion. Data were extracted in relation to author and study details, sample characteristics, trial arm details, outcomes, outcome data, and inequalities addressed.

### Synthesis

Extracted data were tabulated and narratively described. Included studies were grouped based on route of transmission and condition or infection. STIs were grouped within the blood-borne route to align with the approach of the Department of Health and Social Care pandemic preparedness program at the time of conducting the review [18]. Interventions and outcomes were then described within those groups, with studies presenting similar interventions and comparators discussed together where possible. Comparators were described as usual care or standard of care as described by study authors. The CT element of each intervention was categorized into 1 of 4 groups:

- Provider-initiated contact tracing (PICT): CT is instigated by a trained provider (often health care worker) who notifies the index case's contacts.
- Partner referral (PR): CT is instigated by the index case who notifies their contacts.
- Household investigation (HI): the home of the index case is visited by a health care worker to notify and assess household members for signs of infection.
- Technology-based contact tracing (TECH): CT facilitated using digital tools, programs, or applications.

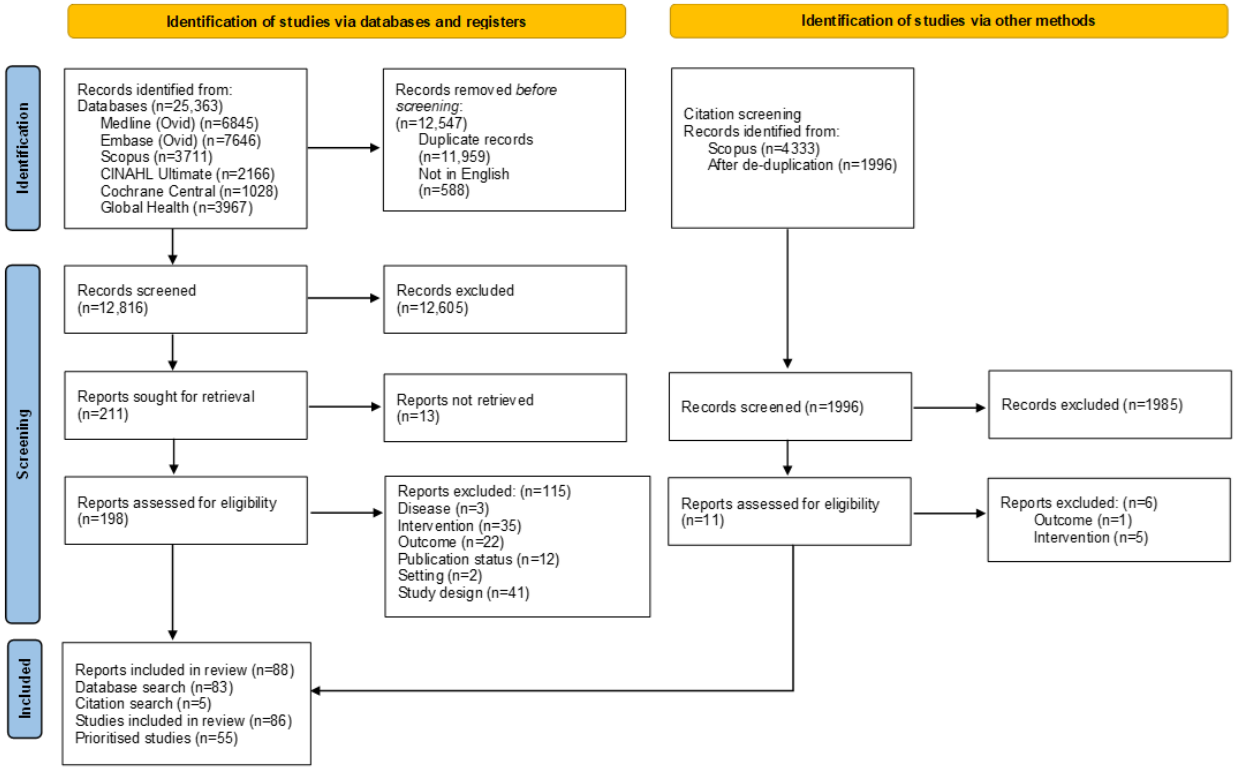
Contract referral (where the index case is given a set amount of time to contact their partners before a health care worker notifies the contacts) was categorized as a mix of both PICT and PR.

Where study design, route of transmission, intervention, comparator, and outcome were similar in multiple studies, we considered meta-analysis. In the event, heterogeneity precluded this, and we opted for a narrative synthesis approach, guided by Synthesis Without Meta-Analysis [19].

### Patient and Public Involvement and Engagement

This review benefited from discussions with PERSPEX (Public Engagement in Research for Health and Social Policy at Exeter), a group of 17 public collaborators who bring their carer, patient, or public perspective to the work of Isca Evidence. PERSPEX members meet monthly online, and membership is culturally, geographically, and demographically diverse. The review team discussed the project 3 times with PERSPEX, enabling the review team to gain insights about CT from a patient, carer, and public perspective.

## Results



### Study Selection

The initial searches identified 25,363 records. After deduplication and removal of non–English-language references, a total of 12,816 titles and abstracts were screened for relevance. After excluding 12,605 records for clearly not meeting 1 or more inclusion criteria, a total of 211 full-text articles were sought. Thirteen were unavailable, resulting in 198 records assessed for eligibility at full text. A total of 5 additional studies were found through supplementary searching. The most common reasons for exclusion at the full-text stage were intervention (40 reports) and study design (41 reports). Finally, 88 reports (of 86 studies) were included in the review. Of these, 57 reports (of 55 studies) were prioritized. The PRISMA flow diagram shown in Figure 1 summarizes this process. Multimedia Appendix 4 contains a list of studies with reasons for exclusion at full-text. Multimedia Appendix 5 contains the search summary table, which documents the origin of included references [20].

XSL•FO
RenderX

**Figure 1.** PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart summarizing the results of the literature search and screening for eligibility.

## Sample Characteristics

Table S1 in Multimedia Appendix 6 displays the sample characteristics of the 55 prioritized studies, reported in 57 papers [21-77], including study design and location, condition of interest, study dates and sample sizes, settings and recruitment criteria, and sample demographic characteristics. A total of 36 studies were a form of RCT [21,22,24-31,35-39,42,43,45,51-60,65-67,69-71,74-77]. The 19 non-RCT studies included 9 observational studies with concurrent control [23,32,33,44,61-64,73], 4 controlled before-and-after studies [46-49], 3 interrupted time series [40,41,50], and 3 nonrandomized trials with concurrent controls [34,68,72]. Populations across 6 continents were sampled, with the majority taking place in Africa (n=18 [24,26,27,29,32,39,42,43,47,48,50,51,54,60,65,66,70,76]), North America (n=13 [44,52,53,56-58,61,63,68,71,72,74,77], and Europe (n=11 [21,22,34-38,40,41,59,64,69,73]. A total of 8 studies took place in Asia [23,28,45,46,49,55,62,67], 3 in South America [25,30,75], 1 in Oceania [33], and 1 across Asia and Oceania [31].

All evidence was related to either respiratory or sexual or blood-borne routes of transmission. Within the respiratory route, 5 studies related to COVID-19 [40,41,64,73,76] and 15 to TB [23,25,42,43,46-51,54,55,65,67,75]. Under the sexual or blood-borne route, 35 studies were related to STIs [21,22,24,26-39,44,45,52,53,56-63,66,68-72,74,77]. Of the STIs, 13 studies included HIV [24,26-29,31,32,44,45,58,60,62,63], 13 chlamydia [21,22,33-38,52,53,56,59,68,69,77], 7 gonorrhea [34,39,53,56,68,72,77], 3 nongonococcal urethritis or urethritis [34,52,56], 6 syphilis [30,39,44,61,70,71], and 3 trichomoniasis [39,57,74]. Several papers investigated more than 1 STI [34,39,44,52,53,56,68,77]. One paper included chancroid and lymphogranuloma venereum alongside syphilis, gonorrhea, and trichomoniasis [39], while another referred to STIs but did not specify which ones [66].

Where reported, sample size ranged from 55 [31] to 59,027 [41], with the total sample in this review being 125,635 participants. A total of 27 studies were set in a form of clinic or outpatient services [22,24,26-28,32-39,42,45,50-52,54,56,58,62,63,66,68,70,72,74,78]. Of these, 14 studies were in generalist services [32,33,35,36,39,42,45,50,51,54,58,68,70,72,74] and 13 in services specialized for the condition of interest, such as an STI clinic [22,24,26-28,34,37,38,52,56,62,63,66,77]. A total of 19 studies took place in the community [21,23,25,29,41,47-49,55,59,61,64,65,67,69,71,73,75,76] and 5 in both clinic and community settings [30,43,44,57,60]. One study took place in both a clinic and on the internet [53], 1 was set in a prison [31], 1 in a nationwide program [40], and 1 setting was not reported [46].

## Critical Appraisal

Of the 55 appraised studies [21-77], a total of 9 received an overall rating of "strong" [28,42,44,57,64,65,70,76,77], 18 received an overall rating of "moderate" [21,26,30,39,40,45,49,51,52,55,59-61,67,69,71,74,75], and the remaining 28 were rated as "weak" [22-25,27,29,31-38,41,43,46-48,50,53,54,56,58,62,63,66,68,72,73]. Overall, the criteria on which studies scored most highly were study design and data collection. Studies scored most poorly on criteria related to researcher and participant blinding. Ratings are summarized in Table 1. A more detailed description of critical appraisal findings is available in the full report [10].

## Deprioritized Studies

Table S2 in Multimedia Appendix 6 displays the 31 studies that were deprioritized because of lack of a concurrent control. Like the prioritized evidence, the deprioritized evidence consisted largely of STI studies, with 9 studies on bacterial infections (eg, chlamydia) [78-86] and 8 studies on HIV [87-94]. In addition, there were 11 studies focused on TB [95-105], 2 on COVID-19 [106,107], and 1 on chronic hepatitis B [108]. None of the 31 deprioritized studies investigated a route of transmission that was not already covered by the prioritized evidence. Sample sizes ranged from 70 [78] to 2,022,127 participants [101], and the median was 919 (IQR 253-3192). Most studies compared an intervention with some variation of standard practice protocol (n=24).

## Synthesis

### *Respiratory or Airborne Transmission*

Studies of CT in respiratory transmission focused on TB and COVID-19. Table S1 in Multimedia Appendix 7 summarizes the characteristics, key components, and overview of outcomes for these studies. Further details about the characteristics of interventions evaluated within these studies are available in Table S2 in Multimedia Appendix 7, and detailed outcome data are available in Table S3 in Multimedia Appendix 7. More extensive interpretation is available in the full report [10].

### *Characteristics of CT Interventions in TB*

Of the 15 trials focusing on TB, 6 were cluster RCTs [25,42,51,65,67,75], 3 RCTs [43,54,55], 4 controlled before-and-after designs [46-49], 1 interrupted time series [50], and 1 observational study [23]. The TB studies were conducted outside high-income countries, except for 1 study conducted in Taiwan [46]. Nearly half of the TB studies were rated as being of weak quality, with only 2 rated as strong [42,65].

The interventions in 7 of the 15 TB studies incorporated PICT methods [27,29,47,50,53,54,58], 4 were HI [51,55,65,79], 3 involved a combination of PICT and HI [46,52,71], and 1 involved PR [55]. The majority of TB interventions were community-based, and most aimed to counteract the disease by encouraging people to attend health care facilities for screening or by facilitating access to home-based screening; 11 of the 15 interventions involved home visits [23,42,47-50,55,65,67,75]. Home visits varied in nature, but tended to involve health care staff [23,55] or recruited community members [46-48,50,67] carrying out symptom screening at the home. Some studies also carried out testing in the visits [55,65]. A total of 3 studies involved community members [46,47] or research fieldworkers [65] following up patients' households for monitoring, while incentives were offered to contacts to present for screening in 4 studies [23,25,42,43]. Several studies included training components in which health care workers or key community figures were educated to help carry out the intervention (n=8) [23,46-48,50,54,55,67].

A total of 6 studies specifically focused on improving case finding in younger ages [51,52,54,55,59,75]. Three studies referred contacts aged 5 years or younger irrespective of symptom status [51,52,59]. Three focused their intervention on children aged 15 years or younger [75]. Some interventions were multicomponent, with activities such as attempts to increase awareness of TB [50] and screening children at school [49] being examples of additional components.

TB interventions were usually compared with a form of standard care. Often this was a national program, and in all but 1 comparator this involved passive case finding, whereby potential

XSL•FO
RenderX

cases self-report for testing; the 2023 study by Hanrahan et al [43] used household CT. In 4 studies, the control or baseline program was described as a form of directly observed treatment, short-course (DOTS) program that was adapted or enhanced to improve CT and case finding [23,25,46,49]. It is likely that baseline programs used in other studies resembled DOTS, but they instead described their comparators as a national standard of care [25,42,47,50,55]. One study incorporated CT and active monitoring vs CT and passive monitoring [75].

TB interventions tended to be longer or have longer follow-ups than COVID-19 and STI interventions. The median and most frequently reported intervention duration (or time until last follow-up) was 12 months (n=5) [23,47-49,54], with a range of 3 months [51] to 5 years [25].

While all TB studies involved treatment for contacts with a pharmaceutical in both the intervention and comparator groups, some interventions focused more heavily on improving this aspect compared with the comparator. In particular, 7 studies used various approaches to encourage treatment access or adherence [25,46-48,50,54,65]. These approaches included integration of indigenous case managers, community-led home visits, improving access to chest radiography for young children, and provision of prophylaxis.

### *Synthesis of Findings of CT in TB*

#### Disease Incidence or Prevalence

Six of 7 studies reporting TB incidence or prevalence observed a decrease in this outcome with CT [23,25,48,50,67,75]. Effect estimates varied in nature; no between-group statistical analyses were performed in 2 studies [50,67], and 4 of these studies were rated as weak quality [23,25,48,50]. Therefore, findings should be interpreted with caution.

All 6 interventions associated with reduced disease incidence or prevalence used home visits, and 3 included active follow-up of contacts [23,25,48]. The 1 study showing no effect also included home visits, but the authors speculated that working in a high-burden area, where motivation for testing and treatment was already high, may explain their null findings [65].

#### Case Detection

A total of 4 studies reported case detection outcomes, with 2 studies showing greater numbers of cases detected with intervention [49,55] and 2 showing no difference [51,54]. In the controlled before-and-after study by Joshi et al [49] intensified childhood TB case finding yielded 33% more cases after the intervention compared with 16% more in regions without intensified childhood TB case finding. Intensified case finding included activities such as household contact screening and mobile chest health camps, while usual care was poorly described. However, standard DOTS took place separately for TB cases as usual in both intervention and control areas, as per national guidelines [49]. In the quasi-RCT by Khatana et al [55], their active case-finding strategy led to a nearly 4-fold increase in the odds of detecting TB cases (odds ratio [OR] 3.97, 95% CI 1.73-9.11).

#### Treatment Rates

A total of 6 TB studies reported treatment rates. The 3 studies reporting increased treatment rates were all of weak quality [46,47,54]. Only 1 of these outcomes related to successful completion of treatment [46], while all others recorded initiation of treatment. Two of the 3 studies reporting increased treatment rates involved interventions designed to be culturally relevant or sensitive to the populations of interest, with usual care being generic [46,47]. In both cases, this meant that intervention deliverers understood local customs and dialects and could access people living in remote areas [46,47].

Only 3 studies reported outcomes in more than 1 category [51,54,65], with mixed findings in all instances. No studies reported on the unintended consequences of CT.

### *Characteristics of CT Interventions in COVID-19*

A total of 5 trials evaluating CT in COVID-19 were included [40,41,64,73,76], based in the United Kingdom, Belgium, Portugal, and Cameroon. Two studies were rated as strong quality [64,76], 1 as moderate quality [40], and 2 as weak quality [41,73]. Interventions in 3 studies were categorized as technology-based CT methods [44,45,80], and 2 incorporated PICT [68,77].

The cluster RCT by Tchakounte et al [76] investigated digitized CT using a smartphone app. This intervention involved individuals registering for an app, where upon receiving a positive test, their information was sent to the CT unit, a clinical interview conducted, and automated text messages sent to notify contacts of their exposure to COVID-19. A total of 2 studies reported on the same natural experiment which occurred due to an error in the UK CT system [40,41], when a technical issue caused around 16,000 positive cases to be missed by the national CT system, thereby delaying the tracing and self-isolation of missed cases. Finally, there were 2 cohort studies with concurrent control groups [64,73]. One study evaluated a standard COVID-19 CT program with contact-eliciting interviews and mandatory quarantine [64]. Symptomatic close contacts were then referred for evaluation and testing [64]. The other program tested different durations of tracing windows, with contacts traced if their last interaction with the index case was 2 days before onset or test for the standard window, and 3-7 days in the extended window group [73]. Comparators were standard care protocols including national CT programs [40,41], as well as manual CT [76] and no CT [64,73]. The median intervention period was 1 week, and 3 studies had a 1-week intervention arm [40,41,73]. Intervention durations ranged from 2 days [73] to 23 weeks [76]. Interventions were delivered by local public health authorities [64], government contact tracers [73], and health care workers [76].

### *Synthesis of Findings of CT in COVID-19*

Both studies evaluating the impact of CT on disease prevalence found positive associations [40,73]. Fetzer et al [40], reported there was an association between delayed notifications to quarantine, as a result of a fault in the UK Test & Trace program, and increased disease prevalence and mortality per case traced with a 6-14 day delay (multiple outcomes in Table S3 in Multimedia Appendix 7) [40].

XSL•FO
RenderX

Extending the backward CT window from 2 to 3-7 days led to 42% more cases being detected among contacts [40,73]. However, 3 studies found no impact of CT on case detection rates [41,64,76].

Additional outcomes were reported in the 2 studies evaluating the effect of delayed notification of close contacts due to an error with the UK Test & Trace system [40,41]. In the study by Findlater et al [41], they observed that the delay in CT led to primary contacts of index cases being slightly more likely to be admitted to hospital within 14 days (OR 1.1, 95% CI 1.0-1.2), although there was no impact on patient mortality or hospital admission rates in their secondary contacts. Fetzer et al [40] reported higher mortality rates in the delayed CT group (additional 0.007 deaths per capita; SE 0.003; $P<.05$). No studies reported on the unintended consequences of CT.

### *Summary*

A total of 15 evaluations focused on TB [23,25,42,43,46-51,54,55,65,67,75], and 5 on COVID-19 [40,41,64,73,76]. Studies on TB typically evaluated interventions with the broad aim of encouraging the identification, testing, and treatment of contacts via home visits, active follow-up, incentives, and other measures. There was just 1 study that incorporated CT and active monitoring vs CT and passive monitoring [75]. Findings were inconclusive across outcome domains and studies, but the greatest change associated with intervention was observed for reductions in disease incidence or prevalence. However, the nature of the evidence, which was highly heterogeneous in design and quality, means that only tentative conclusions may be drawn. Five studies of varying designs, quality and outcomes, provide limited evidence about the impact of CT interventions on outcomes in the context of COVID-19.

## Sexual or Blood-Borne Transmission

### *Overview*

A total of 35 studies focused on CT in sexually transmitted or blood-borne diseases. Table S1 in Multimedia Appendix 8 provides a broad overview of their key characteristics, trial arm components, and findings. Further detail about the characteristics of interventions evaluated within these studies is available in Table S2 in Multimedia Appendix 8, and detailed outcome data are available in Table S3 in Multimedia Appendix 8.

### *Characteristics of CT Interventions in STIs*

Of the 35 prioritized studies falling into the sexually transmitted route of spread, 13 included chlamydia [21,22,33-38,52,53,56,59,68,69,77], 13 included HIV [24,26-29,31,32,44,45,58,60,62,63], 6 included syphilis [30,39,44,61,70,71], 6 included gonorrhea [34,53,56,68,72,77], 3 included nongonococcal urethritis [35,52,56], 3 included trichomoniasis [39,57,74], 1 included chancroid and lymphogranuloma venereum [39], and 1 did not specify which STIs were included [66]. A total of 7 trials evaluated 2 intervention arms [24,29,34-36,52,70,71], and 2 evaluated 3 intervention arms [30,62].

The duration of the interventions was recorded in 28 studies [22,24,26-31,33-39,45,53,56-58,62,63,66,68-72,74,77]. The duration ranged from as little as 45 minutes for the counseling session in the study by Mathews et al [66] to 13 months, the whole study period that personnel were introduced in the study by England et al [33], but 82% of the interventions were less than 6 months in duration. Most interventions involved a clinic setting (n=26) [22,24,26-30,33,34,37-39,44,45,52,53,56,57,62,63, 66,68,70-72,74,77] or took place within the community (n=6) [21,57,60,61,69,71]. One study was based in a prison with community follow-up of partners [31]. Two were primary care–based [35,36,59], 1 an unspecified health facility [32], and 1 a public health facility [58]. Interventions were delivered by a range of different health care professionals, and in all but 11 studies [24,26,34,52,57,59,60,63,68,74,77] this was the same for both intervention and control.

As the interventions were broadly similar across all conditions within this group, they have been summarized together.

One study involved household contact investigation where all household members of the index case were identified and tested, not solely sexual partners of the index case [60]. In all remaining studies, the CT method involved partner notification (PN), where the sexual partners of patients diagnosed with an STI were identified and informed of their exposure to an infection and the need to be tested and treated [21,22,24,26-39,44,45,52,53,56-59,61-63,66,68-72,74,77]. One study also included notification of social contacts [26]. The majority of the PN methods were patient referral notification, where the index patient was responsible for informing their partners of their risk of exposure and referring them to services for testing (n=17) [21,22,29,30,34-39,53, 56,57,59,61,69,70,72,77]. Contact or referral slips were used in 11 of these studies [22,24,26,30,39,56,57,59,70,72,77], and 2 studies trialed the use of a web-based notification service [30,53]. Provider referral (where notification was instigated by a health care professional) was used in 9 studies [24,27,32,44,52,62,63,68,71], and 3 studies involved contract referral, whereby the index case was given limited time to notify partners before the provider stepped in [24,26,74]. In 5 studies, index cases had the choice of PN approach [28,31,33,45,58,66]. In 1 study, provider referral was used if the index case refused to notify their partners [39], and in another the index case could choose which method of PN to use (patient-initiated with nurse support or provider-initiated) [61].

In 4 studies, the nature of the partner elicitation interview with the index patient was varied [44,59,72,74]. A total of 12 studies incorporated reminders or active follow-up as part of their interventions [27,29-31,35-38,45,52,62,68,70,72].

A total of 12 studies adapted the testing process to encourage partners to engage with testing, thereby enhancing CT [21,22,27,29,31,34-38,45,62,69,71]. In 7 of these studies, index cases were provided with sampling kits to pass directly to partners [21,22,29,37,38,45,62,69]. In 2 studies urine sampling was evaluated rather than swab sampling [21,22]. Of the 7 home-based testing interventions, 3 studies provided the means to return samples to the laboratory [21,45,69], whereas partners or index cases were responsible for returning tests to a site in 3 studies [22,29,62]. The study by Choko et al [19] had an additional intervention arm incorporating a financial incentive

XSL•FO
RenderX

for positive partners that attended clinic [29]. Estcourt et al [34-38] conducted 3 studies that involved the provision of sampling kits and treatment either after partner consultation through a telephone hotline [35-38] or consultation with a pharmacist [34-36]. Sampling kits and treatment were provided to the index case for their partners in the 2022/2024 study [37,38], and this was also an option for some partners in the 2015/2016 study, while other partners collected the tests and treatment from clinic reception or from the pharmacist [34-36]. Luo et al [62] incorporated an additional intervention arm where testing was completed as a couple in a clinic setting [62]. Home or field testing was offered to partners in 4 studies [27,31,60,71].

Anonymity of the index case was a feature of the interventions in 8 studies [26,30-32,45,62,67,68], 5 of these were HIV studies [26,31,32,45,62].

New or specialist personnel were introduced to deliver PN services in 5 studies [33,52,59,60,63,74]. In 1 study this was the introduction of 2 public health officers to assist with CT [33], and in another a practice nurse–led PN strategy was evaluated [59]. In 3 studies disease intervention specialists were used [52,63,74]. The introduction of different staff allowed for some studies (n=3) to evaluate the effectiveness of delivering a field-based PN service [52,60,74].

A total of 5 studies incorporated additional counseling and education for the index case, in part providing extra time and support to plan for PN [28,33,39,66,77]. Index cases in the study by Chiou et al [28] also had phone access to a counselor during working hours and through an app or via email 24 hours/day [28].

Most of the study comparators (n=25) involved patient referral PN methods [21,22,24,26,27,29-31,34-38,45,52,53,56-58,60,62,68-70,74,77], and of these, 13 used contact or referral slips, cards, or vouchers as a means of facilitating notification [20,21,23,25,28,29,33,51,57,59,67,69,76]. A total of 3 studies involved provider referral comparators [44,61,63], 2 involved contract referral [71,72], 4 included various PN methods [28,32,33,59]. In 1 study, no detail was given for which method of PN the comparator used [66]. Two comparators involved no CT [27,39]. In the study by Cherutich et al [27], the comparator arm was delayed (by 6 weeks) provider-initiated PN (compared with immediate provider PN in the intervention arm), and outcomes were collected prior to this delayed PN occurring. The study by Faxelid et al [39] did not involve PN.

In 30 studies, the comparator was the usual care or standard of care [21,22,24,26,28-39,44,45,52,53,56-60,66,68-70,72,74,77]. In 11 studies, the intervention group received usual care or standard care plus an additional element in the intervention [28,30,34-38,45,53,66,70,74].

Information (written or online) provided to the index case was a feature of the comparator in 6 studies [30,34-38,68,74]. In 9 studies, the comparator involved a counseling session or interview with the index case, which was face-to-face in 8 studies [24,28,31,52,58,66,72,77] and telephone based in 1 study [44]. The comparator group in 9 studies involved some form of follow-up [28,30,31,37,38,45,58,62,68,70]. This predominantly involved follow-up of the index case (n=7) for feedback and experience on partner notification [28,31,37,38,45,62,68,70]. The comparator groups in 2 studies followed up partners directly [30,58].

### *Synthesis of Findings of CT Interventions in STIs*

#### Case Detection

Case detection was the most frequently assessed outcome domain, being evaluated in 21 studies [21,24,26-29,31-33,44,45,58-63,69-72]. Seven of these studies observed that interventions were associated with a favorable outcome [26,27,29,31,44,60,69], while the rest observed no difference between intervention arms. In addition, the study by Luo et al [62] provided case detection rates but did not analyze between-group differences. All but 1 of the positive outcomes came from studies of HIV, including in the study by Heumann et al [44], which focused on both HIV and syphilis and only found improved detection of the former. The study by Lugada et al [60] may be considered an outlier in that it used household contact investigation to test for HIV rather than relying on PN. Compared with clinic-based detection, this led to a near 3-fold increase in the odds of case detection (OR 2.76, 95% CI 1.97-3.86; $P$<.001). The study by Ostergaard et al [69] found that home sampling, rather than office sampling, was associated with more infected partners identified per index case (mean difference 1.63 cases; 95% CI 1.1-2.3).

The remaining 5 studies observing positive case detection outcomes used a wide variety of intervention components, and other than the use of active follow-up in 3 studies [26,27,31], they rarely shared common components. Comparators were more passive forms of CT, including passive “self-tell” PN [26,31], telephone rather than in-person contact elicitation interviews [44], delayed notification [27], and referral slips alone [29]. Given that the components used in the successful studies were also used across several other interventions showing no effect, it is unclear whether specific components are associated with success. For example, the studies led by Brown et al [24], Hu et al [45], and Chen et al [26] all used a form of provider-led PN in their interventions, all in HIV samples, but while Chen et al [26] saw an improvement in case detection rates, Brown et al [24] and Hu et al [45] observed no differences.

The magnitude of effect varied widely, with Chen et al [26] finding the ratio of persons referred per index case (ratio 1.9, 95% CI 1.2-3.1) and new cases per index case (ratio 2.0, 95% CI 1.2-3.2) to be nearly doubled with intervention, and Cherutich et al [27] finding a nearly 5-fold greater likelihood of detecting new cases per index (incidence rate ratio [IRR] 5.0, 95% CI 3.2-7.9). Choko et al [29] detected 4.3% more new HIV-positive contacts with HIV self-testing kits and 6.9% more with the addition of an incentive to HIV self-testing [29], while Culbert et al [31] identified 5 new HIV-positive partners compared with 0 with assisted PN vs self-tell alone (no statistics provided) [31]. Finally, Heumann et al [44] found that the number of partners diagnosed with HIV was more than twice as high in the in-person interview arm compared with the telephone interview arm (risk ratio [RR] 2.17, 95% CI 1.04-4.50) [44].

### Treatment Rates

A total of 15 studies looked at treatment rates, with 7 finding that interventions were associated with improvements [27,34,39,44,52,56,61]. Two of these studies included people living with HIV [27,44]; the rest were interested in multiple STIs [34,39,52,56,61]. Similarities between successful studies were minimal, with interventions having different approaches and components, all of which were also present in unsuccessful studies. In the study by Cherutich et al [27], treatment rates were more than 4 times higher at 6 weeks in the group that was immediately assisted with PN services compared with the group that received no services (IRR 4.4, 95% CI 2.6-7.4) [27]. The addition of a consultation hotline (24% greater) or consultation with a pharmacist (23% greater) led to greater treatment rates than routine PN in the study by Estcourt et al [34]. In-person interviews, rather than telephone interviews, led to a 19% greater likelihood of partners being treated for syphilis in the study by Heumann et al [44] (RR 1.19, 95% CI 1.03-1.37). Katz et al [52], in their study from 1988, found that active follow-up was associated with increased treatment rates among contacts compared with both an interview (72% vs 22% treatment rates; $P<.001$) and standard nursing referral (72% vs 18%; $P<.001$), while Kissinger et al [56] found that the provision of booklets led to greater odds of contacts of patients with STIs being treated (OR 1.66, 95% CI 1.22-2.27). Faxelid et al [39] observed that individual counseling and assisted PN resulted in a greater proportion of partners of male index patients attending treatments than with standard care (no CT; 85% vs 55%); however, this was not observed in partners of female index patients (65% vs 56%). In the study by Lukac et al [61], patient-initiated PN, with the support of public health nurses, led to better treatment rates than provider-initiated PN (65% vs 59%, no statistics provided).

### Disease Incidence or Prevalence

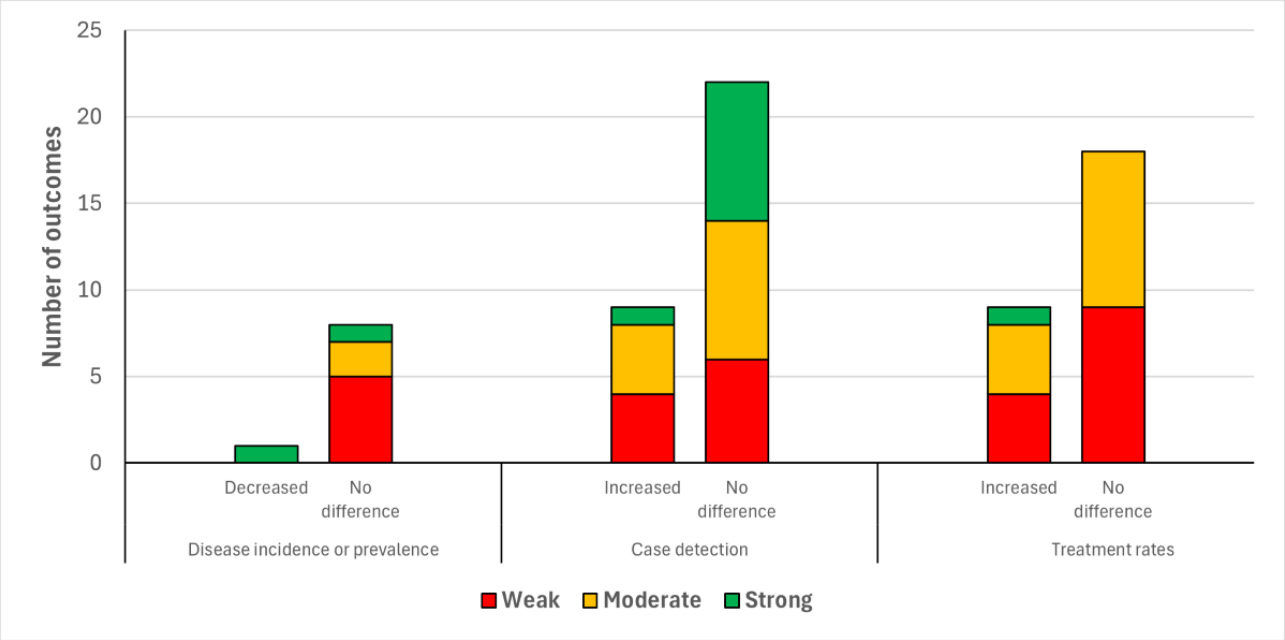
A total of 7 studies evaluated disease incidence or prevalence, with 2 detecting a reduction in incidence or prevalence associated with intervention [56,77], and the rest finding no difference between intervention and comparator arms [35,37,57,66,74]. In the studies observing improved outcomes, Kissinger et al [56] reported that the odds of reinfection among index cases were lower (OR 0.22, 95% CI 0.11-0.44), while Wilson et al [77] observed a 5% drop in reinfection rates of index cases ($P=.02$).

### Unintended Consequences

A total of 2 studies assessed unintended consequences. Both were RCTs, 1 from South Africa and 1 from Kenya, and both found that the incidence of intimate partner violence was not affected by the intervention [27,66]. However, Mathews et al [66] observed that abandonment was slightly but significantly more likely following the intervention (risk difference 1.7%, 95% CI 0.2%-3.3%; $P=.02$).

### *Summary*

This review included 35 prioritized studies focusing on CT interventions in STIs, including 13 in HIV. In all but 1 study, interventions were a form of PN, which was either provider- or patient-led. Such interventions typically incorporated the use of referral slips, CT, active follow-up, and self-testing kits.



Despite the sizeable body of evidence, there was considerable heterogeneity across study design, intervention components, and outcomes evaluated, and there were only 5 studies rated as being of “strong” quality. Across all effectiveness outcome domains (case detection, disease incidence or prevalence, treatment rates, and other outcomes), it was most often observed that interventions had no effect on outcomes, though this was not exclusively the case, with several instances of improved outcomes, as depicted in Figure 2. Case detection, the most frequently assessed outcome domain, was typical of the pattern of results, featuring in 21 studies, with 7 interventions associated with greater case detection rates and the rest showing no differences compared with their comparators. There were only 2 instances in which outcomes related to unintended consequences were reported: 1 showing no difference between intervention and comparator for the risk of intimate partner violence, and 1 instance in which the intervention was reportedly associated with an unfavorable outcome—an increased likelihood of abandonment. Overall, there were 19 instances of improved outcomes across the 69 outcomes reported, with 1 negative outcome. Positive findings were more likely to be observed when provider referral was compared with patient referral.

There was little consistency in findings or patterns of intervention components that may be more likely to be associated with successful outcomes. The heterogeneity of the evidence, in terms of design (both at the study and intervention level), quality, and outcomes, precludes robust conclusions. However, the overall picture for CT in sexually transmitted or blood-borne diseases is one in which interventions either do no harm or may improve outcomes.

### Public and Patient Involvement and Engagement

The review was discussed 3 times with PERSPEX, our standing patient and public involvement and engagement group. This enabled the team to gain insights about CT from patient, carer, and public perspectives. In December 2024, the review team introduced the concept of CT and discussed its use as a public health intervention in general terms. Members drew on their experiences of COVID-19 CT. A majority opinion shared by members was that reviewers should not underestimate the concerns about, and lack of trust in, government agencies that are prevalent in some communities, which could affect the success of CT initiatives. Members were also concerned that some communities may experience additional barriers affecting the outcome of CT. This emphasized the importance of including health equity data in the review protocol. This was taken forward into the review and is available in the full report [10].

In February 2025, PERSPEX received a brief update on the progress of the review. In March 2025, the team reported the emergent main discussion items from the review. PERSPEX members raised a number of matters, which included a query about the role of technology in CT; a view that people respond in different ways to CT and not everyone sees the need to take action; and, for members of PERSPEX whose country of origin was outside the United Kingdom, discussion about the cost of medications even if they are traced and how this could affect the success of CT. Members also spoke about the taboos in many families and cultures around some illnesses and how this could hinder CT and subsequent management within the home. This discussion about culture fed into our thinking about the generalizability of interventions.

Some members shared their experiences of TB management requirements and visa entry for their relatives and visitors from South Asia and Africa. They also discussed UK maternity ward visitor restrictions aimed at preventing the spread of TB. These were shared as positive preventive measures, understood within the community and therefore indicative that CT may be positively received if supported by simultaneous patient education and delivered by community-based teams.

## Discussion

### Statement of Principal Findings

Our systematic review of the best available evidence relating to the effectiveness of CT identified 57 reports of 55 studies including randomized or prospective nonrandomized comparisons, interrupted time-series designs, or retrospective studies with concurrent controls. A sizeable evidence base drawing on uncontrolled pre-post comparisons was deprioritized given the extent of the higher-quality evidence identified. Included studies related to bacterial or parasitic STIs, HIV, TB, and COVID-19, covering only 2 relevant routes of transmission. Most studies compared different forms of CT against each other. More than half of the included studies had notable methodological limitations, raising an important question about the certainty of our conclusions, though no one critical appraisal domain was identified as driving this. In brief, included studies were inconclusive with respect to the impacts of CT in COVID-19 but provided some tentative evidence for reductions in disease incidence and prevalence in TB attributable to CT. Included studies focusing on STIs and HIV were similarly inconclusive, but some signal of improved effectiveness emerged in the use of provider-led referral vs patient-led referral. Interventions were broadly categorized as including technological methods, HI methods, PR, and PICT, with clear splits based on route of transmission. The heterogeneity of interventions, outcome definitions, and comparators precludes a clear assertion of effectiveness of any one CT strategy.

### Comparison With Previous Literature

Although there are some differences in the pool of evidence drawn upon, our findings are broadly in keeping with recent

XSL•FO
RenderX

reviews that covered multiple conditions, led by Hossain et al [2] and Guy et al [3]. Hossain et al [2] focused on PICT as the intervention, with slight differences in definitions of CT and outcomes of interest, while Guy et al [3] included descriptive studies, leading to inclusion of nearly 380 studies, had a broad definition of CT, and included a focus on sociocultural factors influencing uptake and success of CT strategies. Ours was also the only review to consider the unintended consequences of CT. Despite these differences, all 3 reviews concluded that there was some promise for PICT interventions but that evidence was highly heterogeneous and of mixed quality. The varying foci of reviews provide complementary evidence in the quest to develop successful CT strategies suitable for a variety of infectious diseases, such as identifying CT strategies that may be successful across a variety of infectious diseases and learning about the important sociocultural factors influencing their uptake.

## Interpretation and Implications

### *Background Disease Context*

We included conditions with epidemic or pandemic potential. In the case of COVID-19, all comparisons drew from a pandemic in progress. Evidence relating to TB generally drew from explicitly endemic contexts. However, a challenge in the evidence related to characterization of the "background" disease context; for example, whether STI CT was implemented in the context of a live outbreak. As a general point, it was nearly always unclear from non–COVID-19 studies how background disease surveillance specifically influenced the design of innovations in CT. Most studies resorted to appeals to health care system efficiency or general disease burden to justify why CT was evaluated.

### *Intervention Generalizability*

Related to the above, a key challenge in the evidence was identifying how different approaches to CT might generalize to "true" pandemic contexts, or across conditions and routes of transmission. The substantial literature relating to bacterial STIs and HIV focused on PN, which implies a specific, and easily identifiable, form of "contact" that may be less relevant in a pandemic driven by airborne transmission, for example. Similarly, evidence relating to TB focused primarily on household contacts. Another facet of generalizability related to intervention context. Our review was global in nature, meaning we included substantial amounts of evidence from the Global South. A challenge, but also an opportunity, for public health in well-resourced settings will be to identify how innovations successful in low-income or middle-income country contexts might be relevant in the Global North [109]. Finally, generalizability may be impacted by the human capital, and other forms of capital, that CT strategies require. Many CT strategies included a focus on training and deploying community health care workers, disease intervention specialists, or community health nurses, or culturally embedded local volunteers. These may not be available at speed and in the required quantities in a pandemic context.

### *Outcomes*

This review did not focus on contact yield as a key outcome, preferring instead measures of disease prevalence and incidence, transmission, and treatment, alongside a parallel focus on unintended consequences. Contact yield is an important outcome because it reflects engagement of contacts with public health services, but it does not capture meaningful impacts on health and well-being of contacts or on disease control. It is an important challenge to the field to consider why an outcome that is primarily about health system outputs, rather than population health impact, is so paramount. This is also important because anecdotally, even where interventions reported improved contact yield, this did not always translate to improved prevalence, incidence, transmission, or treatment outcomes.

About half of all studies in this review reported on a case detection–specific outcome, with treatment rates among contacts a close second. Treatment rates were particularly well described in evidence from CT for bacterial or parasitic STIs but will be less relevant for infectious diseases where treatments either do not exist or are not widely available. The ultimate test of CT effectiveness is whether it reduces, or even eliminates, longer-term incidence or prevalence of the condition, or whether it reduces morbidity or mortality where this is a risk. These outcomes were comparatively rare, and mortality analyses specifically were linked to TB and COVID-19 evidence. In addition, the link between treatment rates and improved mortality is driven by adherence to treatment regimens. In conditions such as TB that require extended courses of therapy, CT-driven improvements in treatment uptake may not translate into improvements in incidence, prevalence, and disease-specific mortality [110].

### *Unintended Consequences*

An innovative feature of our review was the inclusion of unintended consequences of CT. It is notable that despite an exhaustive search for a wide range of unintended consequences, only 2 studies presented evidence in this respect. These studies evaluated CT in sexual health contexts and focused on intimate partner violence or relationship breakdown, with neither finding a difference in intimate partner violence but one finding an increase in relationship abandonment attributable to PN. While these are important, it is likely that the generalizability of these findings to other disease contexts is limited. A broader focus on the potential unintended consequences of health and social interventions is important to fully account for the health impacts of CT, especially for conditions with airborne transmission. For example, in situations where enhanced enrollment into TB treatment is rolled out because of CT, suboptimal concordance with treatment regimens may amplify the challenge of antimicrobial resistance in communities [111].

## Unanswered Questions and Future Research

CT strategies in a future pandemic will need to be designed from an understanding of disease transmission pathways. In this light, then, what is the relevance of CT strategies for other conditions, particularly given that we were only able to identify relevant evidence for 2 routes of transmission? Learning from CT for STIs and HIV could support management of stigma and

XSL•FO
RenderX

linkage into treatment, and the use of contact-delivered testing where feasible. Learning from CT for TB could support appropriate services for household contacts, especially where those household contacts might be more susceptible. Finally, learning from CT for COVID-19 could focus on rapidly accelerating CT in the context of a pandemic, in addition to management of contacts where these are an ill-defined set. An important consideration for policymakers and commissioners will be to identify how innovations in CT could support new approaches for conditions, including how these relate to learning from the Global South.

This review will be used to inform the development of UK Health Security Agency advice and guidance as part of pandemic preparedness and to help inform research priorities and future evaluation and improvement approaches to CT. For future preparedness, this means developing flexible CT strategies tailored to specific diseases, investing in higher-quality evaluation methods, and ensuring fairness considerations are built into program design from the outset.

### Strengths and Limitations of the Review

An extensive and comprehensive search, selection, and appraisal were undertaken to the highest standards, though as with any systematic review, eligible studies may have been missed. Due to the quantity of identified evidence, we prioritized evidence from evaluations with a concurrent control. Although this was a post hoc decision, we believe this strengthened analysis because it focused on the best available evidence, and the deprioritized studies provided no unique coverage. As a general point, while CT is often presented as a highly prescriptive, medicalized intervention, it was not our experience that this was reflected in included studies. This was both in situations where CT was bundled as part of multicomponent interventions and where specific comparisons undertaken in the context of CT were judged by our team as not relevant. An example of this is partner-delivered treatment, which is largely applicable to bacterial STIs alone. In addition, studies compared CT against heterogeneous comparators, such as usual care and other forms of CT. Usual care was frequently described in scant detail, precluding precision in defining the comparator. Some element of subjectivity, shaped by the challenging and complex nature of CT interventions and their descriptions, may mean that an alternative review group would have included different studies with possibly different overall conclusions. However, we have sought to mitigate this with an auditable and comprehensive account of how judgments were undertaken throughout the review process.

### Conclusion

CT is a mainstay of public health response to infectious diseases. Our review found inconsistent evidence for the effectiveness of CT, focused primarily on TB and on contrasts between PICT and patient-led referral in STIs and HIV. While most outcomes did not demonstrate a difference between CT and the comparator intervention, there was some evidence of reductions in disease prevalence in TB and for PICT to be superior to patient-led approaches in STIs. These results do not necessarily reflect a lack of effectiveness of CT strategies. However, they highlight the need to build evaluation into the implementation of CT strategies to improve evidence generation. Heterogeneity of intervention, comparator, and outcome precluded any clear assertions as to optimal strategies for CT, including with respect to relevant subgroups. Future work should consider generalizability of learning across contexts, including by route of transmission and from the Global South; a clearer focus on health equity; and a more thorough account of unintended consequences of CT.

## Acknowledgments

We would like to thank Sue Whiffin and Jenny Lowe for administrative support, and the members of PERSPEX for their valuable insights. The authors declare that no generative artificial intelligence was used in any portion of the manuscript generation.

## Funding

This review was funded by the National Institute for Health and Care Research (NIHR) Evidence Synthesis Programme (grant number NIHR153420). ## Abstract

**Background:** Scales for measuring health literacy and numeracy have been broadly classified into performance-based (objective) and self-reported (subjective) scales. Both types of scales have been widely used in research and practice; however, they are not always consistent and may assess different latent constructs. Furthermore, an increasing number of objective measures have been developed, and it is unclear how many latent factors should be assumed.

**Objective:** This study aimed to examine the psychometric properties and factor structure of items assessing objective health literacy across multiple scales and to clarify which aspects of objective health literacy would be correlated with subjective measures, as well as health behaviors and lifestyles.

**Methods:** A total of 5 objective scales (72 items in total) were administered to Japanese-speaking adults (N=16,097; women: 7722/16,097, 48%; mean age 54.89, SD 16.46 years). The analyzed scales included items assessing the numeracy, comprehension, and application of health information, some of which were contextualized for specific diseases, such as diabetes and cancer. Participants' responses were submitted to exploratory factor analysis, and individual factor scores were calculated to test correlations with subjective health literacy, health behavior, and lifestyle.

**Results:** Exploratory factor analysis identified 3 factors, which were interpreted as conceptual knowledge, numeracy, and synthesis. The conceptual knowledge factor consisted of items about medical word comprehension. All numeracy items loaded onto the same factor, even when contextualized for different diseases. The synthesis factor was characterized by items assessing the ability to read and understand health-related information and make judgments on it using one's own knowledge. The identified factors showed high interfactor correlations ($r$ values 0.53 - 0.64) and small-to-moderate correlations with subjective health literacy ($r$ values 0.14 - 0.45). Additionally, each factor indicated small positive correlations with healthy diet and nutrition and lower substance use ($r$ values 0.17 - 0.26).

**Conclusions:** Our findings suggest that scales of objective health literacy have at least three latent constructs (ie, conceptual knowledge, numeracy, and synthesis) and that disease specificity is not psychometrically prominent. Each factor has some overlap with subjective health literacy, but overall, subjective and objective health literacy should be interpreted as independent constructs, given the small-to-modest correlations.

## Introduction

### Background

Health literacy plays a pivotal role in acquiring and maintaining healthy lifestyles, which help individuals prevent diseases and maintain their well-being [1]. Although the definition of health literacy varies across studies, the core concept refers to the ability of an individual to obtain, process, understand, and use health information and services [2]. This conceptualization covers health numeracy, namely, applying numerical and quantitative reasoning skills to navigate a health care environment, access care, engage in treatment, and make informed health decisions [3]. Empirical studies have demonstrated that lower health literacy, including lower health

XSL•FO
RenderX

numeracy, is associated with lower autonomy and self-control in health behaviors as well as negative health outcomes, such as higher older adult mortality, increased emergency and inpatient facility use, lower medication compliance, and lower preventive service use [3,4].

Health literacy assessment has long been a research target, and hundreds of measures have been developed and published over the past 3 decades [5-8]. As Nguyen [6] noted, a typical assessment approach is to ask respondents to self-report about their experience on Likert scales (ie, subjective measurement), whereas it is also common to challenge individuals using standardized test stimuli to evaluate their underlying traits, knowledge, skills, and numeracy [9-12] (ie, objective measurement). For example, the Lipkus Numeracy Scale (henceforth, Lipkus) requires respondents to perform numeracy tests in general (eg, "Imagine that we rolled a fair, six-sided die 1,000 times. Out of 1,000 rolls, how many times do you think the die would come up even (2, 4, or 6)?") [12]. Another typical approach is to assess word comprehension of health-related and medical terms [13]. It is also common to present responders with hypothetical scenarios or visual materials, such as nutrition labels [14,15] or maps of hospitals [16], to assess their ability to read, interpret, and process relevant information. Objective measures have been suggested to be suitable for estimating individual skills guiding actual health behavior [6]—an experimental study showed that individuals with high levels of objective (but not subjective) health literacy were able to critically evaluate health information on websites, which further helped them to choose an appropriate treatment option [17]. In addition, a prospective cohort study on patients with cardiovascular-related diseases showed that the lack of objective health literacy predicted poor refill adherence [18].

In contrast, most subjective measures ask respondents to self-report their perceptions and experiences of handling health information, typically using a Likert scale [6]. The 47-item European Health Literacy Survey Questionnaire (HLS-EU-Q47) [19] is one of the most widely used measures to assess individuals' perceived abilities to access, understand, appraise, and apply health information (eg, "Finding information on symptoms of illnesses that concern you is..."; respondents indicate from very easy to very difficult) [19]. Another example is the Subjective Numeracy Scale (SNS), which assesses individuals' beliefs about their skill in performing various mathematical operations (eg, "How good are you at working with fractions?") and individuals' preferences regarding the presentation of numerical information (eg, "When reading the newspaper, how helpful do you find tables and graphs that are parts of a story?") [20]. Subjective measures typically assess individuals' self-perceived ability to find and understand health-related information as well as their confidence in doing so [17]. Also, some measures cover a wider range of psychological (eg, motivation and self-efficacy) aspects of health literacy [21]. A study suggested that individuals with lower levels of subjective numeracy are less motivated and less confident in numeric tasks [22]. Furthermore, the European Health Literacy Survey showed that subjective (but not objective) health literacy is predictive of self-perceived health [23], which might suggest that subjective measures may be more suited to studying perception and beliefs about health status and behavior.

The objective and subjective measures appeared to tap into the same latent construct, that is, the ability to process health information. However, Waters et al [24] suggested that these 2 types of measures assess conceptually related but psychometrically distinct constructs and that numeracy should be separated from general health literacy. Begoray and Kwan [25] found almost null correlations between objective (word recognition and reading comprehension) and subjective (self-reporting of skills to access and communicate health information) assessments. Marks et al [26] suggested that objective measures may reflect medication knowledge, whereas subjective measures may not. For the associations with health outcomes and behaviors, a systematic review [27] concluded that the evidence is mixed. Several studies observed no differences between performance-based and self-reported health literacy for the associations with relevant health outcomes (eg, diabetes, stroke, and hypertension), whereas others documented objective-subjective discrepancies (eg, for cancer screening use). Hirsh et al [28] noticed that the self-reported disease severity of rheumatoid arthritis was associated with subjective health literacy but not with objective health literacy, including the ability to read and pronounce medical terms.

The possibility that objective and subjective measures assess different constructs of health literacy may make it difficult for researchers and practitioners to determine which type (or both) to include in their assessment batteries. Another challenge when building an assessment battery for health literacy research is that an enormous number of measures have been developed; thus far, there is no clear guidance on which to use and when [8]. Recently, we conducted an exploratory factor analysis of 219 items across 11 subjective measures (encompassing 45 subscales), indicating that dimension reduction was effective, as the items were well explained by 7 latent factors [29].

## Objectives

In this study, we aimed to expand these findings to objective health literacy measures; namely, we conducted an exploratory factor analysis on 5 performance-based measures of health literacy and numeracy (see the *Methods* section for the selection criteria of the analyzed scales), including general and disease-specific (ie, chronic pain, cancer, and diabetes) scales. Through the analyses, we explored how many and what factors would emerge. In addition to the number of factors identified, we were also interested in whether disease-specific items would be recognized as independent factors or factors that reflect common skills and performances regardless of target diseases. Simultaneously, the identified factors were tested for their correlations with lifestyle and health status, as well as subjective health literacy and numeracy, to explore the consistencies and inconsistencies (or validity) with perceived health literacy and behaviors.

## Methods

### Data

Data from a larger longitudinal survey on the health behaviors, psychological characteristics, and lifestyles of Japanese-speaking adults (aged >18 y living in Japan) were used. We used quota sampling to represent the population distribution for age and gender in Japan, and thus, we did not use a survey weight in the analysis. The overarching project (still ongoing) is a 3-year longitudinal study that includes multiple waves with different focuses: wave 1 (N=20,573; early 2023) for physical activity (PA) and psychological characteristics [30] and for mobile health technology use [31], wave 2 (conducted in 2023; 6 mo after wave 1) for changes in PA and digital health behaviors [32], and wave 3 (conducted in early 2024) for health literacy and lifestyle. Wave 3 included both subjective and objective health literacy scales; the psychometric properties of the subjective scales have been reported elsewhere [26]. This study used the wave 3 data (N=16,097; women: 7722/16,097, 48%; mean age 54.89, SD 16.46 years), of which 87% (14,064/16,097) participated in wave 1. As the dropout rate was high, an additional sample of 2033 participants was recruited at wave 3. This addition was for the overarching project but not for this study specifically. Although we could not use quotas in this extra sampling due to the time pressure that we had, we found that the age and gender distributions were similar to those of the general population, so we included this additional sample in the analysis. This study focused exclusively on objective scales. We used data from 5 objective health literacy (or numeracy) scales together with the validation measures of subjective health literacy, health behavior, and lifestyle (refer to the *Measures* section).

### Ethical Considerations

Participants were paid for online panels recruited by a survey firm. Interested individuals followed a link to the survey site, and on the top page, they received study information (written) and provided informed consent to proceed to individual questionnaire pages. Each participant was assigned a study ID, which was used as the key in merging their responses across different waves. No personal information was obtained throughout the study. The study was approved by the Ethics Committee of the National Institute of Advanced Industrial Science and Technology (approval ID: 2022‐1279).

### Measures

#### *Objective Health Literacy and Numeracy Scales*

We selected the scales for inclusion in this study following published reviews (eg, [8,33,34], including Tavousi et al [8], the latest review on health literacy scales over the past 3 decades when the study was conceptualized, and Nakadai et al [34], a narrative review of the scales available in Japanese). Among the scales listed, we included those that met the following criteria: the scale was available in English or Japanese and could be implemented on a static online survey (ie, did not require audiovisual materials or in-person interactions), and specific instructions and items were available from published articles, supporting materials, or personal correspondence with the authors of the scales. This selection process resulted in four objective health literacy or numeracy scales: the Lipkus [12,35], Newest Vital Sign (NVS) scale [14,15], Functional Health Literacy Scale for Young Adults (funHLS) [13], and Cancer Health Literacy Test (CHLT) scale [16]. An additional database search (Google Scholar and PubMed) identified the Diabetes Health Numeracy (DHN) scale [36], which was eligible for this study. Table 1 summarizes the characteristics of each included scale; most objective health literacy scales are not Likert type. For example, the funHLS presented medical stem terms (eg, caries) and asked participants to indicate the most relevant words for each stem term among 3 response options (eg, virus, bacteria, and fungus). Across the scales, each response was binary coded to represent 1 (correct) and 0 (incorrect), and the total score was calculated for each scale, with higher values indicating higher levels of objective health literacy or numeracy. It should be noted that the current analyses included translated versions of the scales, and responses to some of the items were potentially affected by cultural differences. For example, the NVS and CHLT included items assessing comprehension of food nutrition and prescription medication labels. These stimuli were modified to be familiar to Japanese respondents—particularly for the NVS, the translation and adjustment were conducted rigorously in accordance with the established cross-cultural adaptation guidelines [37,38].

XSL•FO
RenderX

**Table .** Overview of the objective health literacy and numeracy scales.

| Scale name (abbreviation) | Items, n (Cronbach α) | Test format | Description |
|---|---|---|---|
| Lipkus Numeracy Scale (Lipkus) [12,35] | 10 (0.79) | Numeric response questions | Measures the ability to understand and use numeric information, particularly for probability: (eg, "Imagine that we rolled a fair, six-sided die 1,000 times. Of 1,000 rolls, how many times do you think the die would come up even (2, 4, or 6)")? |
| Newest Vital Sign (NVS) scale [14,15] | 6 (0.63) | Numeric response questions and open-ended questions | Measures comprehension, numeracy, and application and evaluation skills. Responders are presented with a nutrition label of ice cream, from which they are required to extract necessary information for calculation (eg, "If you eat the entire container, how many calories will you eat?") and evaluation (eg, "Pretend that you are allergic to the following substances: penicillin, peanuts, latex gloves, and bee stings. Is it safe for you to eat this ice cream?") |
| Functional Health Literacy Scale for Young Adults (funHLS) [13] | 19 (0.93) | Multiple choice questions | Measures knowledge and comprehension of health-related and medical terms. Responders are presented with stem words, for each of which they are asked to indicate the most relevant among 3 response options (eg, stem=caries: response options=virus, bacteria, and fungus). |
| Diabetes Health Numeracy (DHN) scale [36] | 7 (0.85) | Multiple choice questions | Measures numeracy skills, contextualized for diabetes (eg, "If you walk for about 30 minutes you can burn 100 calories. If you want to burn 150 calories, how long do you have to walk?"). Several items tap into interpretation skills (eg, "read a table about diagnostic criteria for diabetes and indicate the stage of an example patient"). |
| Cancer Health Literacy Test scale (CHLT) [16] | 30 (0.85) | Multiple choice questions | Measures knowledge (eg, "Which is the highest in calories and protein? – French fries, cheeseburger, hard-boiled egg"), comprehension skills (eg, "In people who develop oral cancers, 25% of these cases occur in the tongue. Oral cancer occurs in the tongue..."), and their synthesis, contextualized for cancer. |

### *Subjective Health Literacy Scale*

The HLS-EU-Q47 [19,39] was used to assess subjective health literacy. The HLS-EU-Q47 and other self-report scales (see below) were used as validation measures to test for correlations with objective health literacy measures. The HLS-EU-Q47 measures 4 information-processing competencies (ie, how easy it is to access, understand, appraise, and apply health information) for 3 health-relevant domains (ie, health care, disease prevention, and health promotion). Participants indicated how applicable each item was to them using a 4-point scale (1=very easy and 4=very difficult). For ease of interpretation, each item was reverse scored, with higher values indicating higher health literacy levels, and the total score was normalized to a range between 0 and 50 using the following formula: (mean−1)×(50/3). This scale has shown good reliability in the current data (Cronbach α=0.97).

### *Subjective Health Numeracy Scale*

The SNS was used to assess subjective health numeracy levels [20]. The SNS measures one's perceived ability to perform mathematical tasks (eg, How good are you at working with fractions?) and preferences for the use of numerical (vs prose) information (eg, When reading the newspaper, how helpful do

XSL•FO
RenderX

you find tables and graphs that are parts of a story?). Participants indicated how applicable each item was to them using a 4-point scale (1=not good at all, not helpful at all; 4=very good, very helpful). This scale has shown good reliability in the current data (Cronbach α=0.75).

### *Physical Activity*

The International Physical Activity Questionnaire Short Form [40,41] was used to assess PA levels. Respondents were asked to indicate the number of days and minutes per day spent walking, engaging in moderate-intensity activities, and engaging in vigorous-intensity activities. We did not use sedentary time for the current analyses. The weighted sum of the reported durations was calculated across the 3 activity categories, representing the total PA in the form of metabolic equivalents (METs hours per week). According to the Ministry of Health, Labour and Welfare in Japan, the recommended amount is 23 METs hours per week or higher for adults aged <65 years and 10 METs hours per week for older people [42].

### *Quality of Life and Health State*

Quality of life (QoL) and health status were assessed using the 5-level EuroQol 5-Dimension (EQ-5D) version [43]. Participants indicated their health status by selecting the most appropriate statement (ie, no problems to extreme problems) for the following five dimensions: mobility, self-care, usual activities, pain or discomfort, and anxiety or depression. Participants' responses were combined into a 5-digit code, which was then converted into a numerical QoL score. The QoL score ranges from −0.025 to 1, where a negative value signifies a condition worse than death, 0 represents a state equivalent to death, and 1 denotes the highest possible health utility. At the end of the EQ-5D questions, participants were asked to rate their health status using a visual analog scale, ranging from 0 to 100, with 0 representing the worst health condition they could imagine and 100 representing the best health condition they could imagine.

### *Health-Related Lifestyles*

The Short Multidimensional Inventory Lifestyle Evaluation (SMILE; [44]) consists of 45 items covering seven domains of health-related lifestyles: diet and nutrition, substance use, PA, strategies to deal with stress, sleep pattern, social support, and environmental exposure. Items asking about the use of illegal drugs (ie, items 10 and 11) were excluded to adhere to the ethics standards of the administering survey firm, and the remaining 43 items were used in the survey. Participants rated each item on a 4-point scale (1=always and 4=not at all). Summed scores were calculated for each domain, whereas items were reverse scored (with higher values indicating healthier lifestyles). The global score (sum of the 7 domains) demonstrated good internal consistency in the current data (Cronbach α=0.88).

### Statistical Analysis

An exploratory factor analysis was conducted on the 5 objective health literacy and numeracy scales. We excluded from the analysis (1) an item (funHLS12) exhibiting high correlations with other items (*r* values 0.72 - 0.80) and (2) 5 items to which >90% of participants responded correctly (ie, items 2, 4, 14, and 27 of the CHLT and item 5 of the Lipkus). The final dataset consisted of 66 items. As each item was binary scored (correct vs incorrect), polychoric correlations were calculated and used in factor analysis. The number of factors was determined based on the reduction in eigenvalues (ie, a scree plot), as well as on the interpretability of the identified factors. Exploratory factor analysis was conducted on randomly sampled 70% of the data (n=11,268), and the remaining 30% (n=4829) was used for confirmatory factor analysis as testing data. Before factor analyses, each dataset was tested with the Kaiser-Meyer-Olkin sampling adequacy measure (≥0.8; Kaiser 1970; [45]) and Bartlett sphericity test ($P \leq .05$; [46]). Confirmatory factor analysis was conducted with maximum likelihood estimation to replicate the factor structure obtained in the exploratory factor analysis. Our focus was on the goodness of fit of the model to the data, evaluated by the following indices: chi-square [47], comparative fit index [48], root mean square error of approximation [47,49], and the standardized root mean square residual [47]. For each factor, items with factor loadings of 0.40 or greater (a commonly used threshold for identifying meaningful loadings; eg, see [50]) were interpreted and were used to calculate a factor score (as the mean of raw item scores). For each factor, items with factor loadings of 0.40 or greater were interpreted and were used to calculate a factor score (as the mean of raw item scores). These factor scores were tested for correlations with validation measures (ie, subjective health literacy and numeracy scales, PA, QoL, health status, and health-related lifestyles). All analyses were performed using R (version 4.3.3; R Foundation for Statistical Computing). The *factanal* function was used for the exploratory factor analysis, and the *cfa* function of the *lavaan* package [51] was used for the confirmatory factor analysis.

## Results

### Descriptive Information

Table 2 presents the descriptive statistics. For the objective measures, the mean scores were comparable to those reported in previous studies—for example, in the general Japanese population (Lipkus, mean 9.6) [35], an Italian population-based sample (NVS, mean 4.1) [52], and a sample from the United States (CHLT, mean 22.3) [16]. The total score on the HLS-EU-Q47 was slightly higher than that reported among Japanese people (mean 25.3) but lower than that reported among Europeans in the literature (mean 33.8) [39].

## Exploratory Factor Analysis

The factor analysis performed on 66 items across 5 scales revealed eigenvalues of 16.43, 3.09, 1.93, and 1.59 for the 1- to 4-factor solutions. The reduction in the eigenvalue supported the 3-factor solution, with explained variances of 0.16, 0.15, and 0.10 for the 3 factors (total explained variance: 0.41). Additionally, the 3-factor solution had good interpretability; the factor loadings are visualized in Figure 1, which confirms that no items had double or triple loadings. The exact factor loadings for each item are listed in Table S1 in Multimedia Appendix 1. Table 3 summarizes the characteristics of each factor.

**Table .** Interpretations of identified factors.

| Factor[a] and item with a factor loading of 0.40 or higher | Example item |
|---|---|
| FA1 (conceptual knowledge) | |
| funHLS[b] (items 1 - 11 and 13 - 19) | funHLS 6: "Indicate the most relevant word for *Vitamin C*. Response options*: Vegetables, Fat, Grain, and I Don't know.*" |
| FA2 (numeracy) | |
| Lipkus[c] (items 1 - 4, 6 - 10) | Lipkus 6: "If Person A's risk of getting a disease is 1% in ten years, and person B's risk is double that of A's, what is B's risk?" |
| NVS[d] (items 3 and 4) | NVS 3: "Your doctor advises you to reduce the amount of saturated fat in your diet. You usually have 42 g of saturated fat each day, which includes 1 serving of ice cream. If you stop eating ice cream, how many grams of saturated fat would you be consuming each day?" |
| DHN[e] (items 1 - 7) | DHN 2: "A male diabetic patient weighs 80 kilograms (kg). The doctor advised this patient to lose 10% of his weight. How much weight does this patient need to lose?" |
| CHLT[f] (item 5) | CHLT 5: "In people who develop oral cancers, 25% of these cases occur in the tongue. Oral cancer occurs in the tongue..." |
| FA3 (synthesis) | |
| NVS (items 5 and 6) | NVS 5: "Pretend that you are allergic to the following substances: Penicillin, peanuts, latex gloves, and bee stings. Is it safe for you to eat this ice cream?" |
| CHLT (items 3, 7 - 8, 11, 15 - 16, 18 - 20, 22, 25, and 29 - 30) | CHLT 18: "An appointment card says not to eat or drink anything 9 hours prior to the appointment. Sally has an appointment at 11:15 a.m. on Friday. What time should she stop eating or drinking?" |

[a]The means and SDs of each item as well as their factor loadings are provided in the supplementary materials in Multimedia Appendix 1.

[b]funHLS: Functional Health Literacy Scale for Young Adults.

[c]Lipkus: Lipkus scale.

[d]NVS: Newest Vital Sign scale.

[e]DHN: Diabetes Health Numeracy scale.

[f]CHLT: Cancer Health Literacy Test scale.

Factor 1 (FA1) consisted exclusively of items from the funHLS, which asked participants to indicate the word most relevant to a stem (medical) word. Items from the funHLS assess word comprehension and knowledge about diseases and symptoms that young adults often experience, as well as nutrition, diet, and human biology. All items of the funHLS showed loadings of >0.40 on FA1. Although the funHLS items covered a range of topics (eg, caries, depression, and BMI), most items loaded on the same factor, and items from other scales were not included in FA1. This factor could be interpreted as a conceptual knowledge of health-related and medical terms in general (ie, not limited to a particular disease or health condition); however, it is still possible that the factor may reflect the unique test format, as the other scales require binary (true-false) responses or numeric responses, for example, to calculate a probability or health risk.

Factor 2 (FA2) included items from 4 of the 5 analyzed scales (ie, Lipkus, NVS, DHN, and CHLT), representing performance-based health numeracy in general (eg, "Imagine that we rolled a fair, six-sided die 1,000 times. Out of 1,000 rolls, how many times do you think the die would come up even (2, 4, or 6)?"). These 4 scales target different populations—Lipkus was designed for the general population, whereas the other 3 were contextualized for particular diseases and health conditions (DHN for diabetes and CHLT for cancer). The test format also differed across the 4 scales; the CHLT used multiple-choice questions, whereas the NVS and DHN included numeric response questions. These results suggest that the items assessing performance-based numeracy correlate well with each other, regardless of heterogeneity in the target diseases and test format.

Factor 3 (FA3) included items from 2 scales, the NVS and CHLT, which assess the ability to process and synthesize

XSL•FO
RenderX

health-related information. For example, item 5 of the NVS concerns abstract reasoning, integrating reading, comprehending, and interpreting skills as applied to material with health content [15]. Respondents were presented with a hypothetical nutrition label of ice cream and asked to judge whether the ice cream would be safe if the respondents were allergic to the indicated substances. Similarly, many of the items loaded onto FA3 required respondents to comprehend and synthesize the presented information (eg, the nutrition label) to make the correct response. Items from the CHLT are contextualized in a daily cancer patient routine at a clinic (eg, instructions for the use of medicines and reading a floor map of a hospital), assessing respondents' knowledge, numeracy, navigation, and synthesis [16]. Therefore, compared to FA1 (word comprehension and knowledge) and FA2 (numeracy), FA3 is distinguished in that it broadly measures higher order skills that require the synthesis of multiple skills (eg, reading, comprehension, and interpretation) to apply in a daily health context.

## Confirmatory Factor Analysis

The testing dataset was found suitable for factor analysis: Kaiser-Meyer-Olkin=0.98 and the Bartlett Test of Sphericity, $P \leq .001$. We built a confirmatory factor analysis model with the 3 factors identified through exploratory factor analysis. This model showed an excellent fit to the testing data, $\chi^2_{1271}=7015.7$, comparative fit index=0.97, root mean square error of approximation=0.03, and standardized root mean square residual=0.05, which reassures that the analyzed scales can be reduced to the 3 factors.

## Correlation Analysis

The 3 identified factors were tested for their correlations with subjective health literacy and numeracy, as well as with health status and lifestyle (Table 4). Each correlation was interpreted for magnitude but not for statistical significance, given the large sample size of the analyzed dataset. The Cohen guideline was used, with $r$=0.10, 0.30, and 0.50 being interpreted as small, moderate, and large effects, respectively [53,54]. FA1 to FA3 showed large interfactor correlations. However, these factors showed small-to-moderate correlations with the HLS-EU-Q47 (subjective health literacy), SNS (subjective numeracy), and SMILE (subscales of diet, nutrition, and substance use). Moreover, FA1 and FA2 showed small correlations with SMILE sleep and social support ($r$ values 0.10 - 0.13). None of the factors showed interpretable size correlations with the International Physical Activity Questionnaire Short Form (total PA) or EQ-5D (QoL and subjective health) scores. The 2 subjective measures, the HLS-EU-Q47 and SNS, presented stronger correlations with the SMILE subscales, except for substance use, than FA1 to FA3.

# Discussion

## Principal Findings

This study examined the factor structure of the multiobjective health literacy and numeracy scales among Japanese-speaking adults. Specifically, we explored how many factors would emerge in the pool of 72 items extracted from 5 scales, with or without being contextualized for specific diseases. The exploratory factor analysis indicated that the items could be categorized into three factors: performance-based conceptual knowledge (FA1), numeracy (FA2), and synthesis (FA3).

Most funHLS items loaded on FA1, assessing the conceptual knowledge of health-related and medical terms. FA2 consisted of items from 4 scales targeting people with different health conditions and diseases that typically assess their ability to perform mathematical calculations. The NVS and CHLT items not included in FA1 were identified as FA3, which required the synthesis of multiple skills to handle health information, such as reading, knowledge, navigation, and interpretation skills, to provide a correct response. A correlation analysis indicated that all factors had weak correlations with subjective health literacy, moderate correlations with subjective health numeracy, and weak correlations with lifestyle (eg, diet, nutrition, and substance use). Lifestyles concerning sleep and social support demonstrated small correlations only with FA1 and FA2 but not with FA3.

In line with Altin et al [9] and Wu et al [55], we observed small-to-moderate correlations between the 3 factors and the

XSL•FO
RenderX

subjective scales (ie, HLS-EU-Q47 and SNS). Furthermore, the 3 identified factors were highly correlated with each other, yet were recognized as independent factors. These findings echo Waters et al's [24] argument—health literacy and numeracy are related but distinct constructs, each of which can be psychometrically divided into performance-based (objective) and self-reported (subjective) constructs. Another important point is that our analysis did not identify disease-specific factors, although we included cancer- and diabetes-specific items in the item pool. Therefore, it is plausible to assume that the 3 identified factors—conceptual knowledge, numeracy, and synthesis—form a common basis for processing health information in general. Health literacy covers a range of skills from basic to advanced levels. Basic skills include reading and writing (ie, literacy), which allow individuals to function effectively in everyday situations. These skills serve as a foundation for more advanced ones, for example, extracting information, deriving meaning from different sources of communication, and applying new information to changing circumstances [1]. We assume a similar hierarchical structure for the identified 3 factors, which may explain the interfactor correlations; that is, synthesis represents higher order skills that require more basic ones, such as numeracy and knowledge, along with other cognitive and literacy skills (eg, reading, comprehension, and interpretation).

Regarding the associations with health behaviors and lifestyles, each factor presented small correlations with diet and substance use but not with PA. Some overlaps were noticed at the item content level; for example, the NVS includes items about caloric calculation as well as reading and interpreting a nutrition label, whereas the SMILE asks how often respondents eat high-calorie sweet or fatty foods and how frequently they check the food ingredient labels. A similar association was found in patients with diabetes; performance-based numeracy is positively correlated with a healthy diet [56]. These findings suggest that skills and abilities assessed by objective measures underlie perceived health behaviors (eg, individuals are able to read and interpret ingredient labels and check them regularly when shopping for food). However, the size of the correlations was modest, and the results should be interpreted carefully, particularly for the practical significance.

Compared with objective measures, subjective measures demonstrated overall larger correlations with health behaviors and lifestyles. The conceptual knowledge and numeracy factors (FA1 and FA2) had small correlations with sleep and social support of the SMILE ($r$ values 0.11 - 0.13) but subjective health literacy (HLS-EU-Q47) and numeracy (SNS) presented slightly larger correlations with sleep and nutrition ($r$ values 0.17 - 0.33) as well as with other subscales (eg, PA, $r$=0.24; stress management, $r$=0.33). Higher levels of objective health literacy are thought to be associated with an inclination to behave in a manner that is beneficial to one's own and others' health (eg, choosing beneficial treatments for a disease) [17]. However, subjective health literacy may share even larger variance with the perception of health behaviors; that is, how people perceive their ability to process health information may overlap with how they believe to behave in a context where their health matters. It is too early to conclude that subjective measures are more suited for studying health behaviors based only on the correlations found in this study. Instead, it is fair to argue that objective and subjective measures reflect different psychological processes, and further research is warranted to clarify which type (or both) of health literacy measure is associated with actual health behaviors that can be assessed using sensors and devices, such as accelerometers for PA.

## Limitations

This study has several methodological limitations. First, the item pool was neither exhaustive nor comprehensive. Importantly, we did not include Test of Functional Health Literacy in Adults (TOFHLA) [10] and Rapid Estimate of Adult Literacy in Medicine (REALM) [11], which are the most widely used objective measures, because of language and cultural differences (all materials had to be in the Japanese language) and technical limitations of the survey platform (audio-visual recording could not be implemented). Both tools are closely bound to the English language (or even to the culture and health care system of the country where the scales were developed). For example, the REALM evaluates whether respondents pronounce medical terms correctly, and the TOFHLA assesses the ability to read and understand health-related materials contextualized in the US health care system. Yet, our analyses covered the scales and items conceptually overlapping with the REALM and TOFHLA; the funHLS is a word recognition test for medical terms, the CHLT and NVS assess reading comprehension of texts and tables, and the Lipkus evaluates numerical ability. However, we acknowledge that the exact items of the REALM and TOFHLA were not included here, and this may affect the interpretation of the results, particularly for the generalizability of the study findings. Furthermore, it is highly likely that the results of the factor analysis and subsequent analyses might differ if the item pool were expanded. Second, the exploratory factor analysis showed that the 3-factor structure explained less than half of the total item variance. A possible explanation is that measurement invariance might not be assumed in subgroups of participants as the data covered a diverse range of people in terms of demographics and other psychosocial variables. Different factor structures could be found across participants with different backgrounds, which should be clarified in future research. Third, participants were recruited using quota sampling to match the known population distribution in Japan for age and gender. Quota sampling is useful to ensure broad coverage of different groups and to prevent overrepresentation of a particular group in data. However, this approach is known to be vulnerable to sampling bias within a subgroup, which could be addressed by the use of self-weighted sampling if the cost of random sampling does not matter. Fourth, diagnostic information on physical or mental disorders was not collected. Testing patients with a particular disease or disorder was out of our focus, as we set a community sample as our target population. Health literacy is essential in maintaining one's health and preventing future diseases. However, it is important to widen the focus to include patient care and disease management, for which health literacy and assessments are highly relevant. Fifth, convenient self-reporting tools were used to assess PA and lifestyle habits. Health behaviors can be assessed using wearable devices and e-diaries

XSL•FO
RenderX

(eg, food recordings), which may allow for a more reliable estimation of healthy lifestyles [57]. It was technically impossible for us to use device- or sensor-based assessments, given the sample size of this study, but objective assessment tools could be considered when a focused sample is the research target.

## Conclusions

Despite these limitations, our findings contribute to the psychometric evidence base of objective health literacy and numeracy scales. The results of the exploratory factor analysis identified 3 factors—conceptual knowledge, numeracy, and synthesis—among 66 items from 5 scales, independent of disease specificity and different contextualizations of the items. These 3 factors showed marginal correlations with subjective measures of health literacy and numeracy, highlighting the distinction between performance-based and self-reported assessment approaches [58]. Researchers and practitioners should be aware that self-report measures do not always reflect the skills and abilities reflected in performance on tests assessing conceptual knowledge, numeracy, and more integrated information processing skills. In other words, both subjective and objective measures should be considered if one wishes to assess different aspects of health literacy. In general, subjective measures are easier to administer and less cognitively demanding [6,7]; also, these measures are more suitable for assessing meta-cognitive, emotional, or motivational aspects of health literacy rather than knowledge and numeracy [22,27]. However, self-reported measures are vulnerable to social desirability and other biases owing to health beliefs [20], which may reduce the accuracy of assessing health information skills [9]. In contrast, objective measures are less affected by response biases [6,17] but may feel like examinations and evoke a sense of shame and stigma. This aspect is particularly relevant for individuals feeling uncomfortable with examinations and not confident in their skills (eg, test anxiety). Also, objective measures often cover a limited, highly contextualized range of skills [6]. Given these advantages and disadvantages, it is not readily possible to uniformly determine the best measures to assess health literacy. It is important for individual researchers to be aware of what aspects of health literacy they want to assess, which then helps them select appropriate scales and items in line with their objectives.

## Abstract

**Background:** Surveillance of tuberculosis (TB) is challenging given the typically long course of the disease and treatment as well as the often complex socioeconomic factors that are associated with it. In Spain, surveillance is decentralized across autonomous communities (CCAAs), leading to additional challenges in heterogeneity and data quality.

**Objective:** We aimed to quantify changes in internal data completeness following introduction of annual regional surveillance quality reports and assess the acceptability and perceived usefulness among CCAAs.

**Methods:** This mixed methods assessment consisted of 2 stages. First, we quantitatively assessed the internal completeness of 40 key TB variables for all reported cases from 2018 to 2023, comparing 2 periods: before (2018 - 2020) and after (2021 - 2023) the implementation of feedback reports. Mean completeness for each variable was calculated for each period, and the differences were compared using either the paired *t* test or Wilcoxon signed rank test depending on whether differences were normally distributed. Analyses were conducted nationally and by CCAA as well as for different variable groups (patient-, illness-, and laboratory-related groups). For the second stage, we circulated the results to regional TB surveillance focal points, along with a survey to assess acceptability, perceived usefulness of reports, and barriers to data completeness.

**Results:** There were 25,229 reported cases across the study period: 13,328 in period 1 (2018 - 2020) and 11,901 in period 2 (2021 - 2023). Nationally, mean completeness increased from 66% in period 1 to 76.2% in period 2 (+10.2%, *P*<.001). Improvements were greatest for laboratory-related (+13.9%, *P*=.001) and illness-related variables (+12.8%, *P*<.001), while patient-related variables showed minimal change that was not statistically significant (+2.4%, *P*=.48). Most CCAAs (16/19, 84%) demonstrated improved completeness in period 2, though substantial regional variation persisted. Of the 19 CCAAs, 18 responded to the survey. Respondents reported high acceptability of the surveillance system and considered feedback reports useful. Challenges included resource constraints, system interoperability between laboratory and surveillance, and patient follow-up.

**Conclusions:** Following the introduction of annual feedback reports, which were well accepted by all regional stakeholders, Spain saw significant improvements in TB data completeness. Sustained feedback mechanisms, streamlined reporting requirements, and improved integration between epidemiological and laboratory systems are key to strengthening TB surveillance.

## Introduction

Tuberculosis (TB) remains the world's deadliest infectious disease, despite being both preventable and usually curable [1]. In 2024, an estimated 10.7 million people worldwide developed TB, corresponding to an incidence rate of 131 cases per 100,000 population [2]. The same year, 11.5% of those diagnosed with TB died from the disease, a total of 1.2 million people.

XSL•FO
RenderX

To address the global TB burden, in 2014, the World Health Organization (WHO) launched the End TB Strategy, aiming to reduce incidence by 90% and deaths by 95% by 2035, compared with 2015 levels [3]. Although there is large regional variation, the number of TB cases and deaths globally decreased in 2024, following 3 consecutive years of increases due to disruptions caused by the COVID-19 pandemic [2]. The WHO European Region has achieved substantial progress since WHO targets were introduced, with a 39% reduction in incidence rate observed by 2024 [2]. However, significant challenges remain in the region; according to a 2026 report, multidrug-resistant TB rates are 7 times higher in Europe than the global average, 21% of TB cases are undiagnosed or unreported, and 22% of people who start treatment are not followed up after 1 year [4].

As countries continue to strive to meet these goals, robust TB surveillance systems are essential, enabling monitoring of trends in incidence and mortality, detecting outbreaks, identifying affected populations to create targeted interventions, and evaluating the impact of TB control measures to ensure accountability for national and international commitments. However, achieving comprehensive and accurate TB surveillance remains challenging. Common barriers identified in European countries include fragmented integration between clinical and laboratory information systems and heterogeneity in reporting across jurisdictions [5], as well as loss to follow-up during the long treatment courses required, particularly for vulnerable populations such as migrants or people experiencing homelessness [6]. Regular assessments of TB surveillance systems are therefore critical to ensure their effectiveness, identify gaps, and prioritize improvements.

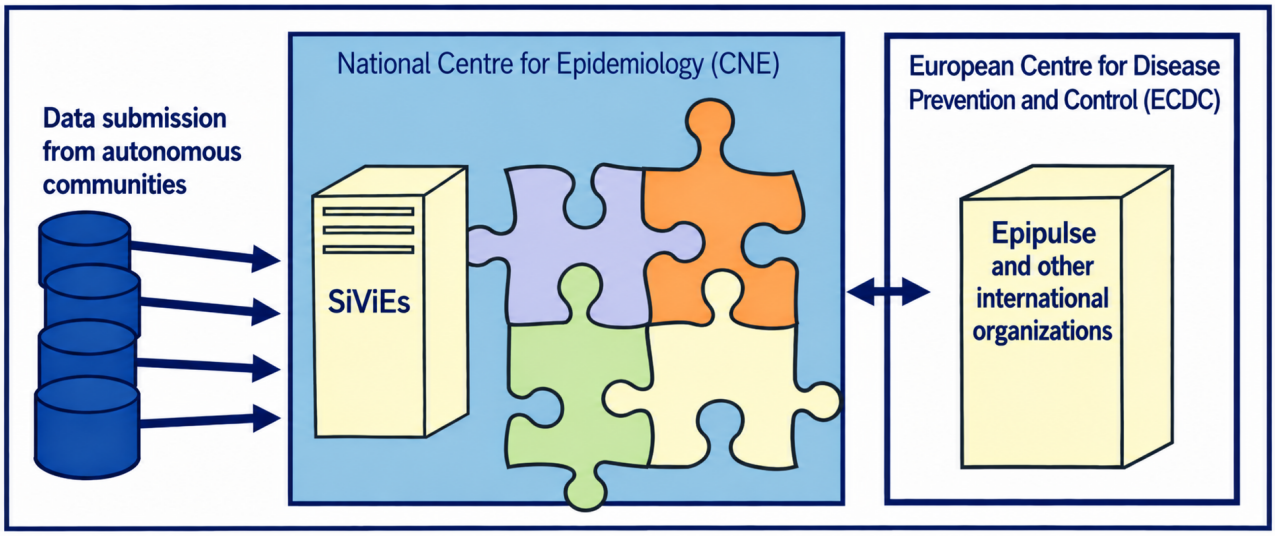
In Spain, reported TB cases and hospitalizations showed a gradually declining trend between 2012 to 2020 [7]; however, recent surveillance reports show a slight rebound, with the notification rate rising from 7.7 to 8.8 per 100,000 population from 2020 to 2024 [8]. This trend was observed among children as well as adults in Spain; although a lower incidence is generally observed among children, following a decrease after 2012, increases have been observed in both notification and hospitalization rates among this group since 2021 [9]. Nevertheless, compared with global figures, the incidence and deaths rates are low, with WHO recategorizing the country from incidence group “low moderate” in 2015 to “low” by 2025 [2].

However, the decentralized nature of surveillance presents a challenge, with each of the 17 autonomous communities (CCAAs) and 2 autonomous cities (Ceuta and Melilla) having their own surveillance systems, with annual integration of data at the national level. In 2021, a rapid internal review by the National Center for Epidemiology (CNE) recognized that there were deficiencies in the completeness of some variables and a large degree of variation among CCAAs. To support improvements in TB surveillance data quality, the CNE began sharing annual personalized feedback reports to each CCAA applying to submissions of consolidated annual data from the year 2021 onward. These reports summarize completeness across TB surveillance variables, highlighting any inconsistencies identified and identifying areas for improvement.

We performed a mixed methods study aiming to quantify changes in internal data completeness following the introduction of annual regional feedback reports on the quality of surveillance data and to assess acceptability and perceived usefulness among CCAAs. The purpose of this was to evaluate whether this quality improvement initiative of annual feedback reports should be recommended to continue and, if so, whether they should be refined. The study comprised 4 objectives: (1) quantitatively evaluate the internal completeness of TB surveillance data before and after implementation of feedback reports, (2) qualitatively assess the acceptability and perceived usefulness among CCAAs of both the current surveillance system and the feedback reports, (3) update annual feedback reports based on findings from objectives 1 and 3, and (4) assess the impact of the newly updated reports on completeness of TB surveillance data for 2024.

## Methods

### Data Sources



The Spanish TB national surveillance system is passive, case-based, and at the population level; each CCAA is responsible for collecting and annually reporting patient-level data on predefined variables into the Spanish Surveillance System (SiViEs Plus) according to the TB protocol published by The National Epidemiological Surveillance Network (La Red Española de Vigilancia Epidemiológica [RENAVE]; Figure 1) [10].

We extracted data on 40 key variables from all reported cases in Spain from the SiViEs Plus database between January 1, 2018, and December 31, 2023. We divided variables into 3 categories: (1) patient-related information (11 variables), (2) illness-related information (18 variables), and (3) laboratory-related information (11 variables).

XSL•FO
RenderX

**Figure 1.** Flow of data from autonomous communities into the national Spanish Surveillance System (SiViEs Plus) and the ECDC.

For the second aim, we developed a questionnaire based on a literature review and consulting with TB and surveillance experts at the CNE. The 17-question online questionnaire included both closed and open-ended questions to gather information on the perceived usefulness of the annual feedback reports, challenges around TB surveillance, and suggestions on how to improve TB surveillance in Spain. We piloted the questionnaire with the TB surveillance lead from 1 CCAA. In April 2025 and May 2025, we circulated the final version via Google Forms among the Spanish TB Surveillance Working Group. The survey was completed by the lead individual responsible for TB surveillance in each CCAA; these individuals were considered best placed to respond on behalf of their CCAA as they have an overview of all areas of TB surveillance in their region, they are responsible for submission of data at the national level, and they are the person who receives the annual feedback reports. The survey invitation emphasized that results would be reported anonymously and not attributable to any CCAA or individual.

## Ethical Considerations

This study used anonymized data from RENAVE in Spain. RENAVE collects data on cases notified through the national reporting electronic platform SiViEs Plus, and it is hosted by the CNE. These data are generated under a legal public health mandate and are routinely used for epidemiological monitoring. As the study involved secondary analysis of anonymized administrative surveillance data accessed under legally mandated confidentiality safeguards, formal ethics committee approval was not required. This exemption is consistent with Spanish and European data protection regulations governing the processing of anonymized public health surveillance data, including Ley Orgánica 3/2018 de Protección de Datos Personales y Garantía de los Derechos Digitales (LOPDGDD) and Reglamento (UE) 2016/679 (GDPR).

Survey data were submitted by a regional focal point from CCAAs in Spain. For survey participation, informed consent was obtained from participants prior to beginning the survey. Participants were made aware that taking part was voluntary, that there would be no consequences for not taking part, and that they could withdraw from participating at any time without consequence. One response was obtained from each CCAA; however, responses were reported anonymously in the analysis and write-up to maintain confidentiality. All data were stored and analyzed within secure, password-protected ISCIII systems in compliance with institutional data protection policies.

## Definitions

Internal completeness and acceptability surveillance attributes were chosen as they align with those set out by the European Center for Disease Control and Prevention (ECDC) technical handbook “Data quality monitoring and surveillance system evaluation” [11] as key for high-functioning surveillance systems.

We defined internal completeness according to ECDC [11] as “the number of completed data fields out of the total number of data fields (unknown and missing items should be included in the denominator).” The denominator was not always equal to the total number of cases; for example, the variable “number of years living in Spain” was only applicable to cases born outside of Spain.

## Surveillance Cycle and Feedback Reports

TB data are submitted continuously by CCAAs to SiViEs Plus; however, each annual dataset is only considered complete once regions confirm that all records for the previous year have been uploaded, typically in Q2 of the following year (eg, annual data for 2021 would be consolidated in Q2 of 2022).

Since 2022, following the annual submissions from the CCAAs, the national level (CNE) performs data validation and generates feedback reports highlighting missing or inconsistent information (see Multimedia Appendix 1 for an example report in the original Spanish and in an English translation that was carried out using the generative artificial intelligence [AI] tool, Copilot). These reports are typically shared with CCAAs between May and July, with variation in timing depending on when each region finalizes its initial submission. CCAAs subsequently update their annual data before final national consolidation, which usually occurs in the third quarter (Q3).

XSL•FO
RenderX

The feedback reports disseminated in a given year are therefore designed to inform and improve data reporting practices for the year prior. As feedback reports began being disseminated in 2022, the year 2021 was considered the first year in which reporting could be influenced by the feedback process.

### Data Analysis

#### *Part 1: Internal Completeness Analysis*

We first calculated the percentage internal completeness for each of the 40 variables across each year from 2018 to 2023. For each variable, we then calculated the mean percentage completeness (see the definition in the "Definitions" section) for two 3-year periods: (1) before reports were implemented (period 1): 2018 - 2020 and (2) after reports were implemented (period 2): 2021 - 2023.

For each period, we then calculated a mean across all variables by summing the mean percentage completeness for each variable and dividing by 40; we used the same approach to calculate means for period 1 and period 2 for each of the 3 subcategories (patient-, illness- and laboratory-related variables).

For each variable, we calculated the difference in completeness before and after implementation of feedback reports by subtracting the mean percentage completeness of that variable in period 1 from that of period 2.

For all variables combined and for each of the 3 subcategories, we used the Shapiro-Wilk test to examine whether the differences in completeness between the 2 periods were normally distributed or not; if found to be normally distributed, the paired *t* test was used to test for statistical significance (set at 5%). Otherwise, the Wilcoxon signed-rank test was used. This analysis was carried out at the national level and separately for each CCAA. All analyses were performed using R version 4.4.1.

We also carried out a sensitivity analysis to examine whether the COVID-19 pandemic may have impacted the results. We repeated the internal completeness analysis after removing the 2 years of 2020 and 2021; therefore, the comparison periods each contained 2 years (2018 - 2019 and 2022 - 2023), and we compared the results with those obtained for the original comparison periods.

#### *Part 2: Survey Analysis*

Together with the questionnaire, we circulated to each CCAA a preliminary analysis of national-level data compared with the regional data. This included a written summary and figures showing changes in completeness of surveillance data with respect to the 3 categories of variables across the 2 periods, comparing the values for their CCAA with the national averages (see Multimedia Appendix 1).

We calculated the proportion of respondents in each category of closed-ended questions. We reviewed free-text responses and grouped them into categories based on recurring content and meaning.

#### *Part 3: Annual Report Updates and Continuous Quality Improvement*

In June 2025, to support the CCAAs to make continual improvements in TB surveillance, we shared with the regions a summary of the qualitative analysis, along with a description of changes made to the upcoming feedback report (for 2024 data submission) based on the findings. Following this, we later performed an analysis of the 2024 TB surveillance data to determine whether the updated feedback report supported further improvements, as part of a continuous improvement cycle.

## Results

### Part 1: Internal Completeness Analysis

TB surveillance data for 25,229 reported cases were extracted across the study period. In period 1 (2018 - 2020), there was a total of 13,328 cases, and in period 2 (2021 - 2023), there was a total of 11,901 cases. Comparing internal completeness of 40 variables across period 1 and period 2, there was a mean improvement of 10.2% (Wilcoxon signed rank test $P<.001$), from 66% in period 1 to 76.2% in period 2, with 78% (31/40) variables showing an increase (Table 1). No change was observed for 4 (10%) of the 40 variables (age, sex, TB classification, date of case report), which all had a completeness rates ≥99.9% in period 1, while 5 (13%) of the 40 variables had a decrease in completeness (country, CCAA, province and municipality of residence, and mother number of years in Spain; Table 1).

Patient-related variables had the highest overall completeness for both periods (80.3% for period 1 and 82.7% for period 2). However, the mean increases of 2.4% across the 11 variables was lower than that of other variable groups and was not statistically significant (Wilcoxon signed rank test $P=.48$). All 5 variables with a decrease in completeness were within this category.

Illness-related variables significantly increased by 12.8% (paired *t* test: $t_{17}=-5.185$, $P<.001$), from 64.6% in period 1 to 77.4% in period 2. Of the 18 variables within this group, 2 did not increase (TB classification and date of case report) as they were already at 100% completion during period 1.

The greatest improvement was seen with laboratory-related variables, with an increase of 13.9% (paired *t* test: $t_{10}=-4.392$, $P=.001$) from 53.9% in period 1 to 67.7% in period 2. All 11 variables increased, the largest of which was for "date of laboratory diagnosis," which increased by 37.5%.

[a]N/A: not applicable.

There was a large degree of variation across the 17 CCAAs and the 2 autonomous cities (Figure 2). For period 1, mean annual percentage completeness across all variables ranged from 44.9% to 88.7%, and for period 2, it ranged between 56.9% and 87.5%. Comparing period 1 with period 2, differences in completeness ranged from a decrease of 5.2% to an increase of 26.2% in period 2. For all regions, 84% (16/19) had an improvement in period 2, 69% (11/16) of which had statistically significant improvements (*P*<.05). Of the 3 (3/19, 16%) CCAAs where a decrease in completeness was observed, only 1 was statistically significant.

**Figure 2.** Heat map showing mean percentage completeness of 40 tuberculosis (TB) variables reported by autonomous communities (CCAAs) in period 1 (P1: 2018 - 2020) and period 2 (P2: 2021 - 2023) in Spain.

Results obtained were similar across all analyses when the pandemic years of 2020 and 2021 were excluded (Table S2 in Multimedia Appendix 2). Across all 40 variables, there was a statistically significant increase of 12.5% (*P*<.001), compared with 10.2% (*P*<.001) in the original analysis. For patient variables, results were identical to the original analysis, with a nonstatistically significant increase of 2.4% observed. Differences between the 2 periods were slightly greater for illness-related variables and laboratory-related variables when excluding the pandemic years: 14.8% (*P*<.001) compared with 12.8% (*P*<.001) and 18.9% (*P*<.001) compared with 13.9% (*P*=.001), respectively.

## Part 2: Survey Analysis

### *Satisfaction With Surveillance System*

Overall, 95% (18/19) of CCAAs completed the online questionnaire. All 18 respondents reported that having high-quality TB surveillance data at the national level is either "very important" (17/18, 94%) or "important" (1/18, 6%). However, satisfaction with the current system varied; although most reported feeling either "very satisfied" (3/18, 17%) or "satisfied" (8/18, 44%), 33% (6/18) were neutral, and 1 (1/18, 6%) CCAA reported feeling unsatisfied. Regarding the completeness of data reported from the CCAAs, results were similar, with most reporting being either very satisfied (2/18, 11%) or satisfied (9/18, 50%), while 33% (6/18) were neutral and 1 respondent was unsatisfied. Satisfaction with the current system did not appear to vary depending on the completeness of data submitted by CCAAs.

Reported issues included the challenging context of TB surveillance given the complex interactions between the social, cultural, and health care–related aspects of the disease. Some respondents felt that the amount of information requested for each case was too high and that some variables may not be necessary, particularly those that are hard to define or calculate such as time to follow-up.

Respondents suggested that the current system could be streamlined to focus on high-priority indicators for TB control. Several respondents called for clearer guidance on variable definitions and their categories, as well as integration of case follow-up information given the long disease course and, in particular, how to manage surveillance and declaration of cases that transfer between CCAAs.

In addition, the need for a strong system for identifying unreported cases and the extent of under-ascertainment in Spain was highlighted; suggestions included examining differences in proportions (eg, confirmed or extrapulmonary TB) across regions to detect inconsistencies that could indicate under-ascertainment.

### *Usefulness of Annual Feedback Reports*

The annual feedback reports were considered to be useful by all respondents; 17% (3/18) felt they are "extremely useful," 61% (11/18) "very useful," and 22% (4/18) "moderately useful." . As with the attribute of usefulness, this did not seem to be associated with how well the region performed with respect to data completeness. Free-text responses indicated that CCAAs felt that reports help improve data quality by identifying missing or inconsistent entries. Some respondents noted that reports contribute to an environment of continuous quality improvement, stimulating internal reviews and priority areas to improve regional surveillance, as well as helping to evaluate interventions. Several also highlighted their value in raising awareness among TB units, nurses, IT staff, and public health leadership.

Of respondents, 78% (14/18) and 83% (15/18) felt that the format and content of the feedback reports, respectively, were appropriate, while 22% (4/18) and 17% (3/18) felt that the format and content of the feedback reports, respectively, were partially appropriate. None of the participants reported that they were not appropriate. Suggestions for improvements included highlighting the poorest performing variables within each section, considering simplifying data, and including fewer variables so that those of higher importance can be prioritized. In addition, one respondent suggested that coherence and internal validity between variables could be highlighted as well as completeness. Of all respondents, 72% (13/18) thought that the timing of report distribution allowed for improvements before the next data submission cycle; however, 22% (4/18) felt that they were sent too late, and 1 respondent thought they arrived too early. One person commented that they would prefer to receive reports more frequently, every 4 months. In terms of dissemination, 50% (9/18) of respondents reported sharing the reports within their regional teams, including with epidemiologists, TB units, IT teams, primary care, hospital services, and regional public health directors and leadership. Better-performing CCAAs appear to be more likely to circulate reports to colleagues; among the 5 regions with highest period 2 completeness, 4 reported sharing reports with colleagues; however, none of the bottom 5 performing regions reported sharing the reports.

### *Barriers and Enablers*

Barriers to complete TB data reporting varied across regions but commonly included limited human resources and time (15/18, 83%); technical restrictions (9/18, 50%); insufficient training (5/18, 28%), which is exacerbated by high staff turnover; and lack of clear surveillance guidelines (4/18, 22%). Many CCAAs had already implemented measures to improve surveillance, including integration of laboratory and microbiological data into their surveillance systems, local data validation prior to submission, feedback loops between regional TB units and central teams, automated quality checks to flag inconsistencies within information systems, and continuous improvements to electronic reporting platforms.

Suggestions for broader system improvements included online training resources for surveillance staff and continuous quality improvement initiatives, including maintaining the annual feedback reports and possibly increasing their frequency, improved variable definitions in the national protocol to ensure consistency, and national guidelines for follow up of cases who move between regions.

## Part 3: Annual Report Updates and Continuous Quality Improvement

In June 2025, to support CCAAs with making continuous improvements in TB surveillance, we shared with regions a summary of Part 1 and Part 2 of the assessment, along with a description of changes made to the upcoming feedback reports (for 2024 data submission) based on the findings:

- Number of variables included reduced to the 40 key variables included in the analysis
- Variables separated into 3 groups to coincide with the analysis: patient, illness, laboratory
- Addition of various cross-checks, including infective agent classification and diagnostic test used, date of case registration and result of treatment, date of treatment

XSL•FO
RenderX

completion, and result of treatment; also, the addition of several new cross-checks related to antimicrobial resistance testing
- Time to diagnostic and time to treatment added to reports as a new variable, calculated using the difference between the date of diagnosis and date of symptom onset and between the date of initiation of treatment and date of symptom onset, respectively

Following this, we analyzed the preliminary 2024 TB surveillance data to determine whether the updated feedback report supported further improvements, as part of a continuous improvement cycle. We found that, at the national level, mean completeness across all variables increased to 78% in 2024 (compared with 66% in 2018 - 2020 and 76% in 2021 - 2023).

## Discussion

### Summary of Principal Findings

This study aimed to quantitively assess the internal completeness of TB surveillance data before and after implementation of feedback reports in Spain and to qualitatively assess the perceived usefulness among CCAAs of both the current surveillance system and the feedback reports. We identified significant improvements in completeness across most variables and regions following the introduction of annual feedback reports, although there was some variation across both type of variable and CCAAs. At the national level, mean completeness increased from 66% in 2018 - 2020 to 76.2% in 2021 - 2023 (with nearly four-fifths of variables indicating improvements) and increased further to 77.8% in 2024. Both the surveillance system and feedback reports were generally viewed as acceptable and useful among regional stakeholders included in the survey. The additional study aiming to update the feedback reports for the 2024 surveillance cycle based on our findings and assess the potential impact of the updated reports on TB surveillance data completeness found that mean completeness continued to improve in 2024 relative to previous years.

### Principal Findings in Context

Although the highest completeness levels were seen among patient-related variables, no statistically significant improvement was observed in this group. This is partly due to many variables being at or close to 100% completeness in period 1, leaving minimal opportunity for further improvement. This is in line with findings from other European Union (EU) and European Economic Area (EEA) countries, where, in 2023, most countries had complete or near complete data (>95%) for variables requiring mandatory reporting to the ECDC, such as age and sex [12]. Patient-related variables that continued to have low completeness rates in period 2 were those that applied to individuals born outside of Spain: number of years in Spain, mother country of birth, and mother number of years in Spain (62.3%, 12.3%, and 55.3% period 2 completeness, respectively). This is pertinent, as individuals from countries of origin with higher TB prevalences may have an increased risk of importation; therefore, efforts should be made to improve data collection for these variables.

Although illness-related variables had similar percentage completeness (77.4%) to that of patient-related variables in period 2, a larger improvement of 12.8% in illness-related variables was observed relative to period 1. However, some variables remained poorly completed, including follow-up result, which, despite a 23.8% increase, had 39.3% completeness in period 2. Supporting this, survey respondents called for improved protocols and better integration of case follow-up and laboratory information, particularly for patients who move between CCAAs. The respondents' call is in the context of the WHO recommendations for a 6-month regimen of 4 first-line drugs (and longer treatment and additional drugs for resistant TB) [13], which complicates patient follow-up. Continuity of TB treatment is essential for effective control of the disease, particularly with increasing movement of individuals both within and between countries across Europe [14]. In particular, interruption of treatment among mobile populations (including migrants, refugees, and asylum seekers) is a recognized challenge in Europe, often leading to poorer health outcomes, higher risk of transmission, and the emergence of resistant strains [15]. In line with this study, evidence from other countries has found that variability regarding migrant health policies and unclear or absent referral mechanisms can hinder treatment continuity [6,14,16].

Improvements were most pronounced for laboratory-related variables, with a mean increase of 13.9%; however, increases were particularly pronounced for those with lower baseline completeness, such as for date of laboratory diagnosis and variables related to antimicrobial susceptibility testing. Although this highlights substantial improvements in capturing microbiological information, challenges persist due to the lack of interoperability between clinical and laboratory systems. Despite improvements, some laboratory variables continue to have low completeness in period 2, including lab tests carried out (50.6%) and results for the 4 included antimicrobial resistance testing variables, which ranged from 31.9% to 50.4%. This finding reinforces the need to consolidate mechanisms for the automatic integration of microbiological data into epidemiological surveillance, as demonstrated effectively in some CCAAs. In Catalonia, for example, which ranks higher than most CCAAs with respect to completeness in period 1 (7th) and period 2 (6th), laboratory results are linked to the regional surveillance system [17]. At the European level, models such as the MiBa (Danish Microbiology Database) in Denmark [18], Osiris system in the Netherlands [19], and MycobNet network in the United Kingdom [20] enable automated laboratory result reporting and the genomic integration of *Mycobacterium tuberculosis* strains, improving outbreak detection and resistance surveillance.

This finding that variables requiring integration between clinical and laboratory systems or ongoing follow-up were the most incomplete is consistent with the ECDC [11] and United States Centers for Disease Control and Prevention (CDC) guidance [21], emphasizing that data involving multiple sources or complex definitions are generally more vulnerable to missingness. In line with this, across EU/EEA countries in 2023, the availability of data related to clinical and laboratory information was lower than for patient-related variables, for

XSL•FO
RenderX

example for previous treatment history (86%), treatment outcome at 12 months (61.5%), and HIV status (39.3%) [12].

At the regional level, 16 of Spain's 19 CCAAs (84%) saw an improvement in period 2, although the magnitude varied widely, ranging from modest gains to more than 25% increases. The one region where a statistically significant decrease was observed already had a high level of completeness in period 1 (the 5th highest among all CCAAs). These disparities reflect the decentralized nature of the Spanish surveillance network RENAVE. This is in line with other countries with decentralized surveillance systems, where regional disparities have been found in evaluations of the surveillance systems, for example in Italy where northern regions were found to report acute viral hepatitis cases in a more timely manner than central and southern regions [22].

Survey findings provided important explanatory context. Respondents were generally satisfied with TB surveillance in Spain and considered it to be important, indicating high level of acceptability and perceived usefulness of the system, providing a strong foundation for future quality improvement initiatives. There appeared to be a possible association between higher-performing CCAAs and the extent to which the feedback reports are disseminated among colleagues within the region; further investigation would be required to understand whether this is because the reports are more effective at driving improvements if disseminated more widely or simply that higher-performing CCAAs have both better communication channels and better surveillance systems.

Overall, our findings show an improvement in internal completeness of TB surveillance data following implementation of feedback reports and positive perceptions of these reports among regional stakeholders. Although a causal link is difficult to establish, our findings suggest that systematic data quality monitoring and feedback may help to strength surveillance, consistent with international guidance that emphasizes regular evaluation as a cornerstone of high-performing systems [11,21]. The observed improvements, together with respondents' endorsement of feedback reports, suggest that feedback cycles may contribute to improved completeness and system acceptability and continuous quality improvement.

### Limitations

This analysis is subject to several limitations. First, due to the descriptive nature of the analysis, it was difficult to establish a causal link between the observed improvements in data quality and the implementation of the feedback reports. For this reason, we included the qualitative element of the survey, but it is not possible to rule out other explanations for the observed results, such as improvements in surveillance across all areas or increased focus on infectious diseases after the COVID-19 pandemic. Furthermore, although improved completeness likely reflects better data capture, it does not guarantee data accuracy; although the feedback reports were designed to examine this by including validity cross-checks, there are variables for which this was not possible. Case ascertainment and the sensitivity of the system—the number of cases captured by the system divided by the true number of cases in the community [11]—were flagged as a potential area of risk by survey respondents and remains an important attribute of surveillance that has yet to be explored.

There were additional limitations related to the survey component. The survey was circulated to the lead individual responsible for TB surveillance in each CCAA, meaning that there was only one response per region. This individual is the person receiving the feedback reports so they were considered best placed to respond to our survey; however, it is possible that this could introduce bias and may not fully reflect the breadth of opinions of individuals in the CCAA. In addition, although it was emphasized that survey responses were anonymous, there may remain some degree of social desirability bias or underrepresentation of more critical perspectives.

Comparisons with other European countries with similar decentralized systems remains a challenge given the limited number of similar studies published internationally. It is hoped that this study will serve as a useful tool for other countries wishing to carry out future assessments examining the attributes of internal completeness, acceptability, and usefulness.

### Recommendations and Conclusions

Surveillance of TB is inherently challenging given the typically long-term course of the disease and treatment within the context of complex socioeconomic risk factors. This study indicated that completeness of TB surveillance data in Spain has improved following the introduction of annual feedback reports in 2022, although variation persists by variable and region. Importantly, the combination of quantitative and qualitative analyses highlights not only the measurable progress in surveillance quality but also the perceptions, barriers, and enablers that shape the system's performance. Although the reasons underlying observed improvements can be uncertain and are likely multifaceted, feedback reports were valued by regional stakeholders and appear to support a culture of continuous quality improvement.

Our findings suggest that the CNE should continue to send annual feedback reports to regions; however, they could be refined to be of even more benefit, for example, by focusing on a smaller number of key variables and indicators that align with those set out by the WHO guidance on TB surveillance published in 2024 [23]. This guidance defines a set of core indicators for countries with a case-based digital surveillance system as well as recommended reporting intervals, visualization, and interpretation for these indicators. This would support regions to target efforts where they are most effective and facilitate comparison with other countries. More broadly, strengthening alignment with international standards may help Spain position itself within global TB monitoring frameworks and contribute more effectively to regional benchmarking efforts.

In addition, the CNE should provide improved guidance on follow up of individuals who move between CCAAs or internationally during the long treatment course and how information from these individuals should be reported in the surveillance system. This could be supported by encouraging use of the ECDC "International tuberculosis care transfer form" [24]. This tool aims to support cross-border collaboration

XSL•FO
RenderX

between health care providers to ensure the care needs for people with TB are transferred securely and efficiently, minimizing delays and reducing the risk of treatment interruption. In addition, the availability of a national personal identifier in Spain would facilitate interoperability of laboratory and surveillance systems within regions, as well as support easier transfer of care of patients between regions. These improvements would not only enhance data quality but also strengthen continuity of care, an essential component of TB control in decentralized health systems.

To fully realize the potential of TB surveillance, future assessments could consider expanding beyond completeness and perceptions of feedback reports, for example using standardized methods to carry out a formal evaluation and examining a more comprehensive list of attributes, such as validity, timeliness, representativeness, and sensitivity, in line with established frameworks [11,21,25]. Future evaluations could be also carried out using the WHO TB surveillance guidelines [23] as a framework, with completeness of data fields measured against those required to calculate the recommended indicators. In addition, to examine the possible determinants of changes observed beyond descriptive analysis, approaches such as multilevel logistic regression analysis with adjustment for covariates including CCAA could be considered to complement future evaluations. Finally, embedding assessments into a continuous improvement cycle, as already initiated by revising the most recent feedback reports, will help ensure that the system evolves and continues to provide reliable and actionable information that meet both national and international TB control objectives.

## Acknowledgments

We would like to thank all the professionals involved in data collecting, from clinicians, coders, administrative staff, computer scientists, epidemiologists, microbiologists, and the community participating in the National Surveillance Network. Finally, we would also like to acknowledge the important work of the members of the Spanish Working Group on Tuberculosis:

The authors declare the use of generative artificial intelligence (GAI) in the research and writing process.

According to the GAIDeT taxonomy (2025), the following tasks were delegated to GAI tools under full human supervision: code optimization, proofreading and editing, and translation. The GAI tool used was: Microsoft Copilot. Responsibility for the final manuscript lies entirely with the authors. GAI tools are not listed as authors and do not bear responsibility for the final outcomes.

## Funding

This research was supported by CIBER (Consorcio Centro de Investigación Biomédica en Red), Instituto de Salud Carlos III, Ministerio de Ciencia e Innovación and Unión Europea, European Regional Development Fund. AR is the recipient of a postdoctoral Sara Borrell contract funded by the Instituto de Salud Carlos III, Ministerio de Ciencia, Innovación y Universidades (CD23CIII/00008). The authors declare no other additional financial support was received for this work.

## Data Availability

The datasets analyzed in this study are not publicly available because they contain sensitive patient information reported to the National Epidemiological Surveillance Network (RENAVE) in Spain. RENAVE data are submitted through the national electronic reporting platform SiViEs Plus and are hosted by the National Centre for Epidemiology (CNE). Access to RENAVE data can be requested formally through the CNE website (subject to institutional approval and data protection regulations) [26].

## Abstract

**Background:** The Philippines accounts for 7% of the global tuberculosis (TB) burden. In 2022, an estimated 741,000 Filipinos developed TB, and 40,000 died as a result. Approximately 350,000 new TB diagnoses remain unreported annually.

**Objective:** In October 2023, we undertook an assessment of the accuracy, completeness, and timeliness of the national TB surveillance system using globally accepted TB surveillance standards and benchmarks.

**Methods:** A team of Filipino and international evaluators conducted field visits to 9 purposively selected health facilities across 4 regions. Health records were reviewed, and key informants were interviewed to assess essential activities and best practices for TB surveillance.

**Results:** Of 16 applicable performance standards, 4 (25%) were fully met, 9 (56.3%) were partially met, and 3 (18.8%) were not met. This was an improvement from a similar assessment conducted in 2019. Although electronic case-based recording and reporting had expanded greatly since 2019, large local variations in the adoption of quality assurance practices were evident. More than 50% of persons with reported TB had no bacteriological confirmation despite the presence of a functional national laboratory network. Underreporting due to underdiagnosis was also noted. Delayed reporting was common, especially in locations with limited internet connectivity or limited access to anti-TB medications.

**Conclusions:** Issues related to data quality assurance, gaps in case verification, and timeliness emerged as potential threats to data integrity and surveillance fidelity. Enhanced monitoring and evaluation, along with tailored studies, such as a national TB inventory study, could assist in quantifying potential underreporting and clinical overdiagnosis, guiding future funding, and assessing progress toward elimination targets.

## Introduction

Surveillance is a key component of global efforts to eliminate tuberculosis (TB) [1,2]. To support countries in strengthening their surveillance systems and achieving TB management goals, the World Health Organization (WHO) developed a standardized assessment tool that countries can use to evaluate the performance of their TB surveillance and vital registration systems [3].

The Philippines currently ranks fourth in the list of countries with the highest TB incidence and accounts for 7% of the global TB burden [4]. WHO incidence estimates for 2022 indicated approximately 741,000 incident TB cases in the Philippines compared with 435,890 notified new and retreatment cases, yielding a treatment coverage of 59% [5]. The estimated number

XSL•FO
RenderX

of unreported TB cases reflects the residual between WHO-modeled incidence and observed notifications (derived from the WHO's standardized incidence estimation framework rather than from calculations performed by the authors) [5]. The Philippines Department of Health introduced an internet-based TB surveillance system, the Integrated TB Information System (ITIS), in 2016 [6]. This facilitates the systematic recording and reporting of case-based information in accordance with National Tuberculosis Control Program (NTP) guidance [7,8]. Currently, TB case data are captured from all primary public facilities and several tertiary facilities. A growing number of private healthcare practitioners also participate in mandatory TB notification [9]. All participating network facilities collect TB information in logs and then use ITIS to enter data electronically. Quality assurance procedures guide systematic data entry. Data are reviewed and validated by provincial and regional NTP offices each quarter. The national NTP office reviews data annually and produces an annual TB report to document programmatic performance over time [10].

We aimed to assess the ability of the NTP to accurately enumerate TB cases and deaths using the WHO's TB surveillance assessment tool, which comprises a checklist of standards and benchmarks covering metrics such as TB data quality, surveillance system coverage, and treatment coverage [11]. The previous surveillance evaluation conducted in 2019 using the same standards and benchmarksfound that a total of 5 benchmarks were met, 1 was partially met, 6 were not met, and 5 were not applicable (Multimedia Appendix 1).

## Methods

### Overview

In October 2023, a team of Filipino and international evaluators from the Epidemiology Bureau of the Philippines Department of Health and the US Centers for Disease Control and Prevention (CDC) conducted field visits to 9 health facilities in 4 of the country's 18 regions: Calabarzon, Cordillera Administrative Region, Ilocos Region, and National Capital Region. The facilities were selected to gain perspectives from a variety of settings and included urban and rural, primary and tertiary care, and private and government settings. These included regional and provincial NTP offices. We interviewed stakeholders (including clinicians, program managers, and frontline workers) to learn about essential activities and best practices regarding TB surveillance. Each visit included a presentation from the facility, discussion of surveillance processes, and a walkthrough of TB-specific areas. Selected paper-based registries, clinical records, and electronic-based data (ITIS) were reviewed for accuracy, completeness, and timeliness. Additional publicly available data sources were also consulted [12-14]. After site visits and discussion with local and national partners, the WHO's assessment tool checklist was completed and compared with the previous assessment conducted in 2019 [11,12]. The previous TB surveillance assessment used the same WHO standards and benchmarks [12]. That assessment included field visits to a comparable number and mix of health facilities across selected regions of the Philippines, representing varied geographic, administrative, and health system contexts. While the specific facilities and regions assessed in 2019 were not identical to those included in the 2023 assessment, both evaluations were designed to capture perspectives from urban and rural settings and from multiple levels of the health system, allowing for broad comparability of findings over time. This evaluation focused on 5 standards: TB surveillance system data quality, system coverage and vital registration, specific populations, TB treatment outcomes, and programmatic management of TB preventive treatment. We used the same set of 16 standards and benchmarks as in the previous assessment; changes between successive versions of the checklist were relatively minor. An indicator was considered "partially met" if at least one, but not all, of the outcome measures for each benchmark was met.

### Ethical Considerations

This activity was reviewed by the CDC and deemed not research and was conducted consistent with applicable federal law and CDC policy (see, eg, Title 45, part 46.102(l)(2), and Title 21, part 56, of the Code of Federal Regulations and Title 42, §241(d); Title 5, §552a; and Title 44, §3501 et seq of the United States Code [15]). As this activity was classified as a public health surveillance evaluation rather than human subjects research, formal written informed consent was not required. Key informants were verbally informed of the voluntary nature of their participation prior to being interviewed. No personally identifiable patient information was collected or retained. Participants received no compensation.

## Results

On the basis of 2022 data, of the 17 total checklist indicators, of which 1 (5.9%) was not applicable, 4 (23.5%) were fully met, 9 (52.9%) were partially met, and 3 (17.6%) were not met (Multimedia Appendix 1).

### TB Surveillance System Data Quality

Benchmarks B1.1 to 1.3 (B1.4 was not applicable to electronic systems), which relate to case-level data capture, were fully met (Multimedia Appendix 1). Case definitions were consistent with WHO guidelines and the TB case-based reporting framework (B1.1) [2,3]. Persons with TB were identified using unique, anonymized registration numbers. The surveillance system captured a minimum set of variables for all cases (B1.2). These included sociodemographic characteristics (ie, age, sex, and residential address), date of registration, clinical and diagnostic information (ie, anatomical site of disease, radiographic interpretations, and treatment history), laboratory test results, and current treatment regimens. Test results and treatment status were recorded as patients moved through the care pathway. Information was captured in near real time; once data was entered at local levels, they were immediately available for view by the higher-level offices. We observed that ITIS was widely used and that sufficient training and infrastructure were in place. This included training on data collection and entry into the electronic system. Infrastructure included computer availability, electricity, and internet connection at various facilities. However, several users reported that, on occasion, ITIS was slow to load and unsaved data could be lost due to unstable internet connectivity. In facilities with insufficient internet

XSL•FO
RenderX

bandwidth, paper-based registers were transferred for entry at hubs with adequate connectivity. In addition, ITIS was not fully integrated with laboratory information systems. Laboratory staff manually entered results into ITIS; automated reporting of molecular-based testing (ie, Xpert MTB/RIF; Cepheid) was not in place.

The B1.5 benchmark, which measures the accuracy, completeness, and internal consistency of data in the national database, was partially met. ITIS has integrated mechanisms to ensure data quality, such as checking for duplicate names with the same spelling. However, although less than 1% of records were invalid or incomplete (judged against a minimal set of variables, including sociodemographic characteristics, date of registration, and clinical and diagnostic variables), the internal mechanisms did not include checking for duplicate entries with different identifiers or spelling, and no evidence of addressing these potential duplications was observed. Furthermore, data validation checks were inconsistent and widely varying. ITIS features a simple, one-click validation step, which users were able to demonstrate during site visits. While ease of use can be an advantage, the current validation process may be insufficient to verify the accuracy of the entered data. Because HIV-associated information is restricted at some levels (ie, patient records are confidential and not integrated into ITIS), validation of records for people with HIV-TB appeared limited. Electronic surveillance systems provide opportunities to automate a portion of the data quality assurance process, but only minimal automated checks for internal validity were in place.

The B1.6 and B1.7 benchmarks related to the internal and external consistency of TB surveillance data, respectively, were also only partially met. Among newly notified persons with TB in 2022, a total of 8% were children aged 0 to 14 years. This was within the recommended acceptable range standard (5% - 15% for low- and middle-income countries). Across all ages, only 50% of reported persons with TB had bacteriological confirmation, well below the 70% to 90% recommended standard [4]. Surveillance data appeared to be internally consistent over time even after considering year-to-year differences experienced during the COVID-19 pandemic. The ratio of pulmonary to extrapulmonary TB was 37:8, and for male to female patients, it was 26:14, which was consistent with pre–COVID-19 levels. The proportion of newly notified TB cases had steadily increased to 49.6% (Table 1; [13,14,16]).

**Table .** Selected tuberculosis (TB) surveillance system indicators (the Philippines, 2018 - 2022)[a].

| | 2018 | 2019 | 2020 | 2021 | 2022 |
|---|---|---|---|---|---|
| TB programmatic indicator | | | | | |
| Ratio of notified pulmonary to extrapulmonary TB cases | 32:7 | 36:7 | 22:5 | 28:6 | 37:8 |
| Ratio of male TB cases to female TB cases | 21:11 | 24:13 | 2:1 | 2:1 | 26:14 |
| Childhood TB cases out of all TB cases (%) | 13.9 | 11.6 | 7.7 | 7.0 | 8.1 |
| Proportion of newly notified TB cases with bacteriological confirmation (%) | 36.1 | 33.9 | 43.9 | 45.0 | 49.6 |
| Year-to-year change in new case notification rate (%) | 8.4 | 9.2 | –59.5 | 20.2 | 26.2 |
| Vital registration indicator | | | | | |
| Proportion of documented primary cause of death among all registered deaths (%) | 96.3 | 96.3 | 95.7 | 93.5 | 94.2 |
| Deaths attributed to TB—all forms, n (%) | 23,409 (4.0) | 23,877 (3.8) | 19,430 (3.2) | 19,952 (2.3) | 20,588 (3.0) |

[a]As a population-level health system indicator, the universal health coverage service index was 48 in 2010, 57 in 2015, 60 in 2017, 60 in 2019, and 58 in 2021 [13,14,16].

## System Coverage and Vital Registration

B1.8 assesses how well the surveillance system captures TB cases. By default, ITIS only captures persons who received treatment at NTP facilities. Despite mandating notifications from all private health care providers who diagnose persons with TB in 2018, only selected health care providers complied, leading to occasional nonreporting among private sector facilities. Without a complete census or representative survey of private facilities, it is unknown how many facilities are not reporting in ITIS.

XSL•FO
RenderX

In a few facilities, staff were uncertain of who was responsible for reporting TB cases and validating records; in others, staff asserted that they were only responsible for entering data into ITIS for TB treatment initiations, not TB diagnoses. Both scenarios may result in underreporting. A few facilities reported waiting to encode diagnosed patients until treatment was initiated. This practice had major implications for reporting timeliness in settings where supply chain issues have caused months-long treatment initiation delays. Facilities without the human resource capacity to enter data into ITIS on-site or with limited internet connectivity sent TB registers to regional or provincial offices for encoding, resulting in reporting and patient referral delays. In light of such evidence, the B1.8 benchmark was deemed as only partially met.

Although access to health care in the Philippines has steadily improved over the past decade (Table 1), the universal health coverage index was 58 in 2021, well below the recommended benchmark of 80. Thus, the B1.9 benchmark was not met (Multimedia Appendix 1). However, benchmark B1.10, which relates to the coverage and quality of vital registration data provided by the civil registration and vital statistics system, was partially met. According to the Philippine Statistics Authority, the primary cause of death was documented for 640,175 (94.2%) of 679,766 registered deaths in 2022, including 20,588 (3%) attributed to all forms of TB (Table 1). However, the extent of mortality reporting and recording was variable between regions.

## Specific Populations

Of the 3 supplementary indicators pertaining to specific TB populations (people with drug-resistant TB, people with HIV coinfection, and children), only the B2.1 benchmark was met. In 2022, 52% of new cases were diagnosed without laboratory confirmation despite increased Xpert MTB/RIF testing. However, among patients with bacteriologically confirmed pulmonary TB, the vast majority (97%) had drug susceptibility test results, and a total of 9791 rifampin-resistant cases were detected. This meant that benchmark B2.1 was met.

Benchmark B2.2 was not met because, in 2022, the proportion of patients with newly reported TB tested for HIV (70%) remained below the recommended target of 80%. The data in Table 2 show that not only has the annual proportion of patients with newly notified TB tested for HIV increased in recent years but the proportion of patients with TB who tested positive for HIV has also remained low (range 0.8% - 1.5%). Moreover, the proportion of persons living with HIV who initiated antiretroviral treatment after testing positive in the last 3 years was exceptional; only 1 person with newly discovered TB and HIV coinfection did not start antiretroviral treatment.

**Table .** HIV testing and percentage of positivity among persons with newly reported tuberculosis (TB; the Philippines, 2018 - 2022)[a].

| Indicator | 2018 | 2019 | 2020 | 2021 | 2022 |
|---|---|---|---|---|---|
| Persons with TB with a documented HIV test result, n (% of total) | 101,681 (31) | 136,749 (38) | 85,672 (39) | 109,952 (39) | 263,846 (70) |
| Persons with TB who tested positive, n (% of persons tested) | 1477 (1.5) | 1615 (1.2) | 898 (1.0) | 1350 (1.2) | 2201 (0.8) |
| Persons with TB who tested positive and initiated ART[b], n (% of positive cases) | 1350 (91) | 1509 (93) | 898 (100) | 1349 (99) | 2201 (100) |

[a]Source: Global TB Data Repository [14] .

[b]ART: antiretroviral therapy.

In 2022, children and adolescents aged 0 to 14 years accounted for 8% of all reported persons with TB (Table 1). Benchmark B2.3 requires a rate ratio of cases notified among children aged 0 to 4 years to those aged 5 to 14 years in the range of 1.5 to 3.0; the observed ratio of 0.82 fell outside the expected range, and therefore benchmark B2.3 was not met. A ratio lower than expected suggests that TB cases are proportionally higher among older children, which may reflect either underdiagnosis in children below the age of 5 years, overdiagnosis in children and adolescents aged 5 to 14 years, or both. Formal investigations of childhood TB epidemiology to determine the extent of under- or overreporting have not been conducted.

## TB Treatment Outcomes

Both treatment outcome standards (B3.1 and B3.2) were partially met. We observed variations in the accuracy, completeness, and consistency of TB treatment recording and reporting by both setting and region. However, individual treatment outcomes were disaggregated by treatment history, HIV status, and drug resistance test results. Overall, there was limited evidence of local-level surveillance data use. Facilities generally focused on variables associated with targets and on measuring success based primarily on target achievement. We found no evidence that checks had been made to verify that the number of patients with an assigned treatment outcome in any given year matched the number of patients notified the preceding year.

## Programmatic Management of TB Preventive Treatment

While monitoring and evaluation indicators for TB preventive therapy (TPT) were consistent with global guidance [17] and the data collected included the minimum set of variables (people living with HIV, children aged <5 years, individuals aged ≥5 years, and TPT completion), monitoring of TPT was noted in a few settings, and there was significant variation. Thus, B4.2

XSL•FO
RenderX

(TPT programmatic management data were accurate, complete, and consistent) was only partially met (Multimedia Appendix 1).

## Discussion

### Principal Findings

The global standards and benchmarks for TB surveillance and vital registration systems were developed to be applicable to TB control programs in various contexts [3]. By implementing this tool, we demonstrated that it is both applicable and feasible in the Filipino context. Overall, this assessment was an improvement from the previous assessment in 2019, in which 5 benchmarks were met, 1 was partially met, 6 were not met, and 5 were not applicable [12]. In this assessment, fewer indicators were not met, and more were fully or partially assessed.

This assessment revealed progress in several key areas of TB surveillance since the last review. Most notable was the impressive expansion and implementation of electronic case-based recording and reporting. However, we also identified several opportunities for further improvement.

### Improving Data Quality

Data quality issues predominantly stemmed from staff time constraints and a lack of coordination between facilities. Procedures were in place to encourage data quality assurance prior to reporting. However, greater use of automated checks for internal validity, data completeness, and deduplication could reduce the burden on data entry staff and the risk of human error in the reporting process. Losses to follow-up and the number of duplicate records could be reduced by implementing monitoring at higher administrative levels of patients who are transferred but unclaimed in ITIS.

It should be noted that, while the proportion of bacteriologically confirmed pulmonary TB with drug susceptibility test results was considerably higher than the 80% recommended standard (Multimedia Appendix 1), the proportion of all TB cases with bacteriological confirmation still ranked among the lowest in the world [5]. Proposed explanations for the low rates of bacteriological confirmation include health care provider mistrust of molecular testing results, underuse of molecular diagnostics, and the high number of specimens rejected by laboratories due to low-quality sputum collection.

### Hastening the Transition From Aggregated Paper-Based to Electronic Case-Based Recording and Reporting

ITIS represents a triumph in the transition to electronic, person-level reporting. However, it is hampered by slow loading speeds, which prevents users from accessing the system. Taking steps to reduce loading times, such as increasing the number of servers, would significantly improve both user satisfaction and the timeliness of data entry and is highly recommended. A mobile-based platform, which does not require a continuous internet connection or expensive hardware, would also help overcome connectivity barriers. Initiating automated transmission of molecular test results could also improve efficiency and data quality. Shifting from manual to automated validation measures offers the dual benefit of reducing the burden on staff and improving data quality. Increasing the number of dedicated personnel at each health facility would expedite implementation of these changes and ensure continuity.

### Reducing Underreporting and Underdiagnosis

Ensuring that all persons with TB have timely access to treatment will help reduce household contact transmission risk and case reporting delays; resolving supply chain issues will further support this. Increasing the proportion of people with bacteriologically confirmed TB would also help tackle the problem of underreporting and underdiagnosis; while clinical diagnoses are important in the absence of laboratory-based alternatives, they can result in under- or misdiagnosis, especially for drug-resistant TB. Pooling samples and providing standardized sample collection instructions to facilities could improve bacteriological diagnosis and reduce the number of rejected sputum samples. Thus, studies to determine the causes of overreliance on clinical diagnosis and the extent of underreporting in the private sector are strongly recommended.

### Promoting the Use of Surveillance Data to Drive Public Health Decision-Making

Informing public health action is a central objective of conducting disease surveillance activities. Training public health workers to analyze and use their own data could be undertaken in collaboration with epidemiology and surveillance units as well as the NTP.

### Limitations

This evaluation took place over a short period and included a small number of field observations at 9 representative facilities. This limitation is particularly important given the geographic and socioeconomic heterogeneity of the Philippines. In addition, we focused on direct observation in reporting facilities and interviews with key informants rather than the more in-depth data evaluation that traditionally takes place during a larger and more formal epidemiologic or TB program review.

### Conclusions

Data quality assurance, case verification, and timeliness were identified as potential risks to data integrity and TB surveillance fidelity in the Philippines. Enhanced monitoring and evaluation, along with tailored studies, such as a national TB inventory study, are proposed as possible measures to quantify underreporting and clinical overdiagnosis, guide future funding, and assess progress toward TB elimination targets.

### Funding

This report was funded by the Department of Health Epidemiology Bureau of the Government of the Philippines, with technical assistance, personnel, and travel funds from the US Centers for Disease Control and Prevention.

## Abstract

**Background:** Heated tobacco products (HTPs) expanded rapidly after 2014; yet globally, comparable estimates of the number of HTP users remain limited. National surveys rarely include standardized HTP measures, and international surveillance systems do not provide harmonized global user counts.

**Objective:** The aim of the study is to construct a reproducible annual global time series of HTP user estimates for 2014 - 2024 using publicly available manufacturer disclosures, quantify uncertainty, and compare these estimates with user counts derived from nationally representative survey prevalence data where available.

**Methods:** We compiled annual HTP user counts and heated-tobacco stick shipment volumes from publicly available reports of major transnational tobacco companies. In the primary series, we used company-reported user counts when available. For company-year observations without reported user counts, we estimated user numbers by converting reported shipment volumes into implied user counts, applying brand-specific assumptions on average daily consumption per user. As an alternative sensitivity analysis, all company user counts were excluded, and all shipments were converted using a common literature-based consumption parameter. As a complementary check, nationally representative current-use prevalence data from 35 countries were converted to user counts.

**Results:** Global HTP users reached 48.9 million in 2024 in the primary series (range 45.6 - 52.1 million). The shipment-only series showed higher totals (67.9 million; range 59.7 - 78.7 million). Survey-based estimates yielded 21.8 million users across 35 countries, reflecting partial geographic coverage.

**Conclusions:** A transparent, updateable global time series documents rapid HTP growth from 2014 to 2024, with 2024 totals ranging from 45.6 to 78.7 million users depending on the estimation approach. As standardized HTP measures are incorporated into national surveys, future estimates can be refined, and uncertainty reduced.

heated tobacco products; global estimates; tobacco and nicotine market; tobacco industry data; user prevalence; surveillance and monitoring

## Introduction

Heated tobacco products (HTPs) are electronic devices designed to heat processed tobacco and generate an aerosol without burning the tobacco. Unlike conventional cigarettes, which combust tobacco at high temperatures (>600 °C), HTPs typically operate at lower temperatures (250 - 350 °C) using an electrically powered heating element. HTP systems generally consist of a specially manufactured tobacco consumable (commonly in the form of sticks), a heating mechanism, and a battery-powered control unit that regulates device operation [1-3].

Introduced commercially in 2014, HTPs have become a notable segment of the global nicotine market, expanding rapidly from initial launches in Japan and South Korea [4-9]. Despite this expansion, globally comparable estimates of the number of HTP users remain scarce. National tobacco surveys rarely include HTP questions, and where they do, definitions and measurement approaches vary, limiting cross-country comparability and time-series analysis. The most comprehensive systematic reviews to date highlight persistent surveillance gaps and heterogeneity in measures [4,5]. These reviews reflect prevalence data from surveys conducted up to 2020 and identify current adult HTP prevalence estimates from 34 countries; only a small number of countries (Japan, Italy, the United States, and the United Kingdom) contribute 3 or more prevalence

XSL•FO
RenderX

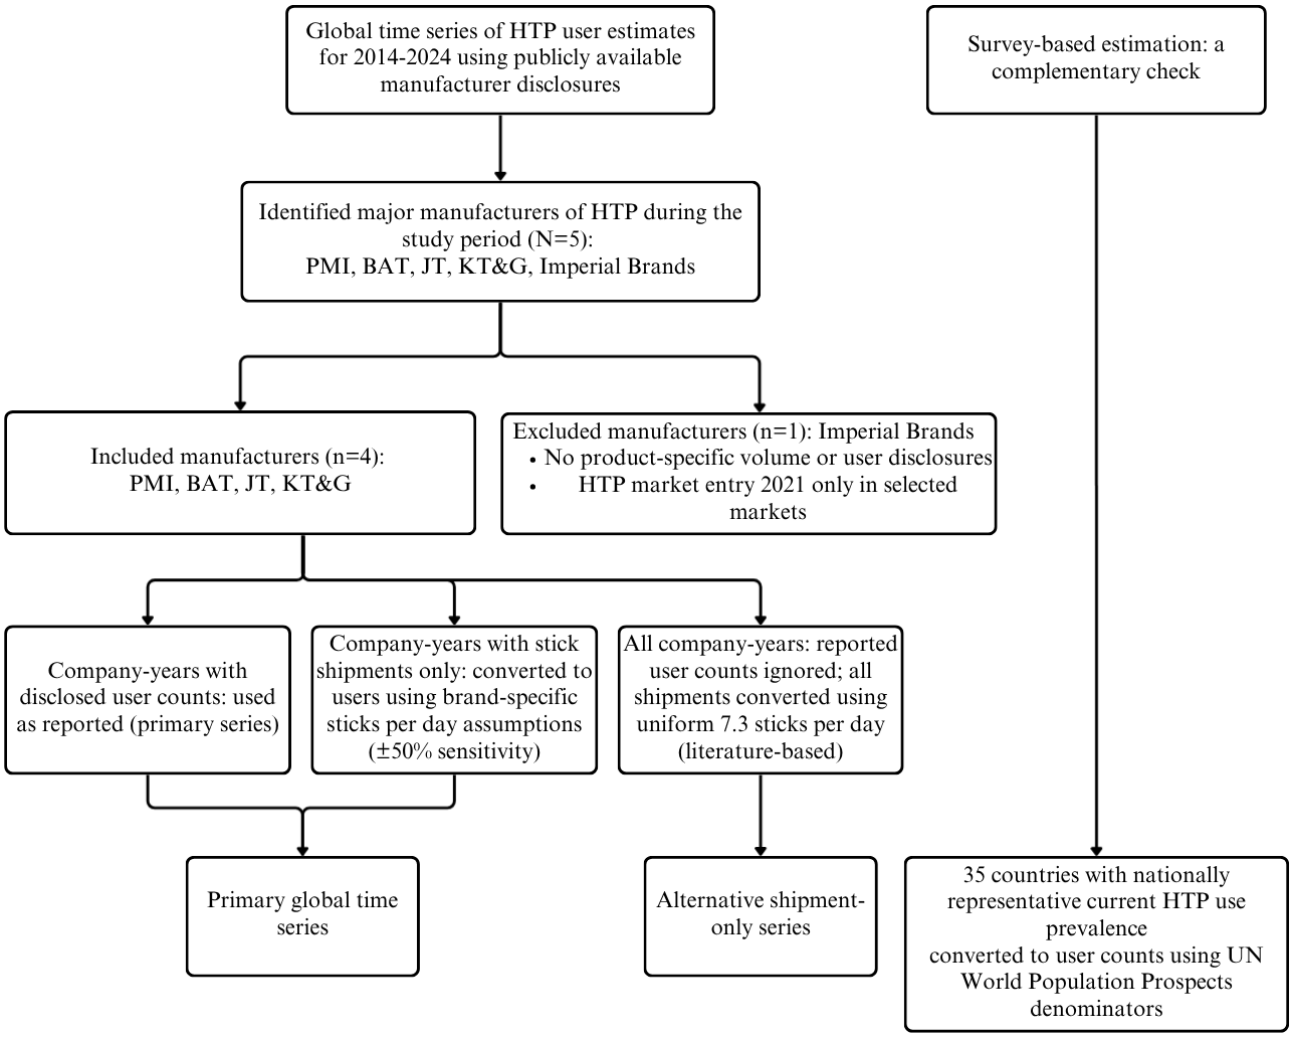
estimates across different years [5]. By contrast, HTPs are legally available in at least 72 countries as of 2025 [10], indicating a substantial mismatch between product availability and the coverage of nationally representative prevalence evidence. To date, global surveillance has not produced an annual time series of the number of HTP users that spans the full period of commercial uptake.

Similar measurement challenges previously existed for other noncombustible nicotine products, e-cigarettes, where global user estimates were initially constructed by compiling heterogeneous sources and then iteratively updated as evidence improved [11-13]. The World Health Organization has recently reported adult e-cigarette user estimates based on nationally representative surveys. However, a comparable evidence base does not yet exist for HTP, which are not consistently separated from broader smoked tobacco categories [14]. A systematic assessment of Eurobarometer tobacco surveys documented that HTP-specific questions were not introduced until 2020 (6 years after HTPs entered European markets) and identified significant inconsistencies in question wording and product definitions across survey waves, further limiting comparisons [15].

This study addresses that empirical gap by generating a global time series of HTP user estimates for 2014 - 2024. In contrast with existing estimates, which are primarily survey-based, we systematically compile manufacturer-reported user counts and sales volumes and convert volumes to user numbers when necessary using explicit assumptions about daily consumption. The rationale for using company data is pragmatic: such disclosures are often the only publicly available and regularly updated source of information on global HTP uptake. Furthermore, the HTP market is highly concentrated among a small number of multinational firms [16,17], which allows the construction of consistent and comprehensive annual estimates.

The aim of this study is to construct a transparent and reproducible global time series estimate of the number of HTP users from 2014 to 2024 using publicly available manufacturer disclosures. Specifically, we address the following research questions: (1) What is the estimated global number of HTP users annually from 2014 to 2024 based on manufacturer-reported data? (2) How do estimates differ across alternative estimation approaches: company-reported user counts, shipment-based conversions, and survey-based prevalence? (3) What are the principal sources of uncertainty in these estimates, and how sensitive are results to key methodological assumptions?

## Methods



### Overview

This section describes the study design, data sources, analytical procedures, and ethical considerations. The study is a descriptive global surveillance analysis based on secondary data from publicly available manufacturer disclosures. No primary data were collected. Figure 1 summarizes the data identification and estimation workflow.

XSL•FO
RenderX

**Figure 1.** Data identification and estimation workflow for global HTP user estimates, 2014 - 2024. BAT: British American Tobacco; HTP: heated tobacco product; JT: Japan Tobacco; KT&G: Korea Tobacco & Ginseng Corporation; PMI: Philip Morris International.

## Study Design

This study estimates the global number of HTP users from 2014 to 2024 by synthesizing secondary data from publicly available manufacturer disclosures to construct a replicable annual time series. Two parallel disclosure-based global series were developed to address definitional heterogeneity and reporting differences across manufacturers: a primary series combining company-reported user counts with shipment-based conversions, and an alternative series relying solely on shipment-based conversions using a common literature-based consumption parameter. As a complementary check, nationally representative survey prevalence data were converted to user counts independently.

## Data

Manufacturer-reported data were extracted from publicly available corporate disclosures (annual reports, investor presentations, regulatory filings, and press releases). These sources provided information on (1) HTP user or consumer counts and (2) annual shipment volumes of HTP consumables (sticks), typically reported at the global level [18-22].

Companies were included if they (1) manufactured and sold HTPs at a material global scale during 2014 - 2024 and (2) publicly disclosed annual user counts or stick shipment volumes sufficient to construct year-by-year estimates. Five major manufacturers of HTP were identified during the study period: Philip Morris International (PMI; IQOS), British American Tobacco (BAT; glo), Japan Tobacco (JT; Ploom), Korea Tobacco & Ginseng Corporation (KT&G; lil), and Imperial Brands. Four companies met the inclusion criteria: PMI, BAT, JT, and KT&G. Imperial Brands was excluded because the company entered the HTP market only in 2021 in selected European markets and does not disclose product-specific volumes or user counts [23]. No other manufacturers met the inclusion threshold of material global scale and public disclosure. For each included company, all available annual observations from 2014 to 2024 were extracted. Where multiple disclosures existed for a single company-year, the most recent published figure was used.

Reporting conventions differed across companies. PMI and BAT publish headline user or consumer counts alongside annual HTP stick shipments. PMI reports “total IQOS users,” defined as adults who used PMI HTPs for at least part of their daily tobacco consumption in the past 7 days, and in some reports, also distinguishes “switched” users. BAT reports user counts only in selected years and does not provide a formal definition. JT does not disclose global user counts; instead, it reports stick

XSL•FO
RenderX

volumes in selected years and, more recently, market-share indicators based on stick volumes. KT&G generally reports stick shipments and does not publish global user counts.

Notably, under the PMI-KT&G distribution or supply agreement, initiated in January 2020 (extended in January 2023), PMI commercializes KT&G's HTPs outside South Korea [24]. PMI's disclosures state that, from December 2020, its reported figures include licensed KT&G products in non-Korean markets [25]. To prevent double-counting, we therefore treat PMI's 2021 onward published user totals as already inclusive of KT&G users outside South Korea. KT&G's domestic (South Korea) stick shipments are converted to user estimates and counted separately, while KT&G volumes outside South Korea are not added on top of PMI's user totals.

Table 1 summarizes the availability of company-reported user counts and stick shipment data by company and year. It documents the availability and structure of input data rather than estimated results and functions as a data inventory.

**Table .** Manufacturer-reported heated tobacco product (HTP) user counts and heated-tobacco stick shipment volumes used to construct global HTP user estimates, by company and year, 2014 - 2024[a].

| Year | PMI[b] (IQOS) | | KT&G[c] (lil) | | BAT[d] (glo) | | JT[e] (Ploom) | |

[e]JT: Japan Tobacco

[f]N/A: not available.

## Analysis

To address definitional heterogeneity and variable disclosure completeness across manufacturers, we constructed 2 parallel global time series.

### *Primary Time Series: Company-Reported Users and Shipment-Based Conversions*

For company-years with disclosed HTP user counts, we used those values as reported. For company-years with only HTP stick shipment volumes, we converted shipments to implied user counts using:

$$\text{Users}_y = \frac{\text{HTP stick shipments}_y}{\text{average number of sticks per user per day} \times 365}$$

Brand-specific assumptions were applied as follows: (1) KT&G—12 sticks per day (derived from years in which PMI disclosed both sticks and users) and (2) BAT and JT—7.6 sticks per day (based on BAT years reporting both sticks and users). For each year, we then aggregated company-level user counts (reported or converted) across firms to produce global totals from 2014 to 2024.

Additional assumptions were required where data were unavailable:

- JT's global heated tobacco stick share in 2017 - 2018 is assumed to be equal to its 2019 level (2.5%).
- BAT launch year: glo launched in December 2016; we assume 0 consumers for 2016 [26].
- BAT revisions: When BAT revises historical "consumer acquisition" figures in later reports, we use the most recent published figures for that year.
- PMI launch year: IQOS launched in 2014; given that the national prevalence of HTP use in Japan was 0.2% in 2015, we set 0 users in 2014 [27].
- KT&G 2020 market split: The domestic versus international split for KT&G in 2020 is not reported. We assume the proportion matched the 2021 level.

Because daily stick consumption might vary by brand, device generation, market maturity, and user profile, we applied a

XSL•FO
RenderX

±50% sensitivity around each brand's central sticks-per-day assumption when converting stick volumes to users. Lower and upper bounds were reported alongside central values for any company-year derived from shipments. No sensitivity was applied to directly reported user counts.

### *Alternative Time Series: Shipment-Only Conversions Using Literature-Based Consumption*

To address uncertainty arising from inconsistent or noncomparable manufacturer user definitions, we constructed an alternative series that ignores all manufacturer-reported user counts and converts all companies' stick shipments to users using a common consumption parameter derived from the literature.

External survey evidence from Germany (2018 - 2023) indicates that current HTP users reported a mean consumption of 7.3 sticks per day, with IQOS accounting for 84% of current use [28]. Comparable estimates were observed in Italy (2018 - 2020), where IQOS users reported a mean consumption of 7.9 sticks per day [29].

Based on these findings, we applied a central estimate of 7.3 sticks per day and used the corresponding 95% CI (6.33 - 8.27 sticks per day) to generate lower and upper bound user estimates, respectively.

### *Estimation Using National Survey Prevalence*

To complement the industry disclosure-based series, we developed an independent survey-based estimate of HTP users derived from nationally representative prevalence data where available. We extracted country-level estimates of current HTP use from 35 countries compiled in the Global State of Tobacco Harm Reduction database, which combines data from Eurobarometer 2023, Global Adult Tobacco Surveys conducted between 2019 and 2023, World Health Organization's STEPwise approach to noncommunicable diseases risk factor surveillance surveys conducted between 2019 and 2022, and recent nationally representative surveys [10].

For each country, the reported prevalence of current HTP use was multiplied by the corresponding adult population for the survey year, aligned with the survey's defined age range (eg, 15+, 18+, 16 - 74, or 19+ years), using population denominators from the United Nations World Population Prospects [30]. Country-specific user counts were then aggregated to produce a combined total across the 35 countries. All data sources used for this estimation are presented in Table 2.

XSL•FO
RenderX

## Ethical Considerations

This study used only publicly available, aggregated secondary data and did not involve identifiable personal information. Therefore, it does not meet the definition of human subjects research under applicable regulatory frameworks, and formal ethics committee approval was not required. This determination is consistent with the US Common Rule (45 CFR 46.102) [31], which defines human subjects research as involving identifiable private information or interaction with individuals, and with

XSL•FO
RenderX

the European Union General Data Protection Regulation (Regulation [EU] 2016/679) [32], which applies only to personal data.

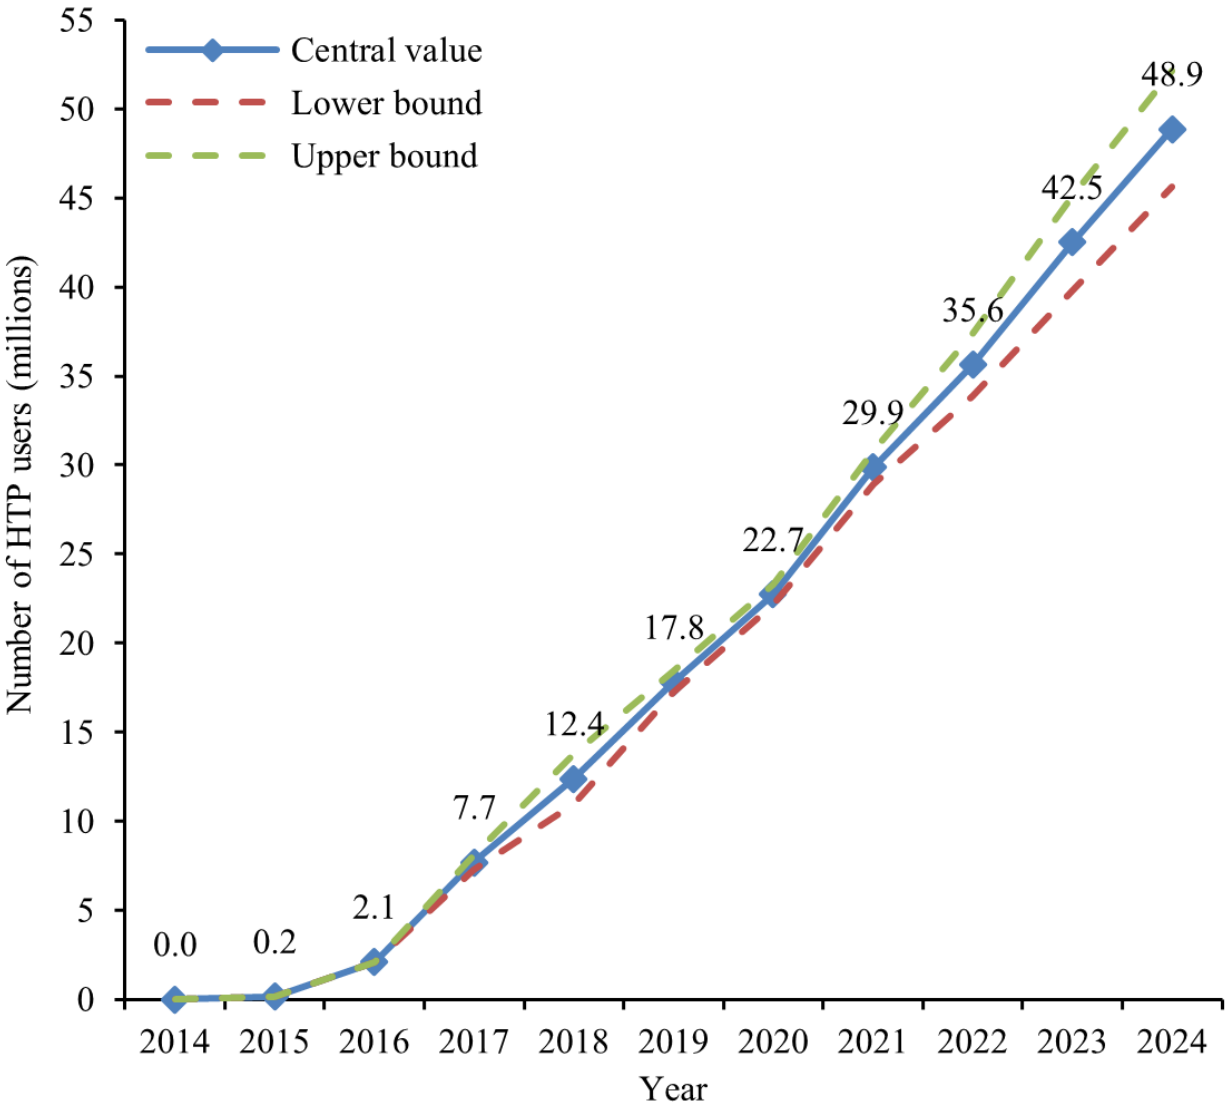
# Results

## Overview

This section presents the findings from the 3 estimation approaches. We first report the primary disclosure-based time series, then the alternative shipment-only series, and finally the survey-based estimation. Results are organized to address the 3 research questions outlined in the Introduction section.

The estimation drew on 44 possible company-year observations (4 companies×11 years, 2014 - 2024). User counts were directly reported by manufacturers for 25 (56.8%) of these observations, while stick shipment volumes were available for an additional 14 (31.8%) observations, resulting in 39 (88.6%) company-year observations with at least 1 usable data point. For the remaining 5 (11.4%) observations, primarily early years before product launch or before public disclosure began, values were set to 0 or imputed using the documented assumptions described in the Methods section. No company-year observations were excluded from the analysis due to missing data; all gaps were addressed through the documented imputation and conversion procedures.

## Primary Time Series: Company-Reported Users and Shipment-Based Conversions



The number of HTP users grew from negligible levels in 2014 to an estimated 48.9 million in 2024 (Figure 2). The estimates indicate a consistent upward trend across the decade, with the lower and upper bounds for 2024 ranging from 45.6 to 52.1 million, respectively, reflecting the ±50% sensitivity applied to shipment-based conversion assumptions. Because more than half of the 2024 global total is anchored in directly reported user counts, the overall uncertainty range remains relatively narrow.

Growth was driven primarily by PMI's IQOS, which accounted for the majority of users throughout the period (Figure 3). BAT's glo gained traction from 2017 onward, while JT's Ploom contributed smaller but steadily increasing shares. KT&G's lil maintained a modest share.

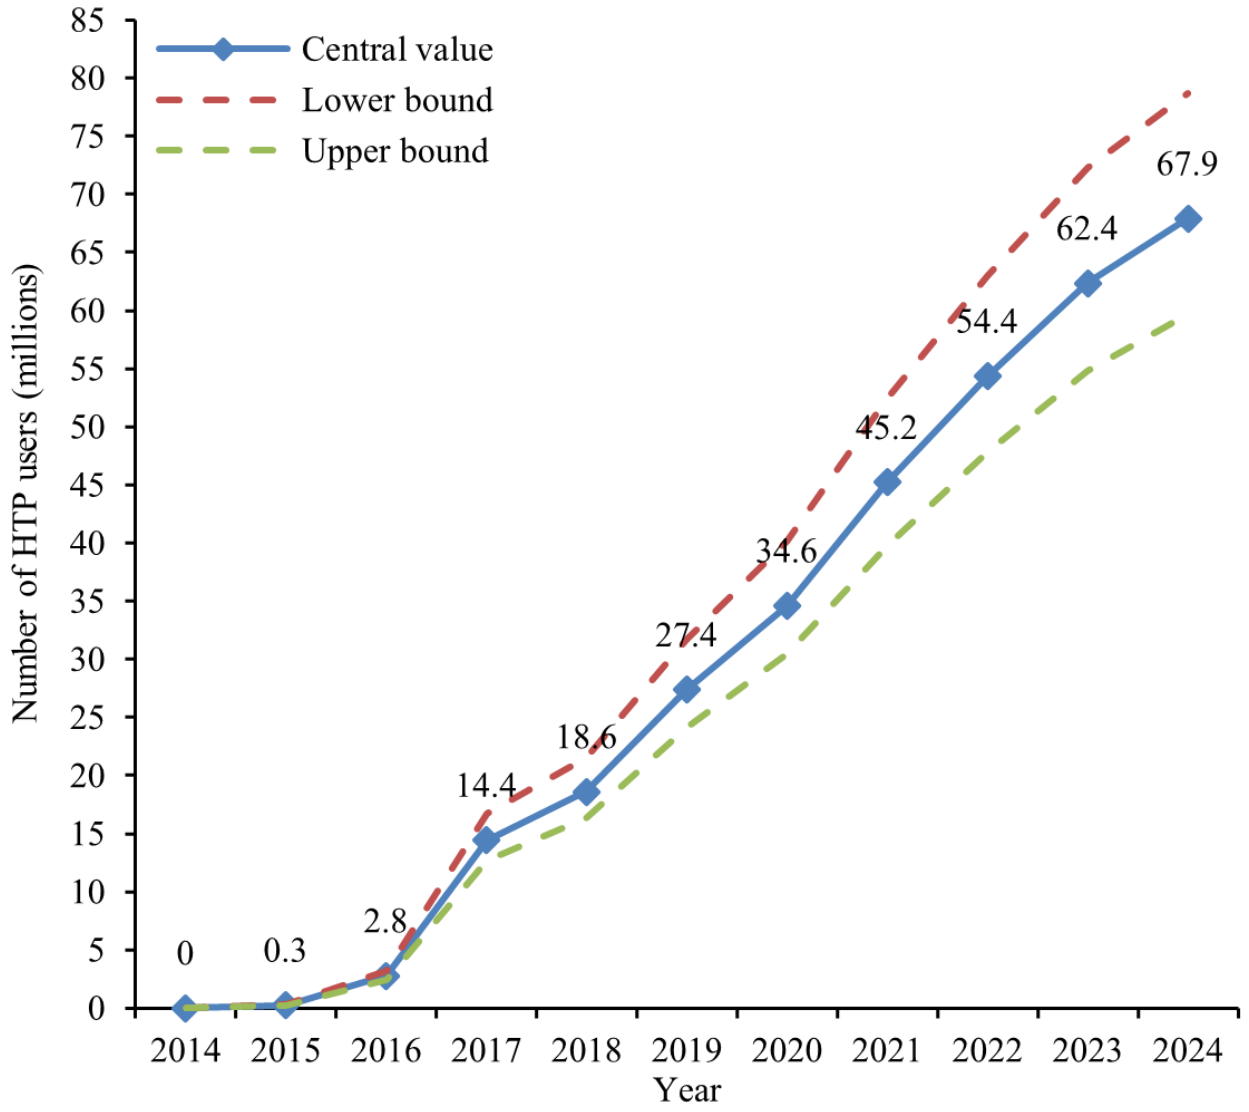
**Figure 3.** Estimated global HTP users by manufacturer, 2014 - 2024—primary disclosure-based series. IQOS, lil, glo, and Ploom are heated tobacco brand names. BAT: British American Tobacco; HTP: heated tobacco product; JT: Japan Tobacco; KT&G: Korea Tobacco & Ginseng Corporation; PMI: Philip Morris International.



### Alternative Time Series: Shipment-Only Conversions Using Literature-Based Consumption

Applying a uniform 7.3 (95% CI 6.33 - 8.27) sticks per day, consumption assumption to all firms' shipment volumes yields a consistently higher series, reflecting the more conservative daily consumption assumption and the removal of unclear company user definitions (Figure 4). In 2024, this approach produces an estimated 67.9 million users (range 59.7 - 78.7 million). The wider uncertainty interval compared with the primary series is expected, because all company-years are derived from shipment conversions, and none are anchored by directly reported user counts. Despite higher absolute levels, the trajectory closely mirrors the primary series.

**Figure 4.** Global number of HTP users, 2014 - 2024—alternative shipment-only time series using literature-based consumption assumptions. Alternative series converting all manufacturer stick shipments to user estimates using a uniform 7.3 sticks per day assumption (95% CI 6.33 - 8.27). Dashed lines indicate lower and upper bounds. HTP: heated tobacco product.

### Estimation Using National Survey Prevalence

Nationally representative prevalence data yielded an estimated 21.8 million HTP users across 35 countries (Table 2). The largest numbers were observed in Japan (10.6 million in 2023), South Korea (2.6 million in 2022), Italy (2.1 million in 2023), Ukraine (1.0 million in 2023), and Germany (0.7 million in 2023). These 5 countries accounted for 78.5% (17.1 million) of the survey-based total. Most available surveys were conducted in 2022 or 2023, with some dating to 2019 - 2021 and only 1 in 2025, meaning that they may not capture more recent market expansion. The survey-based total of 21.8 million users across 35 countries is substantially lower than the disclosure-based estimates for the same period. Given partial geographic coverage, this should be interpreted as a conservative lower bound, rather than an alternative estimate of the global total.

## Discussion

### Principal Findings

This study addressed 3 research questions. First, using publicly available manufacturer disclosures combined with explicit shipment-to-user conversions where required, we constructed an annual global time series of HTP user estimates for 2014 - 2024. The primary series indicates that global HTP users increased from negligible levels to 48.9 million in 2024 (range 45.6 - 52.1 million).

Second, when all shipment volumes were converted using a standardized literature-based consumption parameter, the shipment-only sensitivity series yielded higher 2024 totals (67.9 million; range 59.7 - 78.7 million) but preserved a similar growth trajectory. This upward shift is expected because the shipment-only approach imposes a uniform consumption conversion factor and removes manufacturer-specific user definitions, some of which may reflect partial use, different reference periods, or varying inclusion rules.

XSL•FO
RenderX

Across both disclosure-based series, the direction and magnitude of growth since 2014 were consistent: near 0 user numbers in early launch years, accelerated expansion after 2016, and sustained increases through 2024. While absolute totals varied depending on conversion assumptions and reporting definitions, the upward trajectory was robust across estimation strategies.

Third, survey-derived user counts based on nationally representative prevalence data in 35 countries yielded a combined total of 21.8 million users. This estimate should be interpreted as a conservative lower bound rather than a competing global total. This estimate covers fewer than half of the countries where HTPs are legally available and relies on survey years that are mostly 2023 or earlier, before full expansion in some markets. Moreover, prevalence surveys vary in age frames, question wording, and whether they capture "current use" in a manner comparable across countries. These limitations restrict the survey series' ability to represent the full global market, but the estimates nonetheless provide an important external check for the disclosure-based totals and illustrate how incomplete surveillance coverage remains despite the rapid market expansion documented here.

These findings extend the existing literature on HTP adoption and surveillance. Prior work has primarily focused on country-specific prevalence, particularly in early-adopting markets such as Japan and South Korea, documenting rapid substitution dynamics and substantial category growth within a relatively short period [4-9,28,29,33]. Sun et al [4] synthesized 45 studies across 42 countries but identified adult current-use prevalence data for only 12 countries. More recently, Scala et al [5] conducted the most comprehensive systematic review to date, covering 76 studies published between 2015 and February 2022 and reporting current adult HTP prevalence from 34 countries based on surveys conducted prior to 2021.

Our survey-based analysis covers 35 countries and incorporates prevalence data from surveys conducted in years including 2025. The results align with prior reviews, which have documented that HTP use remains concentrated in certain markets. However, this approach demonstrates the structural limitation of prevalence-based aggregation when nationally representative data are available for only a subset of countries where HTPs are legally marketed.

Unlike prior syntheses based exclusively on survey data, the disclosure-based series presented here generates global totals that are not constrained by survey coverage, thereby addressing a key measurement gap in global HTP surveillance. Methodological precedent for combining survey and commercial data sources exists in the broader tobacco surveillance literature. A comparison of self-reported cigarette consumption from a national survey in England with retail sales data for 2011 - 2018 showed closely aligned trends, supporting the validity of combining survey-based and sales-based approaches to monitor population-level tobacco product dynamics [34].

As of 2025, HTPs are legally available in at least 72 countries, with uptake concentrated in early-adopting and predominantly higher-income markets [10]. Consequently, global estimates must be interpreted in this context. Although tens of millions of HTP users remain small relative to the 1 billion global population of people who smoke cigarettes [35], HTPs can capture substantial shares of the tobacco market within countries where they are widely available. For example, HTPs represented 48.5% of PMI's combined cigarette and HTP market in Japan, 31.8% in Hungary, 28.7% in Lithuania, and 23.9% in Greece, according to company disclosures from the third quarter of 2025 [36].

From a public health perspective, the implications of HTP growth depend on behavioral transitions rather than uptake alone. A decision-theoretic framework indicates that population-level benefits are most plausible when HTP uptake substitutes for cigarette smoking among adults who would otherwise continue to smoke, whereas dual use or uptake among never-smokers may reduce or negate potential benefits [37]. The evidence base summarized in recent reviews remains mixed and is shaped by heterogeneity in study designs and regulatory contexts. The Cochrane review concluded that evidence for HTP as cessation tools remains limited relative to other interventions and highlighted substantial uncertainty [38]. Scala et al [5] emphasized variability in dual use and switching patterns, indicating that aggregate uptake alone does not resolve whether an increase in HTP use represents displacement of cigarette smoking or supplementation. Evidence from Japan suggests partial displacement of cigarette sales after HTP introduction, while also showing heterogeneity in exclusive use versus dual use across survey designs and population subgroups [7,8,27,33]. These findings reinforce that the key policy question is not simply how many people use HTP, but how HTP uptake changes cigarette smoking trajectories over time.

## Strengths

This study has several strengths. First, it relies exclusively on publicly verifiable data sources and documents extraction, harmonization, and revision procedures, enhancing transparency and reproducibility. Second, the dual-series approach (combining a primary disclosure-based series with an alternative shipment-only sensitivity) allows readers to assess how estimation choices affect results and provides bounded rather than single-point estimates. Third, all data sources, assumptions, and conversion formulas are fully documented, enabling independent replication and updating as new disclosures become available. Finally, the analysis covers the full commercially relevant period for HTP (2014 - 2024) and all manufacturers operating at a material global scale, providing comprehensive market coverage.

## Limitations

This study has several limitations that should be considered when interpreting the findings. First, the estimates presented here are derived from secondary data sources rather than from a single harmonized global survey. Manufacturer-reported user counts and shipment volumes were used because nationally representative HTP prevalence data remain unavailable for most countries. Although these disclosures are among the few consistently updated global sources, they may differ in definitions, reporting granularity, and geographic aggregation across firms and over time. Listed firms face strong incentives for accuracy: disclosures are governed by securities laws, audited or reviewed through established internal controls, and

XSL•FO
RenderX

subject to penalties for material misstatement, while reputational and investor-relations risks further discourage misreporting. However, these safeguards do not eliminate error or definitional ambiguity, and they reduce the likelihood of systematic overstatement.

Second, where shipment volumes were converted into user estimates, the analysis relied on explicit assumptions regarding average daily consumption of HTP sticks per user. While these assumptions were transparently documented and subjected to sensitivity analysis, true consumption patterns may vary across countries, over time, and by user characteristics. As a result, the estimates should be interpreted as approximations rather than precise counts.

Third, the presence of illicit or gray-market distribution may affect the allocation of HTP use at the country level, particularly in jurisdictions where HTP sales are restricted or prohibited. However, HTPs are manufactured by a small number of multinational firms, and HTP consumables are technologically standardized and brand-locked, creating substantial barriers to informal or counterfeit production [16]. Consequently, most HTP sticks consumed globally are produced by these firms and are captured in shipment-based disclosures at the point of manufacture and are therefore included in the estimates presented here.

Fourth, the study does not distinguish between exclusive HTP use and dual use with cigarettes. Manufacturer disclosures and most national surveys do not provide information to allow consistent differentiation of these patterns. As a result, the estimates quantify the number of people using HTP but do not directly inform whether HTP uptake represents substitution for cigarette smoking or supplementation alongside continued smoking.

### Scope

The scope of this study is the global population of HTP users as estimated from manufacturer disclosures and a subset of national surveys. The estimates apply to the period 2014‐2024 and to the 4 major HTP manufacturers. They are most informative for understanding the scale and growth of the HTP category in a global market characterized by concentration among a small number of multinational manufacturers. They are less informative for geographic allocation, intensity of use distributions, or product-specific switching dynamics. Generalizability to country-level prevalence trends is therefore limited and depends on the extent to which manufacturer-reported volumes reflect geographically diverse consumption patterns.

The survey-based series is limited to 35 countries with available nationally representative prevalence data, representing fewer than half of the countries where HTPs are legally sold.

### Recommendations for Future Research

Several directions for future research emerge from this analysis. First, as national surveys increasingly incorporate standardized HTP measures, researchers should validate disclosure-based estimates against survey-derived counts at the country level to calibrate conversion assumptions and assess the reliability of manufacturer-reported user definitions. Second, future studies should link HTP uptake estimates with longitudinal data on behavioral transitions (switching, dual use, relapse, and initiation), as aggregate uptake alone does not resolve the key policy question of whether HTP growth displaces or supplements cigarette smoking. Third, the estimation framework introduced here could be extended to incorporate subnational data and to distinguish exclusive HTP use from concurrent cigarette smoking where data permit. Fourth, as additional consumption data become available from diverse markets, the brand-specific and literature-based sticks-per-day assumptions used in this study should be updated and validated against observed use patterns in a wider range of regulatory and cultural contexts.

### Significance

This study contributes to the tobacco and nicotine surveillance literature by providing a reproducible global time series of HTP users, offering population estimates that are currently missing from the evidence base and that are required for epidemiologic modeling, burden-of-disease estimation, and regulatory and fiscal evaluation. The transparent methodology and publicly available data sources enable regular updating as new disclosures become available, supporting ongoing monitoring of the evolving global nicotine product landscape. By generating bounded estimates across multiple approaches, this work provides a more complete empirical foundation for interpreting shifts in nicotine consumption patterns and for informing evidence-based tobacco policy at the global level. Overall, this work complements, rather than replaces, survey-based epidemiology and helps bridge the measurement gap until national surveillance systems expand and standardize HTP measures sufficiently to produce harmonized global estimates.

## Conclusions

This study provides a transparent and replicable global time series estimate of HTP use from 2014 to 2024, addressing a notable gap in international tobacco and nicotine surveillance. Depending on the estimation approach, global HTP user totals in 2024 range from 45.6 to 78.7 million users in the disclosure-based series, with survey-based estimates across 35 countries providing a conservative lower bound of 21.8 million. Across all approaches, the direction and timing of growth are consistent, indicating rapid and sustained expansion of HTP use over the past decade. The analysis documents the scale and trajectory of this growth and provides essential population denominators for interpreting market transitions, supporting epidemiologic modeling, and informing regulatory and fiscal policy.

## Acknowledgments

The authors disclose that the artificial intelligence chatbot ChatGPT was used solely for language editing purposes in the preparation of this manuscript. The model was not used for data analysis, data interpretation, or content generation. All intellectual content, analysis, and conclusions are of the authors, and they take full responsibility for the integrity and accuracy of the work.

## Funding

This study was funded within a grant from Global Action to End Smoking (formerly known as the Foundation for a Smoke-Free World), an independent US nonprofit 501(c)(3) grantmaking organization. The funder had no role in the conception, design, implementation, data analysis, interpretation of the study results, or preparation of this manuscript.

## Data Availability

All data generated or analyzed during this study are included in this published paper and its supplementary materials. Manufacturer-reported user counts and heated tobacco stick shipment volumes were extracted from publicly available corporate disclosures (annual reports, investor presentations, and regulatory filings) accessible through the investor relations sections of the respective companies' websites [18-22]. The survey-based prevalence inputs and corresponding derived user counts are provided in Table 2.

## Authors' Contributions

GM contributed to the conceptualization, data collection, data analysis, and drafting of the manuscript. GVS and TJ contributed to the conceptualization of the study. All authors read and approved the final manuscript.

## Conflicts of Interest

GM works as an independent consultant on various research projects undertaken by multiple research institutions and nongovernmental organizations (NGOs). At the time this research was conducted, the author had a service agreement as a data scientist with Knowledge-Action-Change (KAC), a UK-based private organization that focuses on harm reduction as a key public health strategy. In parallel, the author has a service agreement with the Ukraine-based NGO Healthy Initiatives as an economist. Healthy Initiatives is a nonprofit organization aimed at promoting and strengthening public health and well-being, tackling the most urgent questions in need of an answer. The organization supports and implements projects in Eastern Europe and Central Asia to address the growing risks of noncommunicable diseases. Both organizations receive grants from Global Action to End Smoking. Global Action to End Smoking, formerly known as Foundation for a Smoke-Free World, is an independent, US nonprofit 501(c)(3) grantmaking organization accelerating science-based efforts worldwide to end the smoking epidemic. Its mission is to end combustible tobacco use, which remains the leading preventable cause of death globally. The organization collaborates with academic and research centers and others to accelerate life-saving research and educational projects. Global Action does not seek or accept funding from companies that produce tobacco or nonmedicinal nicotine products. The charitable gift agreement (the "Pledge Agreement") between the organization and its prior funder, PMI Global Services Inc, was terminated in September 2023. To complement the termination of the Pledge Agreement, the organization's board of directors established a new policy to not accept or seek any tobacco or nonmedicinal nicotine industry funding. Global Action to End Smoking's Certificate of Incorporation states that Global Action was formed to, among other things, "support independent scientific research free from the influence of any commercial entity that may be affected by the research outcome." Global Action's organizational documents, including the Certificate of Incorporation and bylaws, are publicly available on its website and fully disclosed in public materials. TJ works as a researcher, sociologist, and data scientist at The Robert Zajonc Institute for Social Studies, University of Warsaw, Poland. At the time this research was conducted, the author had a service agreement as a data scientist with KAC. GVS has been a consultant to KAC since 2023. He was a founder of KAC and director from 2011 until 2022. He was a principal grant holder for grants from the Foundation for a Smoke-Free World (subsequently named Global Action to End Smoking) from 2018 until 2023. The statements above apply regarding the Foundation for a Smoke-Free World and Global Action to End Smoking. He is a shareholder in the Global Forum on Nicotine Ltd, which holds events on nicotine. Authors declare no other financial or nonfinancial competing interests in the past 36 months. This study was conducted as part of the authors' collaboration with KAC.

## Abstract

**Background:** In South Korea, where plain packaging has not been adopted, tobacco packaging continues to function as a key marketing tool for the tobacco industry, using texts, colors, and imagery to attract consumers. Among these, flavor cues are especially important as they enhance product appeal. Cigarette sticks also serve marketing functions through design features such as colors and capsule indicators.

**Objective:** This study aimed to examine flavor-related cues on cigarettes and heated tobacco products (HTPs) packaging and stick design and to assess the presence of flavor additives in these products.

**Methods:** This surveillance study was conducted in November 2024. Tobacco products were purchased from convenience stores located in Seoul, supplemented by cross-referencing with national market monitoring data. Of 353 identified products, 214 products (150 cigarettes and 64 HTPs) were collected. Flavor cues were categorized by pack and stick design features, and additives were identified through sensory analysis of product components.

**Results:** Among the collected products, 63.1% (54% for cigarettes and 84.4% for HTPs) had both flavor cues and flavor additives, while 20.6% (27.3% for cigarettes and 4.7% for HTPs) had neither. Flavor cues were found in 67.3% of cigarettes and 95.3% of HTPs ($P$<.001), and flavor additives in 59.3% of cigarettes and 84.4% of HTPs ($P$<.001). Pack color was the most common cue, and additives were most often delivered through crushable capsules. HTPs used a wider range of flavoring methods, including flavoring in tobacco leaves and inner wrappers.

**Conclusions:** Tobacco packaging and stick design in South Korea remain important marketing tools for the tobacco industry. Flavor cues and additives are widely used in tobacco products, particularly in HTPs. These findings highlight the need for plain packaging policies and bans on flavor additives in tobacco products.

cigarettes; heated tobacco products; packaging; flavor cues; flavor additives; regulation

## Introduction

Tobacco packaging is the first element of the product that people encounter, and it functions as a key marketing tool for the tobacco industry [1], particularly in settings where plain packaging has not been implemented [2]. Packaging elements such as color, imagery, and text can evoke positive perceptions and stimulate tobacco use, particularly among youth and individuals who have quit smoking [3-6]. Accordingly, Article 11 of the Framework Convention on Tobacco Control (FCTC) emphasizes strict regulation of promotional features on tobacco packs and labels [7], and several countries have adopted plain packaging and enlarged health warnings to reduce product appeal [8]. These measures have also been extended to cigarette sticks, restricting the use of stick appearance as a marketing tool [9]. Experimental evidence shows that unattractive stick

XSL•FO
RenderX

colors or warning messages on sticks significantly reduce appeal and purchase intentions, suggesting that plain packaging should extend beyond packs to include sticks [9,10].

Flavor-related experiences are frequently communicated through tobacco packaging using contextual and visual cues [11-15]. In settings without plain packaging, manufacturers use concept descriptors (eg, “Ice” and “Blue”) in combination with color schemes to signal taste and sensation without explicitly naming a characterizing flavor [12,16]. These cues shape consumer perceptions, and products with flavor cues are often perceived as more appealing, better tasting, and smoother than nonflavored or standardized variants [13]. This sensation transfer reduces perceived harshness and creates a health halo that leads consumers, especially youth and young adults, to perceive these products as less harmful [11,14].

To effectively implement and evaluate packaging regulations, systematic surveillance of tobacco packs is crucial. Much of the evidence base for assessing tobacco packaging has been shaped by the Tobacco Pack Surveillance System (TPackSS), developed by the Institute for Global Tobacco Control [11,12,17]. These studies demonstrate how systematic observation can identify flavor cues and other tactics used to enhance product appeal, providing evidence to support stronger regulations [11,12,17]. Recent pack surveillance in the Philippines showed that nearly 60% of tobacco products had explicit flavor cues, often reinforced by imagery, highlighting the persistent appeal of flavored products in the absence of regulation [11].

Building on this evidence, systematic surveillance is particularly important for addressing flavored tobacco products. This aligns with the recommendations of Articles 9 and 10 of the FCTC, which emphasize the need to monitor and regulate product contents, including flavoring [18]. Flavored tobacco products mask the harshness of nicotine and attract youth, women, and racial and ethnic minority groups [19-22]. They make tobacco use more appealing, increase nicotine dependence, and undermine quitting [21,23]. In response to this evidence, an increasing number of countries have banned flavored cigarettes [24]. However, most surveillance studies have primarily focused on cigarettes, with limited assessment of flavor cues in heated tobacco products (HTPs).

In South Korea (hereafter referred to as Korea), this issue has become particularly pressing. Following 3 decades of decline, smoking prevalence rebounded to 19.6% among adults in 2023. Although it declined to 16.7% in 2024, it remains high (28.5% among men and 4.2% among women) [25]. This trend has coincided with increased sales of flavored tobacco products, driven predominantly by flavor capsule cigarettes and HTPs [26]. In 2023, 1.68 billion packs of flavored cigarettes and HTPs were sold, accounting for 46.5% of total tobacco sales (3.61 billion packs). This marks an increase from 270 million packs (6.1%) in 2011 and 860 million packs (24.4%) in 2017 [26].

Despite the rapidly increasing sales of flavored cigarettes and HTPs, Korea still lacks comprehensive regulatory measures addressing flavor-related marketing. Although flavored tobacco products remain legal to manufacture and sell, Article 9 - 3 of the National Health Promotion Act (NHPA) prohibits the use of explicit text or imagery indicating flavors on tobacco packaging [27]. However, enforcement has been limited. Indirect flavor cues are also not regulated, allowing manufacturers to imply flavors through concept descriptors, colors, and other design elements [27].

In addition, while the NHPA mandates health warnings covering at least 50% of the main surfaces, with pictorial warnings accounting for at least 30% [27], Korea has not adopted plain packaging, despite its inclusion in the 2019 Tobacco Control Plan [28]. Other measures outlined in the Plan, such as a ban on flavored additives, also remain unimplemented. Moreover, there is no display ban at retail points of sale, and tobacco packs are predominantly showcased on power walls [27]. Together, these gaps leave visitors to approximately 140,000 tobacco retailers (primarily convenience stores and supermarkets) [29] continuously exposed to tobacco marketing, thereby increasing product appeal and the likelihood of tobacco use, particularly among youth [1,4,5].

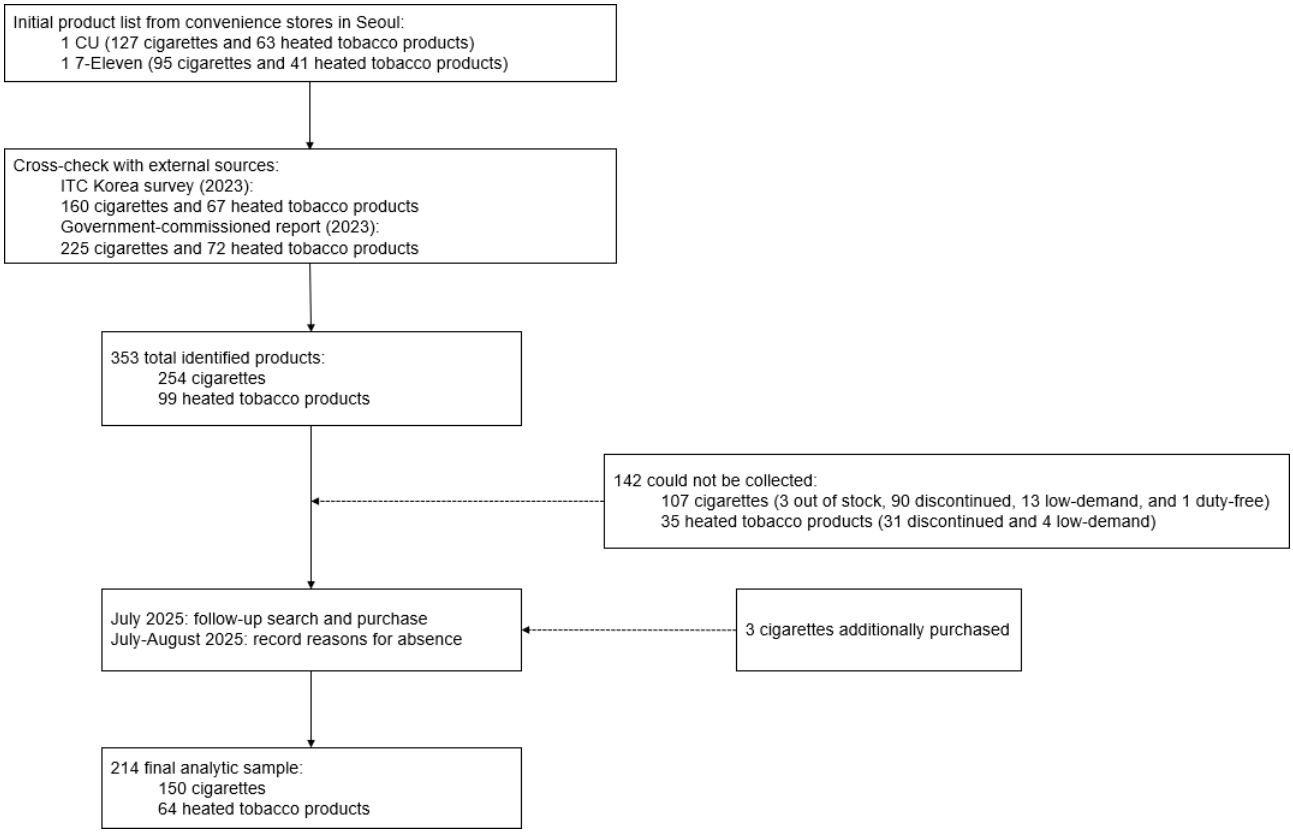
In this study, we conducted a systematic assessment of cigarettes and HTPs sold in Korea, examining pack- and stick-level flavor cues as well as flavor additives at the component level. By combining pack- and stick-level surveillance with component-based sensory screening, we address a key gap in the literature on how flavor marketing cues align with flavoring and how these patterns differ between cigarettes and HTPs. We aimed to generate evidence to inform regulation and strengthen surveillance in Korea and internationally.

## Methods

### Study Design

To assess the packaging of cigarettes and HTPs sold in Korea, we used a market-based purposive sampling strategy designed to capture the diversity of unique brands and pack variants available on the market, rather than to estimate sales volume or market share [17]. Our pack documentation and photography procedures were informed by the TPackSS protocol [17], and we coded pack-level flavor cues such as descriptors, imagery, and capsules based on prior pack surveillance research [11,12]. Furthermore, drawing on prior studies [30-32], we developed an exploratory protocol to cut open individual cigarettes and HTP sticks (hereafter referred to as sticks) to examine internal flavor-related features. We also documented external flavor cues, including capsule indicators on sticks, before disassembly.

### Sample



The product identification process involved four steps: (1) compiling an initial product list, (2) purchasing available products, (3) cross-referencing with external data sources, and (4) investigating reasons for unavailable products (Figure 1). To construct an initial product list, we visited 1 retail store from each of the 2 major convenience store chains in Seoul (CU and 7-Eleven) in November 2024 to collect all available tobacco products. We focused exclusively on convenience stores because they represent the predominant retail channel for tobacco sales in South Korea [29]. Among these, CU and 7-Eleven were selected due to their market dominance; together, they account for 56.3% of all convenience stores nationwide [33]. Within

XSL•FO
RenderX

each chain, 1 store in Seoul was selected based on geographic proximity to the research team. Observational checks at additional outlets suggested that product availability was comparable across stores.

**Figure 1.** Product identification and inclusion flow.

All tobacco products available in the visited stores were purchased, including all unique retail pack variants available at the point of sale. The initial list of purchased products was cross-checked against 2 external sources: the Wave 3 (2023) International Tobacco Control Korea Survey [34], which listed 160 cigarettes and 67 HTP brands, and a government-commissioned tobacco product market report [35], which identified 225 cigarettes and 72 HTP products purchased from 46 convenience stores nationwide in October 2023.

Products missing from the initial list (142 products: 107 cigarettes and 35 HTPs) were assessed using external sources to determine their market status. Products were classified as discontinued or low-demand based on Euromonitor reports (market share <0.3%) [26] and corroborating evidence from news articles and websites describing products as "discontinued," "low-demand," or "unpopular." Duty-free exclusive products were verified through media reports. Among missing cigarettes, 90 (84.1%) were discontinued, 13 (12.1%) were not stocked due to low-demand, 3 (2.8%) were out of stock at the time of purchase, and 1 (0.9%) was duty-free exclusive and therefore excluded. Among missing HTPs, 31 (88.6%) were discontinued, and 4 (11.4%) were not stocked due to low demand.

Products not classified as discontinued, low-demand, or duty-free exclusives were subsequently sought through additional visits in July 2025, resulting in the collection of 3 additional packs. In total, 254 cigarettes and 99 HTPs were identified across all sources, of which 104 (40.9%) cigarettes and 35 (35.3%) HTPs were not collected. Reasons for noncollection are documented in Tables S1 and S2 in Multimedia Appendix 1.

## Coding Procedure and Measures

### *Overview*

After collection, we extracted and coded relevant information based on the assessment guidelines. HK developed a draft codebook, informed by previous pack- and stick-level assessment frameworks, to capture flavoring components in cigarettes and HTPs [11,12,17,32]. The codebook was reviewed and refined by SK and Susan Park. The final codebook included predefined variables with fixed response options and illustrative examples (where applicable).

Three coding teams (team 1: GH, YK, and NC; team 2: DK, AK, and JP; and team 3: EC and NK) assessed the products, with each product coded by 1 team. Each team consisted of 2 or 3 coders who jointly reviewed each product and recorded a single consensus code. Unresolved cases were cross-checked by another team. For data quality control, the final dataset was checked for internal consistency (logical validity across variables) and missingness. As coding was consensus-based and only final codes were retained, intercoder reliability statistics were not calculated. All coding was conducted collaboratively using a shared online spreadsheet.

XSL•FO
RenderX

### *Visual Measures*

Visual measures captured visible pack [11,12,36] and stick features. Packs were measured for size and photographed before and after opening using the TPackSS photography protocol [17], and sticks were measured and photographed using a study-developed protocol (Figures S1 and S2 in Multimedia Appendix 1). Coding was conducted using photographs alongside direct inspection of the physical packs [17] and sticks.

We recorded whether tar and nicotine yields were displayed on the exterior of the cigarette package. Compliance with mandated health warnings was assessed by checking their presence and placement in accordance with national regulatory requirements [37]. Pack shape was coded based on the overall external form of the package. Marketing text was coded as text promoting product features or technological attributes, excluding legally required warnings.

Pack-level flavor cues were identified across 5 elements (Figure S3 in Multimedia Appendix 1): product name, pack color, capsule imagery, pack imagery, and other features [11]. Stick-level flavor cues were additionally coded based on the presence of capsule imagery. Coders were not blinded to brand names or pack descriptors and marketing language, because the study aimed to document consumer-facing packaging cues.

### *Flavor Cue Coding*

Flavor cues were coded using a 2-step approach. First, coders recorded the presence or absence of a cue across the 5 pack elements. Second, for cued elements, coders assigned a predefined descriptive category (eg, product name: “cool or minty,” “color,” “flavor,” “functional,” and “others”) to document how the cue was communicated. Thus, the primary quantitative measure was the binary presence or absence of each cue element, while descriptive labels were used to characterize how cues were expressed across products.

Product names were coded as flavor cues when they contained semantic or lexical descriptors implying a specific flavor(“eg, “Raison Ice Presso”), color-associated sensation (eg, “Mevius Mix Green”), or sensory experience (eg, coolness or sweetness), rather than functioning solely as brand or variant names (eg, “Esse Prime”). This distinction clarified that “cool or minty” terms represented perceived freshness rather than literal colors (eg, aqua, cool shot, and ice). Within the product name category, “cool or minty” cues were treated as a distinct subgroup given the particularly prominent impact on perceptions of reduced sensory harshness and greater appeal [38].

Pack color and capsule imagery were coded by dominant color tones on the principal display panel and grouped into 4 sensory color groups: cool or minty, fruity, nutty, and others [11,12,16,39]. Previous experimental research has shown that the appeal and interpretation of pack color and capsule imagery may vary across flavor contexts, including fruity, nutty, and cool or minty categories, supporting the use of descriptive sensory groupings in packaging research [4,40]. Dominant color was defined as the most visually prominent color on the principal display panel, and only colors corresponding to flavor-related conventions reported in prior tobacco packaging research [4,16,41] were coded as flavor cues. These groupings descriptively captured packaging conventions in which color signals expected sensations [4]. More broadly, evidence on crossmodal correspondences shows that package color can shape flavor and sensory perceptions even without explicit flavor descriptors [42].

Additionally, we coded animal imagery as implicit flavor cues. Animal imagery (eg, penguins and polar bears) was included because such visuals function as established metaphors for coolness or freshness in tobacco marketing [43]. The “Others” category included textual statements promoting a cool or minty sensation (eg, Cuban coolness inside) or presence of flavor (eg, max flavor), which were evaluated as presented on the packs without interpretive modification. The complete coding framework with detailed criteria is presented in Table 1 and Figure S4 in Multimedia Appendix 1.

[a]Only applicable for continuous data.

[b]Not available.

[c]All prices and currency values are reported in Korean won (KRW). The exchange rate as of November 2024 was approximately 1390 KRW to US $1.

[d]Not applicable for heated tobacco products.

[e]Flavor descriptors on tobacco packaging were coded based on prior tobacco packaging studies that typically distinguished menthol or mint, fruit or citrus, beverage, concept or functional, and other descriptors. Consistent with these studies, the further subdivision of flavor cue elements (eg, classifying blue and green as indicators of cool or minty) was informed by and closely aligned with prior studies.

[f]Only applicable for heated tobacco products.

For the stick-level flavor cue, we assessed the presence of capsule imagery on the stick surface. As illustrated in Figure S5 in Multimedia Appendix 1, capsule imagery was defined as a circular symbol resembling a crushable capsule printed on the stick. When present, it was classified using the same 4 color groups applied to pack color cues (ie, cool or minty, fruity, nutty, and others), based on the dominant color tone of the capsule symbol.

### *Sensory Measures*

Sensory measures were collected to detect flavor additives and identify their location within the product. Orthonasal smelling [30], a validated method for detecting flavors through direct olfactory perception without inhalation [30,31], was used as a pragmatic screening method to detect the presence or absence of a perceptible nontobacco odor. This aligns with the definition of a “characterizing flavor” as a clearly noticeable smell or taste before or during consumption [44].

Using orthonasal smelling, each cigarette and HTP was assessed across 7 common components: inner wrapper, cigarette wrapper, tobacco leaves, crushable capsule, cellulose filter, charcoal filter, and others (eg, flavor card) [32]. For HTPs, 2 additional components (polylactic acid filter and hollow tube) were included [45]. Sticks were disassembled, and each component was evaluated separately. When the same odor was detectable in multiple components, the component with the strongest odor was recorded as the primary source. Because orthonasal smelling of tobacco products, even when unlit, may still involve minor sensory irritation or discomfort, all assessments were conducted in a ventilated room to minimize potential irritation and maintain olfactory sensitivity [46]. Coders also took breaks as needed to minimize olfactory fatigue and carryover effects before finalizing their judgments.

## Analysis

Descriptive analyses and data tabulation were conducted using Microsoft Excel. All characteristics were assessed according to tobacco product type (cigarettes vs HTPs). Categorical variables were presented as frequencies and percentages, while continuous variables were summarized using the minimum, median, mean, and maximum values. Continuous variables were additionally

XSL•FO
RenderX

categorized, where applicable, to facilitate comparisons. Differences between cigarettes and HTPs were examined using chi-square tests in SAS (version 9.4; SAS Institute Inc), with a 2-sided significance level of $P<.05$. For variables with sparse expected cell counts (n<5), Fisher exact tests were used instead. For flavoring components, which allowed multiple responses, each component was treated as a binary variable (present vs absent). Proportional differences between cigarettes and HTPs were evaluated using separate chi-square tests.

### Ethical Considerations

This study did not involve human participants or animals. The data were collected from publicly available commercial tobacco products. Therefore, ethics approval was not required and was not sought.

## Results

### Sample General Characteristics

A total of 214 tobacco products were included in the final analytic sample, comprising 150 cigarettes and 64 HTPs. The descriptive characteristics of the collected products are provided in Table 2 and Table S3 in Multimedia Appendix 1. More than half of cigarettes (50%) and HTPs (51.6%) were manufactured by KT&G. The average tar and nicotine contents displayed on cigarette packs were 2.70 mg (range 0.1 - 8.0 mg) and 0.24 mg (range: 0.01 - 0.7 mg), respectively. The display of these contents is not mandatory for HTPs, and none of the HTP packs included them. All products complied with mandated health warnings.

[a]*P* values were obtained from chi-square tests comparing the distribution of characteristics between cigarettes and heated tobacco products.

[b]All prices and currency values are reported in Korean won (KRW). The exchange rate as of November 2024 was approximately 1390 KRW to US $1.

[c]The *P* value was calculated using the Fisher exact test.

[d]None of the heated tobacco product packs displayed nicotine or tar content.

[e]NA: not applicable.

[f]Marketing text includes “activated carbon filter,” “nano capsule technology,” and “smartcore induction system,” among others.

The main differences between cigarettes and HTPs were pack size (*P*<.001) and shape (*P*<.001) (Figure S6 in Multimedia Appendix 1). Cigarette sticks were longer, resulting in taller, vertically oriented rectangular packs with variation in depth. HTP packs were shorter, reflecting the shorter stick length, and had a consistent, landscape-oriented rectangular shape.

Although no distinct qualitative differences in promotional elements were observed between cigarettes and HTPs, a higher proportion of cigarette packs (68.7%) included marketing texts (*P*=.030) compared with HTPs (53.1%). Most of these statements highlighted hand and mouth odor reduction technology. For example, texts such as “activated carbon filter,” “nano capsule technology,” and “smartcore induction system” were frequently displayed, serving as marketing claims to emphasize the companies’ technological capabilities.

## Flavor Cue

The distribution of flavor cues on packaging is summarized in Table 3. Among the 5 components of pack-level flavor cues, pack color was the most common, appearing on 97 (64.7%) cigarettes and 61 (95.3%) HTPs (*P*<.001). Within pack color cues, cool or minty shades (blue, green, and sky blue) were most frequent, followed by fruity (red, pink, and orange), nutty (brown, dark brown, and yellow), and others (dark green and purple). The second most frequent cues varied by product type, but product names and capsule images were frequently used in both. Product names often implied coolness, such as “aqua,” “cool shot,” “frozen,” and “ice.” Capsule images, typically placed on the front of the pack, signaled flavor through colors associated with specific tastes. For example, blue tones for menthol or ice and red tones for cherry or berry. Pack imagery was less frequently used but featured cool- or minty-related images such as animals (eg, penguins) or natural scenes (eg, glaciers), reinforcing coolness, and other cues included promotional terms such as “double capsule” and “refreshing scent.” In addition, capsule imagery on the stick was observed in 71 (47.3%) cigarettes and 37 (57.8%) HTPs (*P*=.16). Among products with capsule imagery, cigarettes were predominantly cool or minty (59.2%), whereas HTPs were more evenly distributed across cool or minty (27%), fruity (29.7%), and other categories (27%).

[a]Total count of all flavor cues identified on the pack.

[b]*P* values were calculated using the Fisher exact test where applicable.

[c]Percentages may sum to more than 100% because categories are not mutually exclusive; a single product may contain flavor additives in multiple components.

[d]Applicable only to heated tobacco products.

[e]Not applicable.

[f]Total count of components with detectable flavor additives among products.

[g]Percentages are calculated among products with crushable capsules.

[h]Total count of components with detectable flavor additives among products containing a crushable capsule combined with at least 1 additional flavoring method.

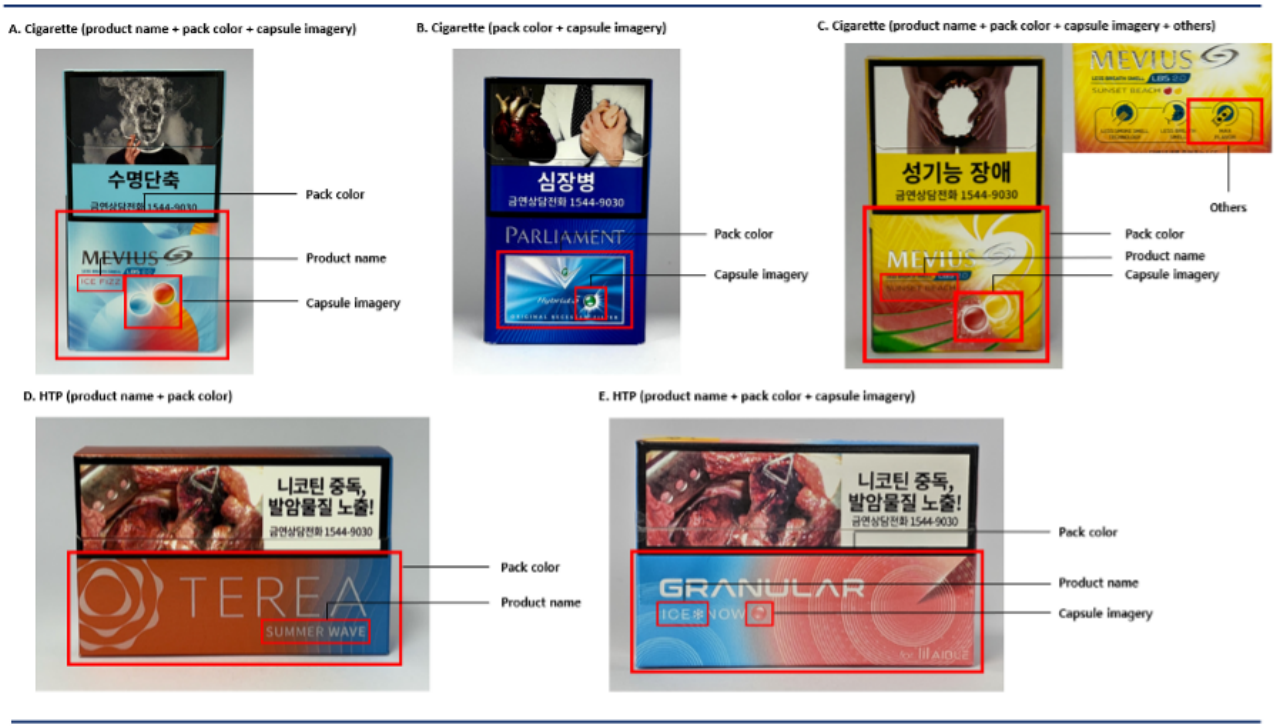

Figure 2 presents examples of flavor cue combinations by product. Overall, 101 (67.3%) cigarettes and 61 (95.3%) HTPs included at least 1 flavor cue (*P*<.001). For cigarettes, color and capsule images were commonly used together, with the most

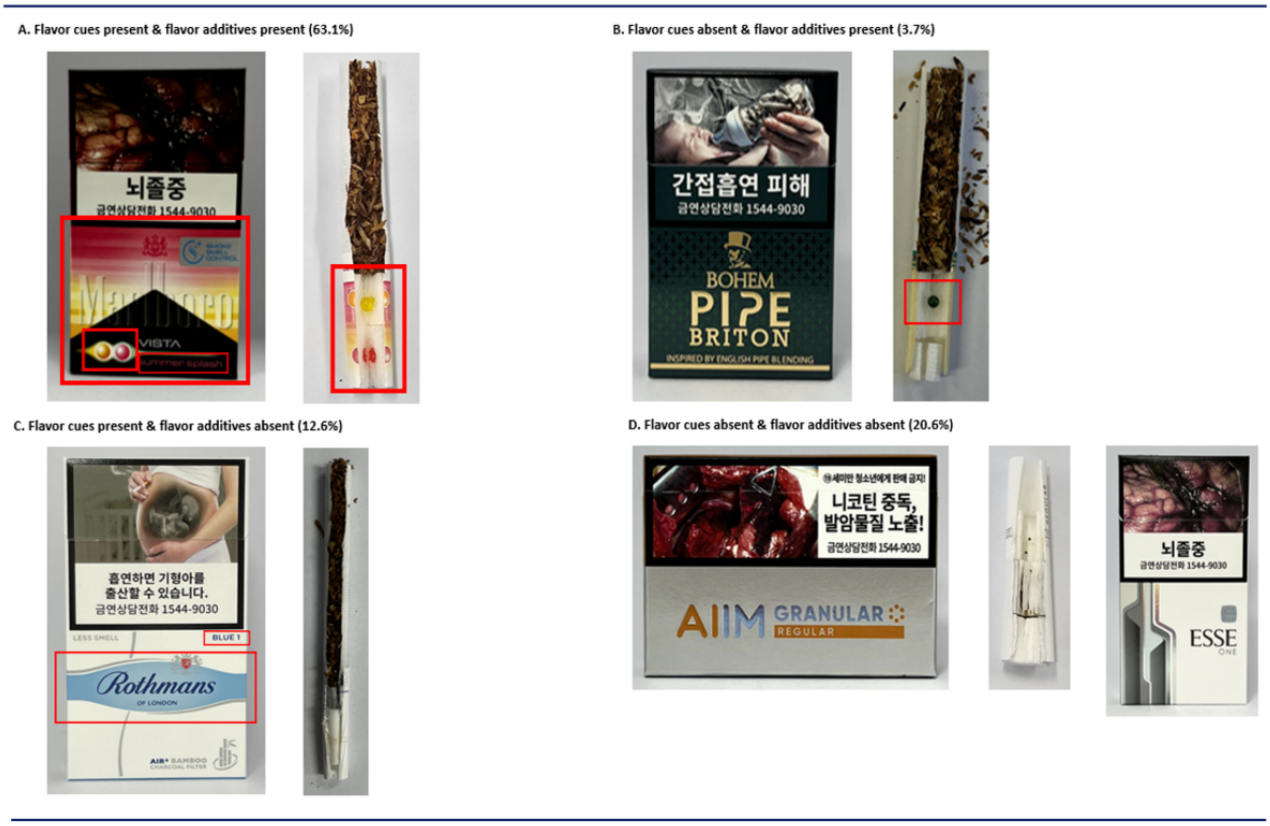
XSL•FO
RenderX

frequent combinations being “product name + color + capsule image” (11.3%; Figure 2A) and “color + capsule image” (10.7%; Figure 2B). All HTPs with flavor cues included pack color as one of the cue elements, often reinforced by additional cues such as product name and capsule imagery (Figures 2D and 2E).

**Figure 2.** Common combinations of flavor cues in cigarettes and heated tobacco products.

## Flavoring Method

Of the 214 products analyzed, 143 (66.8%) contained at least 1 flavoring component (Table 3). Flavoring was identified in 89 (59.3%) cigarettes and 54 (84.4%) HTPs ($P$<.001). Crushable capsules were the most common flavoring method in both cigarettes (48.7%) and HTPs (57.8%) ($P$=.22). In cigarettes, flavor additives were also found in cellulose filters (14.7%) and tobacco leaves (12%). In contrast, HTPs used a wider range of flavoring methods, including tobacco leaves (45.3%), cigarette wrappers (23.4%), and hollow tubes (23.4%).



Although up to 9 flavoring components (7 for cigarettes) were possible, both cigarettes and HTPs showed a maximum of 4 components per product. Overall, 25.4% of cigarettes and 54.7% of HTPs used 2 or more flavoring methods. Among products with crushable capsules, 54.8% of cigarettes and 45.9% of HTPs used capsules as the sole flavoring method. In both product types, up to 3 additional components were combined with capsules. Among capsule-containing products that used at least 1 additional flavoring component, the most common paired components were cellulose filters (51.5%) and tobacco leaves (39.4%) in cigarettes. For HTPs, tobacco leaves (70%) and inner wrappers (25%) were the most frequently paired. The distribution of paired components differed significantly between cigarettes and HTPs ($P$<.001), with a higher proportion of HTPs containing flavoring in tobacco leaves (70%) compared with cigarettes (39.4%).

Across all products analyzed, 63.1% (54% of cigarettes and 84.4% of HTPs) both had flavor cues on the pack and contained flavor additives (Figure 3A), while 3.7% (5.3% of cigarettes and 0% of HTPs) contained flavor additives without any packaging cues (Figure 3B). Conversely, 12.6% (13.3% of cigarettes and 10.9% of HTPs) displayed cues but lacked detectable flavor additives (Figure 3C), and 20.6% (27.3% of cigarettes and 4.7% of HTPs) showed neither cues nor additives (Figure 3D).

**Figure 3.** Comparison of flavor cues and actual flavoring in tobacco products.

## Discussion

### Principal Findings and Implications

We conducted systematic surveillance of cigarettes and HTPs sold in Korea, integrating pack- and stick-level coding of flavor cues with component-based assessment of flavor additives. Our analysis showed that pack sizes and shapes were not standardized and varied across both product types. Pack color was the most common flavor cue, followed by capsule imagery and product names, often used in combination. Most products used 2-3 cues simultaneously, reinforcing flavor signals. Flavor cues and additives were more prevalent among HTPs than cigarettes. Although capsules were the dominant flavoring method, additives were also incorporated into other components.

The flavor cues identified align with previous tobacco pack surveillance studies documenting widespread use of packaging elements to signal flavor. However, regulatory environments shape how these cues manifest. In markets without explicit restrictions, such as the Philippines, 58.5% of tobacco products contained flavor cues through direct descriptors beneath the product name [11]. In contrast, Korea's Article 9‐3 of the NHPA prohibits explicit flavor descriptors such as "menthol" or "cherry," including text or imagery, on tobacco packaging [27]. Nevertheless, flavoring continued to be implied through indirect marketing strategies, using terms such as "Ice" or "Tropical" and capsule imagery on both packs and sticks. Consequently, the prevalence of flavor cues among the products collected in Korea (75.7%) was far higher than the average among countries without flavor bans (22.7%) [12]. These findings suggest that regulatory approaches limited to explicit flavor indicators may be insufficient to eliminate flavor-related marketing.

A key contribution of this study is the combined assessment of flavor cues across both packs and sticks, alongside component-based screening of flavoring additives. Over 60% of products combined flavor cues with detectable flavor additives, but cues were also present in products without detectable flavor additives. Pack-level cues were often reinforced at the point of use, as 47% of cigarettes and 58% of HTPs featured capsule imagery on the stick. This pattern highlights that flavor-related appeal can be generated independently or synergistically through perceptual mechanisms (pack and stick design) [1,47] and material product features (additives) [48]. Linking consumer-facing signals with product-level evidence, therefore, provides a more comprehensive characterization of flavored tobacco products.

These findings have practical implications for enforcing flavor ban policies. Comprehensive flavor bans alone may be insufficient, as they leave room for circumvention. Even without flavor additives, packaging elements that imply flavor can shape perceptions of taste, quality, and harm [41] and may even modulate craving-related neural responses, reinforcing product appeal [49]. Moreover, in jurisdictions where flavor bans have been implemented without plain packaging, the industry has introduced pack- and stick-level design features that insinuate flavor characteristics despite the absence of explicit additives [50]. Flavor bans and plain packaging covering both packs and sticks should therefore be implemented in tandem. However, enforcing flavor bans can be technically complex due to ambiguity in defining "characterizing flavor" [51] and limited

XSL•FO
RenderX

standardized chemical testing capacity [52]. In this context, plain packaging may serve as a more immediately implementable strategy while regulatory systems strengthen enforcement capacity for flavor bans.

Several areas for future research follow from our findings. The high prevalence of flavoring additives among sampled products is broadly consistent with reported sales patterns of flavored tobacco products in Korea [26], highlighting a discrepancy between market patterns and the relatively lower self-reported use of flavored tobacco noted in Korea [53]. Only 29.8% of Korean smokers reported using flavored tobacco products (excluding capsule products), whereas only 26.7% reported that their usual brand contained a flavor capsule [26], which is lower than both the market share of flavored products and the prevalence of additives detected in our assessment. Our findings show that while crushable capsules were common, flavor additives were also frequently incorporated into less visible components such as tobacco leaves, wrappers, and internal filters. Because flavoring in these components is less noticeable and not widely recognized as a marker of flavored tobacco, such products may go unrecognized by consumers as flavored. Future research could examine whether this gap reflects underrecognition of these less salient forms of flavor delivery, or other factors such as higher consumption intensity among flavored-product users [54]. Additionally, the high proportion of discontinued products identified from our sampling procedures suggests rapid market turnover. Continued surveillance research will therefore be important to track evolving product design and flavoring strategies.

Given that evidence on HTP flavoring remains limited globally [55], our findings provide early empirical evidence in this area. Compared with cigarettes, HTPs use more pervasive cues and diverse flavoring methods, often using multiple flavoring methods across various components rather than being limited to capsules alone. As HTP markets continue to expand [56], surveillance frameworks developed for cigarettes, including pack- and stick-level assessment and evaluation of flavor additives, should be extended to HTPs. Our methods and findings offer a preliminary framework that may be applied in other settings to systematically assess the characteristics of HTPs.

Another global implication of our study is that the patterns documented in Korea may extend beyond the domestic market. KT&G, a major Korean tobacco manufacturer and global exporter [57-60], has reported increasing exports of flavored products and capsules [59], with packaging designs in some export markets that are identical or highly similar to those sold in Korea [60,61]. Surveillance of products sold in Korea may therefore provide an early signal of evolving industry tactics that could emerge in other jurisdictions.

## Limitations

Our study has several limitations. First, products were purchased in one metropolitan area and primarily from major convenience store chains, so availability may differ in other regions or retail channels (eg, supermarkets and duty-free outlets). Second, some identified products could not be collected due to discontinuation or low demand, which may have introduced selection bias and affected estimates of flavor cues and additives. For example, niche or experimental flavored variants are more likely to be dropped from retail shelves, potentially leading to an underestimation of the diversity or prevalence of flavor-related features. Third, coding was conducted through team-based consensus rather than independent double coding, which may have introduced bias and precluded calculation of intercoder reliability. Fourth, our sensory screening relied on a pragmatic, nonblinded orthonasal assessment conducted by trained research staff rather than professional sensory analysts. Subtle additives may have been missed, and component attribution should be interpreted as approximate due to potential odor diffusion. Future work should incorporate blinded sensory testing conducted by expert sensory panelists and chemical analyses to improve the detection and localization of flavoring additives.

## Conclusions

To our knowledge, this study is among the first to simultaneously examine flavor cues on cigarette and HTP packaging and sticks, alongside the presence of flavor additives. By integrating pack- and stick-level assessments, we provide evidence on how flavor cues and additives work together to enhance product appeal. Our findings show that flavoring in tobacco products extends beyond visible pack design or crushable capsules to multiple structural components, highlighting the need for regulations that address both perceptual mechanisms and sources of flavoring. Incorporating stick-level monitoring and HTPs into existing surveillance systems will be crucial for identifying concealed flavoring cues and methods. These efforts can strengthen the implementation of World Health Organization (WHO) FCTC Articles 9 and 10 (regulation and disclosure of tobacco product contents and emissions) and Article 11 (packaging and labeling).

## Acknowledgments

We would like to thank the International Tobacco Control (ITC) Project team for providing the list of response options for tobacco product brands, which supported the development of the product list used in this study. During the preparation of this work, the authors used ChatGPT (OpenAI) to improve readability and language. The authors reviewed and edited the content and take full responsibility for the final version of the paper.

## Abstract

**Background:** Aortic pathologies in general and acute aortic syndromes in particular are persistent public health concerns worldwide. Continuous efforts to monitor and update incidence rates are necessary for guided public health interventions and health care policy adaptation.

**Objective:** This study aims to evaluate temporal patterns in the incidence and outcomes of hospital admissions for ruptured aortic aneurysms (rAAs) and aortic dissections (ADs) in Austria over a 15-year period, with a focus on population-wide trends.

**Methods:** This study provides a retrospective, population-wide analysis of aortic syndromes using national health care data from 2009 to 2023. The data were provided by a federal data warehouse that stores all recorded in-hospital services in Austria. We analyzed annual and population-adjusted hospital admissions, in-hospital mortality, comorbidities, complications, and demographic characteristics for rAA and AD cases. Temporal patterns were assessed for annual variations. Exploratory forecasts were made until 2030 using exponential smoothing time series models. Subgroup analyses by sex and age strata were incorporated to contextualize epidemiological shifts and assess differential trends across population segments.

**Results:** Corresponding to worldwide trends, the proportion of individuals aged 65 years and older slightly increased in Austria, from 17.4% in 2009 to 19.6% in 2023. Hospital admissions for rAA decreased from 357 in 2009 to 292 in 2023 (−18.2%), with admission rates falling from 4.3 to 3.2 per 100,000 (−25.2%) over the study period. In-hospital mortality among patients with rAA declined from 38.7% (138/357) to 34.6% (101/292), accompanied by a decrease in major comorbidities and recorded in-hospital complications. The incidence of hospital admissions for AD, however, showed a significant increase from 430 to 872 (+102.8%), with population-adjusted incidence rates rising from 5.2 to 9.6 per 100,000 (+85.6%). In-hospital mortality for aggregated AD cases decreased slightly, from 12.1% to 11.0%. Forecasting analyses suggest a continued rise in AD incidence through 2030, whereas rAA rates are expected to remain comparatively stable.

**Conclusions:** While rAA incidence and mortality declined, AD cases showed a substantial increase, potentially due to improved detection, diagnostic advances, or a true epidemiological shift that warrants further investigation. These diverging trends highlight the need for updated surveillance strategies, improved risk stratification, and adaptation of health care resources to a potentially increasing burden of AD.

**KEYWORDS**

aortic aneurysm; rupture; dissection; incidence; mortality

## Introduction

The worldwide prevalence of both thoracic and abdominal aortic aneurysms (AAAs) has risen over the past two decades, attributable largely to increased detection through screening and the aging of populations in low- and middle-income countries [1-4]. However, high-income countries have experienced a decline in prevalence, rupture rates, and aneurysm-related mortality from historic peaks, reflecting the success of screening programs, reduced smoking prevalence, and improved management of hypertension [3,5,6]. A recent meta-analysis of 54 population-based studies suggested an AAA prevalence of 1.75% in men and 0.57% in women in Europe, which is in line with contemporary screening studies from this region [3,7,8]. Alongside the reduction in non-ruptured AAAs, driven by changes in cardiovascular risk factors, broader use of preventive elective surgeries through screening programs, and the widespread adoption of endovascular aneurysm repair, the prevalence and mortality of ruptured aortic aneurysms (rAAs) have markedly declined [9,10]. Nonetheless, rAAs remain a

XSL•FO
RenderX

relevant cause of vascular death, with pre-hospital mortality often exceeding 50% and reported in-hospital mortality rates of up to 25% even after successful surgical treatment [11-13]. The advent of endovascular aneurysm repair (EVAR) has markedly reduced mortality in patients with rAAs. Compared to open surgical repair, EVAR is associated with lower perioperative morbidity, reduced hospital stays, and improved short-term survival [9].

The epidemiology of aortic dissections (ADs) is well researched, with significant geographical and temporal variations in incidence. A population-based study in Olmsted County, Minnesota, from 1995 to 2015 reported an incidence of AD of 4.4 per 100,000 person-years, with men being more affected than women [14]. A systematic review and meta-analysis estimated a worldwide incidence of acute ADs of 4.8 per 100,000 individuals per year, with type A dissections occurring at 3.0 per 100,000 and type B dissections at 1.6 per 100,000 [2]. In contrast, a study in Miyazaki prefecture in Japan reported a much higher AD incidence of 17.6 per 100,000, likely due to an older population and comprehensive postmortem computed tomography analysis, which better captured pre-hospital deaths [15,16]. European studies have demonstrated variable incidence, with rates ranging from 2.9 per 100,000 in Hungary to 6 per 100,000 in the United Kingdom, while Sweden reported incidences between 3.3 and 7.2 per 100,000, depending on study methodology. Ontario in Canada reported an incidence of 4.6 per 100,000, whereas Medicare data in the United States indicated a higher hospitalization rate of 10 per 100,000. In Asia, estimates range from 2.8 per 100,000 in China to 10 per 100,000 in Tokyo, Japan [17]. Despite geographical differences, the high mortality associated with AD remains a significant concern, with a 30-day mortality rate as high as 57% in Japan [16].

This study provides a detailed temporal analysis of rAA and AD in the Austrian population over a 15-year observational period, leveraging *International Classification of Diseases, 10th Revision* (ICD-10)–coded health claims data. It thereby aims to investigate potentially contrasting trends in hospital admissions for rAA (ICD-10 codes I71.1, I71.3, I71.5, and I71.8) and AD (I71.0) and incidence, explore possible contributing factors, such as diagnostic advancements or a shifting risk profile of patients, and assess the impact of health care accessibility, including potential effects of the COVID-19 pandemic.

## Methods

### Data

Data included in this analysis are derived from a federal database that covers in-hospital medical services in Austria. The database in its current structure was established in 2009; therefore, data between 2009 and 2023 were extracted for analysis. ICD-10 codes were used to classify cases. rAAs were defined as I71.1, I71.3, I71.5, and I71.8; AD as I71.0; acute myocardial infarction as I21, stroke as I63, I64, and G45, respiratory complications as J00-J22, coronary heart disease as I25, diabetes mellitus as E10-E14, and pulmonary comorbidities (including chronic obstructive pulmonary disease, asthma, and chronic bronchitis) as J41-45. The current ICD-10 code I71.0 represents a composite code for all types of AD, encompassing types A and B as well as acute, subacute, and chronic presentations, which is a limitation inherent to ICD-10. Furthermore, the proportion of male and female patients was obtained, as well as age strata (60 years and younger, 60-69 years, 70 - 79 years, and 80 years and older) and length of hospital stay strata (less than 9 days, 10-14 days, 15-19 days, and more than 19 days). These data were obtained as aggregated cases per year. Mortality refers to all-cause in-hospital mortality for cases with rAA or AD recorded as the main diagnosis. Additionally, daily case numbers and associated surgeries were provided for rAA and AD. All data were obtained by the Austrian Ministry of Health through the DIAG (Dokumentations- und Informationssysteme für Analysen im Gesundheitswesen) data warehouse. Diagnoses and services were recorded by health care professionals and administrative staff in hospitals and underwent quality control checks at multiple stages. Data covering population size (at the start of the calendar year) and smoking habits were extracted from the publicly accessible databases of Statistics Austria, the federal Austrian statistical office.

### Ethical Considerations

Requirement for institutional review board approval was waived by the ethics committee of the City of Vienna due to the exclusive use of anonymized, aggregated data.

### Descriptive Analysis

This study is primarily an ecological study investigating national aggregated data. Descriptive analysis included inspection of measures of central tendency and dispersion. A qualitative and quantitative analysis of temporal patterns was conducted, including yearly changes and changes across the observational period. Incidence rates of hospital admissions reflect the number of cases per 100,000 person years. Since all data are aggregated per year, this rate is equal to per 100,000 inhabitants.

### Forecasting Future Event Rates

To estimate future trends in the incidence of rAAs and ADs, we applied time series forecasting using exponential smoothing (Error, Trend, Seasonal [ETS]) models. Analyses were conducted separately for men and women, and rates were calculated as mentioned above. We generated univariate time series for each combination of event type (dissection or rupture) and sex. ETS models were fitted to each time series using the *forecast* package in R (version 4.4.2), which automatically selects the best-fitting model form (additive or multiplicative errors, trend, and seasonality) based on information criteria. Forecasts were projected from 2024 to 2030, including 95% CIs. This approach allowed us to estimate future sex-specific incidence trends under the assumption that past dynamics will continue.

## Results

### Population Characteristics

From 2009 to 2023 the Austrian population increased from 8.3 to 9.1 million inhabitants (Figure 1). The demographic structure remained rather stable over the observational period. The

XSL•FO
RenderX

population consisted of 50% to 51% female inhabitants. Corresponding to worldwide trends, the proportion of individuals aged 65 years or older slightly increased, from 17.4% in 2009 to 19.6% in 2023. As smoking and arterial hypertension constitute major risk factors for both pathologies, we investigated the datasets of Statistics Austria. While yearly data on smoking were not available, Statistics Austria reported that for men and women, daily smoking decreased from 27.5% and 19.4% in 2006 to 23.7% and 17.9% in 2019, respectively. The prevalence of arterial hypertension is also documented by Statistics Austria and did not change substantially between 2006 and 2019, affecting around a fifth of the adult population. The proportion of men with hypertension slightly increased, from 20% in 2006 to 22% in 2019, whereas in women it decreased from 23% to 21.6% [18,19]. Table 1 illustrates the main metrics of interest.

**Figure 1.** Demographics of the Austrian population from 2009 to 2023. (A) Population size (in millions). (B) Proportion of the population aged 65 years or older.

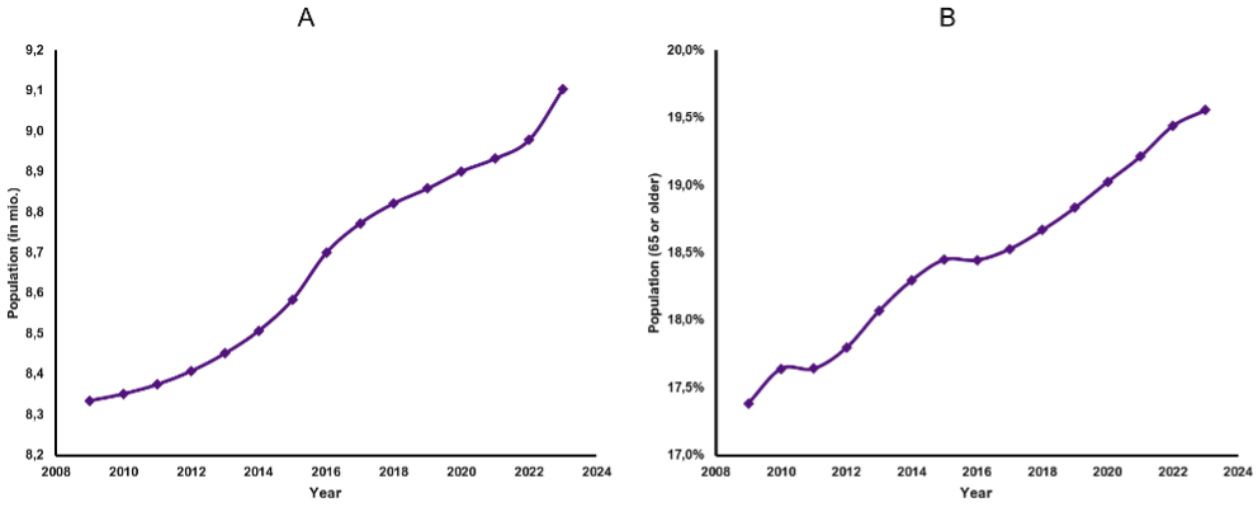

**Table .** Main metrics of interest regarding trends in population size, ruptured aortic aneurysms (rAAs), and aortic dissections (ADs) in Austria between 2009 and 2023.

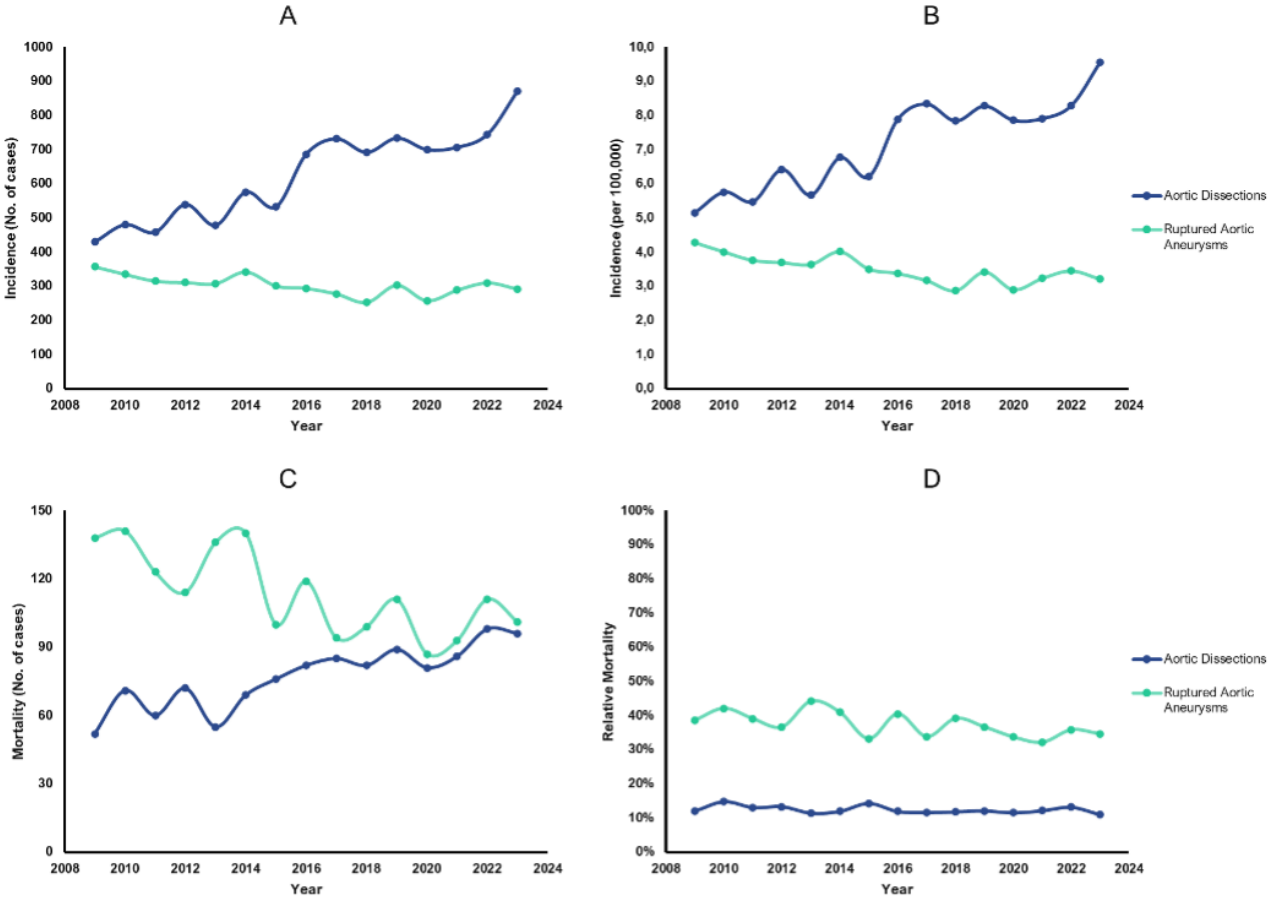
| Metrics | Median (IQR) between 2009 and 2023 | 2009 | 2023 | Relative change |
|---|---|---|---|---|
| Population size (millions) | 8.7 (8.4-8.9) | 8.3 | 9.1 | 9.2% |
| Admissions for rAA (n) | 303 (291-313) | 357 | 292 | −18.2% |
| Admissions for AD (n) | 687 (507-720) | 430 | 872 | 102.8% |
| Admission rate for rAA (per 100,000) | 3.5 (3.2-3.7) | 4.3 | 3.2 | −25.2% |
| Admission rate for AD (per 100,000) | 7.8 (6.0-8.1) | 5.2 | 9.6 | 85.6% |
| In-hospital mortality rate for rAA (%) | 36.7 (34.2-40.0) | 38.7 | 34.6 | −10.6% |
| In-hospital mortality rate for AD (%) | 12.1 (11.7-13.1) | 12.1 | 11.0 | −9.0% |

## Trends in rAAs

Hospital admissions for rAAs declined from 357 cases in 2009 to 292 cases in 2023 (–18.2%) during the observational period (Figure 2A). Adjusting for the increase in population size, admission rates fell from 4.3 to 3.2 per 100,000 (–25.2%; Figure 2B). Cases with a recorded in-hospital death decreased over the study period (Figure 2C). This corresponds to a relative in-hospital mortality decrease from 38.7% (138/357) of all cases in 2009 to 34.6% (101/292) in 2023, even though this was not a monotonic development, with a peak of 44.2% (136/308) in 2014 (Figure 2D). Of note, this was also accompanied by a decrease in major comorbidities (Figure 3A) and recorded in-hospital complications (Figure 3C).



There were no relevant changes in length of hospital stay during the observational period, with a median of 61.6% (range 56.1%-65.4%) of patients having a recorded length of stay of 9 days or less. Age structure also remained rather stable, with a median of 15.9% (range 12.6%-21.2%) of patients being aged 59 years or younger, a median of 21.3% (range 16.9%-26.0%) aged 60 to 69 years, a median of 31.3% (range 22.1%-36.8%) aged 70 to 79 years, and 30.3% (range 26.5%-39.8%) aged 80 years or older. Sex distribution of cases also remained stable, with a median of 29.5% (range 26.0%-38.0%) of rAAs occurring

XSL•FO
RenderX

in female patients and correspondingly a median of 70.5% (range 62.0%-74.0%) in male patients.

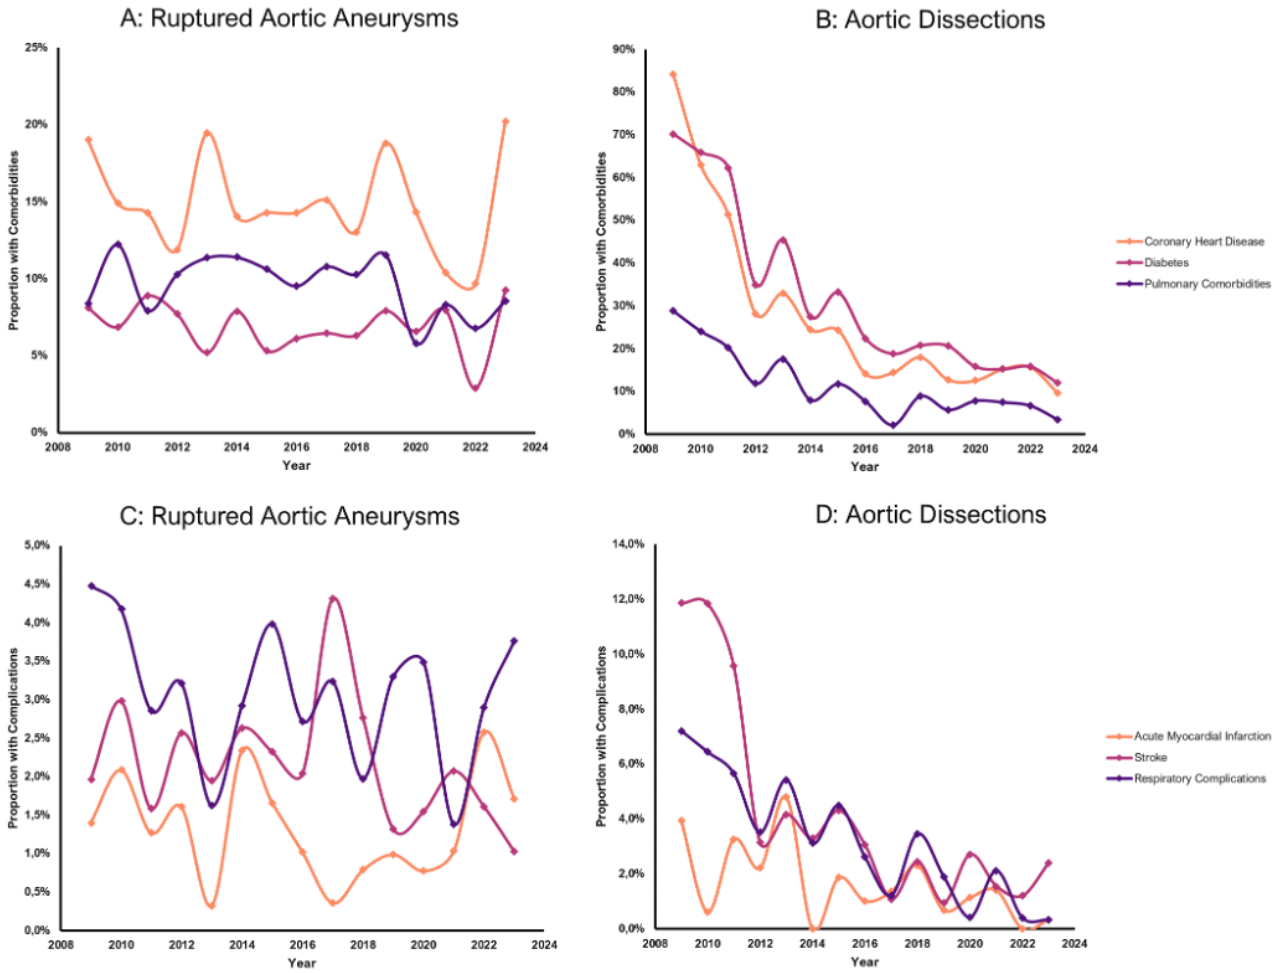


**Figure 2.** Trends in ruptured aortic aneurysms and aortic dissections in Austria from 2009 to 2023. (A) Hospital admissions in absolute case numbers. (B) Admission rate per 100,000 for ruptured aortic aneurysms. (C) Mortality (absolute). (D) Mortality as a proportion of all cases (as a percentage).

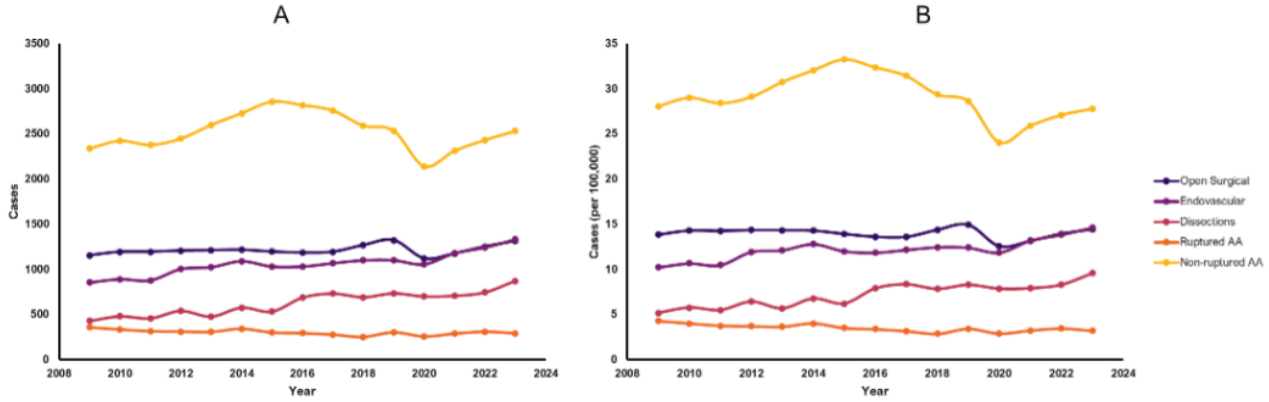
XSL•FO
RenderX

**Figure 3.** Comorbidities and complications in cases of ruptured aortic aneurysms and aortic dissections in Austria between 2009 and 2023. (A) Proportion of ruptured aortic aneurysm cases with coronary heart disease, diabetes, or pulmonary comorbidities (B) Proportion of aortic dissection cases with coronary heart disease, diabetes, or pulmonary comorbidities (C) Proportion of ruptured aortic aneurysm cases with recorded in-hospital complications (D) Proportion of aortic dissection cases with recorded in-hospital complications.

## Trends in ADs

Hospital admissions for ADs increased from 430 cases in 2009 to 872 in 2023 (+102.8%). The incidence rate rose from 5.2 to 9.6 per 100,000 (+85.6%; Figure 2A and B). Recorded in-hospital mortality decreased slightly from 12.1% to 11.0% over the study period (Figure 2C and D). In the early years of the observational period (2009 - 2013), AD cases were more frequently associated with cardiovascular and pulmonary comorbidities than in later years (Figure 3B and D).

A median of 39.1% (range 34.5% - 44.5%) of patients were aged 59 years or younger, a median of 26.6% (range 19.3% - 31.2%) were aged 60 to 69 years, a median of 23.5% (range 19.1% - 29.0%) were aged 70 to 79 years, and a median of 10.2% (range 7.2% - 13.0%) were aged 80 years or older. A median of 35.6% (range 28.1% - 37.2%) of affected patients over the observational period were female and correspondingly a median of 64.4% (range 26.0% - 62.8%) were male.



## Surgical Treatment of Aorta Pathologies

Figure 4A and B illustrate the temporal pattern of aortic surgeries in total and per 100,000 in Austria from 2009 to 2023. To explore a potential relationship between elective invasive treatments for nonruptured aortic aneurysms and the incidence of rAA, we investigated treatment patterns in elective settings. Elective treatments peaked in 2015 and steadily declined after that. With the start of the COVID-19 pandemic in 2020, both nonruptured aortic aneurysm admissions as well as surgical aortic aneurysm treatments showed a local minimum and a recovery of the caseload in the following years, returning to previous patterns. Endovascular aortic surgeries did not exhibit a corresponding trend, as they showed the steepest increase following the pandemic and a gradual increase over the study period. AD cases also showed a rather continual increase throughout the observational period. While no absolute increase in rAA cases was noted after the pandemic, the steepest increase in rAA cases did occur in the years after 2020.

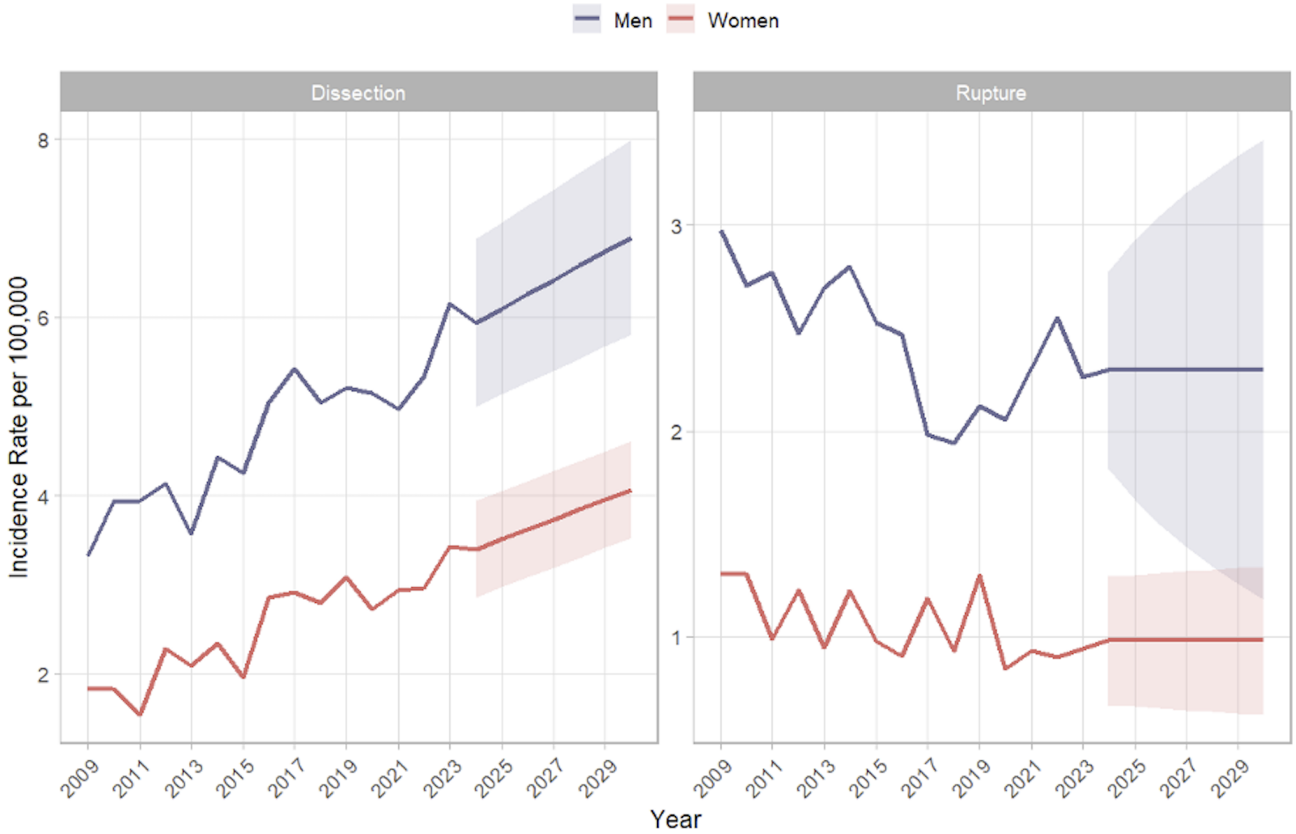

**Figure 4.** Temporal patterns regarding surgical treatments in Austria between 2009 and 2023. (A) Aortic surgeries (absolute). (B) Aortic surgeries per 100,000. AA: aortic aneurysm.

### Midterm Forecasts

In an exploratory analysis, forecasts for AD and rAA cases were made from 2024 through 2030, leveraging ETS models (see Methods). Incidence rate forecasts for AD cases among both male and female patients continuously increased, with a peak of 6.9 (95% CI 5.8 - 8.0) in male patients and 4.1 (95% CI 3.5 - 4.6) in female patients. This would result in a doubling of population-adjusted AD cases in about 20 years. Regarding rAA cases, estimated forecasts remained constant to the observational period from 2009 to 2023 in both sexes. These forecasts are illustrated in Figure 5.

**Figure 5.** Forecasted incidence rates of aortic dissection and aortic rupture by sex from 2009 to 2030. Solid lines represent historical rates per 100,000 population from 2009 to 2023, calculated separately for men and women. Shaded ribbons indicate 95% CIs of the forecasted rates for 2024 to 2030, derived using exponential smoothing time series models.

## Discussion

This population-wide analysis highlights relevant changes in hospital admissions and outcomes of rAA and AD in a growing Austrian population over a 15-year period. The observed decline in rAA-related admissions and mortality contrasts a marked increase in AD cases, warranting further investigation into potential contributing factors. The admission rate for rAA decreased by 25.2% between 2009 and 2023, while the rate of AD increased by 85.6% over the same period. In-hospital mortality decreased slightly for both conditions, with relative reductions of around 10% over the observational period. The epidemiological profiles of affected patients correspond well with previous literature, with rAA occurring more often in older

XSL•FO
RenderX

patient groups, whereas AD was frequently observed in patients younger than 60 years. Both pathologies affected male patients almost twice as often as female patients [20,21].

Epidemiological shifts in aortic pathologies are accompanied by corresponding trends for associated risk factors. Smoking, a main contributor to aortic aneurysm occurrence and rupture, has declined in many high-income countries in recent decades. The World Health Organization (WHO) estimates that tobacco use prevalence has more than halved between 2000 and 2025 in Austria, a trend that can be observed in other European countries, such as Germany or the United Kingdom, to a comparable extent. During the same period, the WHO has reported a decrease in the prevalence of hypertension among many European countries, even though estimates commonly show reductions of 20% to 25% [22]. Nevertheless, it should be considered that the point prevalence of a pathology is merely one aspect, with disease management being at least equally important to understand the epidemiological burden. As for arterial hypertension, advancements in treatment strategies and patient care have resulted in vastly improved blood pressure control in high-income countries [23,24]. The same considerations should be applied when interpreting the present data.

Reports of increased occurrence of AD from different geographical regions are not uncommon in the current literature [14]. The rise may be attributed to a variety of different variables, which may include improved diagnostics and therapeutic advances [25] that allow invasive treatment in historically inoperable cases. Developments in imaging as well as availability and use of high-resolution imaging in Austria may also have led to more frequent detection of AD, especially in the earlier stages, akin to how screenings can temporarily increase incidence rates. Because of this, the critical question remains whether the rise reflects a true increase in disease occurrence or an artifact of improved case ascertainment. A possible explanation could therefore be an increase in elective cases that undergo invasive treatment. Nevertheless, the absence of information regarding urgency and morphology in ICD-10 codes for AD (I71.0) remains a challenge when analyzing health claims data and routine electronic health records. Literature estimates of AD mortality vary widely, being heavily influenced by dissection type, patient characteristics, treatment indications, and modalities. Type A dissections have a reported 30-day all-cause mortality of 16.9% to 22% with surgical intervention and up to 50% to 69% without it [26-28]. In contrast, type B dissections, managed medically or with endovascular repair, have lower mortality, typically 4.5% to 13.8% [28,29]. Patient factors such as age, comorbidities, and genetic predispositions further modulate outcomes, as do treatment settings (acute vs elective) and modalities (open surgery vs endovascular). The current study's aggregation of all AD cases, encompassing types A and B, acute and elective presentations, averaged mortality estimates, as the lower mortality of elective or type B cases may offset the higher lethality of acute type A dissections. Moreover, the exclusion of pre-hospital deaths introduced a significant survival bias, as patients who die before reaching the hospital were not captured. Nevertheless, considering this amalgamation and the reporting of in-hospital mortality rather than 30-day mortality, the present data correspond well to comparable investigations [30].

Regarding rAAs, there might be less scope for interpretation of the present data in detail. A decrease in hospital admissions for AAAs in England and a shift toward endovascular treatment has recently been reported [31]. While reductions in the incidence of rAA were already observed a decade ago [10], the underlying cause, although debated, was considered to likely be multifactorial and at least partially attributable to the implementation of screening programs and subsequent increases in elective repair [32]. The present data correspond to this hypothesis, with increasing elective cases until 2015. Although Austria does not have an established national AAA screening program, we hypothesize that the increased use of EVAR and greater awareness among primary care physicians may have contributed to a concomitant and subsequent decrease in the incidence of rAA. The absence of a national screening program is primarily a policy decision by the federal government and the association of national health insurance institutions and stands in contrast to current clinical practice guidelines [9]. Small decreases and an implied negative trend in mortality over the observational period are also likely multifactorial and certainly require further investigation. However, the fluctuating temporal pattern and overall high rates indicate that ruptures—when they occur—are still a major hazardous cardiovascular event.

Invasive treatment for nonruptured aortic aneurysms in Austria increased continuously from 2009 to 2015, when they peaked, with a subsequent steady decline. However, during the height of the global COVID-19 pandemic, a noticeable decrease was observed, with a recovery in 2023 to prepandemic caseloads. The fact that the COVID-19 pandemic led to delayed access to health care services was a phenomenon observed worldwide [33,34] that affected many pathologies, including cancer [35], stroke [36], and acute myocardial infarction [37]. Despite the challenges the COVID-19 pandemic presented to health care systems worldwide, its effects on aortic aneurysm treatment and associated outcomes were reported to be limited from a public health perspective [38-40]. Nevertheless, it was previously hypothesized that decreases in elective aortic aneurysm repair during the pandemic could have caused an accumulation of untreated aneurysms and an increased risk for rAA [41]. The slight decrease in elective aortic aneurysm treatments in 2020 was accompanied by small increases in ruptures in 2021 and 2022. However, this trend appeared to reverse in 2023, and nonruptured aortic aneurysm treatments were already in decline from 2015 onward. During the same time, both hospital admissions with rAA as well as associated mortality declined. While effects of the COVID-19 pandemic on the treatment of aortic aneurysms in Austria cannot be completely excluded, they appear rather limited for the time being.

The forecasts presented in this study should be interpreted as exploratory and illustrative rather than definitive predictions. Nevertheless, the estimated continuous increase in AD cases could require adaptation of infrastructure and policies, as forecasts indicate a potential doubling of caseloads in 2030 compared to 2009. However, while ETS models provide a

XSL•FO
RenderX

data-driven approach to estimate potential future trends in the incidence of ADs and ruptures, these projections are inherently uncertain and depend on the assumption that past patterns will continue unchanged. Consequently, these estimates should not be used as the sole basis for health care policy or resource allocation decisions. Instead, they should be seen as serving to provide an informed understanding of possible developments that may warrant attention. It is also essential to reassess and update these forecasts as new data become available, particularly because the most recent data included extend only through 2023, and additional information from subsequent years may significantly influence future trends and model accuracy.

The observational period, spanning 15 years, may not have fully captured longer-term trends, and more extensive time series analyses will be required in the future. Additionally, as the analysis was based on data from Austria, generalizing the findings to other countries or regions with differing health care systems, demographics, and lifestyle factors may be challenging. Furthermore, difficulties arise with the recording of ADs via ICD-10, since the code I71.0 condenses both acute and elective clinical presentations as well as variations in morphology, that is, type A, B, non-A, or non-B. Similarly, most rAA cases were coded as I71.8 (rupture of unspecified location), which prevented further analysis of affected anatomic segments. Potential unmeasured confounders, such as changes in diagnostic practices, population health behaviors, or health care access, could have influenced the observed trends. Moreover, limited data on smoking prevalence and other individual-level risk factors precluded a more granular analysis of their impact on AD and rAA. The available information on smoking trends restricts interpretations to broader temporal patterns rather than direct year-to-year associations with incidence changes, as annual fluctuations in smoking cannot be precisely correlated with yearly variations in rAA or AD rates. These limitations highlight the need for multicountry analyses and screening studies with more detailed individual-level data to corroborate and expand upon these findings. Furthermore, the included data are based on recorded in-hospital diagnoses and services, and misclassifications in claims data are a well-described limitation.

The database used here included and represented more than 99% of all in-hospital services in Austria, thereby truly enabling a nationwide evaluation of hospital admissions, practice patterns, and outcomes of aortic syndromes between 2009 and 2023. However, limitations of the available data within the database highlight the value of nationwide registries such as the Vascular Registry in Sweden. Nevertheless, the present analysis offers insights into the evolving patterns of aortic pathologies, which may deserve consideration in health care planning and patient management, while adding recent data to the cumulative body of evidence on aortic pathologies.

In light of shifting demographics, changing comorbidity profiles, and evolving diagnostic and treatment options, aortic syndromes continue to be relevant from a public health perspective.

## Abstract

**Background:** Firearm mortality surveillance relies on aggregate demographic categories or low-dimensional stratifications, obscuring how race, ethnicity, sex, age, and intent intersect to shape risk among youth and young adults. The Centers for Disease Control and Prevention (CDC)'s transition to single-race population estimates created a structural break between historical and contemporary data series. Consequently, the 25-year trajectory of intersectional firearm mortality across changing federal classification frameworks remains uncharacterized.

**Objective:** We aimed to characterize 25-year national trajectories in firearm homicide and suicide across intersecting domains of race or ethnicity, sex, age, and intent among US youth and young adults (aged 0‐24 y), identifying specific sociodemographic groups experiencing the highest and most rapidly changing burdens.

**Methods:** This study used the CDC WONDER Underlying Cause of Death database (25-year window from 1999‐2024). To address the 2018 transition, a 2-period design was deployed: period 1 (1999 to 2020) used bridged 4-category race data, and period 2 (2018 to 2024) used 6-category single-race data. Crude death rates and disparity ratios (referenced to non-Hispanic White youth) were calculated using the Byar approximation. Average annual percentage changes (AAPCs) were modeled via log-linear regression. Analyses incorporated finalized 2024 CDC WONDER data in January 2026.

**Results:** Among 200,704 firearm deaths among youth aged 0‐24 years from 1999 to 2024, overall mortality declined through 2013, reversed in 2014, and rose 28.9% from 2019 to 2020. In 2024, the overall rate declined 12% from 2023 but remained above the 2019 prepandemic baseline. During 2018‐2024, Black non-Hispanic male youth experienced the highest pooled firearm homicide rate (44.03 per 100,000; 95% CI 43.46‐44.61), 23.8 times the rate among White non-Hispanic males. The annual rates within this cohort increased from 33.28 in 2018 to 53.75 in 2021 before declining to 37.06 in 2024 (AAPC, +2.4%; *P*=.56), while the Black-to-White disparity ratio widened from 19.3 to 24.4. Black non-Hispanic female youth had the highest female firearm homicide rate (6.03 per 100,000), exceeding male rates in 7 of 12 other demographic groups. American Indian or Alaska Native non-Hispanic male youth experienced the highest pooled firearm suicide rate (11.74 per 100,000). Firearm suicide increased significantly among Black non-Hispanic male youth (AAPC, +9.2%; 95% CI +3.2% to +15.4%; *P*=.01), with a substantial but nonsignificant upward trend among Black non-Hispanic female youth (AAPC, +11.7%; *P*=.08), while White non-Hispanic male rates remained stable (AAPC, −0.1%; *P*=.91). Consequently, the Black-to-White non-Hispanic male suicide rate ratio shifted from 0.67 in 2018 to 1.07 in 2024, marking the first time Black youth rates surpassed White youth rates in modern public health surveillance history.

**Conclusions:** Firearm homicide and suicide among US youth exhibit distinct demographic concentration patterns that are systematically obscured by aggregated public health surveillance. Disaggregated surveillance remains imperative to design targeted prevention strategies.

## Introduction

Firearm injury has emerged as a leading cause of death among children, adolescents, and young adults aged 1 to 24 years in the United States [1], surpassing motor vehicle crashes, cancer, and all other causes of mortality in recent years [2]. Within this composite burden, firearm homicides and suicides function as 2 epidemiologically distinct phenomena [1]. While both public health crises share upstream structural and social determinants, they diverge in their sociodemographic concentrations, proximal mechanisms, case-fatality rates, geographic distribution, and intervention entry points [3-6]. Two decades of national surveillance have structured prevention science and federal investment around a seemingly stable race-by-intent dichotomy. This paradigm is characterized by disproportionately high firearm homicide rates documented among non-Hispanic Black youth and elevated firearm suicide mortality among non-Hispanic White and American Indian or Alaska Native (AI/AN) youth [1,7-12]. While this framing has clarified the population-level magnitude of firearm injury among these groups, it has also concealed the intersectional gradients within and across other aggregated populations.

National surveillance reports rarely stratify age, sex, race or ethnicity, and injury intent jointly. Where such multiway stratifications are produced in subnational data, strict federal data suppression policies systematically suppress cells containing fewer than 10 deaths to protect privacy [13]. At the national level, the fundamental constraint is not the technical capacity of the underlying surveillance infrastructure, which permits 4-way disaggregation via the Centers for Disease Control and Prevention (CDC) WONDER database, but the reporting conventions that govern what enters published epidemiological records. Consequently, contemporary shifts in firearm violence and injury risk levels among AI/AN, Native Hawaiian or Other Pacific Islander (NH/OPI), multiracial, and non-Hispanic Black adolescent female populations remain underrepresented in standard surveillance literature.

Recent intersectional analyses have started to address these gaps. Mariño-Ramírez et al [9] stratified pediatric firearm mortality by race and ethnicity across the years 1999 - 2020 and called for more granular reporting. Likewise, Lee et al [10] simultaneously stratified by age, sex, race, and ethnicity through 2023 and documented the intersections of firearm and motor vehicle mortality; while Klein-Cloud et al [13] examined racial and ethnic disparities through 2023, raising the data suppression and classification concerns examined further in the present analysis.

However, 3 critical limitations of the current literature remain. First, the 2018 CDC transition from a bridged 4-category race classification scheme to a 6-category single-race scheme has effectively bifurcated the literature into isolated pre-2020 and post-2018 analyses, foreclosing an examination of the longitudinal arc of youth firearm mortality across the classification transition. Additionally, emerging intersectional signals remain underexamined relative to their epidemiological significance; notably, the recent convergence of firearm suicide mortality between non-Hispanic Black and White male youth, and the elevated firearm homicide burden among non-Hispanic Black adolescent and young adult female youth. Finally, this analysis incorporates finalized 2024 mortality data, released by the National Center for Health Statistics (NCHS) in January 2026. This additional year allows examination of whether pandemic-era increases in youth firearm mortality continued, stabilized, or declined.

Intersectionality frameworks, as articulated by Crenshaw [14] and adapted for population health by Bowleg [15] and Bauer [16], emphasize that social positions related to race, gender, class, and other axes are occupied simultaneously rather than additively, producing patterns of risk that are not visible when each axis is examined independently or only through two-dimensional comparisons. Applied to injury epidemiology, an intersectional surveillance lens directs analytic attention to specific demographic groups whose risks may be obscured when surveillance data are stratified by only 1 or 2 characteristics at a time. For example, the firearm mortality burden among Black non-Hispanic adolescent girls or AI/AN non-Hispanic young adult males may be less visible in race-only or sex-only analyses. Although vital statistics cannot directly measure the structural processes that produce these inequities, intersectionally disaggregated surveillance can identify where mortality is concentrated and help guide subsequent etiologic, policy, and prevention efforts [16,17].

This study examines national youth firearm mortality in the United States from 1999 through 2024 using the CDC WONDER Underlying Cause of Death database. To accommodate the federal classification transition, we adopt a 2-period analytic design. Period 1 (1999 to 2020) draws on the bridged-race data to characterize the 25-year temporal arc, while period 2 (2018 to 2024) leverages the single-race dataset to estimate contemporary intersectional patterns at a higher demographic resolution. The overlapping years (2018 to 2020) function as an internal consistency check to verify rate stability across both data structures rather than as an analytic break point. This design contributes to the current literature as it situates youth firearm mortality within the first complete year of postpandemic vital statistics; it treats the bridged-to-single-race transition as an analytic feature rather than truncating estimation at a single classification era, and it isolates several critical, underexamined intersectional signals across race or ethnicity, sex, age, and injury intent.

## Methods

### Study Design and Data Source

We conducted a serial cross-sectional, population-based descriptive analysis of firearm deaths among US children, adolescents, and young adults aged 0 to 24 years between 1999 and 2024, using the CDC WONDER Underlying Cause of Death database. WONDER compiles death certificate records through the National Vital Statistics System and provides annual counts, population denominators, and crude rates by demographic and cause-of-death categories [18]. Population denominators were drawn from CDC WONDER bridged-race population estimates for period 1 (1999 to 2020) and single-race population estimates for period 2 (2018 to 2024). The analytic population was

XSL•FO
RenderX

restricted to US residents of the 50 states and the District of Columbia.

The current study population was defined as individuals aged 0 to 24 years, comprising early childhood (0 to 12 y), adolescence (13 to 17 y), and young adulthood (18 to 24 y), consistent with established developmental and public health frameworks [19,20]. This upper boundary extends beyond the 0-to-17-year range commonly used in pediatric firearm surveillance reports [2,7,21], which exclude young adults aged 18 to 24 years, a developmental demographic that bears a disproportionate share of the national firearm homicide burden, particularly among Black and Hispanic male youth [3,21].

The 25-year analytic window was bounded by historical and administrative considerations of data continuity. The lower bound of 1999 represents the first full calendar year in which the United States implemented the *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision*) for underlying cause-of-death coding, and the first year for which CDC WONDER bridged-race population denominators are available [18,22]. The upper bound of 2024 incorporates the most recently finalized national mortality file released by the NCHS in January 2026 [18]. The window spans 25 years, from 1999 through 2024, and comprises 26 annual observations. This window enables the contextualization of contemporary, postpandemic shifts within a quarter-century historical trajectory.

## Ethical Considerations

This analysis used deidentified, publicly available, aggregated vital statistics data and was therefore determined not to constitute human participants research as defined under 45 CFR (Code of Federal Regulations) §46.102. Institutional review board review was not required under institutional policy governing the secondary analysis of public-use, fully anonymized federal data, and no application was submitted. The CDC WONDER public-use data files contain no direct or indirect personal identifiers. NCHS suppresses cells with fewer than 10 deaths, including finely stratified national cells, to protect confidentiality. The present analysis used visible cells and explicitly identified suppressed and statistically unreliable estimates that satisfied federal analytic reliability thresholds, with unstable rates explicitly flagged. As the underlying records are fully anonymous and collected via routine statutory vital statistics registration, informed consent was not applicable.

## Firearm Fatality Classification

Firearm fatalities were identified using *ICD-10* underlying cause-of-death codes. In this analysis, the term “intent” refers to the manner of death recorded on the death certificate, representing the standard NCHS classification of the circumstances surrounding the fatal injury. Five mutually exclusive intent categories were retained: firearm homicide (X93-X95); firearm suicide (X72-X74); unintentional firearm injury, defined as a fatal accidental discharge of a firearm rather than a category of homicide or suicide (W32-W34); firearm injury of undetermined intent (Y22-Y24); and legal intervention involving a firearm (Y35.0).

Firearm homicide and suicide served as the primary intent categories for all intersectional analyses. Unintentional, undetermined, and legal intervention deaths were retained in cumulative *all-cause* totals but were excluded from intent-specific trend estimation, given high suppression rates across multiway demographic and intersectional strata. Cumulative 25-year death totals were calculated by aggregating all period 1 deaths (1999 - 2020) and adding unique deaths from the nonoverlapping years of period 2 (2021 - 2024) to avoid duplication. All 2024 data reflect finalized counts released by CDC WONDER in January 2026 [18].

## Two-Period Analytic Design

In data year 2021, the CDC fully transitioned its multiple-cause-of-death files from a bridged 4-category race classification scheme (White, Black, AI/AN, and Asian or Pacific Islander, with multiple-race decedents algorithmically assigned to a single category) to a 6-category single-race scheme that separately identifies Asian, NH/OPI, and multi-racial decedents [22]. The legacy bridged-race data preserves long-term trend comparability back to 1999 but obscures contemporary diversity, whereas the single-race file allowed for greater contemporary sociodemographic comparability (back to 2018) but cannot be extended to the prebridging era. As these 2 population denominator systems introduce a structural trend break, a single continuous analytic framework spanning 1999 to 2024 was computationally untenable.

Accordingly, race and ethnicity were combined into a single mutually exclusive variable for all analyses (eg, non-Hispanic Black and Hispanic). The overlapping years (2018 to 2020) were used as an internal validation window to verify rate consistency and mathematical stability across both classification methods. The descriptive simultaneous stratification by race or ethnicity, sex, age, and injury intent used in this study constitutes a surveillance application of intersectional theory to isolate overlooked risk concentrations, rather than a formal quantitative intersectional decomposition [16].

## Statistical Analysis

Crude firearm death rates per 100,000 population were calculated for each demographic subgroup. Crude rather than age-adjusted rates were prioritized because simultaneous multiway stratification renders within-stratum age adjustment statistically volatile and analytically untenable for low-denominator populations, such as AI/AN, NH/OPI, and multiracial youth [9,21,23]. Disparity ratios were computed using non-Hispanic White males as the reference group for male comparisons and non-Hispanic White females for female comparisons; absolute crude rates were also compared directly across sex lines where female burdens eclipsed male baselines. Further, 95% CIs for rates and ratios were derived using the Byar approximation, which provides robust coverage for the small expected cell counts characteristic of fine-grained intersectional strata [24].

Cells based on fewer than 20 deaths were flagged as analytically unreliable per NCHS standards. Within the primary pooled-age contemporary intersectional matrix for period 2 (6 racial groups x 2 Hispanic-origin categories x 2 sexes x 3 primary intent

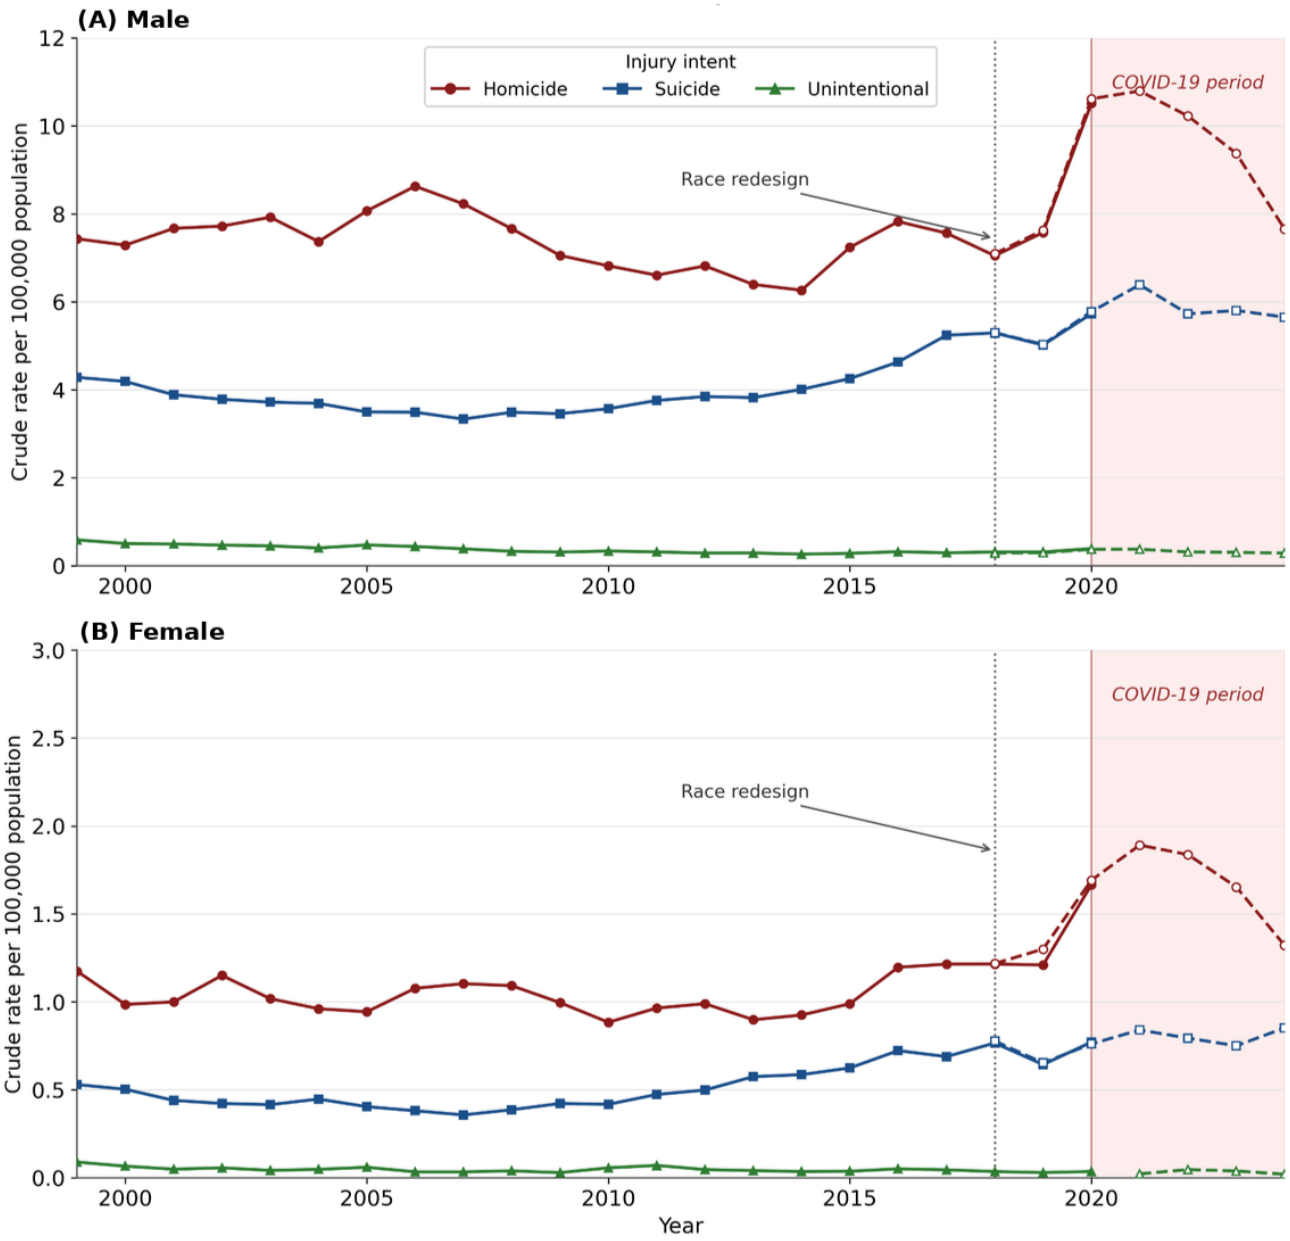
XSL•FO
RenderX

categories [homicide, suicide, and unintentional injury]), there were 72 distinct cells. Of these, 19 of 72 (26.4%) cells had counts fewer than 10 and were omitted from detailed stratification, and 11 of 72 (15.3%) cells were flagged as unreliable, yielding fully stable estimates for 42 of 72 (58.3%) baseline cells. Rate instability was heavily concentrated among NH/OPI youth (10/12, 83.3% cells) and within specific unintentional injury strata.

To characterize directional trends within period 2 (2018-2024), average annual percentage changes (AAPCs) were estimated by log-linear regression of the natural logarithm of the annual crude rate on calendar year. These were calculated separately for firearm homicide and suicide across non-Hispanic race-sex strata that demonstrated 3 or more reliable annual observations. The AAPC was calculated as $(\exp[\beta] - 1)\times 100$, where $\beta$ is the estimated slope parameter. Further, 95% CIs were derived from the t-distribution of $\beta$ with $n - 2$ degrees of freedom. Statistical significance was assessed using 2-sided *t* tests with an a priori alpha =.05. As this study's period encompasses a nonlinear post-2020 mortality surge and subsequent decline, the log-linear AAPC is explicitly interpreted as the net annualized trend velocity across the interval rather than a monotonic trajectory. All analyses were executed in Python (version 3.11; Python Software Foundation) using the Pandas, NumPy, SciPy, Matplotlib, and Seaborn libraries. This study adhered strictly to the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) reporting guideline; see Checklist 1.

## Results

### Cumulative Burden and Temporal Trends, 1999-2024



From 1999 through 2024, a total of 200,704 firearm deaths occurred among US youth and young adults aged 0 to 24 years (period 1: 161,313; period 2, nonoverlapping years 2021 - 2024: 39,391). Firearm mortality remained concentrated among male youth throughout the 25-year period, though the female share of the burden rose modestly, from 11.4% (18,459/161,313) of deaths in period 1 to 13% (8543/65,472) in period 2, even as the sex-specific trajectories diverged by intent (Figure 1). Across the full 25-year window, overall crude firearm mortality declined steadily from 1999 through 2013, reversed direction in 2014, and accelerated sharply during the pandemic period, rising 28.9% between 2019 and 2020 (from 7.69 to 9.91 per 100,000). Rates remained elevated through 2022 before partially stabilizing in 2023 and declining in 2024 (Figure 1). The recent 2024 overall rate of 8.24 per 100,000 represented a 12% decrease from 2023, the largest single-year decline observed during this 25-year period, though overall youth firearm mortality remained above the 2019 prepandemic baseline.

When examined by intent, firearm homicide and firearm suicide followed divergent trajectories within this aggregate trend. Among Black non-Hispanic male youth, homicide rates rose from 33.44 per 100,000 in period 1 to 44.03 per 100,000 in period 2, and Black non-Hispanic female homicide rates nearly doubled from 3.46 to 6.03 per 100,000 (Tables 1 and 2). Firearm suicide rates among AI/AN non-Hispanic male youth rose from 8.47 to 11.74 per 100,000 across the 2 periods, and Black non-Hispanic male suicide rates rose from 3.51 to 6.33 per 100,000. The 2 periods nearly coincide across the 2018 to 2020 overlap in Figure 1. The small residual differences reflect changes in population denominators between the bridged-race and single-race files rather than true changes in mortality; therefore, rates were not directly compared across periods.

XSL•FO
RenderX

**Figure 1.** Crude firearm mortality rates among US youth and young adults aged 0 to 24 years, by injury intent and sex, 1999 - 2024. Homicide, suicide, and unintentional intent are shown as separate trend lines. The shaded region indicates the elevated mortality period of 2020 - 2024. The vertical dashed line at 2018 marks the CDC transition from bridged to single-race classification; dotted lines across 2018 - 2020 indicate overlapping years and do not represent a true mortality trend. Across the 2018 to 2020 overlap, the 2 periods nearly coincide, and any residual difference reflects the change in population denominators between the bridged-race and single-race files rather than a true change in mortality, so rates from the two periods are not directly compared. Source: CDC WONDER [25]. CDC: Centers for Disease Control and Prevention.

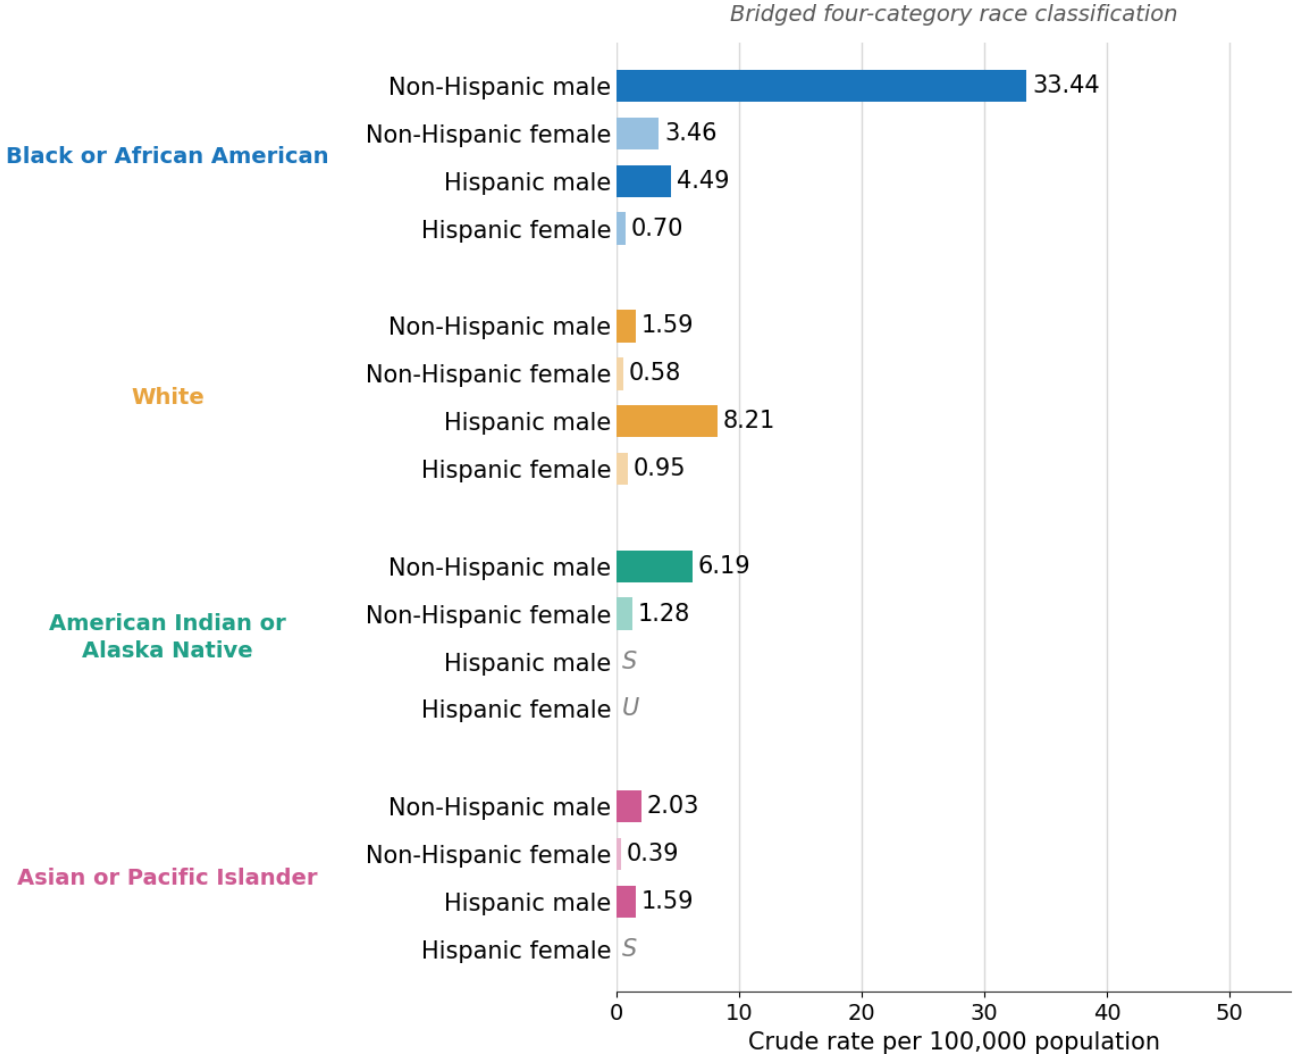
## Firearm Homicide Rates by Race or Ethnicity and Sex, 2018-2024



### *Male Homicides*

During period 2, Black non-Hispanic male youth experienced the highest firearm homicide rate of any group examined (44.03 per 100,000; 95% CI 43.46 - 44.61), which was 23.8 times the rate among White non-Hispanic male youth (1.85 per 100,000; 95% CI 1.79 - 1.92; Figures 2-5; Table 2). AI/AN non-Hispanic male youth exhibited the second-highest rate (9.29 per 100,000; 95% CI 8.20 - 10.38), followed by NH/OPI non-Hispanic males (8.34 per 100,000; 95% CI 6.44 - 10.64). Among Hispanic-origin male strata, White Hispanic males (7.33 per 100,000; 95% CI 7.14 - 7.52) and Black Hispanic males (6.71 per 100,000; 95% CI 6.01 - 7.40) carried the highest homicide burdens.

### *Female Homicides*

Black non-Hispanic female youth had the highest firearm homicide rate of any female stratum (6.03 per 100,000; 95% CI 5.82 - 6.25), 9.3 times the rate among White non-Hispanic female youth (0.65 per 100,000; 95% CI 0.61 - 0.69). Notably, this rate exceeded the homicide rates observed in male youth across 7 of the 12 other male groups examined, a pattern typically obscured by sex-aggregated reporting or by race-only stratifications that pool data for Black non-Hispanic girls with other female populations.

## Firearm Suicide Rates by Race or Ethnicity and Sex, 2018-2024

### *Male Suicides*

The demographic distribution of firearm suicide differed substantively from that of homicide. AI/AN non-Hispanic male youth experienced the highest firearm suicide rate of any group (11.74 per 100,000; 95% CI 10.51 - 12.97), 1.7 times the White non-Hispanic male rate (7.01 per 100,000; 95% CI 6.89 - 7.13; Table 2). Black non-Hispanic male youth also showed an elevated rate (6.33 per 100,000; 95% CI 6.11 - 6.55), placing them above NH/OPI non-Hispanic males (5.13 per 100,000; 95% CI 3.67 - 6.99) and below the AI/AN and White non-Hispanic strata.

XSL•FO
RenderX

### *Female Suicides*

Among female youth, AI/AN non-Hispanic females had the highest firearm suicide rate (1.77 per 100,000; 95% CI 1.32 - 2.33), followed by NH/OPI non-Hispanic females (1.35 per 100,000; 95% CI 0.65 - 2.49, interpret with caution) and White non-Hispanic females (0.95 per 100,000; 95% CI 0.90 - 0.99). Black non-Hispanic female firearm suicide rates (0.87 per 100,000; 95% CI 0.79 - 0.95), while lower in absolute terms than rates for AI/AN and White non-Hispanic females, showed the steepest within-period relative increase of any female stratum examined (see AAPC analysis in the section below titled "AAPCs in Firearm Homicide and Suicide Rates, 2018-2024").

## AAPCs in Firearm Homicide and Suicide Rates, 2018-2024

### *Overview*

AAPCs were estimated for all non-Hispanic race-sex strata with at least 3 nonsuppressed annual observations between 2018 and 2024 (Table 3), separately for firearm homicide and suicide.

XSL•FO
RenderX

**Table .** AAPCs[a,b] in crude firearm homicide and suicide mortality rates among US youth and young adults aged 0 to 24 years, by race or ethnicity and sex, non-Hispanic strata, 2018 - 2024.

| Race/ethnicity group | Sex | Years observed | AAPC % (95% CI) | *P* value | Annual crude rates per 100,000 across years (2018 - 2024) |
|---|---|---|---|---|---|
| Firearm homicide | | | | | |
| Black NH[c] | Male | 7 | +2.4% (−7.2 to +13.0) | .56 | 33.28; 37.10; 52.34; 53.75; 49.74; 45.08; 37.06 |
| Black NH | Female | 7 | +4.7% (−6.2 to +16.8) | .33 | 4.35; 4.60; 6.55; 8.10; 7.11; 6.21; 5.31 |
| White NH | Male | 7 | −1.5% (−8.3 to +5.8) | .61 | 1.72; 1.68; 2.33; 1.99; 1.93; 1.80; 1.52 |
| White NH | Female | 7 | +0.1% (−5.3 to +5.8) | .96 | 0.61; 0.58; 0.77; 0.64; 0.72; 0.64; 0.59 |
| AI/AN[d] NH | Male | 7 | +6.4% (−1.0 to +14.3) | .08 | 7.65; 8.59; 9.07; 6.96; 11.47; 10.70; 10.87 |
| AI/AN NH | Female | 4 | +10.2% (−9.9 to +34.7) | .17 | 2.40; 2.40; 2.48; 3.28 |
| Asian NH | Male | 7 | −2.7% (−14.5 to +10.7) | .61 | 0.94; 1.17; 1.29; 1.28; 1.01; 1.44; 0.69 |
| Asian NH | Female | __[e] | — | — | Insufficient data |
| NH/OPI[f] NH | Male | 5 | −3.0% (−8.3 to +2.7) | .19 | 10.37; 9.46; 10.74; 8.87; 8.41 |
| NH/OPI NH | Female | — | — | — | No data |
| Multiracial NH | Male | 7 | +5.8% (−2.9 to +15.2) | .15 | 2.38; 2.92; 3.21; 4.44; 3.89; 3.58; 3.30 |
| Multiracial NH | Female | 7 | +5.8% (−6.0 to +19.1) | .27 | 0.84; 0.68; 0.94; 1.51; 0.99; 1.20; 0.96 |
| Firearm suicide | | | | | |
| Black NH | Male | 7 | +9.2% (+3.2 to +15.4) | .01* | 4.68; 4.51; 6.05; 7.28; 7.25; 7.24; 7.28 |
| Black NH | Female | 7 | +11.7% (−1.7 to +27.0) | .08 | 0.62; 0.51; 0.68; 1.22; 1.17; 0.81; 1.07 |
| White NH | Male | 7 | −0.1% (−3.4 to +3.2) | .91 | 6.98; 6.54; 7.20; 7.92; 6.79; 6.86; 6.80 |
| White NH | Female | 7 | −0.1% (−3.4 to +3.4) | .95 | 1.02; 0.88; 0.95; 0.98; 0.86; 1.00; 0.96 |
| AI/AN NH | Male | 7 | +5.6% (−5.2 to +17.6) | .25 | 9.01; 8.36; 14.41; 13.23; 14.10; 9.73; 13.59 |
| AI/AN NH | Female | — | — | — | Insufficient data |
| Asian NH | Male | 7 | +2.4% (−4.2 to +9.6) | .40 | 2.02; 2.26; 2.27; 2.98; 2.43; 2.75; 2.17 |
| Asian NH | Female | 6 | +0.5% (−10.0 to +12.3) | .90 | 0.48; 0.43; 0.43; 0.42; 0.35; 0.59 |
| NH/OPI NH | Male | — | — | — | No data |
| NH/OPI NH | Female | — | — | — | No data |
| Multiracial NH | Male | 7 | +2.6% (−2.1 to +7.5) | .22 | 2.86; 3.53; 2.94; 3.52; 3.02; 3.36; 3.72 |
| Multiracial NH | Female | 5 | +4.0% (−2.5 to +10.9) | .15 | 0.49; 0.51; 0.46; 0.58; 0.61 |

[f]NH/OPI: Native Hawaiian or Other Pacific Islander.

### *Firearm Homicides*

No non-Hispanic race-sex stratum showed a statistically significant linear trend in firearm homicide across 2018 - 2024, reflecting the nonmonotonic trajectories across this window. Among Black non-Hispanic male youth, annual rates rose from 33.28 per 100,000 in 2018 to a peak of 53.75 in 2021, then declined progressively to 37.06 in 2024 (AAPC +2.4%; 95% CI −7.2 to +13.0; *P*=.56). Similar nonmonotonic trajectories appeared among Black non-Hispanic female youth (AAPC +4.7%; *P*=.33) and AI/AN non-Hispanic male youth (AAPC +6.4%; *P*=.08), with each group returning toward prepandemic levels by 2024. White non-Hispanic male rates remained low and stable (AAPC −1.5%; *P*=.61). Despite the relative reversion among the burdened groups, the Black-to-White non-Hispanic male homicide rate ratio increased modestly from 19.3 in 2018 to 24.4 in 2024, indicating that the partial reversion in relative rates was concentrated in the reference group rather than in the Black non-Hispanic male group, and that the relative disparity widened rather than narrowed across the period (Table 3).

### *Firearm Suicides*

In contrast to homicide, firearm suicide showed sustained directional trends concentrated in Black non-Hispanic strata. Rates among Black non-Hispanic male youth increased significantly at an AAPC of +9.2% per year (95% CI +3.2 to +15.4; *P*=.01), shifting the Black-to-White non-Hispanic male suicide rate ratio from 0.67 in 2018 to 1.07 in 2024, marking the first year in the 2018 to 2024 series in which the firearm suicide rate among Black non-Hispanic male youth exceeded that among White non-Hispanic male youth. Black non-Hispanic female youth showed a comparable rise in magnitude (AAPC +11.7%; 95% CI −1.7 to +27.0; *P*=.08), falling just outside the conventional threshold for statistical significance and constituting a notable trend warranting close epidemiological surveillance despite the wide CI. White non-Hispanic male and female rates were stable across the same period (AAPC −0.1%; *P*=.91 and *P*=.95, respectively). AI/AN non-Hispanic male suicide rates showed a nonsignificant increasing trend (AAPC +5.6%; 95% CI −5.2 to +17.6; *P*=.25), with substantial year-to-year variability reflecting small population denominators (Table 3).

### Age-Specific Firearm Mortality Patterns

Within period 2, age-specific analysis revealed steep developmental gradients concentrated in 2 intersectional locations (Multimedia Appendix 1). Among Black non-Hispanic male youth, firearm homicide rates increased from 6.63 per 100,000 at ages 10 to 14 years to 86.06 at ages 15 to 19 years and 114.44 at ages 20 to 24 years. The Black-to-White non-Hispanic male homicide rate ratio widened across consecutive age bands, from 26.1 at ages 15 to 19 years to 27 at ages 20 to 24 years, indicating that the greatest absolute firearm homicide burden occurred during late adolescence and young adulthood. This pattern challenges prevention frameworks that define youth as ending at age 17 or 18 because they may exclude young adults aged 18 to 24, including the age group with the highest observed firearm homicide rate.

Among AI/AN non-Hispanic male youth, firearm suicide rates increased from 2.92 per 100,000 at ages 10 to 14 years to 20.16 at ages 15 to 19 years and 31.71 at ages 20 to 24 years. In the oldest age band, the AI/AN non-Hispanic male firearm suicide rate was 1.6 times the corresponding White non-Hispanic male rate (19.61 per 100,000). The parallel adolescent-to-young-adult escalations observed for AI/AN male firearm suicide and Black non-Hispanic male firearm homicide underscore the need for prevention frameworks that extend beyond adolescence into the 18-to-24-year developmental window.

Among female youth, age gradients were less pronounced for homicide but evident for suicide. White non-Hispanic female firearm suicide rates increased from 0.47 per 100,000 at ages 10 to 14 years to 2.40 at ages 20 to 24 years. Black non-Hispanic female firearm suicide rates showed a similar but shallower gradient, increasing from 0.52 to 2.44 per 100,000 across the same age bands. In contrast to the pattern among males, Black and White non-Hispanic female firearm suicide rates across age groups were statistically indistinguishable, with overlapping CIs at ages 10 to 14 and at ages 20 to 24 years, warranting continued monitoring in future surveillance cycles as an indicator of the shifting racial distribution of firearm suicide risk.

## Discussion

### Principal Findings

This 25-year national analysis advances 3 critical findings that aggregate surveillance routinely conceals. Primarily, firearm homicide remains concentrated with extreme disproportionality among Black non-Hispanic male youth and, to a degree not captured by race-only or sex-aggregated reporting, among Black non-Hispanic girls. Annual firearm homicide rates among Black non-Hispanic male youth rose sharply during 2020 and 2021 and substantially reverted by 2024, with the 2024 rate approaching the 2018 level. However, the disparity ratio relative to White non-Hispanic male youth did not narrow across this period. The Black-to-White non-Hispanic male homicide rate ratio increased from 19.3 in 2018 to 24.4 in 2024, indicating that improvement in the absolute homicide rate among Black non-Hispanic males was not accompanied by a reduction in relative inequality.

In addition, firearm suicide burden was highest among AI/AN non-Hispanic male youth and intensified with age, peaking at ages 20 to 24 years. Furthermore, firearm suicide rates among Black non-Hispanic male youth increased at a statistically significant rate of +9.2% per year, with a comparable-magnitude

XSL•FO
RenderX

rise among Black non-Hispanic female youth and stable rates among White non-Hispanic male and female youth. Consequently, the Black-to-White non-Hispanic male suicide rate ratio shifted from 0.67 in 2018 to 1.07 in 2024, marking the first year in recent surveillance history that Black non-Hispanic male rates exceeded those of White non-Hispanic male youth. Our findings show that firearm mortality among US youth represents 2 epidemiologically distinct phenomena that require intent-specific, intersectionally disaggregated surveillance and prevention paradigms.

## Comparison With Prior Work

### *Firearm Homicide*

The firearm homicide rate among Black non-Hispanic male youth (44.03 per 100,000), 23.8 times that of White non-Hispanic male youth, is consistent with prior evidence linking elevated community violence exposure to structural conditions, not limited to residential segregation, concentrated economic disinvestment, and limited access to opportunity in the particular neighborhoods where these conditions co-occur, rather than to membership in any racial or ethnic group [5,26]. Crucially, this disparity ratio widened further with age, reaching 27.0 per 100,000 at ages 20 to 24 years, indicating that the transition from adolescence to young adulthood represents a critical period of escalating rather than declining risk. This age gradient has direct programmatic implications, as prevention frameworks that treat individuals aged 18 years and older as outside the scope of youth-focused intervention may be systematically misaligned and disconnected from the life stage at which absolute homicide risk peaks. Community violence intervention programs, hospital-based violence interruption, and structural investments in housing stability and economic opportunity represent vital avenues for reducing this burden [27]. However, young adults aged 18 to 24 may therefore fall into a prevention and service gap, aging out of pediatric and adolescent systems without a corresponding pathway into adult violence-prevention services unless they experience a violent injury, encounter the criminal legal system, or live in a community served by a dedicated intervention program.

Notably, the firearm homicide rate among Black non-Hispanic female youth (6.03 per 100,000) exceeded that of male youth in 7 of the 12 other racial and ethnic groups. This pattern may be obscured in surveillance reports that aggregate firearm mortality by race and ethnicity without simultaneous stratification by sex [6,8], underscoring the need to explicitly integrate intersectional metrics into clinical and community risk assessment, prevention programming, and policy.

### *Firearm Suicide*

AI/AN non-Hispanic male youth had the highest firearm suicide rate of any group (11.74 per 100,000), 1.7 times that of White non-Hispanic males. The absolute burden was greatest among those aged 20 to 24 years, whose firearm suicide rate reached 31.71 per 100,000. Lethal-means safety counseling and secure storage legislation are associated with reduced firearm suicide risk [28], but universal approaches are likely insufficient for AI/AN youth without culturally grounded multitiered strategies developed with (and led by) AI/AN communities. AI/AN youth live across a wide range of contexts, including reservations, rural nonreservations, urban settings, among others, and effective approaches must reflect these distinct community settings. Tribally led prevention partnerships and collaborations with Urban Indian Health Program partnerships offer important infrastructure for addressing community-defined priorities, including limited behavioral health access, the legacy of historical and ongoing structural trauma, and unequal exposure to firearm-injury risk environments [29]. The high year-to-year rate volatility observed in the AI/AN series further indicates that standard surveillance infrastructure is poorly suited to monitoring risk in numerically small populations with elevated burden, and supports the use of pooled estimates, confidence intervals, and surveillance approaches designed for small populations.

The convergence of Black and White non-Hispanic male firearm suicide rates between 2018 and 2024 represents an emerging disparity signal with direct relevance to prevention planning. As firearm homicide and suicide follow distinct demographic concentration patterns, disaggregating by intent is a prerequisite for prevention systems that can match intervention resources to need [2-5,8,9]. The 2024 overall decline in firearm mortality, the largest single-year decline in the current study period, is encouraging, although rates remained elevated relative to pre-2014 levels, and the trajectories among several subgroups warrant continued monitoring.

## Intersectional Interpretation

Three findings illustrate why an intersectional multi-year lens, rather than race-only or sex-only stratification, is necessary to characterize the firearm mortality burden in this age group. Primarily, the firearm homicide rate among Black non-Hispanic female youth (6.03 per 100,000) exceeded male homicide rates in 7 of 12 other racial and ethnic male subgroups examined, a result that is invisible in sex-aggregated reporting and in race-only reporting that pools Black non-Hispanic girls with girls of all other groups. This is the empirical pattern that intersectional theory predicts, noting that risk concentrates at specific social locations defined by the simultaneous operation of multiple structural axes [14-16]. Moreover, the elevated firearm suicide rate among AI/AN non-Hispanic young adult males (31.71 per 100,000 at ages 20 to 24 y) similarly emerges only when race or ethnicity, sex, age, and intent are considered together, reflecting the joint operation of historical, geographic, and behavioral health system exposures rather than any single attribute [29].

In addition, the convergence of Black and White non-Hispanic male firearm suicide rates between 2018 and 2024 demonstrates that intersectional locations are not static. The rate ratio shifted from 0.67 to 1.07 over 6 years, indicating that the demographic distribution of firearm suicide risk is itself in motion. This shift is reinforced by a parallel rise among Black non-Hispanic female youth (AAPC +11.7%; 95% CI −1.7 to +27.0), which approaches but does not reach the conventional threshold for statistical significance and which is similarly invisible in sex-aggregated or race-only reporting. The sex-symmetric character of the Black non-Hispanic firearm suicide rise is precisely the kind of dynamic that intersectional surveillance

XSL•FO
RenderX

can detect and that aggregated reporting cannot. For prevention planning, these findings imply that resources designed around the historical White male suicide profile or the historical Black male homicide profile cannot be assumed to reach the youth populations now bearing the greatest and most rapidly changing burden. Intersectional surveillance must be matched with intersectional intervention design, developed with the affected communities [15,16].

### Surveillance Implications

Several populations with elevated burden in this analysis, including Black non-Hispanic girls, AI/AN youth, and NH/OPI adolescents, remain difficult to characterize reliably in national datasets because of small population denominators, historical racial category aggregation, misclassification of injury intent, and suppression thresholds that remove cells with fewer than 10 deaths [13,30]. Of the 72 possible intersectional cells in period 2, only 42 (58.3%) yielded stable estimates. NH/OPI youth were the most severely affected by suppression, with 10 of 12 (83.3%) cells either suppressed or unreliable, meaning that a population group with documented elevated homicide burden is effectively invisible in standard surveillance outputs. This gap reflects a systemic shortcoming in national mortality surveillance, particularly for populations facing the highest levels of risk.

Addressing these gaps requires action at multiple levels. Vital statistics systems should improve the completeness and accuracy of race and ethnicity classification, particularly for AI/AN, Hispanic, Asian, and multiracial decedents. In addition, supporting tribally led and tribally governed data-linkage initiatives, developed through sovereign-to-sovereign partnerships among Tribal Nations, Tribal Epidemiology Centers, Urban Indian Organizations, the Indian Health Service, and state vital statistics agencies, may help reduce racial misclassification in mortality records and improve identification of AI/AN deaths. Such initiatives must proceed under tribal authority, community-defined governance, formal data-use agreements, and appropriate tribal review, consistent with Indigenous Data Sovereignty and CARE principles (Collective benefit, Authority to control, Responsibility, Ethics). Because linkage primarily improves numerator accuracy rather than the size or stability of the underlying population denominator, it should be paired with multiyear estimates, transparent uncertainty reporting, and improved population-estimation methods for small and geographically diverse AI/AN populations. Linkage cannot, however, resolve the small-denominator problem itself, as the instability of rates in numerically small populations is a function of population size rather than of counting error.

Tribal data sovereignty frameworks that enable AI/AN communities to generate, govern, and analyze their own public health data could also improve the capacity to detect and respond to concentrated burden [30]. Finally, the 2018 race-classification transition, while methodologically necessary, created a discontinuity that has constrained intersectional analyses for nearly a decade. Prospective planning for future classification updates should include explicit transition protocols that preserve analytic continuity (e.g., bridging algorithms), rather than requiring investigators to construct post hoc bridging designs.

National vital statistics surveillance is not the only level at which firearm injury can be counted or addressed. Community-based surveillance systems, including hospital trauma registries, school-based injury reporting, faith-based and neighborhood-level violence interruption networks, and tribal injury surveillance partnerships, may generate higher-resolution and more contextually grounded data than national mortality files in populations where suppression and small denominators limit the utility of vital statistics; the White Mountain Apache surveillance and prevention system offers one such model [29]. Pairing these systems with community-based interventions [27], such as hospital-linked violence interruption programs, school-based behavioral health, and lethal-means counseling [28], could allow detection and response to be matched at the scale where families and providers actually encounter risk, moving prevention science well beyond universal screening and counseling [27,29]. These findings indicate which populations bear concentrated burden, and do not posit that descriptive mortality data can adjudicate these issues; that work requires evaluation designs this analysis does not provide.

### Limitations

This analysis has several limitations. CDC WONDER suppresses strata with fewer than 10 deaths, which limits estimation for some intersectional subgroups. Small denominators among AI/AN, NH/OPI, and multiracial youth increase rate instability. The 2018 race-classification transition prevents direct cross-period comparisons. Additionally, crude rather than age-adjusted rates were used to preserve interpretability within fine-grained strata but may limit comparability with age-adjusted estimates reported elsewhere. AAPC estimates rest on a 7-year annual series (2018 - 2024); the short window precludes reliable detection of trend inflection points, and log-linear regression may understate nonmonotonic dynamics such as the pandemic-era homicide surge and subsequent partial reversion. Our use of AAPC assumes a linear trajectory across the 2018 - 2024 period. However, firearm homicides in heavily burdened strata followed a distinctly nonmonotonic path (a sharp pandemic-era spike followed by a post-2022 decline). The resulting nonsignificant *P* values reflect this U-shaped deviation rather than a lack of meaningful year-to-year shifts. Future analyses with longer longitudinal windows should use nonlinear modeling to capture these specific inflection points. AAPCs should be interpreted as directional rather than definitive. Our descriptive design does not account for socioeconomic conditions, urbanicity, or state-level firearm violence policies and precludes causal inference. Sex was determined from death certificate records, which did not include gender identity data. Consequently, the analysis could not examine firearm mortality among transgender, nonbinary, and other gender-diverse populations at the intersections of race and ethnicity, age, and gender. Intent and race or ethnicity classification on death certificates are similarly imperfect, particularly for AI/AN, Hispanic, and Asian American or Pacific Islander decedents [13,30]. Geographic variation was not examined, though prior work demonstrates substantial heterogeneity [2,10].

XSL•FO
RenderX

## Conclusions

Twenty-five years of national mortality data show that firearm mortality among US youth follows distinct, intent-specific patterns across race or ethnicity, sex, and age that aggregate surveillance routinely obscures. The post-2020 surge in firearm homicide among Black non-Hispanic male youth has reverted by 2024, with the 2024 rate approaching the 2018 baseline. However, the Black-to-White non-Hispanic male homicide rate ratio widened modestly across the period (from 19.3 in 2018 to 24.4 in 2024), indicating that the partial reversion was concentrated in the reference group rather than in the burdened group, and that the structural drivers producing this disparity did not narrow. Frameworks that interpret the 2024 decline as evidence of progress should attend to this distinction. Concurrently, firearm suicide rates among Black non-Hispanic male and female youth rose at a comparable magnitude while White non-Hispanic rates remained stable, producing the first year in this dataset in which Black non-Hispanic male suicide rates exceeded those of White non-Hispanic males. This study advances 3 contributions to the surveillance literature: (1) a coherent bridging design that links bridged-race and single-race surveillance eras within a single intersectional framework, enabling continued long-term monitoring across the 2018 classification transition; (2) finalized 2024 estimates with explicit attention to nonmonotonic postpandemic dynamics, including parallel computation of homicide and suicide AAPCs that prior partially stratified analyses have not provided; and (3) an empirical case for intersectional surveillance as the unit of analysis appropriate to populations whose burden and trajectory cannot be characterized by race alone or sex alone. Intent-specific, intersectionally disaggregated surveillance and prevention strategies, developed with the affected communities, continue to be the appropriate response [27,29].

## Interpretation Notes for AAPCs

For firearm homicide, the log-linear AAPC understates nonmonotonic dynamics. Annual homicide rates among Black non-Hispanic male youth illustrate this pattern: the rate rose from 33.28 in 2018 to a peak of 53.75 in 2021 (a 61.5% relative increase over 3 years), then declined progressively to 37.06 in 2024 (a 31% relative decline over 3 years). Consequently, the log-linear fit across the overall 7-year window did not reach statistical significance because the pandemic-era increase was partially offset by subsequent declines. The pattern is interpreted as pandemic-era elevation with partial reversal rather than as a sustained directional trend.

For firearm suicide, 2 strata show sustained directional trends consistent with the intersectional pattern described in the main text: Black non-Hispanic male youth (AAPC +9.2%, *P*=.01) and Black non-Hispanic female youth (AAPC +11.7%, *P*=.08, approaching but not reaching the conventional threshold). White non-Hispanic male and female rates are stable, producing the convergence in the Black-to-White non-Hispanic male suicide rate ratio reported in the main text.

## Acknowledgments

The authors thank the National Center for Health Statistics for maintaining the CDC WONDER Underlying Cause of Death public-use database. Generative AI tools (Claude, Anthropic PBC) were used during preparation of this paper for language editing only, including grammar checking, sentence-level clarity, chart displays, and proofreading of author-drafted content. ## Abstract

**Background:** Understanding temporal changes in noncommunicable diseases such as diabetes is crucial for informing health policy precisely and improving population-level outcomes.

**Objective:** This study aimed to evaluate temporal trends in key health metrics of type 2 diabetes using nationwide surveillance data to inform future prevention and care strategies in a resource-rich country.

**Methods:** We conducted a retrospective, population-based cohort study to analyze temporal trends in annual incidence, prevalence, mortality, and life expectancy from 2012 to 2021; the ABC (hemoglobin $A_{1c}$ [$HbA_{1c}$], blood pressure, and cholesterol) control metrics from 2015 to 2021; and complication-specific incidence rates from 2017 to 2021. The selected health metrics were quantified overall and stratified by age and sex and standardized to understand disparities in trends. An autoregressive model was used to evaluate temporal change after appropriately accounting for serial correlation in the data.

**Results:** The standardized incidence and mortality rates of type 2 diabetes slightly declined, by an average of 0.029 (95% CI 0.011-0.047) and 0.043 (95% CI 0.011-0.076) per 100 patient-years annually, respectively ($P$=.006 and $P$=.02). These declines coincided with a significant average annual increase of 0.17 (95% CI 0.15-0.21) in the standardized prevalence proportion ($P$<.001). While glycemic and lipid control improved steadily, blood pressure control remained suboptimal, reaching only 35.9% in 2021. All examined complications, except nephropathy, showed age-specific declines over time. The disparity in life expectancy between people with type 2 diabetes and the general population narrowed over time, but the gap was still pronounced among younger age groups.

**Conclusions:** This nationwide analysis highlights critical care gaps, particularly in blood pressure management, nephropathy prevention, and care for younger individuals with type 2 diabetes. Addressing these deficiencies is essential for achieving more equitable and effective diabetes care.

## Introduction

The global diabetes population is estimated to rise by more than 50%, from 463 million in 2019 to 700 million by 2045 [1]. Early detection of blood glucose abnormalities through the fasting plasma glucose test is essential for initiating further interventions and management [2]. However, despite increasing awareness of diabetes, the International Diabetes Federation recently estimated that nearly 45% of adults with diabetes worldwide remain unaware of their condition [3]. Consequently, delayed blood glucose control interventions can result in the onset of associated complications before the diabetes diagnosis. One large US cohort study demonstrated that more than 10% of patients had developed nephropathy, and 3.3% of patients were comorbid with macrovascular disease at type 2 diabetes diagnosis [4]. In addition, 1% to 3% of the cohort developed cardiovascular disease, nephropathy, and peripheral neuropathy annually. Therefore, early detection and timely delivery of comprehensive care play a key role in preventing the development of diabetes complications.

Improving type 2 diabetes prevention and care can rely on long-term monitoring of multiple health metrics across the disease spectrum. Incidence, prevalence, and mortality are commonly used to assess the overall status of diabetes prevention and care; however, these metrics often involve heterogeneous data collection methods, making comparisons across countries and over time challenging [5]. Moreover, relying solely on these measures provides limited guidance for improving clinical care and disease management. Therefore, incorporating additional process and prognosis metrics, such as glycemic control rates and complication incidence, is essential to provide actionable insights and enable decision-makers to allocate resources more precisely [6].

Comprehensive diabetes management requires both medication and patient self-care, including dietary modifications, lifestyle improvements, and home monitoring of blood pressure and blood glucose. To deliver holistic care, Taiwan launched pay-for-performance (P4P) reimbursement for diabetes to enhance the health care system's support for patient self-care in 2001. In short, this program encourages physicians to deliver more comprehensive care through a multidisciplinary team (physician, dietitian, and nurse educator) based on international clinical practice guidelines. Evidence from the past decade has shown that these programs substantially reduce the risks of complications and mortality, thereby lowering medical expenditures [7-9]. However, updated evidence on type 2 diabetes care from the surveillance data system is useful in re-examining the care framework and process, identifying care gaps and disadvantages, and redesigning an inclusive care program to address patient needs throughout their life.

Disease surveillance through a health data system can help us understand disease dynamics, medical services use, and care quality monitoring, also offering essential insights into future disease trend prediction and resource arrangements [10]. Our previous research has demonstrated how a health surveillance system using administrative health databases helps improve the effectiveness of diabetes and kidney disease care and management evaluations [11-13]. This study aimed to explore the updated trends in incidence, prevalence, mortality, life expectancy, care quality, and relevant complications to sketch out preventive and care challenges, as well as corresponding strategic actions, for type 2 diabetes in the coming decade.

## Methods

### Study Design and Database

We conducted a retrospective, population-based cohort study and performed time-series analyses using data systematically integrated from multiple databases described in the Introduction section [11]. In brief, the National Health Insurance Program in Taiwan is a single-payer, government-administered system that covers most of the population. The Taiwan National Health Insurance Research Database comprises several claims databases that enable linking with various governmental registry databases, including those for cancer, catastrophic illness, and death, through unique pseudo-identifiers under specific regulations. They have been widely applied to detect disease dynamics, assess clinical efficacy, and evaluate health policies [14]. In addition, the study also applied the P4P database, 2015 to 2021, to understand key care elements of diabetes care quality, including blood pressure, blood glucose, and blood lipids [15,16]. The research databases were applied to the Health and Welfare Data Science Center and the Health Research Data Integration Service from the National Health Insurance Administration, Ministry of Health and Welfare, from 2011 to 2022.

### Ethical Considerations

The institutional review boards of the National Health Research Institutes (EC1131006-E) reviewed and approved the study. As all patients' IDs in the study databases are scrambled, the institutional review boards of the National Health Research Institutes waived informed consent. All study procedures were conducted in accordance with the principles of the Declaration of Helsinki (2008 revision) and the regulations of the Health and Welfare Data Science Center.

### Diabetes Mellitus; Hemoglobin A1c, Blood Pressure, and Cholesterol Control; and Relevant Complications

Diabetes cases were identified by a series of diagnosis codes (Table S1 in Multimedia Appendix 1) that appeared 3 or more times in outpatient records or in 1 or more inpatient records within 1 year. The first diagnosis date between 2011 and 2022 was considered the incident date. As patients with type 1 diabetes were registered in the catastrophic illness registry, the type 2 diabetes population can be confirmed by excluding type 1 diabetes from the overall diabetes population. The incidence, prevalence, mortality, and average life expectancy statistics for type 2 diabetes were presented from 2012 to 2021 due to the unreliable data in 2011 and 2022, which resulted from prevalent case contamination and incomplete end-of-year data uploads. An incident case was defined as the absence of diabetes diagnosis codes prior to the first recorded diagnosis date during 2011 to 2022. As incident cases were identified from 2012 onward, this approach ensured that each case had at least a 1-year period without a diabetes diagnosis before classification

XSL•FO
RenderX

as incident. Prevalent cases were identified each year based on the surviving population at the start of the given year.

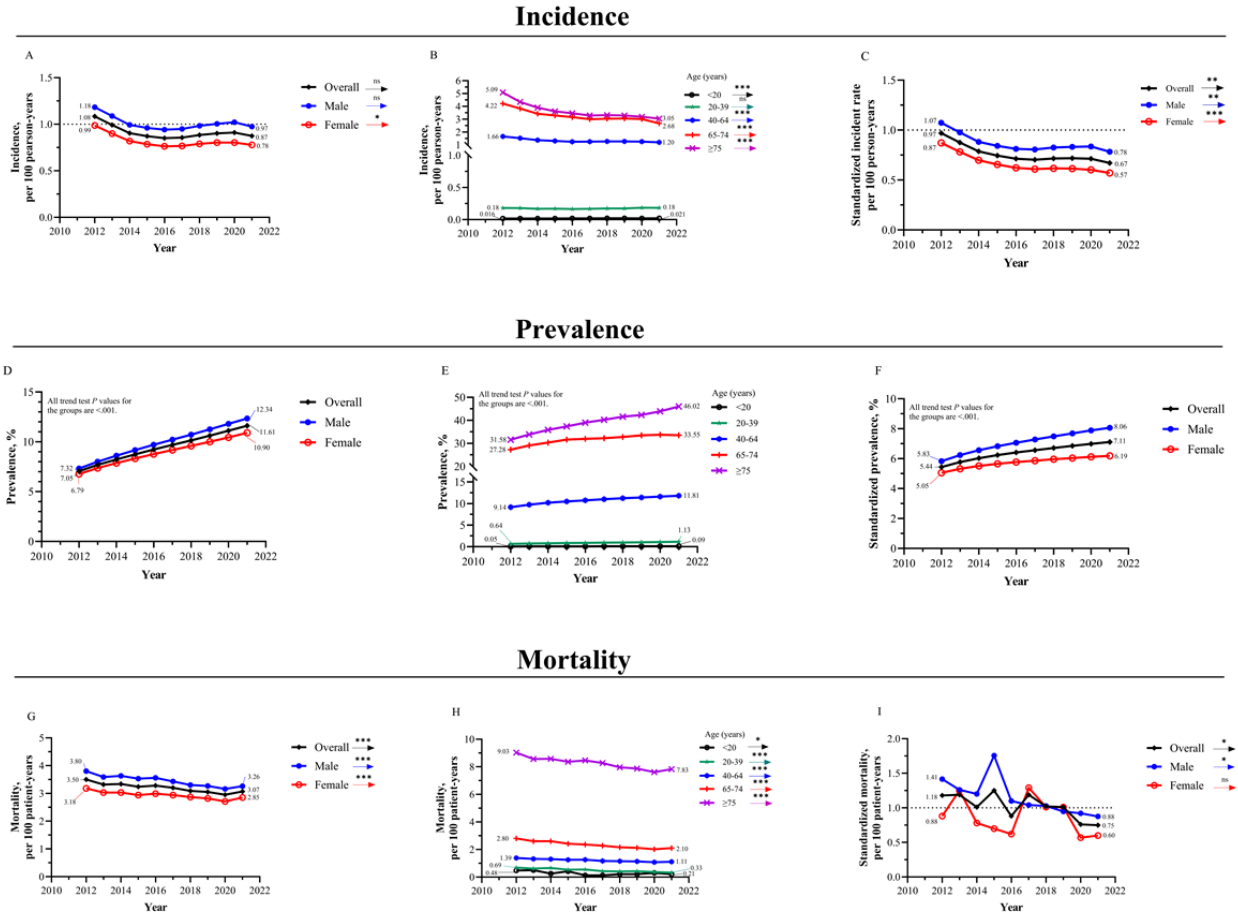
The diabetes P4P care program asks health care providers to upload patients' essential laboratory data seasonally to ensure care quality. ABC (hemoglobin $A_{1c}$ [$HbA_{1c}$], blood pressure, and cholesterol) control trends were obtained for the patients enrolled in the care program from 2015 to 2021. The proportions of individuals achieving $HbA_{1c}$ <53 mmol/mol (7%), systolic blood pressure <130 mm Hg, and low-density lipoprotein (LDL) <2.59 mmol/L (100 mg/100 mL) reflected good control of glycemic status, blood pressure, and lipid profile, respectively. The values of each selected laboratory item within 1 calendar year were averaged to reflect long-term control, with the proportion that met these 3 control criteria considered to constitute optimal control of all 3 risk factors.

The studied type 2 diabetes complications were detected from 2017 to 2021. Stroke, major adverse cardiovascular events (MACEs), retinopathy, diabetic foot, peripheral vascular disease, and nephropathy were determined by the relevant diagnosis appearing ≥2 times in outpatient or once in inpatient records within 1 year and relevant procedure codes in the diabetes population (Tables S1 and S2 in Multimedia Appendix 1). MACEs included death caused by cardiovascular diseases, myocardial infarction, heart failure, and stroke. In addition, heart failure occurrence was identified by the appropriate diagnosis codes appearing in one-time inpatient records, as suggested by the study committee. Mortality was confirmed by linking data to the National Death Registry database.

### Statistical Analysis

The annual incident rate was calculated by dividing the number of newly diagnosed type 2 diabetes cases in a given year by the number of insured individuals at risk at midyear, excluding those with prevalent type 2 diabetes, and multiplying the result by 100. The annual prevalent proportion was calculated by dividing the year's type 2 diabetes prevalent cases by the total number of insurance cases and multiplying the result by 100. The annual mortality rate was calculated by dividing the number of all-cause deaths among individuals with prevalent type 2 diabetes in a given year by the total patient-years of prevalent type 2 diabetes in that year and multiplying the result by 100. For the convenience of international comparison, the overall and sex-specific incident rates, prevalence proportions, and mortality rates were standardized by 5-year age groups (0-4, 5-9...95-99, and >100 years) using the World Health Organization (WHO) 2000 to 2025 standard population as reference [17]. The demographic life table approach [18] was applied to calculate the average life expectancy, and differences were compared with those of the Taiwan general population in the 20- to 24-year, 40- to 44-year, and 65- to 69-year age groups for both sexes. Temporal trends of the studied health metrics were evaluated using autoregressive models to account for serial correlation in the data. The presence and direction of trends were assessed by including a trend variable, defined as a transformed calendar year coded sequentially as (1, 2,...). For each outcome, residual autocorrelation was assessed using the Durbin-Watson test, and autoregressive terms were incorporated as needed to account for serial dependence. The trend effect for each outcome was then estimated using the Prais-Winsten method after adjustment for autocorrelation. Estimates of the trend effect and their 95% CIs are reported. A 2-sided *P* value of <.05 was deemed statistically significant. All data management and analysis were performed using SAS (version 9.4; SAS Institute). Figures were plotted using GraphPad Prism (version 10.4.0; GraphPad Software).

## Results



### Trends in Incidence, Prevalence, and Mortality

During 2012 to 2022, the average annual numbers of new diagnosis cases, existing cases, and deaths due to type 2 diabetes in Taiwan were 187,119, 2,310,140, and 63,694, respectively. In 2012, Taiwan's total population was 23.31 million, and the population at risk of developing type 2 diabetes was 20.75 million. The overall and sex-specific type 2 diabetes annual incidence showed similar patterns, with a slight reduction during the study period, which was more apparent in the early phase (2012-2014) and tended to be moderated tempered in recent years (Figure 1A). After adjusting for autocorrelation, female participants showed a significant annual reduction of .02 in the incidence rate (*P*<.04; Table S3 in Multimedia Appendix 1). It must be noted that male participants had a higher incidence than female participants, with the older age groups (≥40 years) being the main contributors to the reduction in incidence rates (Figure 1B). The standardized incidence of type 2 diabetes slightly declined by an average of 0.029 (95% CI 0.011-0.047) per 100 patient-years annually (*P*=.006; Figure 1C).

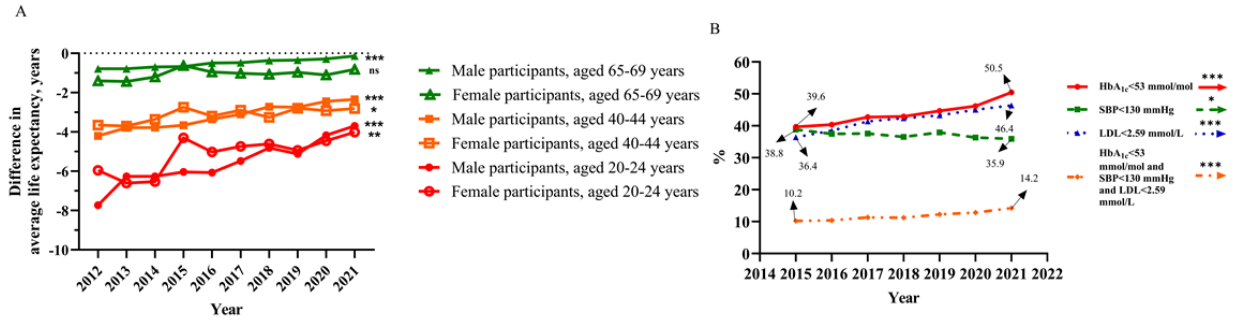
RenderX

**Figure 1.** Trends of annual incidence, prevalence, and mortality for type 2 diabetes in Taiwan from 2012 to 2021. (A) Annual incidence of type 2 diabetes for the overall and sex-specific populations. (B) Annual incidence by age. (C) Annual standardized incidence in the overall and sex-specific populations. (D) Annual prevalence in the overall and sex-specific populations. (E) Annual prevalence by age. (F) Annual standardized prevalence in the overall and sex-specific populations. (G) Annual mortality rate in overall and sex-specific type 2 diabetes populations. (H) Annual mortality rate by age. (I) Annual standardized mortality rate in overall and sex-specific type 2 diabetes populations. For A, C, D, F, G, and I, overall populations are represented by black lines and solid diamonds, male populations are represented by blue lines and solid circles, and female populations are represented by red lines and open circles. For B, E, and H, populations <20 years are represented by black lines and open circles, 20-39 years by green lines and solid stars, 40-64 years by blue lines and solid asterisks, 65-74 years by red lines and plus signs, and ≥75 years by purple lines and X's. The World Health Organization (WHO) 2000 to 2025 standard population was used for age standardization. We used an autoregressive model to estimate temporal change after accounting for serial correlation. Serial correlations were evaluated using the Durbin-Watson test. *P* values for temporal trends are denoted as follows: **P*<.05, ***P*<.01, and ****P*<.001. ns: not significant (P≥.05).

Unlike the observed decline in incidence, the annual type 2 diabetes prevalence in the overall population significantly increased, by approximately 65%, from 7.05% in 2012 to 11.61% in 2021 (Figure 1D). Similarly, male participants had higher annual prevalence proportions than female participants, and the discrepancy in annual prevalence between the sexes tended to be larger in more recent years. The older age groups experienced greater increases in prevalence during the follow-up years (Table S4 in Multimedia Appendix 1), with the most notable increase observed among individuals aged >75 years (Figure 1E). The age-standardized prevalence proportions show similar upward trends for overall and various sexes (Figure 1F). The overall standardized prevalence proportion shows a significant average annual increase of 0.17 (95% CI 0.15-0.21, *P*<.001; Table S4 in Multimedia Appendix 1).

As expected, the annual mortality rate decreased slightly from 3.5 per 100 patient-years in 2012 to 3.1 per 100 patient-years in 2021 (Figure 1G). The standardized mortality rates of type 2 diabetes declined by an average of 0.043 (95% CI 0.011-0.076, *P*=.02) per 100 patient-years annually (Table S5 in Multimedia Appendix 1). Although the mortality rate in 2021 remained higher in male participants and older age groups in general (Figures 1G, 1H, and 1I), the mortality trends suggest that those groups have more declining changes than the others (the estimated annual difference is 0.063 reduction in male participants and 0.136 in those aged ≥75 years; Table S5 in Multimedia Appendix 1).

## Difference in Average Life Expectancy



The average life expectancy of type 2 diabetes populations was shorter than that of the general population, with differences ranging from 0.13 to 7.7 years in the selected groups (Figure 2A). Notably, younger age groups exhibited larger life expectancy gaps between the 2 groups, irrespective of sex. Over the study period, these differences gradually narrowed across all age groups, particularly in male participants. Male participants with type 2 diabetes approached the average life

XSL•FO
RenderX

expectancy of the general population more rapidly than female participants over time (estimates and 95% CIs were significantly larger in male participants than in female participants at the same age level; Table S6 in Multimedia Appendix 1).

**Figure 2.** Trends in average life expectancy differences and ABC (hemoglobin A1c, blood pressure, and cholesterol) control in patients with type 2 diabetes in Taiwan. (A) Differences in average life expectancy by sex and age. Differences in average life expectancy were calculated by subtracting the average life expectancy of the general population from that of the type 2 diabetes population. For ages 65-69 years, green lines and solid triangles represent men and green lines and open triangles represent women; for ages 40-44 years, orange lines and solid squares represent men and orange lines and open squares represent women; for ages 20-24 years, red lines and solid circles represent men and red lines and open circles represent women. (B) Annual proportion of patients with type 2 diabetes enrolled in the pay-for-performance (P4P) program who achieved ABC care targets. Red solid lines and solid circles represent HbA1c < 53 mmol/mol, green dashed lines and solid squares represent SBP < 130 mmHg, blue dotted lines and solid triangles represent LDL < 2.59 mmol/L, and orange dashed dotted lines and solid diamonds represent achievement of all 3 targets. We used an autoregressive model to estimate temporal change after accounting for serial correlation. Serial correlations were evaluated using the Durbin-Watson test. We used an autoregressive model to estimate temporal change after accounting for serial correlation. Serial correlations were evaluated using the Durbin-Watson test. *$P$<.05, **$P$<.01, and ***$P$<.001. HbA1c: hemoglobin A1c; LDL: low-density lipoprotein cholesterol; ns: not significant (P≥.05); SBP: systolic blood pressure.

## Trends of ABC Controls in the National P4P Care

From 2015 to 2021, an average of 670,981 existing patients annually participated in the national P4P care program. During the study period, the annual proportion of participants with $HbA_{1c}$ levels <53 mmol/mol (<7%) increased by 10.9% (Figure 2B). A similarly significant improvement was observed in cholesterol control (the annual proportion of LDL <2.59 mmol/L [100 mg/100 mL] increased by 10.0 percentage points, from 36.4% in 2015 to 46.4% in 2021; $P$<.001). However, less than 40% of patients achieved optimal blood pressure control (systolic blood pressure <130 mm Hg) in 2021, even under the P4P care program. The annual proportion of patients achieving optimal blood pressure control was even significantly lower recently (estimate: −0.383 per year, 95% CI −0.700 to −0.065; $P$=.03; Table S7 in Multimedia Appendix 1). The yearly proportion achieving optimal control in the ABC index (above 3 indexes) only increased by less than 1% per year from 2015 to 2021. The results of the autoregressive models confirmed that the annual percentages of blood sugar and lipid control increased significantly by 1.6, whereas blood pressure control showed a significant declining trend (Table S7 in Multimedia Appendix 1).

## Trends in the Incidence of Associated Complications

The annual occurrence of stroke (10.1% in 2017 to 9.4% in 2021; $P$=.048) and MACEs (16.2% in 2017 to 14.9% in 2021, $P$=.002) in the overall type 2 diabetes population significantly decreased from 2017 to 2021 (Table S8 in Multimedia Appendix 1). However, the reductions were not homogeneous after stratification by sex and age, with no meaningful changes observed in stroke incidence among female participants aged <40 years or in MACEs among male participants aged 40 to 59 years and female participants aged <40 years.

Similarly, the annual heart failure proportion (1.7% in 2017 to 1.4% in 2021; $P$=.04) and the occurrence proportions of peripheral vascular disease (1.8% in 2017 to 1.8% in 2021; $P$=.03) generally reduced (Table S8 in Multimedia Appendix 1). However, several subgroups, including overall male participants, overall female participants, and individuals aged <40 and 40 to 59 years in both sexes, did not show a noticeable improvement in the annual heart failure occurrence. The nonobvious reduction in peripheral vascular disease occurrence was also observed in male participants aged <40 and female participants aged <40, 40 to 59, and ≥80 years.

Except for male participants (3.1% in 2017 to 2.8% in 2021; $P$=.09; Table 1), the type 2 diabetes population showed significant improvement in diabetic foot development across the selected groups. However, retinopathy showed only slight improvement among male participants overall and male participants aged ≥80 years (overall male participants: −14% from 2017; $P$=.04; male participants aged ≥80 years: −14.2% from 2017; $P$=.04; Table 1).

In contrast, annual nephropathy occurrence across time tended to be stable (36.5% in 2017 to 37.6% in 2021; $P$=.18; Table 1). The Prais-Winsten analysis confirmed significant annual declines in the incidence of stroke, MACEs, heart failure, peripheral vascular disease, diabetes-related foot complications, and retinopathy (Tables S9-S14 in Multimedia Appendix 1).

| ≥80 | 42.7 | 43.8 | 44.4 | 44.2 | 44 | .31 |

[a]We used an autoregressive model to estimate temporal change after accounting for serial correlation. Serial correlations were evaluated using the Durbin-Watson test. The *P* value for the temporal change was <.05, considered statistically significant.

Interestingly, the annual nephropathy occurrence noticeably increased in younger age groups (<40 and 40-59 years) of both male participants and females participants (<40 years: increase of 0.33 per year, 95% CI 0.16-0.51 in male participants; *P*=.009 and increase of 0.24 per year, 95% CI 0.03-0.44 in female participants; *P*=.03; 40-59 years: increase of 0.32 per year, 95%

XSL•FO
RenderX

CI 0.06-0.58 in male participants; *P*=.03 and increase of 0.28 per year, 95% CI 0.05-0.50 in female participants; *P*=.03; Table 1 and Table S15 in Multimedia Appendix 1).

## Discussion

### Principal Findings

The study identified several important features by systematically quantifying and integrating time-series analyses from different universal databases. We found that the annual incidence of type 2 diabetes remained stable, whereas mortality declined over time, contributing to an approximately 65% increase in type 2 diabetes prevalence from 2012 to 2021. The older age groups were the major contributors to reductions in incidence and mortality. Although the differences in average life expectancy in the type 2 diabetes population gradually decreased between the sex and age groups, the younger age groups still had substantial gaps in their average life expectancy compared to the general population. Analysis of the annual proportion of optimal ABC control trends indicated that the annual proportion of individuals achieving optimal blood pressure control did not improve as expected. The time-series analysis in the occurrence of associated complications demonstrated that the proportions were generally stable or reduced, except for nephropathy in younger patients (<40 or 40-59 years).

A reduction in the global incidence of type 2 diabetes was supported by a recent study using high-quality databases from resource-rich countries [19]. Studies in the United States also reported a declining trend in type 2 diabetes incidence and a lower lifetime risk of type 2 diabetes in 2014 to 2015 than in 2009 to 2010 for both sexes [19-21]. However, some argue that these reductions may be a result of a change in type 2 diabetes diagnosis criteria in 2011 or using survey-based data with different approaches [22]. Notably, the Global Burden of Disease Study 2017 also reported a decrease in the age-standardized incidence of diabetes from 1990 to 2017 in Australasia and Tropical Latin America [23]. Previous evidence combining the current findings suggests that controlling air pollutant concentration rather than changing personal lifestyles in Taiwan may contribute to the reduced incidence of type 2 diabetes [24], but more research is required to clarify the causal effect.

The differences in the analyzed trends between age- and sex-specific groups raise concerns about the social determinants of health, the need to promote precise preventive actions, and health equity. Youth-onset type 2 diabetes is a global public health challenge, particularly in disadvantaged populations [25]. Modern societal environments may limit access to healthy foods and opportunities for physical activity, potentially contributing to the development of metabolic conditions that increase the risk of type 2 diabetes among younger individuals. In addition, our findings identified another vulnerable population, middle-aged adults, as evidenced by a less reduced incidence of type 2 diabetes and heart failure development. Most of these individuals are working, raising concerns about whether health care and working environments offer sufficient resources to support medical access and self-care for diabetes management. Further studies are needed to clarify the underlying mechanisms.

The WHO launched a global diabetes initiative to promote early diabetes diagnosis and control: 80% of people with diabetes are diagnosed, 80% of the diagnosed patients have good glycemic control ($HbA_{1c}$ <64 mmol/mol [8%]), 80% of the diagnosed patients have good blood pressure control (systolic blood pressure/diastolic blood pressure of 140/90 mm Hg [18.67/12.00 kPa]), and 60% of the diagnosed patients aged >40 years use statins. Our findings on ABC control trends align with the WHO targets, demonstrating gradual improvements in glycemic and lipid control, whereas improvements in blood pressure control were less pronounced. It is reasonable to speculate that the stable occurrence of nephropathy is likely related to long-term, uncontrolled high blood pressure, which accelerates kidney dysfunction to end-stage kidney disease more quickly in Taiwan than in other countries [26]. Nonetheless, this insight may help governments allocate resources for the subsequent preventive actions more precisely. For example, the government can develop strategies to detect key unmet chronic conditions earlier and implement the necessary procedures in line with the WHO's targets.

Life expectancy in the type 2 diabetes population is not always quantified and compared with the overall population in previous studies. Similar to the recent observations that display years of life lost due to type 2 diabetes from 23 developed jurisdictions [19], our results reflect that those with type 2 diabetes have a lower average life expectancy than the general population. Additionally, younger individuals with type 2 diabetes tend to experience a substantially greater loss in life expectancy than older individuals, with nearly 5 years of life lost among those aged 20 to 24 years versus less than 2 years among those aged 65 to 69 years. Encouragingly, both the overall gap in years of life lost between individuals with type 2 diabetes and the general population and the age-related disparity in life years lost have narrowed. This trend may be attributed to the widespread adoption of more effective interventions, such as sodium-glucose cotransporter 2 inhibitors and glucagon-like peptide 1 receptor agonists, which remarkably reduce the risks of complications and mortality [27].

The study has several advantages. First, high-quality databases with strict definitions were used to ensure the findings' accuracy and reliability. Next, integrating several meaningful health metrics across the lifetime of patients with type 2 diabetes offers more comprehensive health and care insights for stakeholders, allowing decision-makers to optimize their health decisions and explore possible mechanisms continuously.

However, some limitations need to be disclosed. First, the strict definitions to ensure accurate results may compromise generalizability to some patients with mild conditions, both for diabetes and its relevant complications. In addition, the ABC control time-series analysis from the P4P care program may be subject to optimistic bias and may not be representative of the entire population with type 2 diabetes in Taiwan. Factors influencing ABC control are likely multifactorial, involving patient and physician behaviors as well as broader social determinants, which are not captured within this surveillance system. Finally, the study was conducted in a high-income country with a single-payer health insurance system, so caution

XSL•FO
RenderX

should be exercised when generalizing the findings to other countries, particularly those in low- and middle-income settings or with different health care systems.

### Conclusions

In conclusion, the comprehensive analyses revealed substantial progress across several type 2 diabetes metrics but highlighted warning signs, particularly in blood pressure management, nephropathy prevention, and care for younger individuals. The surveillance results underscore the need for timely, targeted policy actions, including strengthening blood pressure control, enhancing early kidney protection strategies (eg, the use of sodium-glucose cotransporter 2 inhibitors), and delivering more accessible care for younger age groups to increase health parities.

## Acknowledgments

The authors thank the Taiwan Instrument Research Institute, National Applied Research Laboratories, for its assistance with project coordination. In addition, the authors thank Miss Chi-Ting Huang for her assistance with data management. Portions of this work were presented orally at the Annual Meeting of the Taiwan Society of Nephrology in December 2024. The authors used ChatGPT to review selected author-written sentences for language fluency and grammatical accuracy. ## Abstract

**Background:** Lung cancer is the leading cause of cancer-related death globally, with a significant burden in China, which accounts for more than one-third of the world's new cases and 40% of related mortalities. Despite evidence that low-dose computed tomography screening can reduce mortality, its limited uptake in China means that most patients are diagnosed at an advanced stage, contributing to a low 5-year survival rate compared to high-income countries. Although overall incidence trends have been well documented, there is a scarcity of population-based data on the temporal trends of different histological subtypes of lung cancer in China.

**Objective:** This study aimed to analyze population-based cancer registry data to assess lung cancer incidence trends by histological subtype and sex from 2001 to 2020 and to forecast future incidence rates through 2030 in Xihu District, Hangzhou, Zhejiang Province, eastern China.

**Methods:** The study used population-based surveillance data from the Xihu Cancer Registry from 2001 to 2020. Statistical analyses were conducted to assess the burden of each tumor subtype, including the average annual percentage change (AAPC) to evaluate temporal trends and the Bayesian age-period-cohort (BAPC) model to forecast incidence rates through 2030.

**Results:** Lung cancer incidence rates were generally low among individuals aged <45 years but escalated markedly with age, reaching a peak of 567.6 per 100,000 person-years in among those aged 80 to 84 years. Notably, a significant rise in incidence was observed among those aged 30 to 44 years in recent years. Sex-based differences in histological distribution were pronounced. Adenocarcinoma accounted for 66.65% (2322/3484) of female cases compared to 37.1% (1795/4838) of male cases, while squamous-cell carcinoma was substantially less common in female cases (86/3484, 2.47% compared to 829/4838, 17.13% in male cases). Among male cases, the age-standardized incidence rates (ASIRs) of adenocarcinoma increased from 1.39 to 42.18 per 100,000 between 2001 and 2020; among female cases, the corresponding increase was even more pronounced, rising from 2.81 to 67.37 per 100,000. Joinpoint regression analysis demonstrated a consistent long-term increase in adenocarcinoma (AAPC=35.1, 95% CI 14.2-50.2), with peak acceleration observed from 2005 to 2012 (annual percentage change [APC]=76.7, 95% CI 45.2-124.2), and a steady increase in large-cell and other specified carcinomas (AAPC=32.7, 95% CI 12.5-45.7), while unspecified carcinoma showed a long-term decline (AAPC=−3.1, 95% CI −14.2 to −1.1). BAPC projections indicated that adenocarcinoma ASIR will continue to surge between 2020 and 2030, emerging as the dominant histological subtype, while unspecified carcinoma, squamous-cell carcinoma, and small-cell lung cancer are anticipated to decline modestly.

**Conclusions:** The increase in lung cancer incidence, particularly among female participants, underscores the need for effective prevention and control strategies, including targeted interventions to reduce smoking.

## Introduction

Globally, lung cancer represents one of the most commonly diagnosed malignancies and remains the leading cause of cancer-related mortality. According to the latest GLOBOCAN estimates, approximately 2.5 million new lung cancer cases and 1.8 million deaths were recorded in 2022 worldwide [1]. China is one of the countries most affected by lung cancer. According to the latest national cancer statistics, lung cancer is the leading cause of both cancer incidence and mortality in China, with approximately 1,061,000 new cases and 733,000 deaths recorded in 2022, accounting for approximately 43% of global lung cancer incidence and 40% of global lung cancer mortality [2]. Cancer incidence rates often differ markedly across regions and between sexes, influenced by variations in lifestyle and environmental factors. In urban settings, the number of incident cases reached 457,000, representing a 1.4-fold increase compared to rural regions, with higher incidence observed among male patients than female patients [3]. Zhang et al [4] indicated a modest rise in the age-standardized incidence rate (ASIR) for men (annual percentage change [APC] 0.4%) alongside a decline for women (APC −0.2%) over the period from 2000 to 2014. In contrast, death rates increased during more recent periods, rising from 5.47 per 100,000 in the mid-1970s to 17.27 per 100,000 in the early 1990s and further to 30.83 per 100,000 during the 2000s [5].

Many studies have confirmed the mortality-reducing benefits of low-dose computed tomography (LDCT) for lung cancer screening [6,7]. However, lung cancer screening has not been widely adopted in China. Consequently, most cases are detected at advanced stages, leaving only a small proportion diagnosed early, when treatment is most effective [8]. The high proportion of late-stage diagnoses is reflected in the low 5-year survival rate of lung cancer in China [9], reflecting the continued predominance of late-stage diagnoses at presentation [10]. This rate was substantially lower than the 5-year survival rates reported in other high-income countries, which ranged from approximately 22% in Australia to 32% in Japan [11]. Besides stage and anatomical location, cancer histology (eg, adenocarcinoma, squamous-cell carcinoma, and large-cell carcinoma) is another major determinant of prognosis and treatment approach [12].

Although temporal patterns of lung cancer incidence have been extensively studied [13-15], data on histological subtype trends in China remain limited. One previous study reported trends in lung cancer incidence rates by histological type in Sichuan, China [16]; however, this study relied on data from a large hospital rather than population-based surveillance data. Population-based surveillance data can provide a more representative sample of the population and help identify trends and patterns in the incidence and prevalence of different subtypes of lung cancer. Therefore, this study aimed to perform a population-based analysis using cancer registry data to assess lung cancer trends, focusing on the most prevalent histological types from 2001 to 2020. Additionally, we projected future incidence rates (2020-2030) across different lung cancer subtypes.

## Methods

### Data Source

This study examined incident lung cancer cases in Xihu District, Zhejiang, China, from 2001 to 2020. Xihu District is 1 of the 11 districts of Hangzhou, located in Zhejiang Province, eastern China. It has an area of 7265 $km^2$ with about 1 million inhabitants and is situated between 29°16′N and 30°03′N and 118°20′E and 119°15′E. The Xihu Cancer Registry was founded in 1986 and is a member of the International Association of Cancer Registries. Incident cancer cases were classified using the *International Classification of Diseases for Oncology, 3rd Edition* (*ICD-O-3*) [17] and the *International Statistical Classification of Diseases, 10th Revision* (*ICD-10*) [18]. Lung cancer, categorized by *ICD-10* codes C34.0-C34.9, was identified and classified. Data were extracted from the Cancer Registration Database, with preliminary reviews conducted by local cancer registries. Case reporting primarily relied on hospital records, community health centers, and village-level health care providers. Additional sources included the national health insurance system, the rural cooperative medical scheme, and vital statistics. Detailed methodologies for data collection, management, and analysis in China's cancer registries have been described elsewhere [2]. Population data for the study period were obtained from the Xihu Bureau of Statistics. The registered population of the district was approximately 510,000 persons in 2001 and 989,000 persons in 2020, with a mean annual population of approximately 760,000 persons over the study period. This research followed the Guidelines for Accurate and Transparent Health Estimates Reporting (GATHER) [19].

### Ethical Considerations

This study was approved by the ethics committee of Xihu District Center for Disease Control and Prevention (2023-065). As this study used retrospective, population-based cancer registry data from the Xihu Cancer Registry, the requirement for informed consent from individual participants was waived by the ethics committee, given the observational and noninterventional nature of the study. All data used in this study were fully anonymized and deidentified prior to analysis, ensuring the privacy and confidentiality of all individuals. No participant compensation was applicable, as this study involved a secondary analysis of existing registry data.

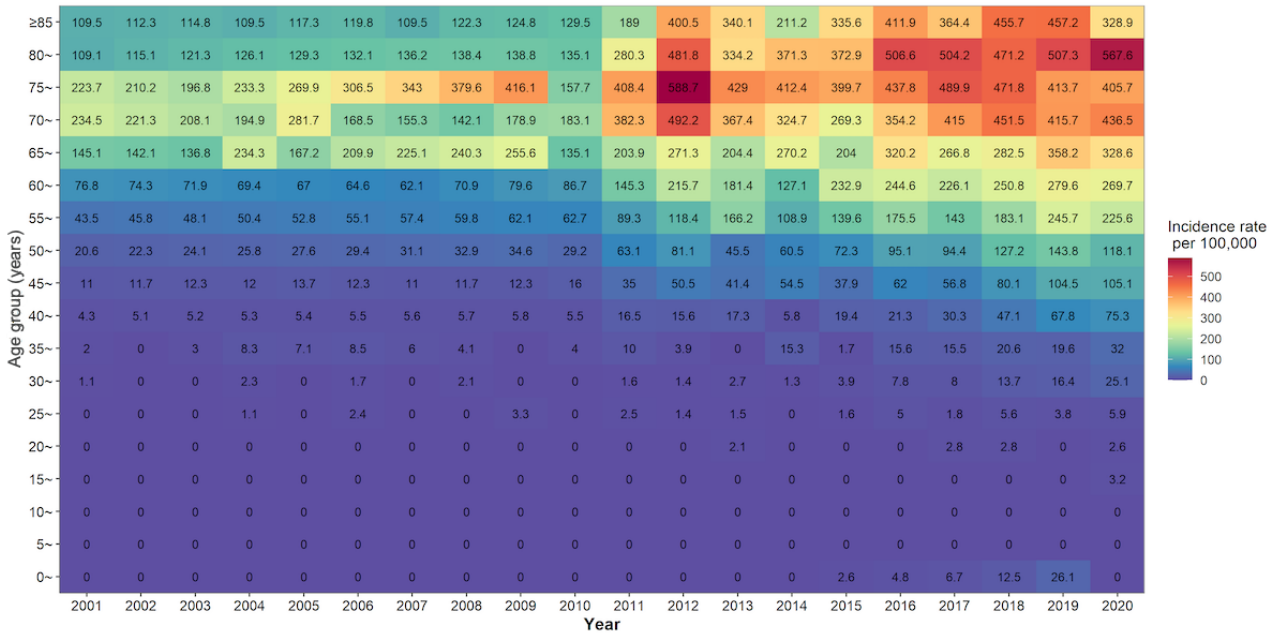
### Histological Classification

All cases were histologically subtyped according to the most recent World Health Organization (WHO) classification system for lung tumors. We divided lung cancer histology, coded as *ICD-O-3*, into the following subtypes: small-cell lung cancer (SCLC; *ICD-O-3* 8002 and 8041-8045), adenocarcinoma (*ICD-O-3* 8015, 8050, 8140-8141, 8143-8145, 8147, 8190, 8201, 8211, 8250-8255, 8260, 8290, 8310, 8320, 8323, 8333, 8401, 8440, 8470-8471, 8480-8481, 8490, 8503, 8507, 8550, 8570-8572, and 8574, 8576), squamous-cell carcinoma (*ICD-O-3* 8051-8052, 8070-8076, 8078, 8083-8084, 8090, 8094, 8120, and 8123), large-cell and other specified carcinomas (8003-8004, 8012-8014, 8021-8022, 8030-8035, 8082, 8200, 8240-8241, 8243-8246, 8249, 8430, 8525, 8560, 8562, and

XSL•FO
RenderX

8575), and unspecified carcinoma (8000-8001, 8010-8020, 8046, 8230) [20].

### Statistical Analysis



To evaluate the disease burden across different tumor subtypes, we analyzed both crude incidence rates and ASIRs. The ASIRs were calculated using the World Standard Population, following the Segi methodology [21]. For longitudinal trend analysis across the study period (2001-2020), we used the average annual percentage change (AAPC) to quantify temporal variations in age-standardized lung cancer incidence rates. Joinpoint regression was used to estimate the AAPC, with a maximum of 2 joinpoints allowed the ASIR to balance model complexity and avoid overfitting given the 20 annual data points [22]. We modeled temporal trends by fitting a linear regression to log-transformed rates ($\ln(ASIR)=Y=\alpha+\beta X+\varepsilon$), where $\beta$ quantifies the direction and magnitude of annual change. The AAPC was then calculated as $100\times(e^{\beta}-1)$. Instead of stratifying by gender, we incorporated sex as a covariate in the joinpoint model to explicitly test for differential trends between male patients and female patients. If the interaction between sex and year was significant ($P<.05$), we reported sex-stratified AAPCs; otherwise, we reported the overall trend adjusted for sex.

To forecast the incidence rates of lung cancer through 2030, we used a statistical model known as the Bayesian age-period-cohort (BAPC) model. Age-period-cohort modeling has become an established analytical framework for examining temporal patterns in cancer epidemiology, particularly for incidence and mortality trends. In this case, the incidence rates are examined in relation to 3 distinct time frames: age, period, and cohort. These time frames help account for various factors that influence the rates, such as consistent external factors linked to aging, external factors that affect all age groups equally during a specific period (eg, pollution or medical advancements), and generational effects (eg, malnutrition among children during or after wars). The projection of incidence rates using age-period-cohort models is particularly important due to changes in demographics, as well as advancements in therapeutic and diagnostic practices. BAPC models offer methodological advantages over conventional approaches by integrating prior knowledge about temporal smoothing across all 3 dimensions. This inclusion helps reduce random fluctuations and enhances the accuracy of the projections [23]. In the BAPC model, we established prior distributions for the effects of age, period, and cohort. These distributions smooth each data point based on the 2 preceding points, resembling a second-order random walk pattern. Trend analysis was conducted using Joinpoint software (version 4.8.0.1; Statistical Research and Applications Branch, National Cancer Institute), with complementary analyses performed in the R statistical environment (version 4.0.0; R Foundation for Statistical Computing).

## Results

Figure 1 illustrates the temporal trends in lung cancer incidence among different age groups from 2001 to 2020. The incidence rates of lung cancer were generally low among individuals aged <45 years. However, as age increased, the incidence rates of lung cancer also escalated, reaching their peak among those aged 80 to 84 years, with a maximum of 567.6 per 100,000 person-years recorded during the study period. Notably, we observed a significant rise in the incidence rates among younger individuals in recent years, particularly those aged 30 to 44 years. In Figure 2, we present the temporal trends in the ASIRs for lung cancer based on histological type. The ASIR for adenocarcinoma exhibited a consistent and substantial increase from 2001 to 2020. On the other hand, there were some variations in the ASIR for unspecified carcinoma during the same period for both sexes. Regarding other histological types, the ASIRs remained stable or slightly decreased between 2001 and 2020.

**Figure 1.** Temporal trends in lung cancer incidence rate by age groups (2001-2020).

XSL•FO
RenderX

**Figure 2.** Temporal trends in age-standardized incidence rates for lung cancer based on histological subtypes.

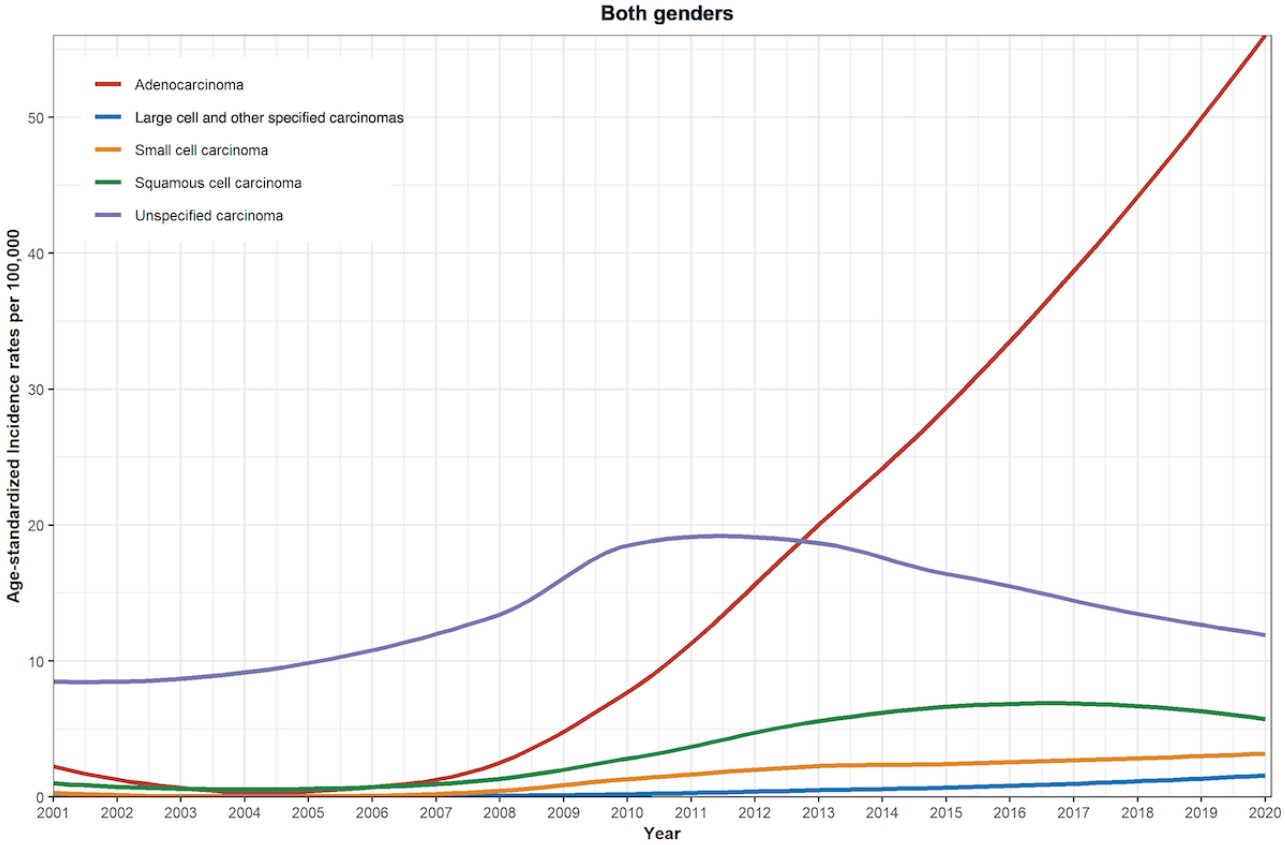


Table 1 illustrates the relative change in ASIR of lung cancer between 2001 and 2020, categorized by histological type and age. Notably, in male patients, with the exception of unspecified carcinoma, all other histological types experienced an increase in ASIR over the mentioned time period. Of particular interest is the substantial rise in ASIR for adenocarcinoma, which escalated from 1.39 per 100,000 in 2001 to 42.18 per 100,000 in 2020. Similarly, among female patients, the highest increase in ASIR was also observed in adenocarcinoma, surging from 2.81 per 100,000 in 2001 to 67.37 per 100,000 in 2020. In contrast to the male population, we noted a rise in ASIR for squamous-cell carcinoma among the female population, with rates increasing from 0.35 per 100,000 in 2001 to 0.50 per 100,000 in 2020.

**Table 1.** Estimated age-standardized incidence rates for lung cancer by histological subtypes and their percentage change in male and female participants.

| Characteristics | Age-standardized incidence rates per 100,000 (95% CI) | | Percentage change (%) |
|---|---|---|---|
| | 2001 | 2020 | |
| **Male** | | | |
| Small-cell carcinoma | 0.42 (0.33-2.78) | 4.84 (3.17-7.72) | 1052.38 |
| Squamous-cell carcinoma | 1.04 (0.73-4.21) | 9.51 (7.01-13.15) | 814.42 |
| Large-cell and other specified carcinomas | 0.21 (0.02-2.83) | 1.84 (0.87-4.19) | 776.19 |
| Adenocarcinoma | 1.39 (0.94-4.32) | 42.18 (36.61-48.77) | 2934.53 |
| Unspecified carcinoma | 19.32 (16.28-25.34) | 13.49 (10.3-17.44) | −30.18 |
| **Female** | | | |
| Small-cell carcinoma | 0 (0) | 1.06 (0.38-3.25) | —[a] |
| Squamous-cell carcinoma | 0.35 (0.17-1.44) | 0.50 (0.10-2.58) | 42.86 |
| Large-cell and other specified carcinomas | 0 (0) | 1.34 (0.57-3.57) | — |
| Adenocarcinoma | 2.81 (1.05-5.42) | 67.37 (60.33-75.38) | 2297.51 |

RenderX

Table 2 summarizes the demographic characteristics of the study population by sex, histology, age, diagnosis period, and stage. Histological distribution patterns differed markedly between sexes: unspecified carcinoma predominated in male participants (1832/4838, 37.87%), followed by adenocarcinoma (1795/4838, 37.10%) and squamous-cell carcinoma (829/4838, 17.13%), while adenocarcinoma accounted for two-thirds of female cases (2322/3484, 66.65%), with unspecified carcinoma (972/3484, 27.90%) and squamous-cell carcinoma (86/3484, 2.47%) being less common. Large-cell and other specified carcinomas represented the rarest subtype in both groups. Notable sex-based differences emerged, with female participants showing a 1.8-fold higher adenocarcinoma prevalence (2322/3484, 66.65% vs 1795/4838, 37.10%) but an 86% lower squamous-cell carcinoma incidence (86/3484, 2.47% vs 829/4838, 17.13%) than male participants. Age-stratified analysis revealed that adenocarcinoma predominated in younger patients (≤40 years; 854/1077, 79.29%), while unspecified carcinoma was most prevalent in the oldest group (≥80 years; 716/1242, 57.65%).

**Table 2.** Distribution of patients included in the analyses by sex, age, and period of diagnosis according to histological subtype.

| Characteristics | Small-cell carcinoma, n (%) | Squamous-cell carcinoma, n (%) | Large-cell and other specified carcinomas, n (%) | Adenocarcinoma, n (%) | Unspecified carcinoma, n (%) |
|---|---|---|---|---|---|
| **Age group (years)** | | | | | |
| <40 (n=1077) | 23 (2.14) | 28 (2.6) | 18 (1.67) | 854 (79.29) | 154 (14.3) |
| 40-59 (n=2157) | 75 (3.48) | 139 (6.44) | 22 (1.02) | 1470 (68.15) | 451 (20.91) |
| 60-69 (n=2129) | 115 (5.4) | 234 (10.99) | 39 (1.83) | 1230 (57.77) | 511 (23.99) |
| 70-79 (n=2030) | 93 (4.58) | 288 (14.19) | 28 (1.38) | 882 (43.45) | 739 (36.4) |
| ≥80 (n=1242) | 40 (3.22) | 140 (11.27) | 18 (1.45) | 328 (26.41) | 716 (57.65) |
| **Sex** | | | | | |
| Male (n=4838) | 298 (6.16) | 829 (17.13) | 84 (1.74) | 1795 (37.1) | 1832 (37.87) |
| Female (n=3484) | 71 (2.04) | 86 (2.47) | 33 (0.95) | 2322 (66.65) | 972 (27.9) |
| **Period of diagnosis** | | | | | |
| 2001-2005 (n=1357) | 60 (4.42) | 166 (12.23) | 21 (1.55) | 521 (38.39) | 589 (43.4) |
| 2006-2010 (n=1598) | 76 (4.76) | 186 (11.64) | 17 (1.06) | 645 (40.36) | 674 (42.18) |
| 2011-2015 (n=1963) | 96 (4.89) | 230 (11.72) | 19 (0.97) | 842 (42.92) | 776 (39.55) |
| 2016-2020 (n=3404) | 137 (3.98) | 333 (9.68) | 60 (1.74) | 2109 (61.29) | 765 (22.23) |

Table 3 presents the results of a joinpoint regression analysis of lung cancer ASIR by histological type from 2001 to 2020. The interaction between sex and year was not significant ($P$>.05); therefore, we reported the overall trend adjusted for sex. In terms of specific histology, we observed a consistent long-term decrease in unspecified carcinoma (AAPC=−3.1, 95% CI −14.2 to −1.1) and a steady long-term increase in large-cell and other specified carcinomas (AAPC=32.7, 95% CI 12.5-45.7). The greatest increase in ASIR was observed for adenocarcinoma (AAPC=35.1, 95% CI 14.2-50.2) between 2001 and 2020, with peak acceleration observed from 2005 to 2012 (APC=76.7, 95% CI 45.2-124.2).

Figure 3 displays the observed and predicted trends in the ASIR of lung cancer by histological subtype from 2001 to 2030. Our analysis indicates that the ASIR of adenocarcinoma is projected to undergo a substantial surge between 2020 and 2030, emerging as the dominant histological subtype among the different histological subtypes. Conversely, the ASIRs of other histological subtypes of lung cancer, namely unspecified carcinoma, squamous-cell carcinoma, and SCLC, are anticipated to experience modest declines until 2030. The ASIR of large-cell and other specified carcinomas is expected to persist at a consistently low level.

## Discussion

### Principal Findings

This study examined temporal patterns and projected future trends in lung cancer incidence in Xihu, Zhejiang, over the coming decade. Our findings revealed a marked rise in lung cancer rates, aligning with national trends observed across China. Histologically, adenocarcinoma incidence showed sustained growth, while small-cell and squamous-cell carcinomas exhibited stable trends. Notably, female lung cancer cases increased significantly, mirroring epidemiological patterns reported internationally. Together, these findings speak directly to the aims of this study. They delineate 2 decades of

XSL•FO
RenderX

histology-specific incidence trends from population-based registry data and indicate that the rising burden, driven predominantly by adenocarcinoma, is likely to persist through 2030.

In line with other studies [24], our findings indicate that the number of lung cancer diagnoses and the ASIR increased during the period from 2001 to 2020. This upward trend may be attributed to factors such as tobacco use, population aging, and advancements in lung cancer detection and treatment in China. Tobacco use stands out as a major risk factor that contributes significantly to the escalating lung cancer crisis [3]. In response to this public health challenge, China's national "Healthy China 2030" initiative has established ambitious tobacco control targets, including reducing smoking prevalence to <20% by the target year [25]. Various measures have been implemented to achieve this goal, including increasing the cost and taxes of tobacco products and establishing smoke-free zones. Consequently, the smoking rate has shown a substantial decline from 30.2% to 26.9% between 2000 and 2015, as reported by the WHO. Paradoxically, although smoking prevalence has demonstrably declined, China's total number of smokers grew by approximately 5 million (from 310 to 315 million) during the study period [26]. Therefore, considering population growth and population aging, additional efforts are necessary to reduce the incidence of lung cancer by curbing the smoking rate. Furthermore, the growing proportion of older individuals in China's population also contributes to the rising incidence of lung cancer. Presently, China faces a significant aging challenge, with approximately 11.5% of the total population aged >65 years in 2019 [27]. Consequently, it is crucial to focus on monitoring and addressing the incidence and mortality of lung cancer in the middle-aged and elderly population.

For histology-specific lung cancer trends, we observed a consistent rise in adenocarcinoma over a long period, while SCLC and squamous-cell carcinoma reached a plateau. Despite adenocarcinoma being the most prevalent subtype for both men and women, women exhibited an even greater proportion of this cell type. Moreover, women are more likely to develop adenocarcinoma in situ, which is an early-stage, noninvasive abnormal growth [28]. Our results align with previous studies on changing histology patterns of lung cancer in Osaka (Japan) [29], South Korea [30], and other countries [15]. Notably, stabilization of adenocarcinoma rates among post-1950 birth cohorts has been reported in Canada, Denmark, and Australia [15]. The specific risk factors responsible for the rising incidence of adenocarcinoma remain uncertain. One possible explanation for the increasing rates could be the growing exposure to secondhand smoke [31]. It is believed that sidestream smoke, which is emitted from the burning end of a cigarette, may carry lung carcinogens that are unique to tobacco and deposit them in the outer areas of the lungs. Moreover, previous studies have established associations between airborne pollutants (including particulate matter with a diameter of ≤2.5 μm and nitrogen oxides) and increased susceptibility to lung adenocarcinoma development [32]. Furthermore, improvements in diagnostic pathology, including the widespread adoption of immunohistochemistry and the updated WHO classification of lung tumors, may have contributed to the observed rise in adenocarcinoma, as cases previously classified as unspecified carcinoma (AAPC=−3.1) were more precisely reclassified over time.

Global epidemiological data reveal an increasing trend in female lung cancer incidence, with particularly notable rises observed across North American and European populations in recent decades. The ratio of men to women affected by lung cancer is gradually decreasing [1]. Our findings align with the global trend, indicating a significant increase in lung cancer cases among women. Although smoking prevalence among women remains comparatively low, their lung cancer incidence is higher than that observed in several European nations. This discrepancy may stem from exposure to indoor air pollutants, including emissions from inefficient coal stoves and cooking oil vapors in poorly ventilated spaces [33]. Secondhand smoke exposure represents another significant risk factor, disproportionately affecting Chinese women [34], potentially accounting for the elevated female lung cancer burden identified in our analysis. Biological factors may further contribute to this pattern, as evidenced by the retrospective findings of Kligerman and White [28], which suggest that women demonstrate heightened sensitivity to tobacco and environmental carcinogens, potentially mediated through increased CYP1A1 expression and p53 mutations. Additionally, estrogen has been shown to promote lung cancer progression via interactions with both estrogen receptors and epidermal growth factor receptor pathways, suggesting potential therapeutic targets for intervention [35].

The epidemiological patterns identified in this study have direct implications for lung cancer screening and prevention strategies. The sustained rise in adenocarcinoma, particularly among women with low smoking prevalence, highlights a critical limitation of current LDCT screening guidelines, which remain primarily focused on heavy smokers. We therefore advocate for the expansion of screening eligibility to encompass individuals with significant indoor air pollution exposure, such as cooking oil fumes and coal combustion emissions, as well as those with a family history of lung cancer. On the prevention side, a differentiated, subtype-specific approach is warranted: tobacco control efforts should remain a priority to sustain the observed plateau in squamous-cell and small-cell carcinoma incidence, while nontobacco-focused interventions, including improved indoor ventilation, clean cooking technologies, and stricter ambient air quality regulations, are essential to address the continuing rise in adenocarcinoma, particularly among women.

On the basis of our prediction analysis, we anticipate a continued rise in lung cancer rates, specifically for adenocarcinoma. The prevalence of smoking among Chinese men has remained consistently high since the 1980s. Although male smoking rates peaked in 1990 and have somewhat decreased since then [36], if these trends persist, we can expect further reductions in the incidence of lung cancer subtypes strongly linked to smoking, such as small-cell, squamous-cell, and large-cell carcinomas. However, the incidence of adenocarcinomas may continue to increase, possibly in proportion to the overall rise in lung cancer cases. To gain a better understanding of current trends, particularly in nonsmokers, it is essential to conduct additional studies that explore variations in the response to smoking

exposure based on histology and investigate the associations between traditional risk factors for lung cancer and other factors with specific histological types.

Before interpreting our findings, it is important to acknowledge several potential limitations. First, our research is a descriptive study that relies on cancer registry data, which means that we cannot establish causal relationships to explain the temporal trends of lung cancer. The Xihu Cancer Registry follows standard quality control procedures, including case verification, data completeness checks, and regular audits; however, variations in diagnostic practices and registration protocols over the 20-year study period may have introduced some degree of inconsistency into the data. Second, there is a possibility of underreporting and missed diagnoses, which could introduce bias into the cancer registration data and result in an underestimation of lung cancer cases. Finally, our prediction model assumes that current and past trends will continue unchanged, disregarding any potential advancements in the prevention or diagnosis of lung cancer that could affect future incidence rates. Furthermore, as a statistical model, the BAPC projections cannot incorporate the potential impact of emerging public health interventions, which may cause actual future incidence rates to deviate from the predicted trajectory. Therefore, it would be advisable to conduct future studies that incorporate these influential factors to develop more comprehensive forecast models.

## Conclusions

Drawing on 2 decades of population-based registry data, this study shows that the lung cancer burden in Xihu is not only growing but also changing in character, with adenocarcinoma, particularly among women with low smoking prevalence, accounting for an increasing share of the disease. The significance of these findings extends beyond a single district. They suggest that lung cancer control in China can no longer rely on tobacco control and smoker-targeted screening alone: screening frameworks will need to evolve toward risk-adapted criteria that incorporate nontobacco exposures such as indoor air pollution and family history, and prevention strategies will need to become subtype-aware. More broadly, as many low- and middle-income countries undergo similar epidemiological transitions, population-based cancer surveillance capable of resolving histological subtypes will be indispensable for anticipating, rather than merely reacting to, the changing epidemiology of lung cancer, and etiological research into nonsmoking risk factors should be prioritized to inform the next generation of prevention policies.

## Acknowledgments

The authors highly appreciate the people working at local cancer registry sites who contributed to this study. The authors declare the use of generative AI (GAI) in the research and writing process. According to the Generative Artificial Intelligence Delegation Taxonomy (2025), the following tasks were delegated to GAI tools under full human supervision, including literature search and systematization and proofreading and editing. The GAI tool used was DeepSeek (version V4 Lite; DeepSeek AI). Responsibility for the final manuscript lies entirely with the authors. GAI tools are not listed as authors and do not bear responsibility for the final outcomes.

## Funding

This study was funded by the Hangzhou Municipal Science and Technology Plan (grant 20201203B27) and the Zhejiang Provincial Disease Prevention and Control Science and Technology Program (grant 2026JKY015).

## Data Availability

The datasets generated and analyzed during the current study are available from the corresponding author on reasonable request.

## Abstract

**Background:** Hemorrhagic fever with renal syndrome (HFRS) is a severe natural focal infectious disease that remains a major public health concern in Shandong Province, China. Understanding the epidemiological characteristics of HFRS and forecasting its incidence are crucial to provide guidance for policymaking and implement timely interventions against this disease.

**Objective:** This study examined the long-term epidemiological characteristics of HFRS based on 15 years of surveillance data; the analysis used 4 time series models to predict its incidence trends. The aim was to provide a scientific basis for local disease control departments, thereby supporting more accurate prediction and effective prevention and control of HFRS in this region.

**Methods:** HFRS case surveillance data in Shandong Province from 2010 to 2024 were collected through the China Information System for Disease Control and Prevention. Descriptive epidemiological methods were used to analyze the basic characteristics of HFRS. Four forecasting models, namely, seasonal autoregressive integrated moving average, Prophet, the Holt-Winters exponential smoothing method, and Extreme Gradient Boosting, were implemented in R to fit the time series and generate predictions. Their predictive performance was evaluated and compared using the root mean squared error, mean absolute error, and mean absolute percentage error.

**Results:** From 2010 to 2024, a total of 15,184 HFRS cases were reported in Shandong Province, with 188 deaths. The annual incidence rate ranged from 0.45 to 1.84 per 100,000 population, showing an overall fluctuating downward trend. The peak incidence occurred during the autumn and winter months from October to December each year. Spatially, the eastern and southeastern regions of Shandong Province were the primary high-incidence areas. Demographically, the high-risk populations were mainly middle-aged and older adults, male individuals, and farmers. In the 2024 test set, the Holt-Winters model yielded the lowest prediction error metrics among the 4 models, with root mean squared error, mean absolute error, and mean absolute percentage error values of 7.56, 6.43, and 34.56%, respectively.

**Conclusions:** The Holt-Winters model showed the lowest prediction error metrics among the 4 models, suggesting its potential utility for forecasting HFRS incidence. It is recommended to apply this model to enhance precise monitoring and implement targeted prevention and control measures focusing on key areas, peak periods, and high-risk populations.

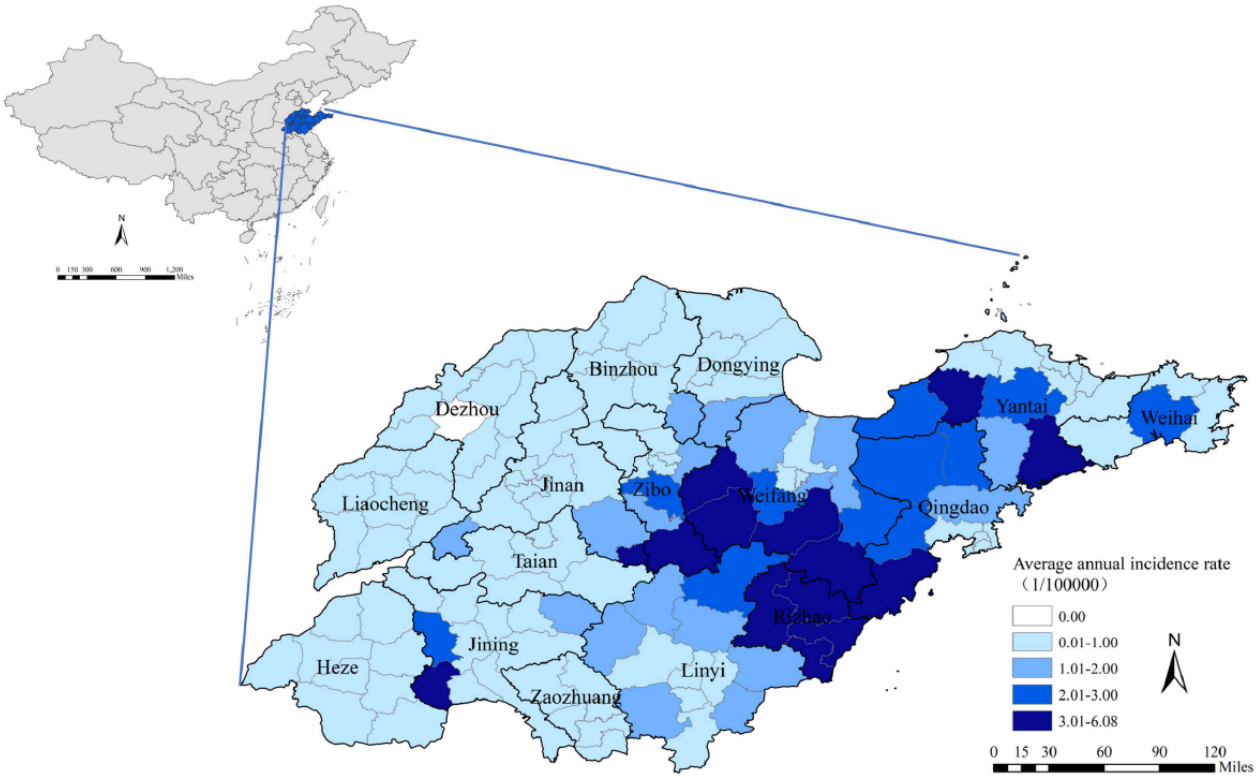
## Introduction

Hemorrhagic fever with renal syndrome (HFRS) is a zoonotic disease, with rodents serving as the primary source of infection [1,2]. Humans are commonly infected through contact with rodent excreta or the resulting aerosols; currently, there is no conclusive evidence of human-to-human transmission of HFRS [3,4]. The disease is primarily characterized by acute fever, hemorrhage, and renal dysfunction, which can lead to a substantial disease burden [5]. HFRS first emerged during World War I and is now distributed across more than 70 countries and regions worldwide, although it is predominantly endemic to Eurasia [6]. China experiences the most severe HFRS epidemics worldwide, with cases having been reported in all 31 provinces (including autonomous regions and municipalities) [7]. The transmission of HFRS is jointly influenced by ecological, meteorological, and socioeconomic factors [8]. Meteorological factors such as temperature, precipitation, and humidity can directly affect rodent population dynamics as well as the survival and transmission of the virus in the environment [9]. Meanwhile, socioeconomic factors, including land use, urbanization, and human behaviors, also impact the risk of human exposure [10]. HFRS is an acute infectious disease caused by various genotypes of hantaviruses [11]. HFRS endemic areas in China are primarily classified into 3 categories, based on virus types and host animal species: the wild rodent–type endemic area, where HFRS is caused by the Hantaan virus (HTNV) and primarily involves dominant wild rodent species such as the striped field mouse; the domestic rodent–type endemic area, where HFRS is caused by the Seoul virus (SEOV) and primarily involves dominant domestic rodent species such as the brown rat; and the mixed-type endemic area, where both types coexist [12].

Shandong Province is one of the primary endemic areas for HFRS in China. Since the identification of the first case in 1968, cases have been reported annually [13-15]. Despite long-term efforts in surveillance, prevention, and control, HFRS in Shandong Province continues to exhibit complex temporal fluctuations, including seasonal peaks and multiyear cyclical variations [16]. Recent studies also suggest that the prevalence of HFRS in Shandong Province is characterized by distinct spatial heterogeneity and environment-driven features, highlighting the need to further enhance surveillance and early warning capabilities [17]. In 2004, China established a unified national web-based direct reporting system for infectious diseases, enabling real-time epidemic monitoring through a hierarchical reporting structure, which has laid a solid foundation for the forecasting and early warning of infectious diseases. Reliable forecasting results help optimize the allocation of health care resources, facilitate the timely issuance of health advisories, and enable the strengthening of vector control prior to the onset of anticipated epidemic peaks [18,19]. Time series modeling has emerged as a crucial method for predicting infectious disease epidemics [20]. Traditional models such as the seasonal autoregressive integrated moving average (SARIMA) model have been widely used to capture linear patterns and seasonal dependencies within HFRS incidence data [21]. Furthermore, exponential smoothing methods such as the Holt-Winters method offer considerable simplicity and practicality in handling trends and seasonality [22]. In recent years, the application of highly complex algorithmic models, including machine learning, has further enriched this research domain [23]. For instance, the Prophet model is well suited for time series with pronounced seasonal characteristics, whereas the Extreme Gradient Boosting (XGBoost) model demonstrates robust potential in forecasting structured epidemiological data [21,24]. However, in highly endemic areas for HFRS such as Shandong, research that systematically characterizes long-term epidemic patterns while simultaneously comparing the performance of classic and modern forecasting models remains relatively limited. Such studies are of profound significance for identifying forecasting tools that better meet the practical demands of public health.

Given the persistent prevalence of HFRS in Shandong Province and the lack of a systematic evaluation of time series forecasting models, this study conducted an in-depth analysis of the long-term epidemiological characteristics of HFRS based on 15 years of surveillance data and used 4 time series models to predict its incidence trends. The aim was to provide a scientific basis for local disease control departments, thereby supporting more accurate prediction and effective prevention and control of HFRS in this region.

## Methods



### Study Area

Located on the eastern coast of China, Shandong Province covers a total area of approximately 158,000 $km^2$ and has a population exceeding 100 million, making it one of the country's most populous and economically significant provinces (Figure 1). The province features a temperate monsoon climate with 4 distinct seasons. Its topography encompasses plains, hills, and coastal areas, providing diverse habitats for the primary host animals of HFRS. As a traditional high-incidence area for HFRS in China, Shandong has experienced long-term, continuous reporting of cases in both urban and rural areas. Its well-established public health surveillance system and significant disease burden make it an ideal region for studying the long-term epidemiological characteristics and incidence trends of HFRS.

XSL•FO
RenderX

**Figure 1.** Geographical location of Shandong Province in China and the average annual incidence rate of hemorrhagic fever with renal syndrome from 2010 to 2024.

## Data Collection

HFRS case data were obtained from the China Information System for Disease Control and Prevention. This surveillance system collects case information based on the unified national diagnostic criteria for HFRS. Prior to analysis, all personally identifiable information was removed to protect patient privacy. According to the Law of the People's Republic of China on the Prevention and Treatment of Infectious Diseases, HFRS is categorized as a class B infectious disease. In China, when patients with a class B infectious disease are identified by any level or type of medical institution, physicians are required to complete direct online reporting within 24 hours. This study collected HFRS case surveillance data in Shandong Province from January 2010 to December 2024, including variables such as sex, age, occupation, date of onset, and current residential address.

## Statistical Analysis

### *Overview*

Descriptive epidemiological analyses were performed using the SPSS software (version 23.0; IBM Corp). Spatial mapping was conducted using the ArcGIS software (version 10.7; Esri). Additionally, packages including *forecast*, *prophet*, and *xgboost* in the R software (version 4.2.3; R Foundation for Statistical Computing) were used to construct 4 time series models (SARIMA, Prophet, Holt-Winters, and XGBoost), whereas the *ggplot2* package was used to visualize the results.

### *SARIMA Model*

As an extension of the autoregressive integrated moving average model, the SARIMA model comprises both nonseasonal and seasonal components, with its general expression denoted as SARIMA($p$, $d$, $q$) ($P$, $D$, $Q$)$s$. Specifically, $p$, $d$, and $q$ represent the nonseasonal autoregressive order, differencing order, and moving average order, respectively; $P$, $D$, and $Q$ denote the seasonal autoregressive order, seasonal differencing order, and seasonal moving average order, respectively; and $s$ indicates the length of the seasonal period of the time series [25]. During model construction, the augmented Dickey-Fuller test was first used as a preliminary assessment of stationarity. A significance level of $\alpha$=.05 was adopted, and a $P$ value below .05 was considered indicative of stationarity. Seasonal-trend decomposition using locally estimated scatterplot smoothing (STL) was then applied to characterize the long-term trend and seasonal variation, and the seasonal period was determined accordingly. The autocorrelation function (ACF) and partial ACF were examined to characterize the temporal dependence structure. Candidate SARIMA models were subsequently screened using the *auto.arima* function, and the optimal model was selected according to the minimum corrected Akaike information criterion. Finally, residual autocorrelation was assessed using the Ljung-Box $Q$ test at a significance level of $\alpha$=.05 [26].

### *Prophet Model*

The Prophet model is a time series forecasting tool developed by Facebook in 2017 [27,28]. It is capable of handling time series data exhibiting both linear and nonlinear characteristics, as well as effectively capturing seasonal effects. Owing to its

XSL•FO
RenderX

simplicity, computational efficiency, and ability to automatically fit future trends, the Prophet model has been widely used; it can autonomously identify underlying patterns and evolutionary trends within the data, thereby generating highly accurate predictions [29]. The Ljung-Box *Q* test was used to examine residual autocorrelation in the Prophet model. Its basic mathematical formulation is expressed as follows:

$$y_t = g(t) + s(t) + h(t) + \varepsilon_t$$

In this equation, $g(t)$ denotes the trend component, reflecting the nonperiodic long-term changes in the time series; $s(t)$ represents the seasonal component, characterizing the periodic fluctuations of the time series; $h(t)$ stands for the holiday effect component, evaluating the impact of specific holidays or events on the time series; and $\varepsilon_t$ is the error term, representing the white noise sequence that remains unexplained by the model.

### *Holt-Winters Model*

The Holt-Winters model, also known as triple exponential smoothing, centers on the core concept of using exponential smoothing techniques to simultaneously estimate the level, trend, and seasonal components of a time series. By dynamically updating these components, the model adaptively captures changing data characteristics and enables multi–step ahead forecasting. The Holt-Winters model is primarily categorized into 2 types: the additive model and the multiplicative model. The former is suitable for scenarios where seasonal fluctuations remain constant regardless of the series level, whereas the latter is appropriate when seasonal fluctuations vary proportionally with the series level. In the field of infectious disease forecasting, the multiplicative model is more commonly used as fluctuations in case numbers are typically highly correlated with the overall scale of the epidemic. The model incorporates 3 smoothing parameters, $\alpha$, $\beta$, and $\gamma$, which adjust the weights of the level, trend, and seasonal components, respectively, with each parameter ranging from 0 to 1. The selection of the optimal model is based on the principle of minimizing evaluation metrics such as the Bayesian information criterion, and the model residuals must pass the Ljung-Box *Q* white noise test [30].

### *XGBoost Model*

XGBoost is an ensemble learning algorithm based on the gradient boosting framework, widely applied to classification and regression problems [31]. Using decision trees as base learners, the algorithm iterates through an additive model where each newly added decision tree aims to fit the residuals of the model from the previous round. Its core idea is to assemble numerous weak learners with simple structures into a high-precision strong predictive model. This study used a grid search strategy to optimize the hyperparameters of the XGBoost model. The parameter space to be optimized included the number of iterations (nrounds), maximum tree depth (max_depth), feature sampling rate (colsample_bytree), minimum sum of instance weight in a leaf (min_child_weight), subsampling rate (subsample), learning rate (eta), and the minimum loss reduction required for a node split (gamma). Simultaneously, 5-fold cross-validation was combined to comprehensively evaluate the performance of each parameter combination, ensuring objective evaluation while effectively preventing the model from overfitting to specific datasets [32]. Residual autocorrelation of the XGBoost model was assessed using the Ljung-Box *Q* test. The mathematical expression of the model is as follows:

In this equation, $\hat{y}_i$ represents the predicted value of the sample, $x_i$ represents the input feature vector, $f_k(x_i)$ represents the output score of the $k$th decision tree, $K$ is the total number of decision trees, and $F$ is the function space of all possible tree structures. $q(x)$ is the tree structure function that maps input features to a specific leaf node, $t$ is the total number of leaf nodes in a single tree, and $w_{q(x)}$ represents the weight of the corresponding leaf node.

### *Evaluation and Comparison of Models*

In constructing the aforementioned models, HFRS incidence data from January 2010 to December 2023 were used as the training set, and data from January 2024 to December 2024 were used as the testing set. This study used 3 metrics, specifically, root mean squared error (RMSE), mean absolute error (MAE), and mean absolute percentage error (MAPE), to evaluate the predictive performance of the models. Smaller values of these metrics indicate higher forecasting accuracy of the models. The calculation formulas for each metric are as follows:

In these equations, $n$ is the number of samples, $y_i$ is the actual value of the $i$th sample, and $\hat{y}_i$ is the predicted value of the $i$th sample.

### Ethical Considerations

This study was approved by the ethics committee of the Shandong Provincial Center for Disease Control and Prevention (SDJK2026-067-01). Given that this study analyzed anonymized data sourced from the China Information System for Disease Control and Prevention, the ethics committee waived the requirement for additional informed consent. All participant-related information was processed under strict confidentiality safeguards, and no compensation was provided to participants in this study.

## Results

### Epidemiological Characteristics

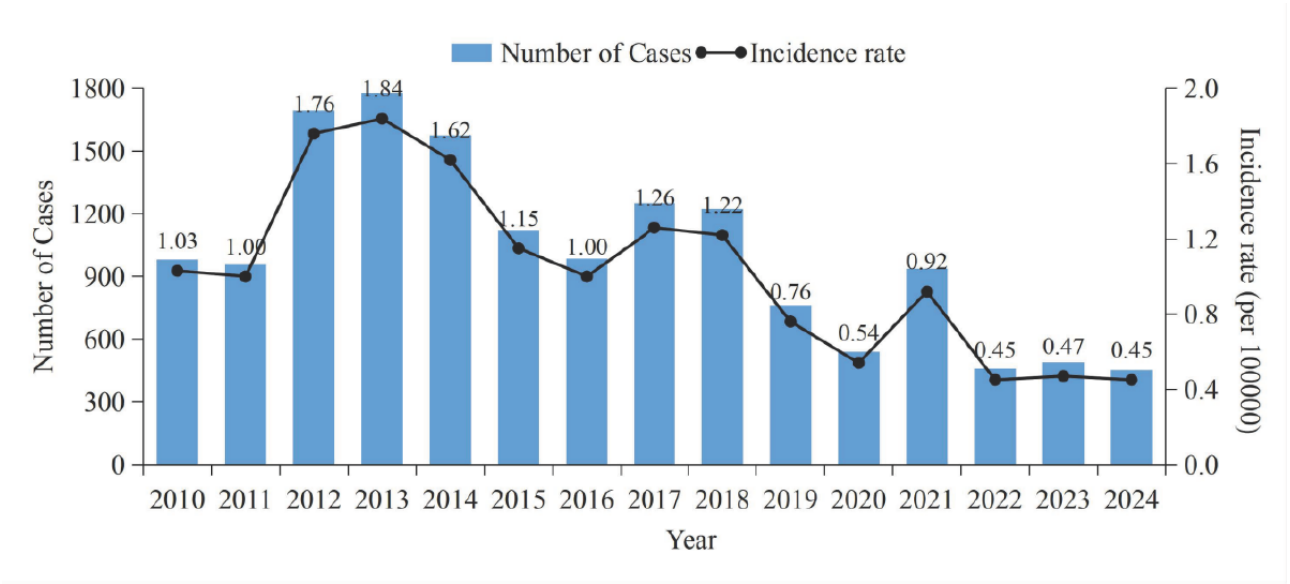
### *Temporal Characteristics*

From 2010 to 2024, a total of 15,184 HFRS cases were reported in Shandong Province, with the annual reported incidence rate ranging from 0.45 to 1.84 per 100,000 population. Overall, the incidence rate of HFRS showed a trend of an initial increase

XSL•FO
RenderX

followed by a decrease, peaking in 2013. During the period from 2013 to 2024, the number of HFRS cases exhibited a fluctuating downward trend, reaching its lowest level in 2024. Of the 15,184 cases, a total of 188 HFRS deaths were reported during the study period. The disease was reported in all months of the year, demonstrating substantially seasonal distribution characteristics; the incidence peak was concentrated between October and December, accounting for 52.8% (8011 cases) of the total cases (Figures 2 and 3).

**Figure 2.** General overview of hemorrhagic fever with renal syndrome incidence in Shandong Province from 2010 to 2024.



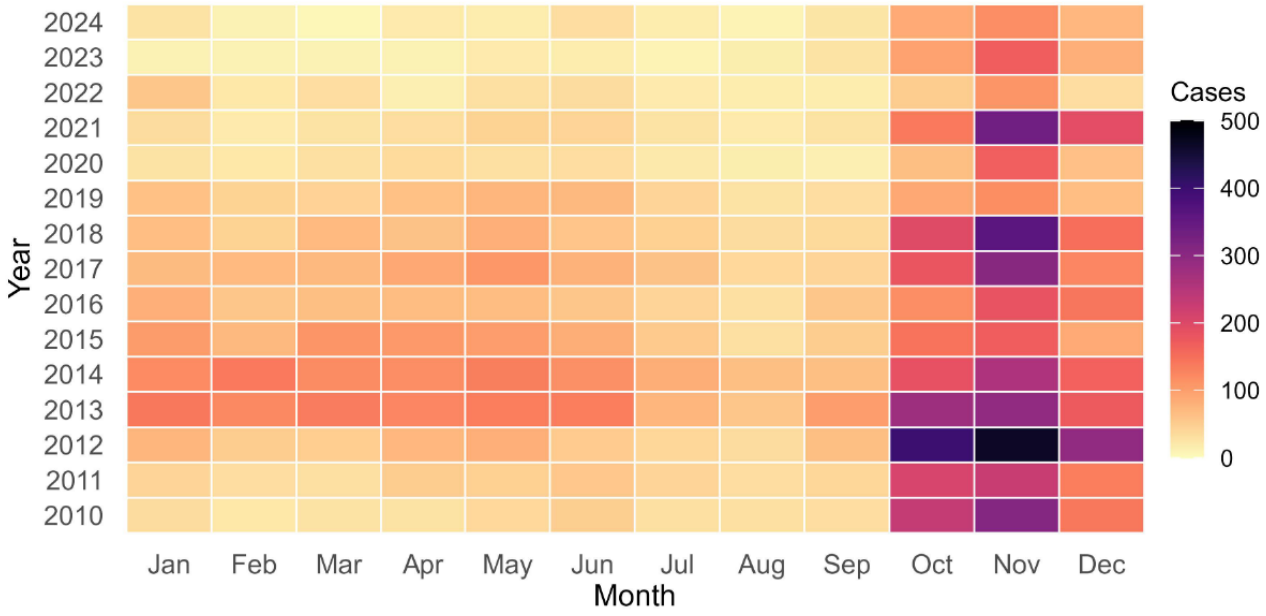


**Figure 3.** Heat map of monthly hemorrhagic fever with renal syndrome incidence in Shandong Province from 2010 to 2024.

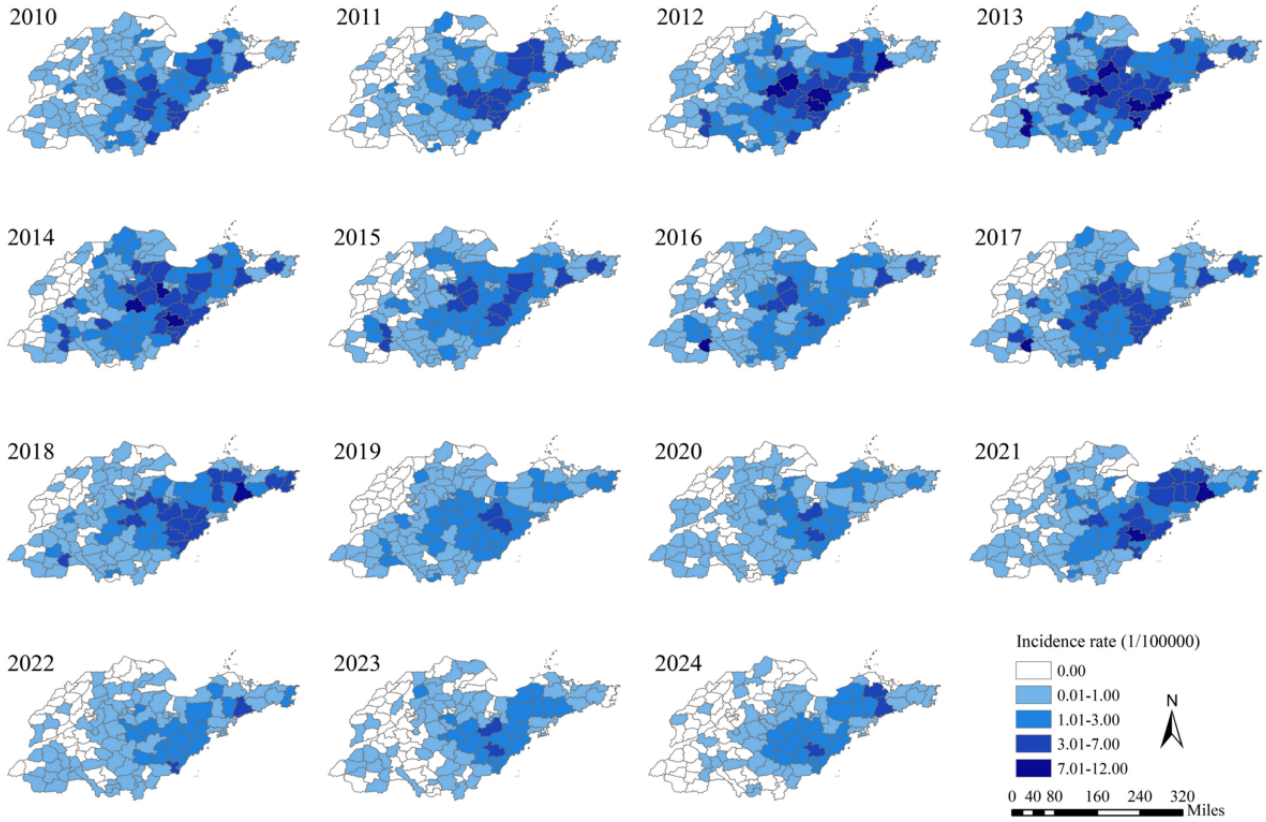

### *Spatial Characteristics*

From 2010 to 2024, all 16 prefecture-level cities in Shandong Province reported cases of HFRS. Of the 136 counties (cities and districts) in the province, 135 reported cases, with the sole exception of Pingyuan County in the city of Dezhou. The top 5 counties (cities and districts) in terms of average annual incidence rates were Wulian County (6.08 per 100,000), the city of Haiyang (5.25 per 100,000), Yiyuan County (4.77 per 100,000), the city of Zhucheng (3.77 per 100,000), and Donggang District (3.59 per 100,000), which are mainly concentrated in the eastern and southeastern regions of Shandong Province. Regarding the evolution of the annual spatial distribution, the geographical extent affected by the HFRS epidemic exhibited a gradually shrinking trend, and the number of high-incidence counties (cities and districts) also decreased year by year (Figure 4).

XSL•FO
RenderX

**Figure 4.** Distribution of hemorrhagic fever with renal syndrome incidence in Shandong Province from 2010 to 2024.

### *Demographic Characteristics*

Among the total HFRS cases reported from 2010 to 2024, there were 11,023 (N=15,184) male individuals and 4161 female individuals, with a male-to-female ratio of 2.65:1. The mean age was 49.91 (SD 14.96) years, and patients were predominantly middle-aged and older adults aged 40 to 69 years, totaling 10,372 (N=15,184) cases. The top 3 occupations were farmers (12,609 cases), workers (896 cases), and houseworkers or unemployed individuals (458 cases; Table 1).

## Time Series Analysis

### *SARIMA Model*

The augmented Dickey-Fuller test rejected the unit-root null hypothesis for the HFRS incidence series ($P$=.01). STL decomposition nevertheless revealed a clear seasonal pattern, with a seasonal period of 12 months (Figure 5). On the basis of the ACF and partial ACF plots and subsequent model screening using the *auto.arima* function, SARIMA(1, 1, 1) $(0, 1, 1)_{12}$ was selected as the optimal model, with the lowest Akaike information criterion value of 237.81. The fitting performance of the optimal model is shown in Figure 6. The Ljung-Box $Q$ test showed no significant residual autocorrelation ($P$=.80; Figure 7). The RMSE, MAE, and MAPE of the model were 11.08, 9.20, and 46.67%, respectively.

XSL•FO
RenderX

**Figure 5.** Seasonal-trend decomposition using locally estimated scatterplot smoothing–based seasonal decomposition of hemorrhagic fever with renal syndrome cases in Shandong Province from 2010 to 2024.

### *Prophet Model*

In the construction of the Prophet model, given the declining trend and annual seasonality of HFRS incidence in Shandong Province, the trend growth parameter was set to linear, the yearly seasonality parameter was set to TRUE, the seasonality mode was set to multiplicative, the seasonality prior scale was set to 10, and the change point prior scale was set to 0.05 (Table 2). Significant residual autocorrelation was detected for the Prophet model through the Ljung-Box *Q* test ($P<.001$). The RMSE, MAE, and MAPE of the model were 11.28, 9.45, and 68.08%, respectively.

XSL•FO
RenderX

**Table 2.** Parameter values of the constructed Prophet, Holt-Winters, and Extreme Gradient Boosting (XGBoost) models.

| Models and parameters | Values |
|---|---|
| **Prophet** | |
| Growth | Linear |
| Yearly seasonality | TRUE |
| Seasonality mode | Multiplicative |
| Seasonality prior scale | 10 |
| Change point prior scale | 0.05 |
| **Holt-Winters** | |
| α | 0.18 |
| β | 0.12 |
| γ | 0.05 |
| Seasonal | Multiplicative |
| **XGBoost** | |
| Number of iterations | 1500 |
| Maximum tree depth | 6 |
| Learning rate | 0.05 |
| Minimum loss reduction required for a node split | 0.1 |
| Feature sampling rate | 1 |
| Minimum sum of instance weight in a leaf | 3 |
| Subsampling rate | 0.6 |

### *Holt-Winters Model*

The results of the Holt-Winters model analysis showed that, through automatic screening in the R software, the multiplicative model was ultimately identified as the optimal fitting model. The smoothing parameters α, β, and γ of the model were 0.18, 0.12, and 0.05, respectively (Table 2). The residual series test indicated that the model residuals exhibited white noise characteristics ($P$=.18). The RMSE, MAE, and MAPE of the model were 7.56, 6.43, and 34.56%, respectively.

### *XGBoost Model*

The results of the XGBoost model analysis showed that, through grid search and 5-fold cross-validation optimization, the optimal parameter combination for the model was determined as follows: 1500 iterations (nrounds), maximum depth (max_depth) of 6, column sampling rate (colsample_bytree) of 1, minimum child weight (min_child_weight) of 3, subsampling rate (subsample) of 0.6, learning rate (eta) of 0.05, and gamma coefficient (gamma) of 0.1 (Table 2). The residuals of the XGBoost model showed significant autocorrelation (Ljung-Box $Q$ test; $P$<.001). The RMSE, MAE, and MAPE of the model were 16.94, 10.96, and 55.66%, respectively.

### *Model Comparison*

Three evaluation metrics (RMSE, MAE, and MAPE) were used to assess the predictive performance of each model. In the 2024 test set, the Holt-Winters model yielded the lowest values for all 3 metrics among the 4 models. On the basis of these point estimate error metrics, SARIMA, Prophet, and XGBoost showed progressively higher prediction errors (Figure 8; Table 3).

XSL•FO
RenderX

## Discussion

As a major endemic region for HFRS in China, Shandong Province has experienced an overall decline in incidence in recent years. However, HFRS's seasonality, spatial clustering, and high-risk population characteristics remain significant, indicating that the underlying endemicity has not fundamentally changed [17]. To further translate epidemiological research into practical prevention, control, and early warning capabilities, this study systematically analyzed 15 years of HFRS surveillance data in Shandong Province and comparatively evaluated 4 prediction models. The results indicate significant spatiotemporal heterogeneity in the transmission of HFRS in Shandong Province, with the Holt-Winters model demonstrating superior short-term predictive performance. These findings contribute to a deeper understanding of the epidemiological characteristics of HFRS and provide a methodological reference for implementing routine surveillance and early warning. Unlike our previous studies [16,17], which mainly focused on spatiotemporal patterns and driving factors of HFRS, the present study examined the long-term epidemiological trends of HFRS in Shandong Province based on a 15-year time series dataset (2010-2024). This extended observation window enabled a more systematic profiling of temporal dynamics, spatial heterogeneity, and demographic changes, together with the evaluation of multiple time series forecasting models. The present study addressed a distinct research question and provided complementary, nonredundant rather than repetitive evidence.

In terms of long-term epidemic trends, this study found that the incidence of HFRS in Shandong Province exhibited a fluctuating downward trend, consistent with the overall epidemic trend in China in recent years [33,34]. Previous studies have indicated that although China still bears the heaviest global burden of HFRS, the national incidence has gradually decreased over the past decades. This decline may be attributed to multiple factors, including the promotion of vaccination, implementation of rodent control measures, improvement of living conditions, and strengthening of disease surveillance [35]. However, the decline in HFRS incidence does not imply the disappearance of its transmission risk as Shandong still possesses the ecological foundation to sustain endemicity in terms of geographical environment, host animal distribution, and population exposure patterns [14]. Furthermore, this study revealed that reported HFRS cases were primarily clustered between October and December, which differs from the previously bimodal seasonal distribution reported in Shandong Province [17]. This finding indicates a potential shift in the recent seasonal pattern of HFRS toward autumn-winter predominance. Previous studies have shown that HFRS seasonality may be influenced by changes in rodent host population composition, circulating hantavirus types, and opportunities for human exposure [36]. Typically,

XSL•FO
RenderX

HTNV-related HFRS cases peak in autumn and winter, whereas SEOV-associated cases tend to show a spring peak [1,37]. Accordingly, the diminished spring incidence peak observed in our study may be attributable to altered predominance of hantavirus types, the spatial distribution of rodent hosts, and seasonal patterns of human-rodent contact. However, the precise mechanisms remain to be explored through further virological and ecological investigations for validation.

HFRS has long been influenced by ecological environments and socioeconomic conditions, which leads to disparities in its regional distribution [8,38]. This study revealed that high-incidence counties for HFRS were primarily located in eastern and southeastern Shandong, whereas both the geographic extent of the epidemic and the number of high-incidence counties gradually decreased in recent years. Previous studies have shown that HFRS occurrence is associated with altitude, land use, and population density, suggesting that ecological suitability for rodent hosts and opportunities for human exposure may jointly influence infection risk [14]. Additional ecological studies in Shandong further showed that land cover and elevation were closely associated with the distribution of hantavirus-infected rodent hosts, whereas southeastern Shandong has been identified as an important natural focus characterized by the presence of striped field mouse and HTNV [39]. Agricultural field activities may further increase opportunities for contact with infected rodents and their contaminated environments [40]. Such ecological and occupational factors may partly contribute to the relatively high incidence observed in eastern and southeastern Shandong. Previous studies have also demonstrated substantial spatial heterogeneity in HFRS across Shandong Province, indicating that provincial-level unified prevention and control measures are insufficient; geographically tailored and risk-stratified intervention strategies should therefore be prioritized [16]. Additionally, consistent with previous findings, HFRS cases were predominantly among middle-aged and older adult male individuals, with farmers representing the highest proportion in occupational distribution [24,41]. The differential distribution of HFRS among the population is likely driven by variations in exposure opportunities. Male farmers often engage in outdoor cultivation, leading to more frequent contact with rodents or their excreta, which suggests that agricultural production settings remain the core focus for HFRS prevention and control [42]. Furthermore, the outflow of young rural labor, the aging of the agricultural workforce, and the fact that HFRS vaccines are not administered to individuals over 60 years of age may also contribute to the high proportion of middle-aged and older adult individuals among HFRS cases [43]. This suggests that middle-aged and older adult male individuals in rural areas should be the primary targets for health education, advocating for active HFRS vaccination and the use of personal protection during labor.

This study shows that all 4 models can effectively capture the seasonal fluctuations of HFRS; however, the Holt-Winters model yielded the lowest RMSE, MAE, and MAPE, outperforming the SARIMA, Prophet, and XGBoost models. This result suggests that for monthly case sequences with a clear annual cycle, a relatively stable long-term trend, and a limited training sample size, structurally simple exponential smoothing methods still possess significant practical value. By separately smoothing and updating the level, trend, and seasonal components, the Holt-Winters model can stably track monthly fluctuations without introducing excessive parameters, making it particularly suitable for data dominated by significant seasonality rather than abrupt changes [30,44]. The overall performance of the SARIMA model was slightly inferior to that of the Holt-Winters model, yet it remains one of the most widely used models in previous HFRS time series analyses. For instance, research in Jiaonan County, Shandong Province, has shown that SARIMA could accurately predict local monthly HFRS incidence, and national-scale studies have also demonstrated its ability to effectively simulate long-term seasonal fluctuations of HFRS [45,46]. The disadvantage of SARIMA lies in its reliance on stationarity and linearity assumptions, and its parameter identification is highly dependent on the sequence structure; thus, its extrapolation capability may be limited when the epidemic is influenced by policy changes or abnormal exposure events [23]. The Prophet model is suitable for time series with prominent trend shifts or holiday disturbances [47]. However, as the changes in monthly HFRS cases primarily reflect fixed seasonality and local volatility, the advantages of the Prophet model were not fully realized in this study. The XGBoost model performed the worst in this study, which contradicts the “naturally superior” expectation some scholars hold for machine learning models. The advantages of machine learning methods are mainly reflected in handling complex nonlinear relationships and high-dimensional features, but their performance typically depends on large training sample sizes, sufficient feature engineering, and the inclusion of external variables. This study modeled HFRS using only monthly case data without incorporating features such as meteorology, host density, or land use that could improve nonlinear fitting capabilities; therefore, the XGBoost model could not fully leverage its strengths. In addition, the residuals of the Prophet and XGBoost models exhibited significant autocorrelation, indicating that neither model fully captured the temporal dependencies in HFRS incidence. This may be attributable to the complex temporal dynamics of HFRS, including evolving seasonal patterns, interannual fluctuations, and occasional abrupt changes in incidence. Therefore, although these models were able to fit the overall temporal trends reasonably well, they remained somewhat limited in characterizing fine-scale temporal variations.

This study also has certain limitations. First, the HFRS case data were obtained from a passive surveillance information system, which may involve reporting biases such as underreporting and diagnostic delays. Second, although the 2024 test set covered a complete annual seasonal cycle, its relatively limited sample size may have affected the robustness of the model comparisons to some extent. Future studies should consider using data spanning longer periods for validation to further confirm the reliability of the models. Finally, to ensure consistency in the input variables across the 4 forecasting models and assess their applicability under routine surveillance conditions, the XGBoost model in this study incorporated only historical monthly HFRS case counts. However, this univariate design may constrain the advantage of XGBoost in capturing multivariable nonlinear relationships. Future studies should

XSL•FO
RenderX

further explore incorporating meteorological conditions, rodent dynamics, ecological and environmental factors, and socioeconomic indicators into multivariable models to further improve prediction performance.

In conclusion, the HFRS epidemic in Shandong Province features low overall incidence at the provincial level, whereas specific local foci continue to exhibit high incidence. The incidence of HFRS shows significant spatiotemporal clustering, including distinct autumn and winter epidemic peaks, obvious geographical concentrations in eastern and southeastern Shandong, and high-risk groups dominated by middle-aged and older adult male farmers. This suggests that future prevention and control efforts should focus more on spatially precise strategies and targeted interventions for high-risk populations. For short-term forecasting based on monthly surveillance data, the Holt-Winters model yielded the lowest prediction error metrics among the evaluated models and may be a useful practical tool for routine provincial HFRS early warning. The results of this study have important implications for the precise monitoring and scientific prevention and control of regional HFRS.

## Acknowledgments

The authors would like to express their sincere gratitude to the Shandong Provincial Center for Disease Control and Prevention for establishing the dataset, which provides high-quality data for research. The authors declare that no generative AI was used in the preparation of this manuscript.

## Abstract

**Background:** In 2021, a total of 82 million people used electronic cigarettes (e-cigarettes) globally. E-cigarette regulations around the globe vary widely from the product being banned in some jurisdictions to being completely unregulated in others. The Tobacco Pack Surveillance System (TPackSS) was initiated in 2012 to monitor tobacco packs available in 14 low- and middle-income countries with the greatest number of people who smoke. The aim of TPackSS is to assess compliance with country-specific tobacco packaging and labeling requirements and identify marketing features and appeals used on tobacco packaging.

**Objective:** The objective of this study was to adapt and expand the previous TPackSS protocol to also include disposable e-cigarette devices and their accompanying products: e-cigarette liquids and pods or cartridges.

**Methods:** E-cigarettes were added to TPackSS data collection in Indonesia in 2022 and in China in 2023. Collection took place in Jakarta, Medan, and Surabaya in Indonesia and Shanghai, Beijing, Chongqing, Guangzhou, Kunming, and Shenzhen in China. A total of 15 neighborhoods per city in Indonesia and 12 per city in China were visited. The TPackSS protocol developed for tobacco products in 2012 to 2013 was used as the foundation for the adapted protocol for e-cigarettes. The adaptation of the original TPackSS protocol followed an iterative process involving extensive discussions among the TPackSS study team, comprising researchers with expertise in tobacco control and 13 years of experience in tobacco product packaging surveillance. The study adapted the sampling frame and sampling strategy, pack collection procedures, photography guide, shipment and translation procedures, and codebook to account for the unique country contexts for e-cigarettes (eg, regulations, market for e-cigarettes, and retailer landscape) and the heterogeneity of e-cigarette packaging observed. These adaptations were based on the review of peer-reviewed literature, white papers, Euromonitor data, and consultation with researchers with expertise in e-cigarette marketing and with in-country public health professionals. Using Indonesia as a pilot country, the protocol was evaluated and further refined post implementation for use in China.

**Results:** The TPackSS study began in 2012 and was funded by Bloomberg Philanthropies. Data collection took place from September to October 2022 in Indonesia and April to May 2023 in China. Across Indonesia and China, 968 unique e-cigarette products were collected. TPackSS data collection, coding procedures, and study findings are publicly available for use on the TPackSS website.

**Conclusions:** The protocols presented here, which were used in 2 countries with contrasting e-cigarette markets and regulatory requirements, can be adapted for use in other countries. Findings from use of this adapted protocol can inform policy by providing insights into the design features and marketing appeals of e-cigarette products available on the market, as well as compliance with health warning label requirements where applicable.

## Introduction

An estimated 82 million people globally used electronic cigarettes (e-cigarettes) in 2021 [1]. In many countries, including Indonesia and China, rates of e-cigarette use among youth exceed those of adults [2]. Many countries do not regulate flavors, nicotine strength, or liquid volumes, nor do they require graphic health warning labels (HWLs) on e-cigarette products [3-6].

### E-Cigarette Packaging as Advertising

Tobacco and nicotine product packaging serves as communication real estate for both tobacco company marketing and health communication through required government warnings [7,8]. E-cigarette packages can be designed to resemble other objects (eg, Tic Tac container and technology devices such as mobile phones) [9-11]. They also feature a wide variety of marketing appeals such as themes of fantasy or violence, graphic elements such as cartoon characters, and heavily stylized brand names [10]. Among youth, there is an increased interest in trying fully branded e-cigarette packaging when compared to e-cigarette products with plain packaging [12-14]. E-cigarette package attractiveness is also enhanced by a variety of flavors, vibrant colors, and other branding that targets specific subgroups [12,15].

In addition to company branding (names, colors, textual elements, imagery, shapes, and sizes), e-cigarette packaging can also include HWLs, nicotine concentration, and ingredient lists. HWLs on e-cigarette packaging are associated with reduced e-cigarette use initiation and higher intentions to quit vaping among adults and youth [15-19].

### Study Overview

The Tobacco Pack Surveillance System (TPackSS) study was initiated in 2012 with the goal to collect and analyze tobacco products (cigarettes, kreteks, bidis, and straw cigarettes) and their packaging in low- and middle-income countries with the greatest number of people who smoke. Data collection started in 2013 [20]. Roll your own and smokeless tobacco were added to tobacco product collection in 2015 and 2016, respectively, and heated tobacco products and nicotine pouches were added to the types of products to be collected in 2021 and 2022, respectively. The data collection protocol aims to collect 1 of every unique package available for sale in each country. The data generated from TPackSS data collection can inform policies that reduce appeal and attractiveness of tobacco product packaging and more effective HWL implementation and enforcement.

Beginning in 2022, e-cigarettes were added to the TPackSS data collection protocol. In the context of this paper, the term “e-cigarettes” refers to disposable e-cigarette devices and/or their accompanying products: e-cigarette liquids and pods or cartridges. It also can be used to refer to the packaging of these products when discussing them together as a whole. It does not include reusable e-cigarette devices such as tank systems or e-cigarette accessories and parts. In the work described here, e-cigarettes are not included in our definition of tobacco products.

E-cigarettes were an important product type to add to surveillance as the market has grown significantly since their debut in 2007 [21]. As of 2025, a total of 12 million youth aged 13 to 15 years across 110 countries reported current use of e-cigarettes [22]. Surveillance is critical in a market where regulations vary across the globe, including many jurisdictions with no or partial regulations [22]. The TPackSS protocol needed to be adapted for e-cigarette products because the retailer landscape often differs between e-cigarette and tobacco vendors (eg, e-cigarettes are commonly sold at vape shops). In addition, they are often shaped differently than tobacco products, can be more heterogeneous, and consist of different components (eg, liquids compared to sticks). Indonesia was the first country in which e-cigarettes were collected as part of the TPackSS study in 2022. Since then, e-cigarettes were also collected in China in 2023, with other country collections planned.

This paper presents an adaptation of the existing TPackSS protocol [20], originally developed for tobacco products, to optimize it for collection of e-cigarettes in parallel with tobacco products and the process for adaptation, including implementation evaluation and protocol refinements. We describe the specific protocol changes made based on product and market differences unique to e-cigarettes and reflect on our experience implementing and refining the adapted protocol in Indonesia and China. Through these case studies, we highlight key methodological considerations for conducting similar research in jurisdictions with varied e-cigarette landscapes and illustrate how these considerations may be incorporated into the protocol.

## Methods

### Overview

The original TPackSS protocol was adapted for e-cigarettes using an iterative process to enhance validity and to ensure revisions aligned with the study objectives while maintaining methodological rigor. Initial adaptations were made based on our knowledge of the e-cigarette landscape, country-specific regulations, and e-cigarette products and marketing, informed by the peer-reviewed literature, white papers, Euromonitor data, and consultation with experts in e-cigarette marketing research and in-country public health professionals. All adaptations to the protocol were extensively discussed and agreed upon by the TPackSS study team, comprising researchers with expertise in tobacco advertising, tobacco package HWLs, and packaging design, who have conducted research on tobacco packaging for

XSL•FO
RenderX

13 years. Using Indonesia as a pilot country, implementation of each phase of the adapted protocol was monitored, and the research team held regular debriefings to identify challenges, assess adherence to the protocol, and address any needed clarifications. Reflections made during implementation of the protocol in Indonesia also informed further adaptations to the China protocol. This iterative process of revisions, observation, group discussion and reflection, and refinement enhanced feasibility and data quality while preserving the study's core objectives.

The original TPackSS protocol included a comprehensive overview of each phase of the research from data collection to dissemination of findings [20]. Here, we present how each step was adapted for e-cigarettes and the factors considered when making adaptations. Descriptions of how the protocol differed in Indonesia and China provide examples of how the protocol can be customized to reflect jurisdiction-specific factors while still adhering to the key steps of the protocol. Table 1 provides a summary of the key differences in the original TPackSS protocol and the protocol developed for e-cigarettes.

**Table 1.** Similarities and differences between the original tobacco product protocol and electronic cigarette (e-cigarette) protocol.

| Steps or procedures included in the protocol | Original tobacco product protocol | E-Cigarette protocol |
|---|---|---|
| Products collected | Cigarettes, kreteks, bidis, straw cigarettes, roll your own, smokeless, and heated tobacco product sticks | Disposable e-cigarettes, pods or cartridges, and e-cigarette liquids (must contain nicotine) |
| Vendor types | Various tobacco vendor types based on country context | Various tobacco vendor types based on country context and vape stores |
| Selecting venues for product purchases | Walking protocol | Preselected vape stores in Indonesia and walking protocol in China |
| Photography guide | Standard photography guide | In addition to the standard photography guide, steps were added to account for extra packaging layers and variety of e-cigarette product packaging |
| Shipment and disposal | Shipped product and packaging back to office in the United States | Shipped empty packaging back to office in the United States |
| Translation | Used professional translation services | Used Chinese-speaking coders (China) or Google Translate (Indonesia) |
| Codebook | Separate intake, HWL[a] compliance, and feature and appeals codebooks | Combined intake, HWL compliance (when applicable), and features and appeals into a single codebook and added a nicotine-related section |
| Features highlighted on the TPackSS[b] website | HWL noncompliance, flavor appeal, brand family, product type, country, city, collection date, price, less harm appeal, lipstick pack, and stick count | HWL noncompliance, flavor appeal, brand family, product type, country, city, collection date, and price |

[a]HWL: health warning label.

[b]TPackSS: Tobacco Pack Surveillance System.

## Study Design and Sampling Framework

### *Defining Inclusion and Exclusion Criteria*

Only e-cigarette products that were prepackaged with liquid containing nicotine were purchased, namely, disposable e-cigarette devices and e-cigarette refills (cartridges or pods or premixed liquids).

### *Determining the Geographic Scope*

The methods used for selection of cities remained the same as the original protocol, apart from adding 1 city in China [20]. In Indonesia, data were collected in Jakarta, Medan, and Surabaya. In China, data were collected in Shanghai, Beijing, Chongqing, Guangzhou, Kunming, and Shenzhen. Shenzhen was added because of its central role in global e-cigarette production.

In the original protocol, 12 neighborhoods per city, stratified by high, middle, and low socioeconomic status (SES), were selected based on diversity in terms of geographic and residential composition [20]. Neighborhood SES in Indonesia was determined by the number of households living in poverty, as reported in the government's integrated social welfare database. Neighborhood SES in China was determined by land area, population, and property prices obtained primarily from government websites. To factor in a low concentration of vape stores in Indonesia, 3 additional neighborhoods in each city, 1 per SES strata, were visited, dependent on where vape stores were located; a total of 45 neighborhoods were visited. In China, where vape stores are relatively concentrated, in addition to the original criteria used for selection of neighborhoods, each neighborhood also had to contain a cluster of vape stores; a total of 72 neighborhoods were visited in China.

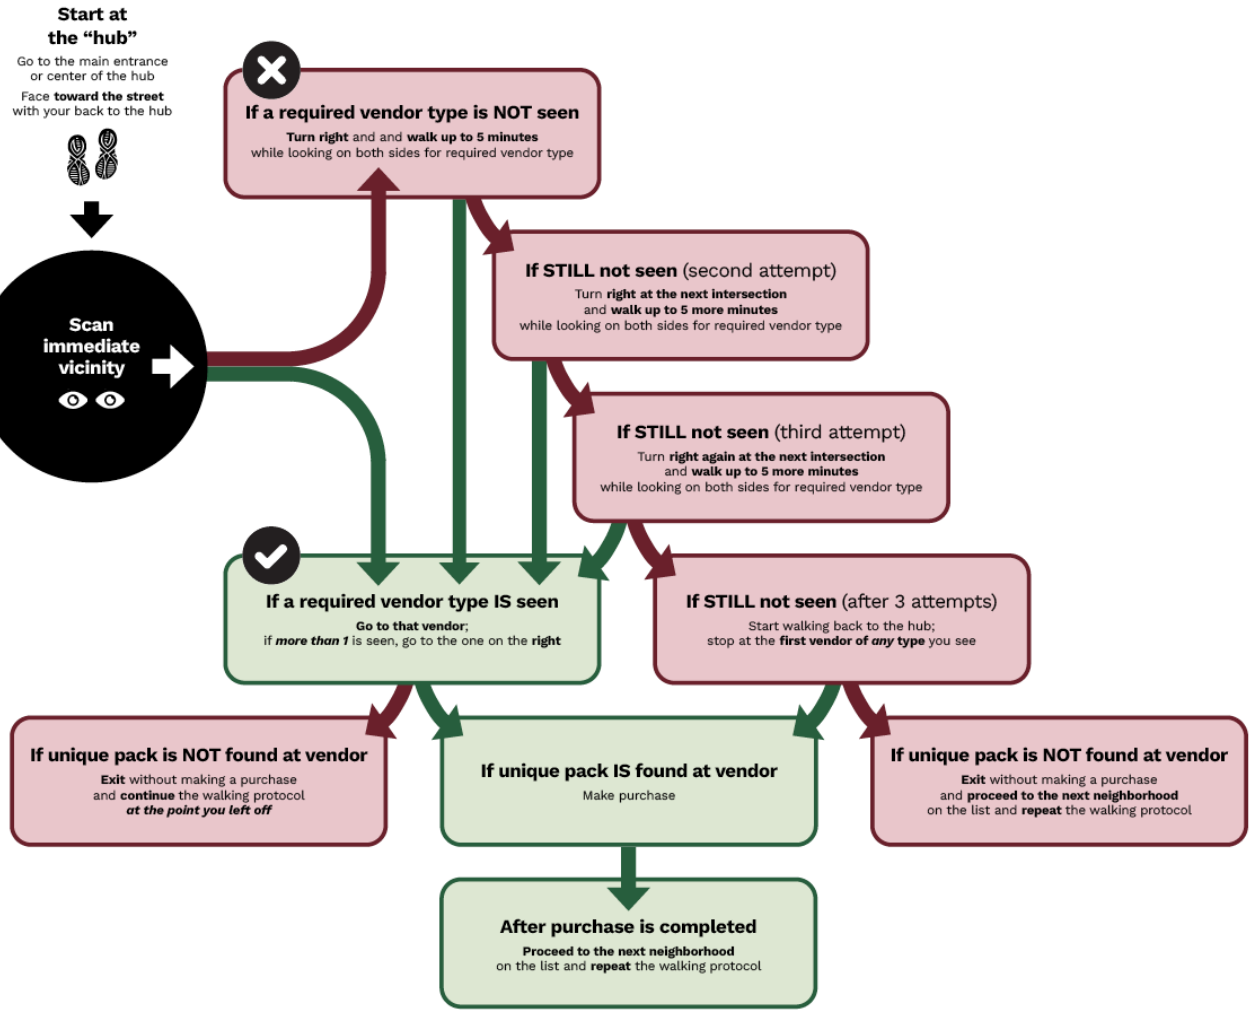
### *Defining the Sampling Frame*

In the original protocol, vendor types were selected based on Euromonitor data on where tobacco products are most frequently sold [20]. To adapt the protocol for e-cigarettes, vape stores were added to the list of vendor types based on Euromonitor data [23]. In China, 2 types of vape stores were identified: (1) branded vape stores that sell primarily 1 name brand (eg, RELX, YOOZ, Snowplus, and MOTI) and (2) nonbranded vape stores that sell many different e-cigarette brands.

XSL•FO
RenderX

### *Developing the Sampling Strategy*

In the original protocol, at the first tobacco vendor in each city, every unique tobacco product package for sale was purchased in what was referred to as the index purchase [20]. Similar to the original protocol, every unique e-cigarette package was purchased at the first vape store in each city. The definition of a "unique package" was expanded for e-cigarettes to account for e-cigarette–specific characteristics, defined as any package with at least 1 difference in an exterior feature of the pack, including volume, flavor, nicotine strength, brand name presentation, descriptor, or colors.



Identification and selection of vape stores was intertwined with the selection of neighborhoods. Being less concentrated in Indonesia, the 3 vape stores selected in each city were those with the greatest variety of products, determined based on online descriptions and pictures, with the requirement that they not belong to the same brand chain or owner [24].

After the 3 preselected vape stores were visited in each city in Indonesia, the original walking protocol was followed by data collectors in the remaining 12 neighborhoods in each city. Data collectors purchased unique e-cigarette packages that had not been previously collected from vape stores if they were identified at subsequently visited tobacco vendors.

In China, with a relatively high concentration of vape stores, the original walking protocol was adapted to include identification of branded and nonbranded vape stores. Following the adapted walking protocol, data collectors identified and visited vape stores and tobacco vendors simultaneously.

When following the walking protocol, in each neighborhood, data collectors started at a hub, defined as a central area in the neighborhood. The hub could be a major transit point (eg, bus terminal and train station), historical landmark, tourist attraction, major shopping center, large plaza, square, or major intersection and source of commerce. In the first city visited in China, data collectors started in a neighborhood classified as middle SES and purchased all unique e-cigarette packages from the first vape store they visited. If unique packages were not found at the first vendor visited, data collectors visited up to 2 additional e-cigarette vendors in a given neighborhood until at least 1 unique package was found (Figure 1). At the second and third neighborhood, similar procedures were followed, except either a brand or nonbrand vape store had to be visited depending on the type of vape stores visited previously to ensure both types were visited and variety was achieved. In the remaining 8 neighborhoods, the same procedures for the third neighborhood were used. The entire method was repeated for the remaining 5 cities in China [24].

**Figure 1.** Main walking protocol steps in China. This walking protocol was also followed in Indonesia for tobacco product collection. While not the primary focus, unique electronic cigarette packages were purchased if they were sold at tobacco vendors identified following the protocol.

XSL•FO
RenderX

### Package Collection

The training for data collectors was adapted to contain e-cigarette–specific content and procedures. The specific procedures followed by data collectors to identify unique e-cigarette packages, label e-cigarette packages with unique IDs, create an e-cigarette image archive, document the details of each e-cigarette purchase at the neighborhood level, and create an inventory of e-cigarette packages purchased mirrored the procedures used for tobacco products, as described in the original protocol [20].

### E-Cigarette Photography Guide

The photography guide for e-cigarettes followed the original guide [20], with instructions added to capture additional e-cigarette pack images as needed to account for multiple layers of packaging not commonly found for tobacco products and the greater variety of e-cigarette packaging shapes relative to tobacco products. All layers of e-cigarette packaging were captured, and for e-cigarette packages with unique shapes, all sides that contained descriptors, imagery, or HWLs were captured.

### Shipping and Receiving the Packages

We received updated approval from the US Food and Drug Administration and the US Federal Trade Commission to import and store empty e-cigarette packages for research purposes. E-cigarette products were disposed of prior to shipping; only empty packaging was imported due to safety concerns with shipping batteries and liquid, an issue not encountered with tobacco products. As with tobacco products, packages are stored in our office space in labeled and cataloged boxes. Unlike the intake procedures described previously for tobacco products, intake for e-cigarettes was completed at the same time as coding [20].

### Translation

Since publication of the original protocol, professional translation services were substituted with Google Translate to translate all non-English text on packaging, including tobacco and e-cigarette packaging, into English. Research assistants now use the image translation feature available via the Google Translate smartphone app to record English translations in Microsoft Excel spreadsheets for reference during coding [24]. For the coding of Chinese e-cigarette packages, all team members were able to read Chinese; therefore, translation was not required.

### Creating an E-Cigarette Codebook

The e-cigarette codebook was developed through an iterative process involving incorporation of existing measures, consultation with subject matter experts, in-person review of e-cigarettes collected in Indonesia, and pilot testing followed by refinement. First, we combined our previously separate tobacco product codebooks on intake, warning labels, design features, and marketing appeals into a single codebook to be adapted for e-cigarettes. We then added questions on external packaging, nicotine type and presentation, and cessation claims and expanded flavor and youth appeal response options based on the literature on e-cigarettes and personal observation of e-cigarette packaging. Next, we conducted a literature review to identify existing content analyses of e-cigarette advertising and packaging, identifying 15 relevant peer-reviewed publications [9,25-38]. We conducted informational meetings with research teams that authored 5 of these publications, which used data from Greece, England, and the United States. Prior to the meetings, research teams received a list of proposed codebook constructs (ie, product information, nicotine content, flavors, packaging features, warning labels and messages, marketing messages and images, and advertising tactics). During the meetings, researchers provided feedback on these constructs and responded to targeted questions about their experiences in codebook development, features they would have liked to have coded, coding challenges, and unexpected findings. Detailed notes were taken to document lessons learned, suggestions for improvement, and recommendations for additional codebook constructs. Insights gathered were incorporated into the first full draft of the codebook to enhance its practicality and relevance.

To aid codebook development, we also viewed the physical e-cigarette packages collected in Indonesia in person. We found that compared to cigarettes, e-cigarettes from Indonesia came in a greater variety of shapes and displayed unique and varied design elements. The design also seemed more tailored to a younger audience, consistent with the literature on cigarette pack design elements that make cigarettes more attractive to youth and young adults (Figure 2) [39,40]. On the basis of these observations, we added questions and response options to the codebook to capture specific packaging elements likely to appeal to youth (eg, cartoons and fun fonts).

XSL•FO
RenderX

**Figure 2.** Comparison between cigarette and electronic cigarette (e-cigarette) packages collected in Indonesia, 2022. All e-cigarette images featured are the external packaging of e-cigarette liquids.

Next, we pilot-tested the codebook with coders and further revised the codebook and accompanying coding guide. A random subsample of 125 packages from Indonesia were used to pilot the first full version of the e-cigarette codebook. Revisions were made for clarity to address package characteristics not previously addressed and to eliminate items that had low interrater reliability. For example, we found the units used to communicate nicotine concentration varied (eg, percentage, “mg,” and “mg/mL”) and added response options accordingly. We also found that “masculine” and “feminine” appeals and brand names could not be determined reliably; these codebook questions were eliminated or edited.

A high level of intercoder agreement was reached for most variables (80%); however, for marketing appeals, there was a trade-off between simplifying the codebook to achieve higher agreement and including appeals that could provide greater context to the marketing being used on the packaging, resulting in lower levels of initial agreement (50%-70%) on some variables.

The codebooks for Indonesia and China e-cigarettes also varied due to different packaging and labeling regulations. At the time of data collection, e-cigarettes were unregulated in Indonesia; therefore, no questions applicable to compliance with existing policies were included in the Indonesia e-cigarette codebook, and only the external packaging layer visible to the consumer at point of sale was coded. Given the existing e-cigarette packaging and labeling policies in China at the time of data collection, the China e-cigarette codebook included related items, and coders were instructed to observe all layers of the packaging and the product. Further revisions were made to the China codebook based on packaging elements specific to Chinese e-cigarettes, additional pilot testing of 10 e-cigarette packages from China, and decisions to simplify the codebook after determining that certain items were not of high priority.

The base codebook structure used in both countries contained 4 sections: product information, nicotine, warning labels, and marketing appeals (Table 2), with some codes only included in the Indonesia or China codebook based on lessons learned and country-specific regulations and context.

XSL•FO
RenderX

**Table 2.** Sections of the codebook and variables used in Indonesia and China (full codebooks are available on the Tobacco Pack Surveillance System (TPackSS) website [24])[a].

| Section | Variables |
|---|---|
| Basic product information | • Duplicate pack status[b]<br>• Purchase date<br>• Price<br>• Product type<br>• External packaging layers<br>• Number of puffs as stated on the pack (for disposables)[b]<br>• Number of pods or cartridges[b]<br>• Brand names<br>• Manufacturer name[b]<br>• Manufacturer location[b]<br>• Presence of English[c]<br>• Web presence[c]<br>• Insert or onsert |
| Nicotine | • Mention of nicotine<br>• Type of nicotine composition<br>• Total amount of e-cigarette[d] liquid<br>• Nicotine concentration units<br>• Nicotine concentration amount |
| Health warning and labeling–related items[e] | • Presence of text and/or image warnings[c]<br>• HWL[f] location (for each layer: product, internal packaging, and external packaging)[b]<br>• Observance of HWL through the internal packaging layer[b]<br>• HWL obstruction (for each layer)[b]<br>• HWL in Chinese language (for each layer)[b,g]<br>• HWL text (for each layer)[b,g]<br>• HWL located on bottom of the pack face (for product and external packaging)[b,g]<br>• Branding beneath HWL (for product and external packaging)[b,g]<br>• HWL color (for product and external packaging)[b,g]<br>• HWL text contrast (for product and external packaging)[b,g]<br>• Part of the HWL not present (for product and external packaging)[b,g]<br>• HWL area (for external packaging)[b,g]<br>• Misleading descriptors (for any layer)[b,h]<br>• Health-promoting descriptors (for any layer)[b,h]<br>• Minor protection descriptors (for any layer)[b,h]<br>• Minor protection imagery (for each layer)[b,h] |

XSL•FO

| Section | Variables |
|---|---|
| Features and appeals (coded for on any layer in China and only for the most external visible packaging layer in Indonesia) | • Branding information on insert or onsert[b]<br>• Presence of branding information on each packaging layer[b]<br>• Web presence (for each layer)[b]<br>• Presence of company phone number (for each layer)[b]<br>• Marketing claims<br>• Claim of cessation aid[c]<br>• Mention of recognition by award or standard[b]<br>• Environmentalism and civic responsibility lexical and imagery appeals[b]<br>• Technology appeal[b]<br>• Taste or sensation terminology<br>• Flavor terminology or imagery (for external packaging)<br>• Full flavor name[c]<br>• Description of tobacco flavor (for external packaging)[b]<br>• Feminine terminology or imagery[c]<br>• Masculine terminology or imagery[c]<br>• Presence of youth appeal[c]<br>• Specific youth appeals[c]<br>• Youth appeals by text, imagery, and shape[b]<br>• China-specific cultural appeals[b]<br>• Global or luxury or quality appeals[b]<br>• Other notable appeals |

[a]Web presence appears in separate sections of the Indonesia (basic product information) and China (features and appeals) codebooks.

[b]Variable appears only in the China codebook.

[c]Variable appears only in the Indonesia codebook.

[d]E-cigarette: electronic cigarette.

[e]All items included in the China codebook are government mandated.

[f]HWL: health warning label.

[g]Repeated for each HWL.

[h]Variables were coded for presence on any layer of the packaging, instead of focusing solely on the HWL.

## Coding

Coding of e-cigarette packages followed the same procedures as previously described for tobacco products [20]. Packages were double-coded independently, and discrepancies were resolved by a third reviewer. Since 2021, we have transitioned to coding all products online using pack images generated using the photography guide rather than in person using the physical packages.

Coders used an extensive coding guide with questions, variable definitions, and package examples as a reference during coding. During a virtual training, coders were introduced to the codebook, coding guide, and coding platform Research Electronic Data Capture (REDCap; Vanderbilt University) and practiced coding packages as a group [41]. As with tobacco products, weekly coding review meetings were held to discuss any unusual packages encountered during coding and resolve coding discrepancies.

For Indonesia, separate qualitative coding of cultural appeals was conducted because the original coders were not all native to Indonesia or closely familiar with its cultural context and, therefore, were not able to adequately assess the meaning of some package elements. Two native Bahasa Indonesian speakers who were raised in Indonesia examined all packages and made an initial assessment of whether text or imagery referred to anything related specifically to Indonesia (eg, a popular character in pop culture, food, or a slang phrase); discrepancies were discussed and resolved by a third party when needed. Next, one of these initial coders reviewed the images of the e-cigarette packages again and wrote a short qualitative description (2-4 sentences) of the cultural appeal. A third study member, who was born in Indonesia, conducted a thematic analysis of the cultural appeals across packages and summarized the results. A fourth study member, who was born in Indonesia, reviewed all packages to determine if cultural appeal overlapped with youth appeal and, when appropriate, categorized and described the culturally specific youth appeal. Two additional Indonesians reviewed these youth appeal categories and descriptions and provided additional insight on whether the appeals were mostly known and liked by younger consumers or if they also appealed to a wider audience. For China, cultural appeals were coded quantitatively as part of the standard codebook because all members of the study team were native to or closely familiar with the Chinese cultural context [24].

XSL•FO
RenderX

## Results

### Packages Collected

The TPackSS study began in 2012 with funding from Bloomberg Philanthropies' Bloomberg Initiative to Reduce Tobacco Use. Between September and October 2022, we collected 825 unique packages in Indonesia, comprising 782 e-cigarette liquid bottles, 26 disposable e-cigarette devices, and 17 disposable pods or cartridges. Of the 825 unique packages collected in Indonesia, 483 were collected in Jakarta, 203 in Surabaya, and 139 in Medan. Between April and May 2023, we collected 143 unique packages in China, comprising 5 disposable e-cigarette devices and 138 disposable pods or cartridges. No e-cigarette liquid bottles were collected in China. This is likely because the law prohibits the sale of e-cigarette products that allow people to add their own e-liquid to a device [42]. Of the 143 unique packages collected in China, 41 were collected in Shanghai, 31 in Beijing, 6 in Chongqing, 25 in Guangzhou, 15 in Kunming, and 25 in Shenzhen. Data analyses for Indonesia are completed, and secondary analyses are being completed for China. Detailed findings from these collections are being disseminated through separate publications scheduled for 2026 [43].

### Presentation on the TPackSS Website

As with our tobacco product collections, we upload images of the e-cigarette packages to the TPackSS searchable online database [20]. Similar to tobacco products, information about a specific pack is provided along with its photos. Individual e-cigarette packages have the same description categories as tobacco products: brand family, product type, country, city, collection date, and price. Additionally, similar to tobacco products, these packages can be filtered and searched by product type, country, brand family, collection year, and specific features. Some of the current features available for tobacco products (ie, HWL noncompliance and flavor appeal) are applicable to e-cigarettes.

The TPackSS website also features a "Share A Pack" section where users can upload and share photos of tobacco packs from their country. These user submissions contain similar description categories and searchable features to the official uploaded TPackSS collections. This user submission feature has been expanded to encourage uploads of e-cigarette products.

As with previous tobacco product collections, in addition to uploading photos of the packages collected to the project website, we are continuing to create and disseminate country-specific fact sheets. These fact sheets are available for download from the website [24]. The field procedures and codebooks used for these collections and our publications on TPackSS findings are also available via the website.

## Discussion

This protocol provides procedures for systematically purchasing unique e-cigarette products; assessing the products and their packaging for HWL compliance, nicotine information, and design features and marketing appeals; and disseminating the findings. This protocol can be adapted to other countries by taking into consideration the unique policy and market context. The protocol is applicable and adaptable to multiple policy and market contexts. It draws strength from being adapted from the TPackSS project's years of experience conducting similar work with tobacco products. The protocol has also been informed by the experience of other research teams that have conducted research on e-cigarette packaging.

The adapted protocol was successfully used to obtain or purchase a wide collection of unique e-cigarette packages sold in Indonesia and China. E-cigarette coding resulted in policy-relevant findings that address the study's main objectives to assess e-cigarette compliance with country-specific packaging and labeling regulations and identify marketing tactics being used on packaging. Findings have been disseminated through fact sheets, peer-reviewed journal publications, academic presentations, and communications with public health professionals in Indonesia and China.

The TPackSS e-cigarette protocol does have some limitations. While the data collection protocol is designed to ideally capture every unique product on the market, it is possible that some unique products are available at vendors we did not visit. In addition, this approach does not allow for the capture of the actual market share of collected products as information on sales is not collected. Products exclusively sold through online retailers or vendors are not captured. For countries where not all coders are culturally tied to the study country, it is possible that specific cultural nuances are missed during coding. Furthermore, coding of appeals such as youth and cultural references involves subjective interpretation. Despite these limitations, this protocol provides a valuable structure for monitoring e-cigarette products and packaging as well as compliance with HWL regulations. Beyond narrative findings, the protocol also ensures the production of visual data that can be incorporated into dissemination materials for diverse stakeholders and aids clear and accessible communication of study findings.

The e-cigarette market is changing rapidly, and continual monitoring is required to inform regulations to protect the public's health. TPackSS data collection of e-cigarettes will be repeated in the future based on warning labels and packaging requirement changes. The findings from these collections can inform policy by providing insights into the design features and marketing appeals of e-cigarette products available on the market, as well as compliance with HWL requirements where applicable.

## Acknowledgments

The authors would like to acknowledge the entire TPackSS team, including the work of our many coders: Chunlin (Eileen) Ren, Emily Xing, Natalie Nguyen, Jaydon Martinez, Raniyan Zaman, Rozanne Lim, Xinao (Lorraine) Luo, Yohana Revi Imanita, and Zhehan Wang. The authors would also like to thank those who assisted with the qualitative coding in Indonesia: Dr Beladenta Amalia, Joshua Sinamo, Adhiyatma Fuaddy, Yohana Revi Imanita, Nabilah Kusuma Wardhani, and Helen Natalia. In addition, the authors acknowledge the invaluable help of the researchers they consulted during codebook development and their in-country partners who assisted with data collection, translation, and disposal of the electronic cigarette products: Tobacco Control Support Center, Dr Abdillah Ahsan and his research team at the University of Indonesia, Rising Sun, and Dr Pinpin Zheng at Fudan University. Furthermore, the authors acknowledge Dr Beladenta Amalia for her contributions in leading the 2022 Tobacco Pack Surveillance System Indonesia data collection. The authors would also like to thank Jared Earley for his contribution to the design of the flowchart figure.

## Funding

This work was supported by the Bloomberg Philanthropies' Bloomberg Initiative to Reduce Tobacco Use.

## Data Availability

The data supporting this research are available from the authors on reasonable request.

## Authors' Contributions

JEC and KCS developed the original Tobacco Pack Surveillance System (TPackSS) protocol. JLB managed the project, and all authors contributed to the development of the modified TPackSS protocol and codebook for electronic cigarettes. QN managed data collection and coding of the China data. HEB and RH oversaw coding of the Indonesia data. RH and QN performed the statistical analyses. RH drafted the initial manuscript. All authors provided critical feedback on the manuscript and approved the final version.

## Conflicts of Interest

JEC was a paid consultant in litigation against a tobacco company.

## Abstract

**Background:** Malaria remains one of the most significant global health threats, and its control depends on timely, accurate entomological surveillance. In Uganda, routine vector surveillance relies heavily on microscope-based mosquito identification by a limited number of trained entomologists, which can delay reporting. VectorCam is an AI-enabled digital tool to support real-time mosquito identification and can be operated by community health workers, supporting rapid data reporting. After co-designing the implementation package using a human-centered design approach with Uganda's Ministry of Health, we are implementing a surveillance strategy that incorporates VectorCam into routine work.

**Objective:** This study aims to evaluate acceptability, fidelity, feasibility, cost, and preliminary effectiveness of VectorCam, the intervention, along with supporting implementation strategies as it is integrated into Uganda's national malaria control program.

**Methods:** This mixed methods hybrid type III implementation-effectiveness study uses district-level restricted randomization to assign 12 districts to four sequential rollout waves following a 2-district pilot phase. The implementation package will be introduced over a one-year period across malaria-endemic districts in Northern and Eastern Uganda. Implementation outcomes, including acceptability, feasibility, fidelity, and cost, will be assessed using qualitative interviews, system usage logs, field observations, and program documentation. Effectiveness outcomes include technical performance of mosquito species identification, time efficiency, and operational use of surveillance data for decision-making. Accuracy will be evaluated through comparison with molecular identification methods, alongside additional classification performance metrics. Data will be analyzed using a mixed methods approach, with triangulation of qualitative and quantitative data and longitudinal analyses across districts and rollout waves. An adaptive learning approach will guide iterative refinement of the implementation package.

**Results:** Fourteen districts were selected by the Ministry of Health in September 2025 for VectorCam introduction. A pilot phase conducted between December 2025 and January 2026 in two districts was used to refine implementation strategies and research tools through stakeholder workshops. Ethical approval was obtained from Johns Hopkins in January 2026 and Ugandan

XSL•FO
RenderX

ethics committees in September 2025. Implementation began in February 2026 and will continue through March 2027 with concurrent data collection and analysis throughout the implementation timeline.

**Conclusions:** This study will evaluate a task-shifting approach to entomological surveillance by integrating an AI-enabled tool into routine workflows of community health workers through a co-designed implementation package. By examining how the VectorCam intervention and supporting implementation strategies function together within real-world health system contexts, this study will generate evidence on the sustainability of digitally enabled surveillance. Findings will provide insight into how task shifting and digital tools can expand surveillance capacity, improve timeliness of data reporting, and strengthen the use of entomological data for decision-making. These results will inform national scale-up efforts in Uganda and offer a model for other malaria-endemic settings seeking to modernize vector surveillance.

# Introduction

## Background

Malaria is a major public health challenge globally, with an estimated 263 million cases and nearly 600,000 deaths recorded in 2023 [1]. Africa is disproportionately affected, as 94% of all malaria cases and 95% of deaths occur on this continent [2]. In Uganda, malaria is endemic in nearly all of the 146 districts and accounts for approximately 30% to 50% of outpatient visits and hospital admissions [3,4]. Despite progress in malaria control over the past 2 decades, recent years have seen a plateau in health gains, highlighting the need for more adaptive, data driven, and locally tailored strategies to work toward elimination [1,5].

A cornerstone of effective malaria control and elimination is timely, accurate entomological surveillance [6,7]. Vector surveillance provides essential data on mosquito species composition, abundance, behavior, and insecticide resistance, all of which are critical for informing targeted interventions such as long-lasting insecticide-treated nets, indoor residual spraying, and larval source management [8-10]. For example, the most common malaria vectors in Uganda are *Anopheles gambiae s.l.* and *Anopheles funestus s.l.* [4]. Previous studies found that certain interventions are more effective in targeting these mosquito groups than others, a fact that underscores the importance of improving the efficiency of surveillance data collection and usage when choosing the correct intervention [11].

However, Uganda and similar locales have a major challenge: the existing vector surveillance systems are limited by their reliance on manual, microscope-based identification of mosquitoes by trained entomologists [12,13]. Uganda's Ministry of Health (MOH) conducts routine monthly mosquito surveillance through district vector control officers (VCOs). The method currently used is a manual process in which mosquitoes are collected, primarily through pyrethrum spray catches (PSCs), human-landing catches (HLCs), or Centers for Disease Control light trap catches (CDC-LTC), and then identified individually under a microscope to determine the genus and species [14-16]. The data are recorded, aggregated, and manually uploaded to centralized health informatics systems such as District Health Information System 2 (DHIS2). The Vector Control Division then uses these data for decision-making and mosquito population mapping [17].

The current vector surveillance methods are labor- and time-intensive and require special expertise. Therefore, generating actionable insights at the pace needed for effective malaria control is challenging [16]. These limitations delay decision-making and reduce the ability to respond rapidly to changes in mosquito populations and malaria transmission dynamics. To address these surveillance gaps, VectorCam was developed at the Johns Hopkins University, Center for Bioengineering Innovation and Design as a low-cost, AI-enabled tool that allows village health teams (VHTs) and other community health workers to perform mosquito identification tasks without prior entomological training [18].

## VectorCam, a Field Tool for Rapid Morphological Identification of Mosquitoes

AI-enabled tools are quickly gaining recognition as some of the most effective ways to improve data quality and dissemination [19-23]. The VectorCam platform uses a novel combination of a low-cost, 3D-printed device, smartphone-based microscopy, AI, and a mobile app to enable real-time mosquito identification. The devices use a convolutional neural network (CNN), running locally on a low-cost smartphone to photographically identify species, sex, and abdominal status of each mosquito specimen [18]. Then, the data are uploaded to a central server, which generates reports that are automatically sent to malaria control teams. VectorCam is designed to work in offline and low-bandwidth environments and integrates easily into existing workflows. A feasibility study by Couret et al [24] applied a similar CNN to images of mosquitoes for classification of sex, genus, species, and strains and found accuracy rates of up to 98%. This type of technology has implications in low-resource settings where AI-assisted technologies could close critical capacity gaps, such as when trained entomologists and surveillance infrastructure are limited.

In 2023-2024, a randomized controlled trial (RCT) conducted in 2 high malaria-burden districts of Uganda (Mayuge and Adjumani) demonstrated VectorCam's efficacy and feasibility [25]. During the RCT's study period, VectorCam generated predictions for primary malaria vectors including *Anopheles gambiae s.l.* (AG) and *Anopheles funestus s.l.* (AF), a heterogeneous grouping labeled Anopheles Other (AO)

XSL•FO
RenderX

representing locally relevant secondary vectors, Culicine genera including Culex spp. (CU), Mansonia spp. (MAN), Aedes spp. (AED), and a nonmosquito class to screen out other arthropods commonly captured during PSCs and CDC-LTCs. Across all taxonomic categories, VectorCam achieved an overall identification accuracy of 93% when compared with the gold-standard entomological identification methods [25]. The VectorCam technology also scored above the 90th percentile on the System Usability Scale, indicating that perceived usability is excellent [25]. Additionally, over 77,000 mosquitoes were identified by 24 VHTs over the 12-month study, with an average processing time of 17 seconds per specimen. This rate is an approximately two-fold improvement over the routine, microscope-based method of mosquito identification, which averages 34.5 seconds per specimen. Additionally, the VectorCam arm of the study accomplished a 98% data completion rate (29,785 entries completed out of 30,360 entries possible), compared to 45% (13,667/30,360) in the paper-based, routine surveillance control arm. These percentages reflect the number of mosquito data entries at day 14 (ie, the standard lag time between data collection and submission in Uganda's routine surveillance workflow) over an 11-month period and across 240 households (120 per arm). By addressing 2 persistent bottlenecks of limited entomological expertise and the slow pace of manual data entry, VectorCam has demonstrated an increase in data reporting efficiency, offering potential for national scale up, ultimately leading to better malaria control.

The technical performance of VectorCam and its feasibility have been established. However, widespread adoption of such technology requires an understanding of how to successfully implement, integrate, sustain, and scale the intervention in real-world health system contexts [4,26]. In Uganda and similar settings, implementation of novel technologies frequently fails or lacks sustainability, with common challenges stemming from technical (eg, infrastructure and expertise) and social (eg, culture, societal context, and human factors) dimensions [27,28]. This study uses an implementation science approach using the Consolidated Framework for Implementation Research (CFIR) and Expert Recommendations for Implementing Change (ERIC) strategies to assess and inform the VectorCam rollout, aiming to improve both uptake and sustainability of its implementation [29-32].

### Objectives

The main objective of this study is to evaluate how VectorCam can be sustainably integrated into Uganda's national vector surveillance infrastructure across 12 districts, with a goal of informing future scale-up efforts across the country and in similar settings. The three aims of the study are to (1) identify contextual factors that enable the implementation of VectorCam in Uganda and evaluate the mechanisms through which they affect the implementation process; (2) assess the acceptability, feasibility, fidelity, and cost of VectorCam's implementation model; and (3) evaluate the effectiveness of VectorCam in providing timely, accurate vector surveillance data and influencing malaria control decision-making.

## Methods

### Study Design Overview

This study uses a mixed methods, hybrid type III implementation-effectiveness design [33]. The primary aim is to evaluate implementation outcomes, including acceptability, feasibility, fidelity, and cost, while the secondary aim is to assess preliminary effectiveness outcomes, including technical accuracy of mosquito identification and operational use of VectorCam data in decision-making. Table 1 outlines these outcomes along with assessment methodology for each, demonstrating our multiple methods of data collection that will generate predefined key measures and are analyzed using both qualitative and quantitative approaches.

XSL•FO
RenderX

**Table 1.** Implementation and effectiveness outcomes, methods, and metrics by aim.

| Outcome | Methods of data collection | Key measures | Planned analysis |
|---|---|---|---|
| Aim 1: assessment of contextual determinants | • CFIR[a]-determinants evaluation survey with implementers; ERIC[b] strategy matching tool<br>• Semistructured pre- and post-KIIs[c] evaluating context with users[d] | • CFIR barriers and facilitators by domain | • Descriptive summaries of survey notes; quantitative summaries of Likert Scale ratings<br>• Thematic analysis of CFIR constructs; cross-district & cross-wave comparison matrices |
| Aim 2: acceptability, feasibility, fidelity (qualitative) | • Semistructured pre- and post-KIIs evaluating implementation with users[d]<br>• Midpoint IDIs[e] with Master Trainers, VCOs[f], and VHTs[g]<br>• Quarterly stakeholder engagement meeting<br>• FRAME-IS[h] documentation tool | • Perceived usefulness, ease of use, workflow fit, perceived protocol adherence, sustained use, pain points, adaptation tracking | • Thematic analysis; descriptive statistics; longitudinal summaries by district and rollout wave |
| Aim 2: fidelity (quantitative) | • App usage and completeness metrics<br>• Field observation checklist and supervisory toolkit | • Completeness of reporting; protocol adherence, district-level sustained use<br>• Protocol adherence rate | • Proportions with 95% CIs; ordinal or binary mixed models where appropriate; district quarter trend plots |
| Aim 2: cost | • Costing database, budgets, procurement and supervision records | • Total and unit costs, budget impact, scale-up costs | • Budget impact analysis modeling for 1-year, 3-year, and 5-year scenarios; ingredients-based costing; annualization of capital costs; one-way sensitivity analysis |
| Aim 3: technical effectiveness | • Validation subset with VectorCam, routine method, and PCR[i] (or equivalent) | • Sensitivity, specificity, PPV[j], NPV[k], F1-score, agreement | • Diagnostic accuracy analysis with 95% CIs; paired comparison when both methods are available; descriptive comparison of classification performance |
| Aim 3: operational effectiveness and data use | • Quarterly NMED[l] meeting attendance checklist<br>• KIIs to measure time allocation with users<br>• KIIs with district and national decision-makers | • Use of data in planning; reporting timeliness<br>• Time allocation; task-shifting model metrics<br>• Data usage by decision-makers; impact on malaria control actions | • Descriptive comparisons of time allocation metrics and data-use indicators across districts and rollout phases; mixed effects regression for time metrics; qualitative thematic analysis of data-use pathways |

The study includes a randomized rollout of VectorCam across a group of 3 districts every 3 months, supporting real-time learning and adaptations. The staggered rollout enables longitudinal assessment of implementation and effectiveness outcomes across districts and rollout waves. A midline review will synthesize this feedback to inform data-driven adaptations to the implementation package and technology design, subject to review and approval by Uganda's MOH officials before rollout in the subsequent districts. Adaptations may include modifications to the intervention (eg, app updates) or to the implementation strategies (revised training toolkit), depending on identified needs. We apply a combination of complementary

XSL•FO
RenderX

implementation science frameworks to guide design, evaluation, and adaptive refinement. Figure 1 illustrates the structure of this study, showing how implementation science theory will be used and the cyclic, stepped rollout that will allow us to systematically gather feedback and improve the intervention prior to each phase. This protocol aligns with the Standard Protocol Items: Recommendations for Interventional Trials (SPIRIT) guidelines, and the intervention description follows the Template for Intervention Description and Replication (TIDieR) checklist (Multimedia Appendices 1 and 2). A protocol timeline is provided in Multimedia Appendix 3.

**Figure 1.** Conceptual overview of the hybrid type III implementation-effectiveness study design. CFIR: Consolidated Framework for Implementation Research; FRAME-IS: Framework for Reporting Adaptations and Modifications–Enhanced for Implementation Strategies.

## Study Setting and Participants

The MOH selected 14 districts in Uganda to receive VectorCam based on the following inclusion criteria: (1) Presence of diverse mosquito species relevant to malaria transmission; (2) workforce capacity - availability of trained VCOs and VHTs to participate in data collection; (3) district–level commitment to adopting digital vector surveillance tools; (4) willingness of local health authorities to support and sustain implementation; and (5) logistical feasibility to operate within the region (eg, security concerns, seasonal accessibility, and surveillance supply availability). A total of 2 districts, Koboko and Mayuge, were selected as pilot implementation districts to provide an opportunity to test and adapt the initial implementation package, methods of data collection, and key measures based on their high level of implementation readiness. Findings from the pilot will be reviewed jointly by the study team and the MOH to inform the refinement of research tools and implementation strategies. The selected districts represent a range of malaria transmission settings and implementation contexts while maintaining sufficient operational readiness to support the initial phase of national rollout. Although this study does not specifically target the most resource-constrained districts, a key objective is to identify the contextual determinants, implementation strategies, and support structures required for successful adoption of VectorCam. Findings from this study will inform future adaptation and scale-up efforts in settings with more limited surveillance infrastructure and workforce capacity.

The remaining 12 districts will implement the package in 4 sequential rollout phases, with 3 districts added every 3 months following completion of the pilot phase. This design enables evaluation of implementation processes across diverse contexts and over time, while allowing for iterative refinement of strategies between phases. Districts are assigned to rollout waves using restricted randomization at the district level via a computer-generated random sequence created by a study programmer prior to implementation. To ensure geographic balance, the allocation sequence will be constrained such that no rollout group includes more than one district from the same region. This approach was developed collaboratively by the study team and Uganda's MOH to support evaluation across different districts while promoting equitable distribution of the intervention across regions during rollout. The rollout waves are intended to support implementation sequencing and adaptive learning rather than serve as comparison groups for causal inference. Multimedia Appendices 4 and 5 show information on the districts in each rollout group. To facilitate interpretation of our outcomes, contextual district characteristics, including malaria burden and workforce composition (eg number of VHTs and VCOs per district), will be documented during implementation activities and added descriptively to the table shown in Multimedia Appendix 5.

XSL•FO
RenderX

Key participants include VHTs, VCOs, master trainers (ie, district-level supervisors who are trained in the VectorCam system), District Health Officers, and staff from the National Malaria Elimination Division (NMED), representing multiple levels of the health system engaged in malaria surveillance and control.

## Intervention Description

The proposed task-shifting model for vector surveillance includes the VectorCam hardware and software (intervention) along with the strategies supporting its integration into Uganda's routine vector surveillance program (implementation package). We used a human-centered design approach to developing the implementation package, with a particular focus on determining the details of the implementation strategies and materials. The implementation package was co-designed in consultation with national, district, and community-level stakeholders during a collaborative workshop held in August 2025. The participants included officials from the Ministry of Health, master (lead) VCOs, district VCOs, and members of the research team.

The intervention includes VectorCam imaging devices, smartphones preloaded with the VectorCam application, and charging accessories provided to each district and shown in Multimedia Appendix 6. The package includes 4 core implementation strategies: (1) a training toolkit and capacity building, (2) data-based decision making, (3) a supervisory toolkit and quality assurance, and (4) learning loops and procedures for ongoing technical support. These strategies are designed to address known barriers to implementation by improving user knowledge and skills, strengthening feedback and accountability systems, reinforcing perceived usefulness, and supporting integration into routine workflows. Because VectorCam is designed to support task shifting of surveillance activities to community-level personnel, the study will also evaluate the training intensity qualitatively and by number of retraining sessions completed, supervision requirements, technical support needs, and workflow adaptations necessary to maintain high-quality surveillance data. Figure 1 depicts the implementation package components conceptually.

Standardized training materials and the supervisory toolkit, including demonstrations, user manuals, inventory tracking procedures, and troubleshooting checklists, were codeveloped by the VectorCam implementation team, the researchers, and the MOH. Training will follow a cascade model in which Master Trainers from NMED will receive training on VectorCam operations, troubleshooting, supervision procedures, and supply management. These Master Trainers will then conduct district-level, hands-on training for VCOs and VHTs during the first week of rollout in the district. The training also includes pre- and posttraining knowledge assessments for VHTs that will identify any remaining gaps prior to VectorCam use in the district. Additionally, the supervisory toolkit includes a structured audit to assess protocol adherence, data quality, and equipment functionality. These toolkits are complemented by the data dashboards and monthly review meetings for regular feedback cadence. Technical support includes a tiered escalation pathway. First-line support is provided by VCOs, with second-line support from the VectorCam technical team for software issues or hardware failures. Procedures for reporting and resolving technical issues are documented using an "Implementation Issues Log" and reinforced during training. These strategies in combination are designed to support fidelity and acceptability of the intervention by improving consistency, knowledge, and quality of data collection.

After each implementation cycle, we will conduct structured stakeholder engagement meetings with district health teams, VCOs, and NMED representatives. This meeting cadence is built into the implementation package specifically to collect feedback from users, disseminate results, and share lessons learned. The Framework for Reporting Adaptations and Modifications–Enhanced for Implementation Strategies (FRAME-IS) will be used to document any significant changes to the implementation package, and these will be shared with stakeholders during the quarterly meeting [34]. Notes from these sessions will also help us identify facilitators and barriers to implementing and sustaining VectorCam, including factors related to resource availability, leadership support, and integration into routine workflows.

## Outcomes Assessment

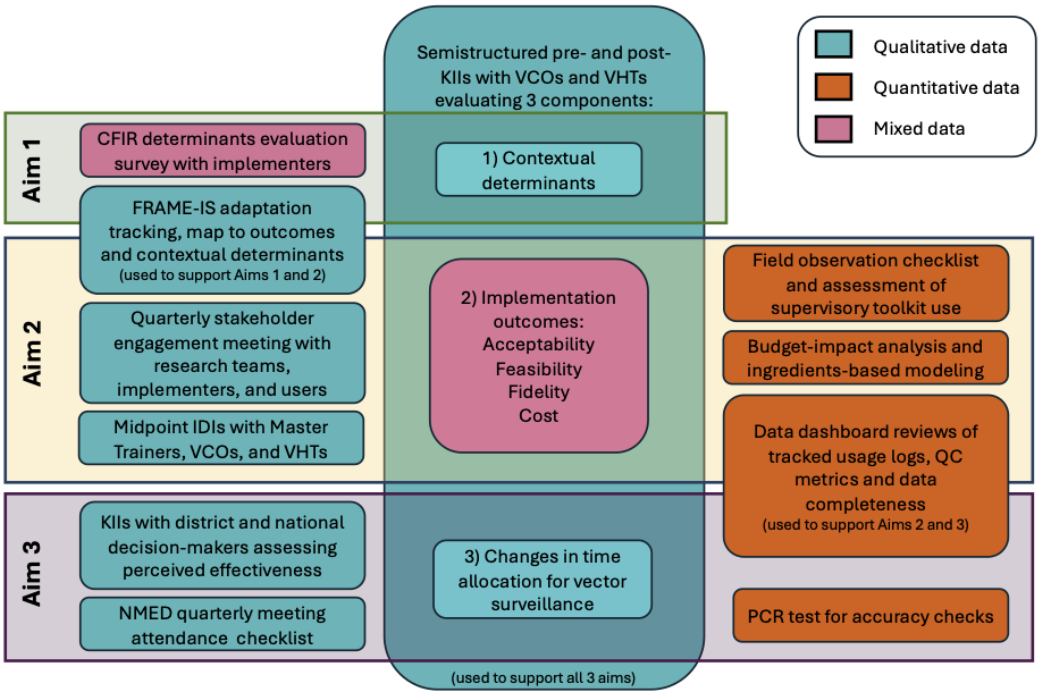

Table 1 shows a breakdown of outcomes, methods for data collection, and evaluation metrics aligned with each aim. The table outlines how implementation and effectiveness will be assessed through mixed methods, ensuring that outcomes are aligned with the study's overall evaluation framework. All surveys and interviews have been developed with feedback from the study's in-country partners and will be administered with printed forms in either English or local languages as appropriate. The interviews will be administered by a researcher who is fluent in both English and the local language and trained to obtain consent before interviews.

Figure 2 illustrates all the methods of data collection used across the aims of this study, correlating with Table 1. An overview of each aim and a description of the methods used for data collection within them is detailed in the following sections.

XSL•FO
RenderX

**Figure 2.** Overview of the mixed methods research tools used by aim. CFIR: Consolidated Framework for Implementation Research; IDI: in depth interview; KII: key informant interviews; NMED: National Malaria Elimination Division; PCR: polymerase chain reaction; QC: quality control; VCO: Vector Control Officers; VHT: village health teams.

## Aim 1: Evaluation of Contextual Determinants

We will assess the contextual determinants that influence implementation of the VectorCam platform by using an approach grounded in CFIR methodology and guided by established implementation mapping procedures [32]. This aim combines semistructured surveys and in-depth, pre- and post-key informant interviews (KIIs) to generate an understanding of the barriers and facilitators to successful implementation and evaluate the mechanisms through which they influence the implementation and effectiveness outcomes of interest.

Methods for data collection for Aim 1 include (1) CFIR-determinants evaluation survey with implementers, and (2) semistructured, pre- and post-KIIs to evaluate contextual characteristics with users. Firstly, for the CFIR-determinants evaluation surveys, we will administer a semistructured survey to select implementers: 4 MOH representatives and 6 VCOs or District Health Officials. This process will yield a total of 10 interviews conducted between months 4 and 6 of the staggered rollout. This survey will collect information on the context, probing for barriers and facilitators to implementation success. The survey instrument will primarily include Likert-scale questions to understand how the participant ranks the importance of specific determinants, supplemented by 5 open-ended questions to probe in-depth explanations for their choice of ranking. All questions are adapted from validated CFIR measurement tools to assess the 5 domains, including perceptions of intervention characteristics (eg, relative advantage and adaptability), inner setting (eg, organizational culture and implementation climate), outer setting (eg, external policies and community support), characteristics of individuals (eg, self-efficacy and knowledge), and process (eg, leadership engagement and planning).

Secondly, in each district, pre-KIIs will be conducted during the first week of intervention implementation (after training), and post-KIIs will then be administered 3 months later, focusing on the evaluation of contextual characteristics with users. Four VHTs and 2 VCOs will be purposely selected per district to ensure a balance of perspectives and varying levels of prior experience with entomological surveillance. The same participants will be contacted again for postimplementation interviews, enabling us to make paired comparisons of changes in attitudes and reported practices over time. Whenever possible, the same participants will be recontacted for follow-up interviews. If a participant is unavailable due to transfer, withdrawal, or other forms of attrition, a replacement participant occupying a similar implementation role will be purposively selected. Data collected through these sessions will inform

XSL•FO
RenderX

iterative refinements to the implementation package and materials for subsequent adaptive cycles. By collecting rich qualitative data, the study team can examine what contextual determinants are most important during the initial phases of VectorCam rollout and, more precisely, how these factors are associated with changes in implementation outcomes.

### Aim 2: Acceptability, Feasibility, Fidelity, and Cost

The primary purpose of this aim is to ascertain the implementation outcomes of VectorCam use as defined by the Implementation-Outcome Framework [35]. Acceptability, fidelity, and feasibility of the implementation package will be assessed by using an integrated mixed methods approach that combines qualitative and quantitative data. For qualitative data, we will deploy pre- and postimplementation semistructured interviews, quarterly stakeholder engagement meeting notes, midpoint in-depth interviews with implementers and users, and FRAME-IS guided survey. Quantitative data collection tools for Aim 2 include data dashboard metrics, such as usage logs and percent completeness, and the field observation checklist. Additionally, the cost of VectorCam integration into Uganda's vector surveillance system will be assessed with a combination of prospective costing methods, budget impact modeling, routine monitoring data, and structured feedback from district and national stakeholders. This aim will generate a comprehensive understanding of user experiences, protocol adherence, ease of use, fit with existing workflows, and evidence on the long-term financial feasibility of maintaining the implementation package at scale. Data from this aim can be used by Uganda's MOH and its implementing partners to plan for a scalable and sustainable nationwide rollout.

Methods of data collection for Aim 2 include:

1. Semistructured pre- and post-KIIs to evaluate implementation outcomes with users
2. Field observation checklist to evaluate fidelity and supervisory toolkit
3. VectorCam app-system usage logs
4. Costing database, budgets, and procurement records
5. FRAME-IS documentation tool

The first data collection tool, pre- and post-KIIs, includes interview guides that are designed to be used at the same time points as the semistructured pre- and post-KII to evaluate context and administered to the same participants (ie, 4 VHTs and 2 VCOs) introduced in Aim 1 data collection methods. The purpose of this interview guide is to collect information about implementation outcomes. It will include structured questions for assessing satisfaction with the technology, perceived ease of use, alignment with existing workflows, confidence in the tool, and reflections on the frequency and consistency of use.

Each month, a VCO will use the second research tool and the field observation checklist to directly observe VHTs using the VectorCam system in the field to assess fidelity and the deployment of the supervisory toolkit. We will review these logs to verify the proportion of eligible VHTs trained in each cycle, equipment distribution, and posttraining support provided. The supervisory tool also contains a standardized field observation checklist and a set of structured questions designed to identify factors that may affect supervision, these questions will explore domains such as availability of logistical resources (eg, transport and devices), communication and coordination mechanisms, and context and barriers that will be used to assess how well VectorCam users are adhering to the protocol, including preparation and calibration of the device, correct specimen handling, adherence to identification procedures, and successful data upload to DHIS2. A VCO and a researcher will complete this checklist separately so that we will have 2 observations with which to assess district-level fidelity. Observers will rate protocol adherence as high, medium, or low and will provide narrative field notes describing deviations and potential contributing factors.

Quantitative data collected from VectorCam's app will be used to assess percent of data completeness, and fidelity will be collected through system-generated usage logs exported monthly for analysis. Completeness of reporting and sustained use metrics will be summarized descriptively. Mixed-effects logistic or ordinal regression models may be used, where appropriate, to explore temporal patterns in completeness of reporting and implementation outcomes related to sustained use while accounting for clustering at the district level.

Throughout the study period, we will use a cost-tracking system to capture direct and indirect costs associated with VectorCam implementation in each district. Cost data will be collected prospectively and will include expenses related to procurement of hardware and consumables, training and supervision activities, technical support, and system maintenance. Financial records, procurement invoices, and project budgets will be reviewed to ensure comprehensive accounting of expenditures. Health economists on the study team will use these data to develop annual and multiyear budget projections, estimate total annual implementation costs, and calculate operational cost savings that result from replacement of manual surveillance methods. These models will generate 1-year, 3-year, and 5-year budget projections to inform national malaria control planning.

Lastly, to ensure transparent reporting of changes to the package over time, we will systematically document all modifications to the intervention and implementation strategies using the FRAME-IS [34]. Throughout implementation, project staff and implementing partners will record proposed or observed changes during routine monitoring and bi-weekly coordination calls. Each adaptation will be documented on a structured form aligned to FRAME-IS domains: (1) the nature of the modification (content, context, personnel, or delivery mode); (2) the level at which the change occurred (individual provider, facility, district, or system level); (3) whether the modification was planned or reactive; (4) the goal of the change, including improving feasibility, acceptability, fidelity, reach, or equity; (5) the decision-making process and actors involved; and (6) the extent to which the change was fidelity-consistent with core program components. We will then categorize adaptations into higher-level themes to enable comparison and identify patterns in how the implementation strategies evolved over time. This process will ensure transparent reporting of adaptations and allow linking of modifications to implementation outcomes and contextual drivers.

XSL•FO
RenderX

### Aim 3: Evaluation of Effectiveness

Effectiveness of the VectorCam intervention (as delivered with implementation strategies) in maintaining accuracy, improving time allocation metrics, and supporting operational use of surveillance data will be assessed with a combination of KIIs, quantitative analyses of system data logs, and qualitative interviews with national and district-level decision-makers. This aim is designed to generate preliminary evidence regarding VectorCam's performance under ideal implementation conditions and whether the task-shifting model is associated with improvements in data quality and timelier, evidence-based decision-making relative to microscopy-based surveillance. Routine microscope-based entomological surveillance conducted by district entomology teams serves as the comparator condition, as it represents the standard of practice within Uganda's national malaria surveillance system.

Methods of data collection for Aim 3 include:

1. Pre- and post-KIIs to evaluate time allocation with users
2. App-recorded data logging time spent per mosquito identification event
3. Molecular analysis comparison
4. KIIs with national and district-level decision-makers on operational effectiveness and data use
5. NMED quarterly meeting attendance and observational checklist

Pre- and postimplementation interviews with VHTs and VCOs will be used to assess the time required for mosquito identification and data submission. This tool is designed to be utilized at the same time point as the pre- and post-KIIs for data collection within Aims 1 and 2. Participants will be asked to describe the average time spent on identification tasks before and after the introduction of VectorCam, including steps related to specimen preparation, processing, and reporting. Questions on the KII guides differ for VHTs and VCOs in order to capture changes to workflow based on the task-shifting model.

Quantitative data on actual time spent per mosquito identification event will be extracted from VectorCam usage logs over the study period. Logs will include timestamps marking initiation of identification, confirmation of results, and data upload.

For the molecular analysis comparison, accuracy of mosquito species identification using VectorCam will be evaluated by comparing system-generated identifications to a gold-standard reference. Molecular identification will serve as the primary gold standard, using polymerase chain reaction (PCR) when species-specific reagents are available and sequencing when they are not. A random subset of 500 specimens collected during routine surveillance will be selected for molecular validation. This sample size was selected to provide sufficient precision for estimating identification accuracy under routine implementation conditions. Based on the 93% species identification accuracy observed in the previous RCT, a validation sample of 500 specimens yields an approximate 95% CI with a margin of error of +/- 2.2 percentage points around the overall accuracy estimate. These estimates will be used to characterize VectorCam performance descriptively where sample sizes are sufficient, recognizing that precision will vary by the number of specimens available for each species. These specimens will be analyzed independently by an entomologist blinded to the VectorCam results and PCR findings. Accuracy will be defined as the proportion of VectorCam identifications that match PCR results when available, or morphologic identification otherwise. In addition, model performance will be evaluated using standard classification metrics from an AI perspective. In addition to this primary accuracy measure, performance will also be evaluated using standard metrics, including precision, recall, and the $F_1$-score, which together provide a balanced assessment of how well the model identifies mosquito species.

Next, we will explore VectorCam's operational effectiveness and data use on malaria control decision-making by interviewing 8-10 MOH-NMED staff and District Health Officers. An interview guide was developed to facilitate the KIIs with national and district-level decision makers to collect qualitative information regarding operational effectiveness and VectorCam data use. The NMED groups that will be interviewed will either have routine interactions with the entomology database, responsibilities for improving the database, and/or responsibilities that involve using the database to make decisions about malaria control programs, including roles such as the Director of the National Malaria Program, Information Technology Senior Developer, lead entomologists, and coordinators of routine surveillance activities. Interviews will explore perceptions of the reliability and utility of VectorCam data, comparisons to previous surveillance approaches, and examples of how data informed vector control interventions or planning. Interviews will be conducted a minimum of 6 months after implementation in each district cohort to allow sufficient time for data review and use.

Lastly, a researcher from either Makerere University or Johns Hopkins University will attend NMED's quarterly meetings and use the NMED quarterly meeting attendance and observational checklist to document how the VectorCam data are reviewed and used during routine decision-making processes. The checklist will capture whether VectorCam data were presented, discussed, or referenced in relation to surveillance planning, vector control activities, resource prioritization, or other operational decisions. Findings from these observations will be triangulated with key informant interviews to assess the perceived utility and operational use of VectorCam data.

## Data Management and Analysis

This study uses a convergent mixed methods analytic approach in which qualitative and quantitative data are collected and analyzed concurrently across all study aims. Data collection and analysis will occur iteratively across the staggered rollout cycles, allowing findings from earlier phases to inform subsequent data collection, refinement of tools, and interpretation of results. This approach is intended to capture the dynamic and context-dependent nature of implementation and to support adaptive learning throughout the study. Across all aims, data collected through multiple methods will be used to generate and validate key measures, and analyses will be

XSL•FO
RenderX

conducted in alignment with the “Planned Analysis” column in Table 1.

All qualitative data, including semistructured key informant interviews, in-depth interviews, open-ended survey responses, and stakeholder engagement discussions, will be collected by trained research staff and transcribed verbatim when audio recording is permitted or expanded into detailed notes immediately following data collection. Research staff involved in observational data collection will receive standardized training on data collection procedures, use of observational tools, and documentation practices to promote consistency across observers and study sites. Data will be managed and analyzed using Atlas.TI. A single, unified codebook will be applied across all qualitative data sources to ensure consistency and enable comparison across stakeholder groups and time points. This approach is particularly important given that the same interview streams (ie, the pre and post-KIIs) contribute to multiple study aims and are intended to capture changes over time in determinants, implementation processes, and operational effectiveness.

Codebook development will follow a hybrid deductive and inductive approach (see Multimedia Appendix 7 for deductive codebook). Deductive codes will be derived from established implementation science frameworks, including the CFIR, as well as the Implementation Outcomes Framework (IOF) to capture constructs such as acceptability, feasibility, fidelity, and cost. After the first implementation rollout, the codebook will be iteratively refined to incorporate inductive codes that emerge from the data, including unanticipated barriers, contextual dynamics, adaptations, and potential district-specific codes. Coding will initially be conducted by at least 2 coders, with regular meetings to reconcile discrepancies, refine code definitions, and ensure consistent application of the coding framework. Prior to independent coding of the full dataset, coders will establish interrater reliability using a subset of transcripts. Interrater reliability will be assessed using percent agreement, with a minimum threshold of 0.75 required before proceeding to full coding. If agreement falls below this threshold, discrepancies will be reviewed jointly, code definitions will be refined, and additional training and calibration exercises will be conducted before reassessment. During coding, disagreements that cannot be resolved through discussion will be adjudicated by a senior member of the research team. Ongoing reflexive discussions will be used to examine assumptions and strengthen interpretive validity within the research teams. Framework analysis will be used to identify themes within and across stakeholder groups and over time, with particular attention to how contextual determinants influence implementation outcomes and how these relationships evolve across rollout cycles.

Quantitative data will be derived from structured surveys, field observation checklists, costing databases, and the data dashboard, which tracks key metrics such as data completeness. Descriptive analyses will be conducted to summarize key variables, including measures of data completeness, usage frequency, and accuracy. Implementation outcomes will be assessed using multiple complementary indicators and, where appropriate, proportions will be calculated with 95% CIs. Fidelity will be evaluated through both system-generated metrics, such as completeness of required data fields, and observational assessments of protocol adherence. Patterns of system use will be examined longitudinally to assess trends over time and variation across districts. Descriptive summaries will be generated by district and rollout wave, including district-quarter trend plots to visualize changes over time.

Cost analysis will be conducted from the program perspective, with scenario analyses for broader health system scale-up. An ingredients-based costing approach will be used to estimate startup and recurrent costs, including hardware, consumables, training, supervision, maintenance, connectivity, and technical support. Capital items will be annualized over their useful life using a standard discount rate. Unit costs will be reported per district covered, per user trained, and per identification event completed. Budget impact models will be developed to project costs under different scale-up scenarios, incorporating both observed expenditures and anticipated changes in resource requirements. Sensitivity analyses will test uncertainty in key assumptions.

Effectiveness outcomes will be assessed using both quantitative and qualitative data. Time allocation will be evaluated through both self-reported data (collected via the pre- and post- KIIs) and system-recorded measures of time spent on surveillance activities. To evaluate the task-shifting model that VectorCam used, time allocation comparisons will be made across pre- and postimplementation periods. Accuracy of mosquito identification will be assessed by comparing VectorCam outputs to the gold-standard molecular identification (PCR or sequencing for species for which PCR reagents are not available). Qualitative data from interviews with decision-makers will be analyzed thematically to assess the perceived utility of surveillance data for decision-making using the same codebook as other qualitative data collection tools.

Integration of qualitative and quantitative data will occur throughout the analytic process to enable triangulation and strengthen the validity of findings. This will occur through joint displays, triangulation matrices, and iterative comparison of quantitative and qualitative findings. Quantitative results will be interpreted alongside qualitative insights to assess convergence and to provide context for observed patterns. Qualitative data will also be used to explain unexpected quantitative findings and to identify mechanisms underlying observed relationships. Integration will be further supported using an Implementation Research Logic Model, which will link contextual determinants, implementation strategies, and outcomes across data sources.

Documentation of adaptations using FRAME-IS will be analyzed alongside implementation and effectiveness metrics to examine whether changes to the implementation approach are associated with improvements in the implementation outcomes we are analyzing. Comparisons across stakeholder groups will also be conducted to assess alignment between frontline experiences, implementation processes, and decision-making.

Through this integrated analytic approach, the study will generate a comprehensive understanding of how VectorCam is

XSL•FO
RenderX

implemented within routine surveillance systems, how implementation processes influence outcomes, and how improvements in data quality and timeliness translate into actionable use for malaria control.

### Sample Size and Power

Across all aims, sample size determination is guided by the descriptive and implementation-focused nature of the study rather than formal hypothesis testing. In each of the 12 districts, 4 VHTs and 2 VCOs will participate in pre- and postimplementation qualitative assessments to collect data across all 3 aims. These KIIs will yield a total of 72 interviews at baseline and 72 at follow-up. The sample size was selected to ensure representation of the primary implementation actors across all participating districts while remaining feasible within a national implementation study. Participants will be purposively selected to capture perspectives across diverse implementation contexts, and the anticipated number of interviews is expected to provide sufficient breadth and depth to identify recurring themes related to implementation processes and outcomes. In addition, approximately 10 KIIs will be conducted with district-level and national decision-makers to assess effectiveness for Aim 3. We again expect this number will be sufficient to achieve thematic saturation for our (preliminary) effectiveness outcomes of interest. Quantitative system data logs will include all identification records generated by trained VHTs during the study period, and for accuracy validation, at least 500 specimens will be randomly selected and assessed across all districts. Because the study primarily employs descriptive rather than hypothesis-driven testing, no formal power calculations were conducted. The overall sample is expected to be sufficient to generate estimates of implementation outcomes and detect meaningful differences in time efficiency, identification accuracy, and data usage.

### Ethical Considerations

This study has received ethical approval from the Johns Hopkins Medicine Institutional Review Board (protocol number IRB00505343) and, in Uganda, from the AIDS Support Organization (TASO) Research Ethics Committee (TASO-2025-879) and the Makerere University School of Public Health Research Review Committee. The VectorCam device was reviewed and determined to be a nonsignificant risk (NSR) device meeting criteria for an abbreviated investigational device exemption. No significant harms are anticipated due to the minimal-risk nature of the study.

This study is embedded within ongoing Ministry of Health routine entomological surveillance activities. For components involving human participants (eg, interviews, surveys, and observational assessments), written informed consent is obtained prior to participation. Consent forms are available in English and in relevant local languages (including Lusoga, Ngakarimojong, Luo, and Lugbara), and trained research staff conduct consent discussions in the participant's preferred language, using certified translations. Participants who complete interviews or surveys will receive 20,000 Ugandan Shillings (UGX) as compensation for their time. The compensation amount was reviewed and approved by the relevant ethics committees and is not considered coercive.

At the start of the consent process, participants will be asked to indicate what language they are comfortable with, and the appropriate consent forms will be selected. All sections of the consent document will be read verbatim in the selected language and explained to ensure comprehension. All participants will be informed that participation in the study is entirely voluntary and that they may withdraw from the study at any time. Signed consent forms are retained in secure study files in accordance with institutional and national regulatory requirements.

All identifiable data will be stored on secure, password-protected servers at Johns Hopkins University and Makerere University, accessible only to authorized study personnel. Deidentified data will be used for analysis, and no identifying information will be shared or published.

## Results

In collaboration with Uganda's Ministry of Health, the study team identified 22 districts that met the inclusion criteria, from which 14 districts were selected to receive the VectorCam intervention in September 2025. The pilot phase was conducted from December 2025 to January 2026, during which research tools were tested during rollout in two districts. Stakeholder workshops in the pilot phase were used to refine the implementation package and research instruments. Ethics approval was granted in January 2026. Data collection for the first rollout group began in February 2026, initiating a year-long data collection period. As of March 2026, the second rollout group of 3 districts is scheduled to begin data collection in June 2026. Data collection and subsequent analysis will be concurrent in districts where the intervention has been deployed and are expected to continue through March 2027.

## Discussion

### Anticipated Findings

This protocol represents one of the first hybrid type III studies to evaluate how an AI-enabled surveillance tool can be scaled and sustained within a national vector control program in low- and middle-income countries (LMICs). Building on strong feasibility evidence from VectorCam's prior RCT, we will assess how contextual determinants influence uptake, identify and refine implementation strategies, and generate robust evidence on both implementation outcomes and effectiveness across diverse malaria-endemic districts in Uganda. The study is designed to contribute to the evidence base on implementation of AI-enabled digital health innovations in routine public health systems of LMICs.

Beyond evaluating digital surveillance technology, this study examines a task-shifting model in which community-level personnel conduct activities traditionally performed by trained entomologists. Understanding the contextual determinants, implementation strategies, training requirements, and supervision structures associated with successful implementation will be critical for future expansion of surveillance activities into districts with more limited workforce capacity and infrastructure. Although the current rollout focuses on districts selected for implementation readiness, findings from this study

XSL•FO
RenderX

are intended to inform future deployment in underserved settings where entomological surveillance remains limited or unavailable.

Several features strengthen the rigor and relevance of this study. First, our implementation strategy development is grounded in the CFIR and the ERIC taxonomy, ensuring a theory-driven and context-sensitive approach to scale-up. Use of the FRAME-IS allows systematic documentation of adaptations to the implementation model, enabling us to address the growing demand for transparency and reproducibility in implementation research. Additionally, we integrate learning processes across all phases of the study to support iterative adaptation and stakeholder co-ownership, which bolsters the probability of long-term sustainability.

### Challenges and Limitations

The reliance on system usage logs and structured observations as proxies for implementation quality may underestimate informal use or undocumented fidelity. However, triangulation with qualitative interviews, cost tracking, and FRAME-IS documentation is expected to provide a more complete picture.

Another limitation is that data from VHTs and VCOs will be collected through self-report and field observations, both of which may be influenced by social desirability bias or observer effects. To mitigate this limitation, researchers will undergo structured training, and all the survey tools will be codeveloped, pilot tested, or both. Additionally, this implementation represents the inaugural national rollout of VectorCam into Uganda's routine vector surveillance program, no prior equivalent program exists against which a concurrent or historical control comparison could be meaningfully constructed. Thus, effectiveness outcomes should be interpreted as preliminary and descriptive rather than causal.

Although VectorCam has demonstrated strong technical performance in prior trials, scale-up may introduce new technological or bandwidth challenges not previously encountered. The monitoring, evaluation, and learning framework and staggered implementation schedule will help mitigate this risk through continuous monitoring and rapid-cycle problem solving. Finally, although the budget impact analysis will model cost scenarios at 1- and 5-year horizons, longer-term sustainability will also depend on shifts in MOH budget allocations and digital infrastructure, which are factors outside the scope of this study but relevant for future planning.

### Conclusions

This study represents an important contribution to implementation science, digital public health, and malaria vector control, as we aim to evaluate the implementation and effectiveness of a co-designed, AI-enabled platform integrated within Uganda’s national malaria surveillance system. Through the examination of contextual determinants, implementation strategies and outcomes, and preliminary effectiveness outcomes, this study seeks to generate evidence on the feasibility of task-shifting routine entomological surveillance activities to community-level personnel. The insights generated from utilizing this protocol for Uganda’s VectorCam rollout can inform the scale-up of similar surveillance technologies across LMICs and help accelerate progress toward malaria elimination.

## Acknowledgments

We would like to thank Justine Inhensiko, Patience Oputan, Samara Toussaint, Kigongo Siriman, James Kawesa, Alex Musiime, Mike Kato, Jovan Bate, David Onanyang, and Jimmy Opigo for their assistance with in-field coordination support, and Neil Lobo, Atul Zacharias, Sai Reddy, Parthvi Mehta, Deming (Remus) Li, Shreya Raman, Christina Heal Kowal, Santiago Sanchez, and Kyle Cooper for their contributions to the design of the VectorCam technology.

## Funding

This work was supported by the Bill & Melinda Gates Foundation [Grant Number: INV-079162]. The sponsor can be contacted at the Bill & Melinda Gates Foundation, Seattle, WA, USA. The funder had no role in the design of the study; collection, management, analysis, or interpretation of data; or decision to submit the manuscript for publication.

## Data Availability

No datasets have yet been generated, as this manuscript reports a study protocol. All research-related datasets, study instruments, implementation materials, codebooks, data dictionaries, and analytic code used to generate published findings will be made publicly available through an open-access repository (eg, OSF) upon publication of primary study results. Where permitted by ethical, regulatory, and Ministry of Health requirements, deidentified datasets or aggregate data supporting published findings may be made available through a controlled-access request process.

## Abstract

**Background:** Rural US communities experience disproportionately high rates of visual disability yet have limited access to ophthalmologists. Teleophthalmology may help address these gaps, but its effectiveness depends on broadband connectivity. The relationship between broadband access and ophthalmologist density has not been well characterized.

**Objective:** The aim of this study is to quantify the association between household broadband access—defined as subscription rates or connection prevalence—and county-level ophthalmologist density and to identify sociodemographic predictors of access.

**Methods:** We conducted an ecological study of all 3141 US counties using 2019 data from the American Community Survey, Area Health Resources File, and National Center for Health Statistics (NCHS). Broadband access was the primary exposure; ophthalmologist count with county population as an offset was the outcome. The primary analysis used negative binomial regression, adjusting for urbanicity, income, education, age, sex, race/ethnicity, unemployment, and insurance status. Sensitivity analyses included population-weighted linear regression and state fixed effects models. County-level heatmaps illustrated geographic patterns.

**Results:** Median household broadband access was 56.6%, ranging from 72.2% in the most urban counties (NCHS category 1) to 49.1% in the most rural (NCHS category 6). In unadjusted negative binomial regression, each 10-percentage-point increase in broadband access was associated with a 68% higher ophthalmologist rate (incidence rate ratio=1.68, 95% CI 1.61 - 1.76; *P*<.001). After adjustment, each 10-percentage-point increase was associated with a 46% higher rate (incidence rate ratio=1.46, 95% CI 1.37 - 1.56; *P*<.001). Sensitivity analyses were consistent with primary analysis. Regions with both low broadband access and zero ophthalmologist density were concentrated in the South, Mountain West region, and Alaska.

**Conclusions:** Broadband access is strongly associated with ophthalmologist availability across US counties, independent of sociodemographic factors. Areas lacking ophthalmologists also tend to lack broadband adoption, creating compounded barriers to both in-person and teleophthalmic care. Efforts to expand broadband may support more equitable access to vision services in underserved regions.

broadband; teleophthalmology; ophthalmologist density; rural urban divide; public health

## Introduction

Roughly 20% of the US population lives in a rural setting; those living in rural settings are more likely than those living in urban setting to experience disability [1]. Of those experiencing disability, visual disability in particular is highly prevalent among adults aged 18 years or older, with recent estimates approximating that 7 million people in the United States live with visual impairment as defined by visual acuity loss [2,3]. Although 90% of people with visual impairment have preventable or treatable conditions [4], areas with limited or no access to local eye care providers pose a significant concern in the United States [5,6]. This disparity is particularly concentrated in rural areas, where there are lower densities of

XSL•FO
RenderX

ophthalmologists and patients are unable to travel the distance required to attend appointments [5,6].

Improving access to eye care in rural areas remains a key health policy; however, many obstacles exist for increasing provider density, access, and funding in these areas. Currently, only 11% of physicians practice in rural areas [7]. This lack of physicians is exacerbated by estimates that predict a nearly 25% reduction in the rural physician workforce as many rural physicians near retirement [8]. The effort to draw younger physicians to rural settings is complicated by fewer opportunities for spousal employment, more limited school resources for their children, and the financial disincentive of a lower income in the face of mounting student debt [7,9,10]. The idea of specialization in ophthalmology is also in particular discordance with the notion that rural physicians must practice more broadly due to fewer health care resources [11,12].

During the height of the COVID-19 pandemic, ambulatory outpatient visits declined by 79% [13], with studies showing lasting reductions in ophthalmic care utilization [14]. As an answer to the physical limitations of pandemic lockdown orders and national policies, teleophthalmology gained unprecedented attention and adoption on a large scale [15]. This growth of interest in teleophthalmology as a potential solution for otherwise geographically limited vision services also highlights the importance of broadband internet access, which is crucial for many components of teleophthalmology visits such as synchronous video with audio and asynchronous messaging and sharing of vital health information between patient and provider [16]. Beyond the primary connection that broadband access enables, it also connects patients to online resources containing vision health information [17].

Given the linkage of broadband access and teleophthalmology services, broadband access may be a useful target to improve access to vision care, particularly for rural populations who otherwise lack access to providers. However, to our knowledge, broadband access has not been studied in association with access to physical ophthalmic facilities, personnel, and services. Additionally, the intersection of broadband access across geographical distributions and other social determinants of health is poorly understood. Exploring this association may help inform public interventions to increase equity in broadband access and access to ophthalmic services. Therefore, we utilized data from the Area Health Resource Files, National Center for Health Statistics (NCHS), and American Community Survey (ACS) to assess for associations between disparities in broadband internet access and access to ophthalmology specialists.

# Methods

## Ethical Considerations

This study was considered exempt from full review per the University of Pennsylvania Institutional Review Board guidelines [18], as it used only deidentified, publicly available, aggregate county-level data and did not involve human subjects research requiring informed consent. The study adhered to the principles of the Declaration of Helsinki. No individual-level patient data were accessed or collected. All data were obtained from 2019 versions of each dataset.

## Study Design

The number of practicing ophthalmologists per county and unemployment rates were obtained from the Area Health Resource Files. Urbanicity was categorized according to the NCHS 6-level urban–rural classification scheme (1=large central metro, 2=large fringe metro, 3=medium metro, 4=small metro, 5=micropolitan, and 6=noncore). This approach avoids the assumption of a linear step relationship between categories that would be imposed by treating the codes as continuous. All other demographic and socioeconomic variables were obtained from ACS, including median household income, percentage of the population who were female, Black, Hispanic, aged ≥65 years, with less than a high school education, and uninsured. Case complete analysis was performed with 91 counties omitted for missing data.

The primary exposure was broadband access, defined as the percentage of households in a county with broadband internet access such as cable, fiber optic, or DSL. This measure reflects the proportion of households with functional internet connectivity, rather than direct availability of broadband infrastructure, speed, or affordability. Broadband access was treated as a continuous variable and adjusted per 10% for interpretability. The primary outcome was the number of ophthalmologists per county. County population size was incorporated as an offset term to model ophthalmologist availability relative to county population.

Descriptive statistics were used to summarize broadband access across all counties. Bivariate associations between broadband access and ophthalmologist count were initially assessed using simple linear regression. Because the outcome variable represented a count of ophthalmologists and demonstrated overdispersion, the primary analysis used negative binomial regression to estimate the association between broadband access and the number of ophthalmologists per county. County population size was included as an offset term to model ophthalmologist supply relative to population. The multivariable model adjusted for potential county-level confounders including urbanicity, median household income, and percentage of the population who were female, Black, Hispanic, aged ≥65 years, with less than a high school education, unemployed, and uninsured. Incidence rate ratios (IRR) were then calculated. To assess potential multicollinearity among predictors, variance inflation factors were calculated for all independent variables.

Sensitivity analyses were conducted to evaluate the robustness of the findings. First, a population-weighted multiple linear regression model was fitted with ophthalmologist density (ophthalmologists per 100,000 population) as the outcome, weighting counties by population size to reduce the influence of sparsely populated counties. Second, models incorporating state fixed effects were estimated to control for unobserved state-level factors, such as regulatory environments, telehealth policy, and workforce training infrastructure.

County-level geographic boundaries were obtained from the US Census Bureau's 2019 TIGER/Line Shapefiles [19].

XSL•FO
RenderX

Broadband access and ophthalmologist density, adjusted into unique deciles for interpretability, were then mapped to US counties. Additional heatmaps identified counties with low broadband access (defined as <1st quartile) and low ophthalmologist density (defined as 0 ophthalmologists per 100,000 people). We also conducted further exploratory analysis to investigate whether household broadband access varies systematically across county socioeconomic characteristics. All analyses and visualizations were conducted using RStudio (version 4.4.0; Posit).

## Results

Data from 3141 US counties were included. Median broadband access across all counties was 56.6%. In the most urban counties (NCHS category 1), 72.2% of households had broadband, and there were 9.1 ophthalmologists per 100,000 people, whereas the most rural counties (NCHS category 6) had 49.1% of households with broadband and 0.43 ophthalmologists per 100,000.

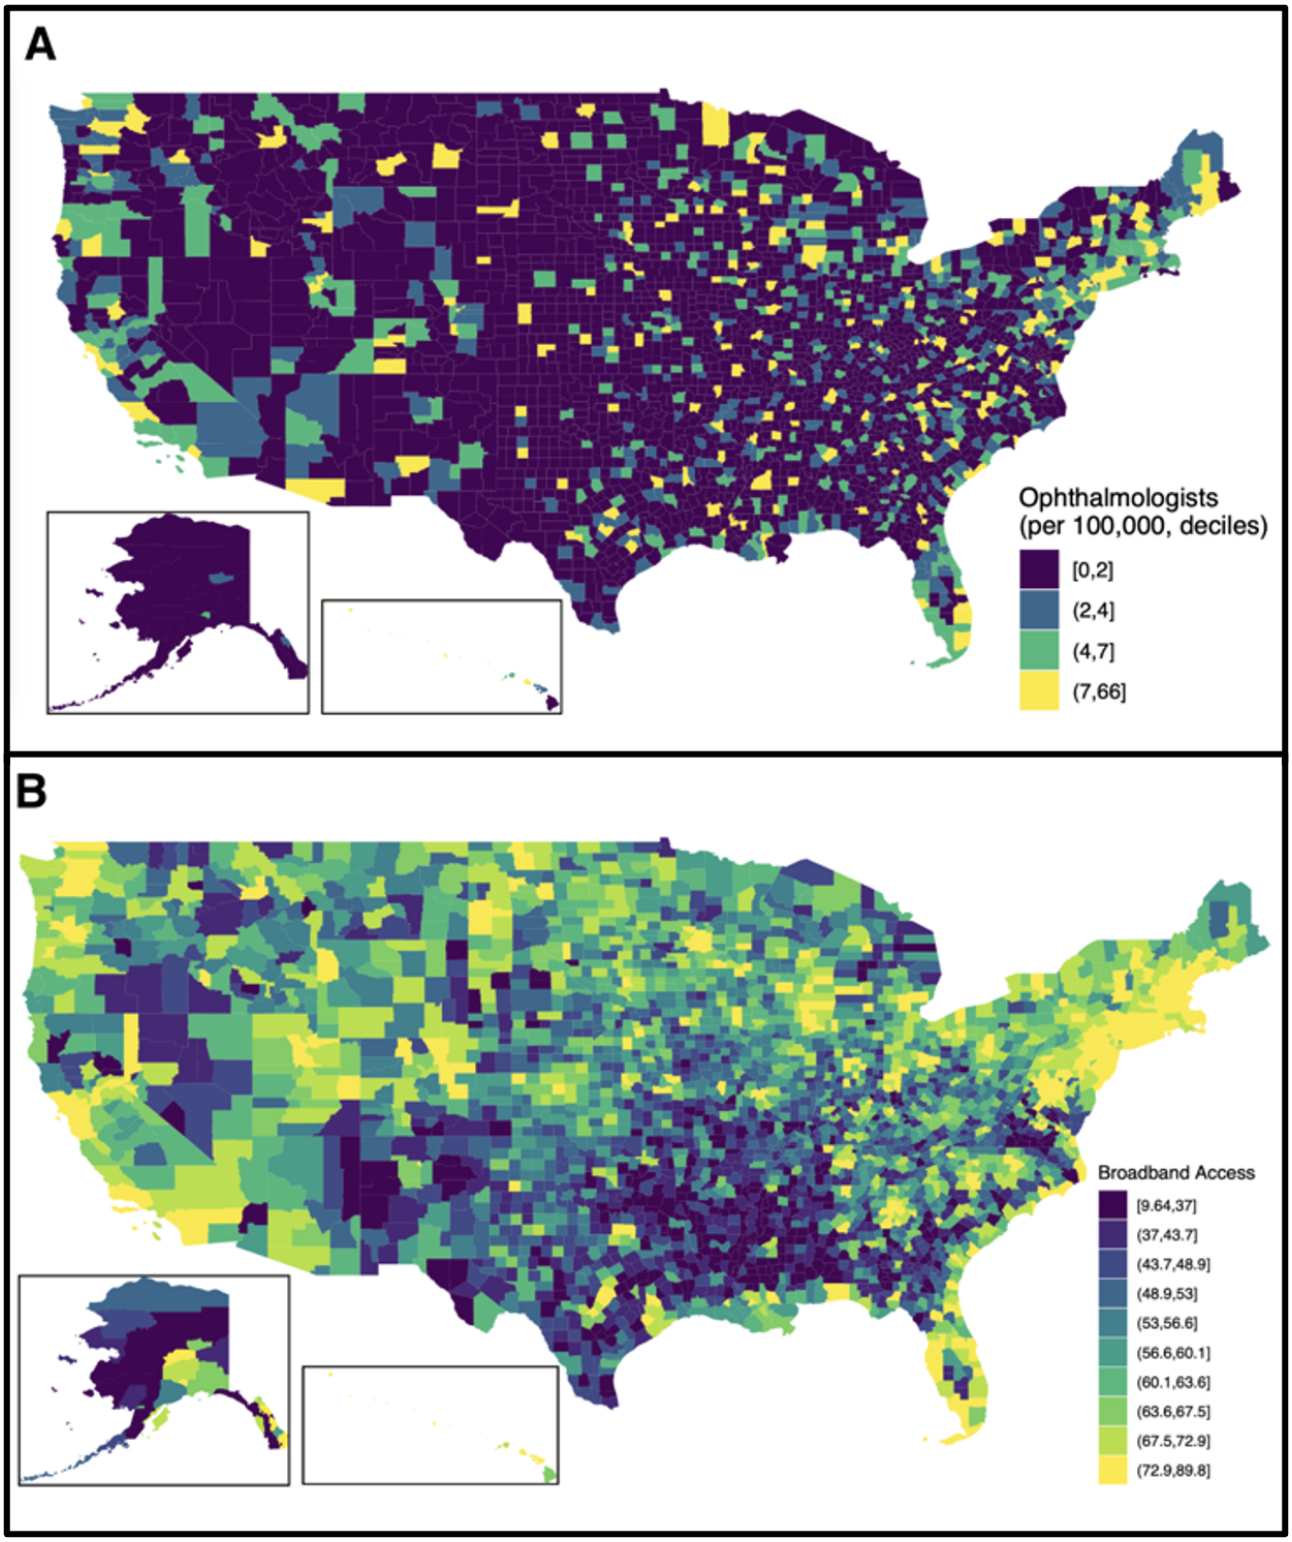
Bivariate analysis showed a significant association between broadband access and ophthalmologist counts, where each 10-percentage-point increase in household broadband access was associated with a 68% higher rate of ophthalmologists per county (IRR=1.68, 95% CI 1.61 - 1.76; *P*<.001). After adjusting for urbanicity, income, education, age, sex, race/ethnicity, unemployment, and insurance status, each 10-percentage-point increase in broadband access was associated with a 46% higher ophthalmologist supply per capita (IRR 1.46, 95% CI 1.37 - 1.56; *P*<.001, Table 1).

**Table .** Negative binomial regression of ophthalmologist counts on broadband access and covariates.

| Variable | Incidence rate ratio | 95% CI | *P* value |
|---|---|---|---|
| Household broadband access (per 10%) | 1.46 | 1.37 - 1.56 | <.001 |
| NCHS category 2 (large fringe metro) | 0.47 | 0.39 - 0.55 | <.001 |
| NCHS category 3 (medium metro) | 0.82 | 0.69 - 0.98 | .03 |
| NCHS category 4 (small metro) | 0.99 | 0.82 - 1.19 | .93 |
| NCHS category 5 (micropolitan) | 0.85 | 0.7 - 1.04 | .12 |
| NCHS category 6 (noncore) | 0.32 | 0.25 - 0.42 | <.001 |
| Median household income (per $10,000) | 0.99 | 0.95 - 1.03 | .54 |
| Less than high school education (%) | 0.96 | 0.94 - 0.97 | <.001 |
| Age ≥65 (%) | 1.01 | 0.99 - 1.02 | .35 |
| Female (%) | 1.21 | 1.16 - 1.26 | <.001 |
| Black (%) | 1.02 | 1.01 - 1.02 | <.001 |
| Hispanic (%) | 1.01 | 1.01 - 1.02 | <.001 |
| Unemployment rate (%) | 0.94 | 0.90 - 0.98 | .005 |
| Uninsured (%) | 0.99 | 0.97 - 1.00 | .08 |

In multiple linear regression, we assessed ophthalmologist density and broadband access after adjusting for urbanicity (NCHS Urban-Rural Classification), median household income (per $10,000), and percentage of the population who were female, Black, Hispanic, aged 65 years and older, with less than a high school education, unemployed, and uninsured.

Compared with large central metropolitan counties, noncore counties had a 68% lower ophthalmologist availability (IRR 0.32, 95% CI 0.25 - 0.42; *P*<.001). Variance inflation factors for all predictors were below 2, indicating minimal multicollinearity.



Population-weighted linear regression produced consistent findings. Each 10-percentage-point increase in broadband access was associated with 0.43 additional ophthalmologists per 100,000 population ((β=.43, 95% CI 0.18 - 0.68; *P*<.001). Furthermore, models including state fixed effects demonstrated a persistent association (IRR 1.63, 95% CI 1.51 - 1.76; *P*<.001), suggesting that the relationship was present even accounting for unobserved state-level factors.

Figure 1 illustrates geographic variation in ophthalmologist density and broadband access by US counties. Figure 2 illustrates that counties with both low broadband access and ophthalmologist density were concentrated in the South, Mountain West, and Alaska regions.

XSL•FO
RenderX

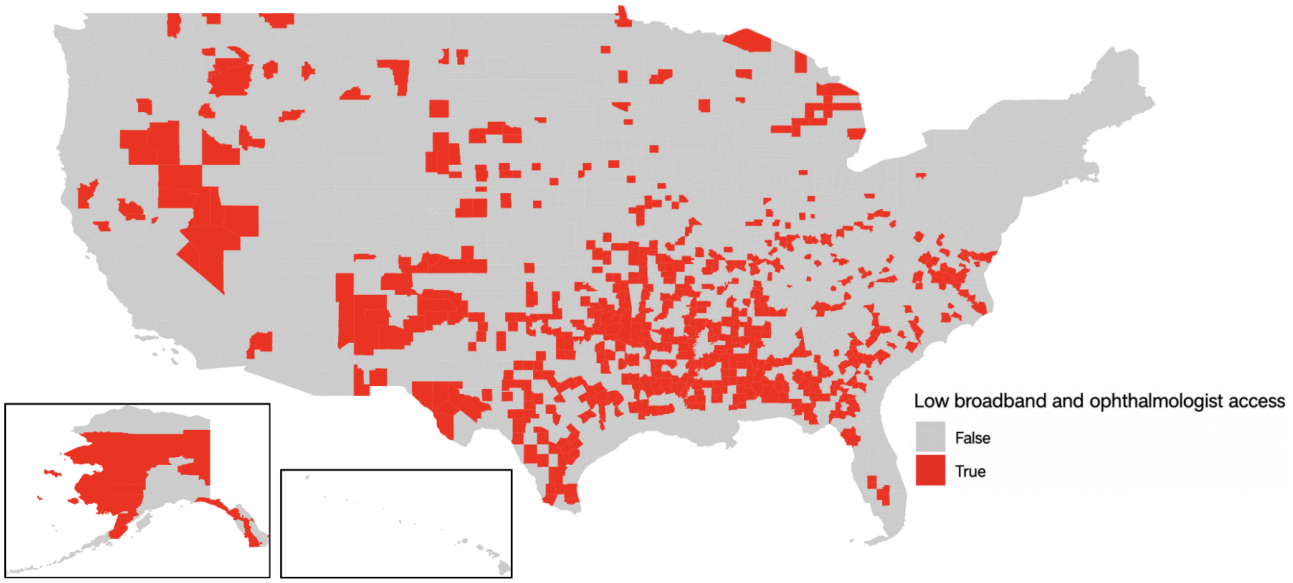


**Figure 1.** Heatmaps of ophthalmologist density (Panel A) and broadband access (Panel B) by US county, 2019.

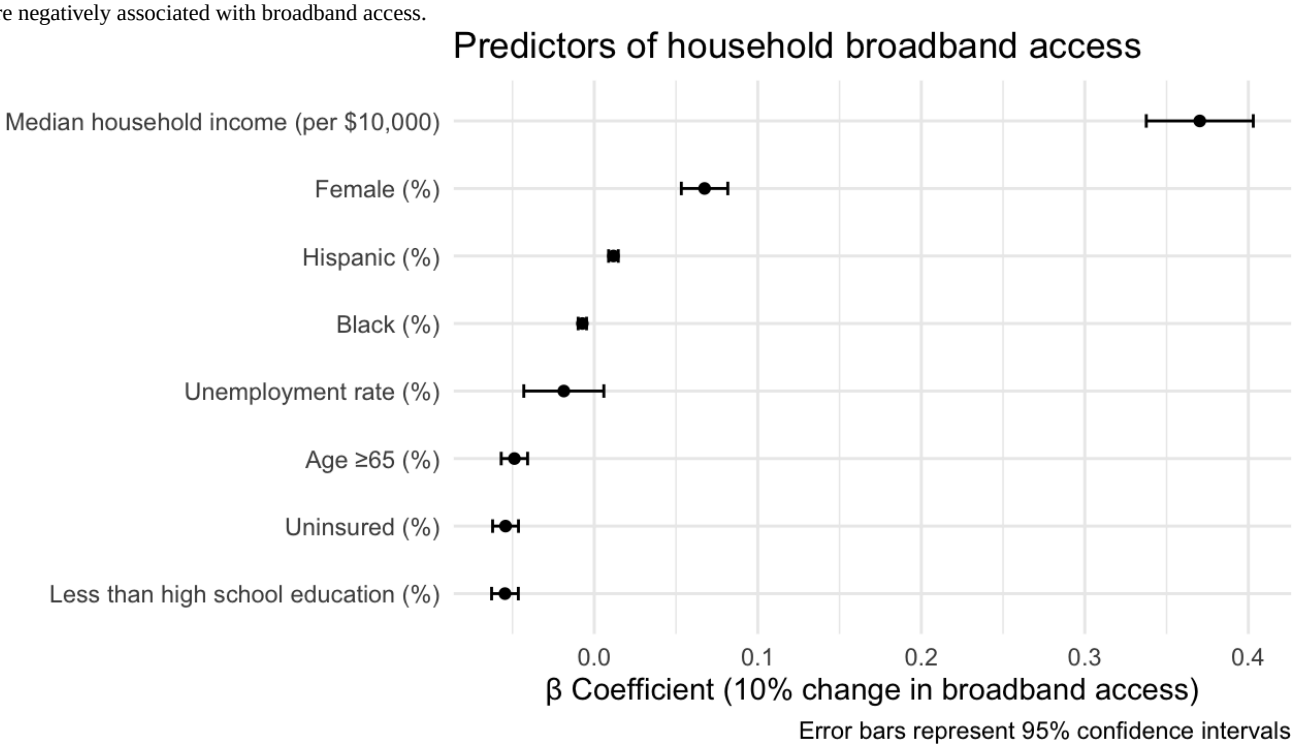

XSL•FO
RenderX

**Figure 2.** Heatmap of US counties with both low broadband access and low ophthalmologist access, 2019. Defined by broadband access <1st quartile (46.27%) and ophthalmologist density of 0 per 100,000 people. In total, 700 counties met these criteria, encompassing approximately 11.4 million residents. The heatmap demonstrates concentration in the South, Mountain West, and Alaska regions.

In multivariable linear regression, several sociodemographic characteristics were associated with household broadband access across the United States. Lower educational attainment (β=−0.05, 95% CI −0.06 to −0.05), higher proportions of adults ≥65 years (β=−0.05, 95% CI −0.06 to −0.05), higher percentages of Black residents (β=−0.007, 95% CI −0.010 to −0.005), and higher percentages of uninsured residents (β=−0.05, 95% CI −0.06 to −0.05) were associated with lower broadband access. Conversely, higher median household income (β=0.37, 95% CI 0.34 to 0.40), greater proportions of female residents (β=0.07, 95% CI 0.05 to 0.08), and higher percentages of Hispanic residents (β=0.01, 95% CI 0.009 to 0.015) were positively associated with access. Unemployment showed a marginal negative association that did not reach significance (β=−0.02, 95% CI −0.04 to 0.006). Although several predictors reached statistical significance, the effect sizes were modest. Results are visualized in Figure 3.

**Figure 3.** Forest plot showing β coefficients and 95% CIs from multiple linear regression of household broadband access among socioeconomic covariates. Results show that higher proportions of females and Hispanic people, as well as higher median household income, are positively associated with broadband access, whereas high proportions of Black people, adults aged 65 or older, uninsured people, and those with no high school education were negatively associated with broadband access.

## Discussion

Teleophthalmology has been suggested as an innovative solution to improve access to ophthalmic services in communities with fewer vision care resources. However, broadband access and adoption to enable the full functionalities of teleophthalmology in these areas has not been well studied. In this study assessing broadband access with ophthalmologist density in 3141 US counties, we found that US counties with reduced broadband access also have lower average counts and densities of ophthalmologists. Importantly, the association between broadband access and ophthalmologist supply remained robust across multiple sensitivity analyses designed to address potential methodological concerns. Results were consistent after population-weighted modeling and incorporating state fixed effects, suggesting that the observed relationship is not driven by small population counties or unmeasured state-level factors, strengthening the inference that broadband access and ophthalmologist distribution are closely linked structural features of health care access. This finding underscores that while teleophthalmology may mitigate key barriers to in-person vision care, lack of broadband access may present an additional, underexplored barrier to care for individuals across the spectrum of urbanicity. These findings may be particularly concentrated among rural regions in the South, Mountain West region, and Alaska. Furthermore, in secondary analysis, we found that broadband access tends to be independently lower in communities that are more rural, have lower levels of educational attainment, and higher proportions of older adults over 65, Black residents, and uninsured individuals, although with modest effect sizes.

An important interpretive consideration is that the ACS broadband measure used in this study captures household subscription rates—reflecting whether households have an active broadband connection—rather than physical infrastructure availability, service speeds, or affordability. A county may have fiber infrastructure yet show low subscription rates due to cost barriers, limited digital literacy, or a lack of devices. Conversely, a county may have high adoption rates despite suboptimal infrastructure due to demographic and socioeconomic characteristics. Therefore, our findings should be interpreted as demonstrating an association between low broadband adoption and low ophthalmologist density, rather than between infrastructure deficits and provider scarcity per se. Efforts to improve broadband equity must therefore address both availability (deployment of physical infrastructure) and adoption (affordability subsidies, device access programs, and digital literacy training), as low adoption can persist even after infrastructure gaps are closed.

Our findings align with current literature demonstrating sociodemographic disparities in broadband access. For instance, several studies suggest that areas with larger proportions of Black and American Indian/Alaska Native populations, lower economic status, and lower educational attainment tend to have less broadband access [20,21]. Our results also further support several studies demonstrating disproportionately limited access to ophthalmic care in rural areas and communities with lower socioeconomic status [22-24]. Our study adds to the current literature that the association between household broadband access and ophthalmologist density persists across the urban/rural divide. This means that even in metropolitan counties where in-person care is relatively accessible, low broadband subscription may independently limit the reach of supplemental teleophthalmology services. This is exacerbated in nonmetropolitan areas, where even fewer ophthalmologists are available and there is poorer broadband access. This study thus expands on the current literature by directly contextualizing broadband access within the broader scope of ophthalmology access, showing that areas void of physical providers also lack the connectivity necessary for remote solutions, creating compounded access barriers.

The clear association between broadband access and socioeconomic factors raises the concern that broadband expansion alone may not lead to meaningful increases in health care utilization. Digital literacy gaps, especially among older adults, disabled people, or low-income populations, may persist independent of connectivity. Indeed, studies have found that older adults and individuals with lower education levels may be less likely to engage with online health tools or complete telehealth visits due to unfamiliarity with technology or distrust in virtual care models [25-29]. Others have argued that teleophthalmology is limited in clinical scope for procedures requiring in-person physical exams, diagnostic imaging, or surgical interventions [30-33]. Another critique is based on cost-effectiveness: broadband infrastructure costs are particularly high in geographically isolated regions, where population density may be too low to justify investment on health care grounds alone [34-36].

However, these concerns, while valid, do not negate the importance of broadband as a foundational infrastructure for equitable health care delivery. First, digital literacy gaps are surmountable with targeted interventions. Programs that pair broadband rollouts with community-based digital navigator training have successfully improved technology adoption in older adults, racial/ethnic minorities, and low-income groups [37-40]. Second, teleophthalmology has evolved beyond synchronous video visits to include asynchronous image-based screening, such as store-and-forward models for diabetic retinopathy and glaucoma, which require minimal digital interaction by the patient and are well-suited for underserved communities [30,41-45]. For instance, Google/Verily's ARDA partnership with Aravind Eye Care in India demonstrates that clinic-based broadband can mitigate household limitations [46]. Nevertheless, widespread household connectivity may enhance patient participation in remote screening and education.

Federal efforts such as the Broadband Equity, Access, and Deployment program, part of the 2021 Infrastructure Investment and Jobs Act, already allocate billions of dollars toward rural broadband with explicit equity goals, aligning policy momentum with the needs demonstrated in this study [47]. Further interventions include the expansion of federal programs such as the US Department of Agriculture Rural eConnectivity Pilot Program [48], including the removal of eligibility restrictions to allow all rural areas with inadequate broadband access to apply for funding. Furthermore, telehealth policy reform, such as reimbursement parity and interstate licensure compacts, will

XSL•FO
RenderX

further support teleophthalmology and eye care access in underserved regions [34,49]. Our results provide empirical evidence that leveraging policy funding to support prioritizing broadband investments, particularly in the rural South, Mountain West region, and Alaska and in regions with lower educational attainment and higher proportions of older adults, Black people, and uninsured people, may be particularly high yield for both technological and health system gains.

This study contains a few key limitations. First, the ACS broadband measure captures household subscription rates, not infrastructure availability, speed, latency, or affordability, and therefore cannot distinguish between cost barriers, digital literacy gaps, device limitations, and physical infrastructure deficits as drivers of low broadband access. Furthermore, our data only consider the percentage of households that lack access to broadband internet. As a result, access to broadband outside the household in facilities such as workplaces, schools, or public facilities remains unclear. However, transportation, lack of convenience, and privacy concerns arising from utilizing broadband access outside of one's home may present as barriers; therefore, accessibility to household broadband internet is still relevant. In addition, our data were obtained from 2019, which was before the massive expansion in broadband internet access in response to the COVID-19 pandemic. Lastly, this ecological, cross-sectional study cannot establish causation or temporal sequence, and unmeasured county-level variables may confound associations, as is the case with all cross-sectional studies.

To our knowledge, this study represents the first national analysis examining the relationship between broadband access and ophthalmologist workforce distribution across all US counties. These two factors appear to be intertwined and may reinforce each other in determining rural and underserved communities' connectivity to vision care. As teleophthalmology becomes integral to future eye care delivery, advancing broadband equity should be positioned as a public health strategy that simultaneously bolsters virtual and in-person specialist access.

## Funding

This research was supported by the National Institutes of Health (NIH) grants T35 EY033704, DP5OD029610, OT2OD032644, and P30EY022589 and an unrestricted departmental grant from Research to Prevent Blindness. The sponsor or funding organization had no role in the design or conduct of this research.

## Abstract

**Background:** Acute respiratory infections (ARIs) remain a significant global health challenge and are the second leading cause of disease burden and mortality. Early warning systems (EWS) play a key role in detecting clinical deterioration, alerting health care providers (HCPs), and supporting pandemic surveillance. While existing literature highlights HCPs' positive experiences with EWS in confirming clinical assessments and guiding escalation, perspectives on how these systems can be optimized for ARI management remain underexplored.

**Objective:** As Canada continues to develop and operationalize EWS for outbreak and pandemic preparedness, this study aims to explore the experiences and insights of primary care providers, emergency department (ED) physicians, and researchers regarding the use of EWS for ARI management in Canada.

**Methods:** Eleven participants, including primary care providers, ED physicians, and researchers from urban and rural settings across 5 Canadian provinces (Ontario, Newfoundland and Labrador, Quebec, British Columbia, and Manitoba), were recruited in 2024. All participants regularly managed patients with ARIs or played key roles in pandemic response. A codebook thematic analysis was conducted to identify patterns and themes, with subthemes organized under broader thematic categories. Data saturation was assessed during the analysis phase. The study adhered to the COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines.

**Results:** Among the 11 participants, there was approximately equal representation across gender and age groups, and more than 90% had over ten years of experience in ARI management. Three overarching themes emerged. First, participants demonstrated general awareness of the use of EWS in ARI management, including outbreak detection, screening and triage support, and informing clinical decision-making. Technologies and surveillance tools used during the COVID-19 pandemic were frequently referenced; however, understanding of specific EWS and their application to ARI management was often limited. Second, participants identified key attributes of an effective EWS as accuracy, timeliness, integration, and equity, emphasizing the need for seamless integration into existing Canadian health care workflows without increasing administrative burden. Third, anticipated challenges were described across 4 stages of EWS development, including initiation (funding and privacy concerns), implementation (outdated data systems and limited legislation), use (staff shortages and capacity constraints), and evaluation (lack of standardized and innovative evaluation approaches).

**Conclusions:** This study engaged 11 experienced HCPs and researchers who were directly involved in patient care and public health response to ARI outbreaks and qualitatively explored their perspectives on EWS for ARI management and pandemic preparedness. The findings identified 3 overarching themes regarding the general knowledge, desired attributes, and anticipated challenges of EWS in ARI management, highlighting the importance of co-designing EWS with clinicians, researchers, and other key stakeholders to improve their effectiveness and integration into clinical practice and pandemic preparedness across Canada.

## Introduction

Acute respiratory infections (ARIs) affect the upper and/or lower respiratory tract, ranging from mild to life-threatening illnesses, and remain a significant public health concern [1], particularly among children [2]. Over the past 2 decades, severe ARIs, including SARS-CoV-2, have caused significant morbidity and mortality worldwide [3-5]. In 2021, SARS-CoV-2 was the second leading cause of global mortality and the leading cause of disability-adjusted life years [6]. Given the highly contagious nature and rapid transmission of ARIs, early detection and timely intervention are essential to mitigating their impact and preventing further transmission.

Early warning systems (EWS) are designed to identify clinical deterioration, alert health care providers (HCPs), and facilitate timely intervention [7,8]. These systems have been widely implemented in acute care settings such as hospitals and emergency departments (EDs) [9-11] and have also been integrated into outpatient and community settings, including general practices and health centers [12,13]. Primary care and ED settings play complementary roles in early outbreak detection; primary care often serves as the first point of contact for patients with early or nonspecific symptoms, while EDs act as sentinel sites during outbreaks by managing surges of patients with acute presentations. Syndromic surveillance using primary care and ED data has been shown to be a valuable tool for early outbreak detection during the COVID-19 pandemic [14]. However, both settings face distinct implementation challenges, including data interoperability and real-time integration in primary care and crowding, time pressure, and workforce constraints in EDs [15,16]. These contextual and workflow-related factors influence how EWS are used in practice, underscoring the importance of understanding frontline clinicians' perspectives when considering EWS implementation and optimization.

In Canada, multiple surveillance and EWS platforms monitor ARIs at various levels of the health care system. FluWatchers, a voluntary, self-reported system operated by the Public Health Agency of Canada, collects data on flu-like symptoms to track respiratory virus activity across the country [17]. The TARRANT Viral Watch initiative links primary care clinics and laboratories to monitor ARI trends in real time [18]. The Sentinel Practitioner Surveillance Network (SPSN) engages health care providers in tracking clinical and laboratory data to assess the epidemiology of influenza and other respiratory pathogens [19]. The Serious Outcomes Surveillance (CIRN SOS) network operates within hospitals to monitor severe ARI cases and evaluate disease burden and vaccine effectiveness [20]. However, challenges related to data interoperability and fragmented governance across jurisdictions remain.

Internationally, EWS-related approaches for ARI include both clinical risk stratification tools and population-based surveillance systems. For example, the National Early Warning Score (NEWS and NEWS2) is used in the United Kingdom, and it has been evaluated during COVID-19 for predicting mortality and Intensive Care Unit admission [21]. In contrast, population-based hospitalization surveillance networks such as the Respiratory Virus Hospitalization Surveillance Network (RESP-NET) in the United States monitor laboratory-confirmed hospitalizations for major respiratory viruses to support situational awareness and public health response [22].

While these systems provide valuable surveillance data, they are not consistently integrated into real-time clinical decision-making, and frontline patient management remains limited. As a result, little research examined how EWS are experienced and used within primary care and ED settings in Canada [23,24] or how system-level limitations affect their practical operations [25]. Understanding these perspectives is crucial for informing optimal EWS implementation and effectiveness in ARI management and pandemic preparedness. Accordingly, this study aims to explore the experiences and insights of primary care providers, ED physicians, and researchers regarding the use of EWS for ARI management in Canada.

## Methods

### Overview

This study was conducted following the COREQ (Consolidated Criteria for Reporting Qualitative Research (Checklist 1) [26].

### Participant Recruitment

Individual online interviews were conducted with health care providers and researchers involved in pandemic response using the Zoom video platform (Zoom Video Communications). Eligible participants included family physicians, ED physicians, and infectious disease specialists whose work primarily involves managing ARIs. Researchers with expertise in pandemic response were also included. Inclusive eligibility criteria ensured representation across a range of clinical roles and practice settings, including providers from both urban and rural contexts. This approach enabled the capture of diverse perspectives from professionals directly impacted by EWS and supported a comprehensive understanding of potential challenges and needs in ARI surveillance. Participants were recruited through professional clinical and research networks focused on primary care, emergency medicine, infectious diseases, and pandemic preparedness, including investigator networks associated with adaptive platform trials, respiratory infection surveillance initiatives, and health services research collaborations in Canada. Recruitment was conducted via email using a standardized recruitment script approved by the Unity Health Toronto Communications Department. Recruitment took place between August and October 2024. The response rate was approximately 52%, with eleven of twenty-one invited individuals participating in the study.

### Data Collection

Interviews were conducted by 2 researchers (KM and MF) between August and October 2024. At the beginning of each session, participants completed a brief demographic questionnaire consisting of 9 questions. The demographic questionnaire collected information on participants' professional role, years of relevant experience, practice setting (eg, urban or rural), and involvement in ARI management or pandemic response. Responses were manually recorded to ensure

XSL•FO
RenderX

confidentiality, and this portion was not audio-recorded. A semistructured interview guide was informed by relevant literature on EWS and ARI surveillance, as well as the study objectives and the research team's research experience (see Multimedia Appendix 1). The guide was designed using Bearman's step-wise approach [27] to interview schedule development and followed DeJonckheere and Vaughn's framework [28] for semistructured interviewing in primary care research. The interview guide was not formally pilot tested; however, it was reviewed and refined by the research team prior to data collection and iteratively adapted during the study to reflect participants' experiences and explore perspectives on the design, implementation, and evaluation of EWS. The full semistructured interview guide, including all questions, is provided in Multimedia Appendix 1.

### Data Analysis

All interviews were audio-recorded, transcribed, and deidentified by a professional transcription service. Participants were offered the opportunity to review their transcripts for accuracy; however, no participants requested transcript review or provided feedback.

Data were analyzed using a codebook-informed reflexive thematic analysis, following Braun and Clarke's 6-phase framework [29-31]. An inductive approach was used to allow themes to emerge directly from the data. All transcripts were coded and analyzed by a single researcher (JQ), who has training and prior experience in qualitative methodology. Iterative feedback from the principal investigator (BH) was used to refine the coding framework and interpretation. Following familiarization with the data, an initial set of codes was generated and iteratively refined as analysis progressed [32,33]. A finalized codebook was developed and validated by applying it to a new transcript before proceeding with full coding. A hierarchical coding structure outlining themes, subthemes, and example codes is provided in Multimedia Appendix 2.

A codebook was developed to support analytic organization and was refined through iterative application across transcripts. Subthemes were developed when related codes clustered under a broader theme. Reflexivity was maintained throughout the analysis, with process through memoing and regular discussions within the research team, which were used to document reflections, potential biases, interpretive decisions, and support analytic rigor [34].

Interviews were coded using NVivo software (version 14 plus; Lumivero). Data analysis began after all interviews were completed. Data saturation was assessed through ongoing discussions, where it was determined that additional data collection was unlikely to yield new insights [35]. Regular meetings were held with the study team to ensure alignment in interpretation and contextual accuracy.

### Ethical Consideration

This study was approved by the Unity Health Toronto Research Ethics Board (REB 24 - 101) prior to the initiation of data collection. The informed consent process, including the consent form, was reviewed and approved by the REB. Written informed consent was obtained via email from all participants before participation. Participants were informed that their participation was voluntary and that they could withdraw from the study at any time without consequence.

To protect participant privacy and confidentiality, interviews were transcribed and deidentified by a professional transcription service before being shared with the research team. All study materials and data were securely stored on a restricted-access drive on St. Michael's Hospital's server and were accessible only to research staff approved under the REB application. Interviews were scheduled for one hour, and participants received a CAD $40 (approximately US $ 30, based on an exchange rate of 1 CAD ≈ US $ 0.74 in 2024) honorarium as compensation for their time.

## Results

### Participant Characteristics

Eleven participants from across Canada (Ontario, Newfoundland and Labrador, Quebec, British Columbia, and Manitoba) were interviewed between August and October 2024, with most interviews lasting 30-45 minutes. Demographic characteristics are summarized in Table 1. Participants were evenly distributed by sex (6/11, 55% male) and age group (6/11, 55% aged 30 - 44 years). The most common occupation was family physician (5/11, 45%), followed by ED physicians (2/11, 18%), infectious disease physicians (2/11, 18%), a critical care physician (1/11, 9%), and a primary care scientist (1/11, 9%). Most (10/11, 90%) had over 10 years of experience, and 9 out of 11 (82%) worked in urban settings. Regarding EWS knowledge, most participants reported moderate familiarity, while 27% (3/11) had minimal knowledge, and 9% (1/11) were highly knowledgeable.

XSL•FO

[a]Others: critical care physician, infectious disease and critical care physician specialist, infectious disease physician, and scientist.

[b]EWS: early warning system.

## Identified Themes

Three main themes were identified from the analysis: (1) general knowledge of EWS for ARI, (2) desired attributes of EWS for ARI, and (3) anticipated challenges in EWS implementation. Within each theme, 3-4 subthemes were identified.

## Theme 1: General Knowledge of EWS for ARI

Participants reported varying levels of experience with EWS but demonstrated a broad understanding of their role in ARI outbreak monitoring and detection. Most discussions focused on lessons learned from the COVID-19 pandemic, with specific emphasis on the utility of EWS in ARI detection and management.

### *General Awareness*

While all participants were familiar with the general concept of EWS, many struggled to name specific systems used for ARI in Canada. When asked for examples, some participants mentioned “wastewater surveillance” (n=3) or “nasopharyngeal swab testing” (n=2), often describing these as ways to track infection trends at the population level rather than as formal EWS. Others referred to public health outbreak updates or case reporting systems as early warning tools. EWS was often described as “a vague term” (P02, ED physician) or “an abstract concept, something of the future” (P05, primary care scientist). Overall, participants’ understanding of EWS appeared to be shaped by their experiences during the COVID-19 pandemic, with limited distinction made between diagnostic testing, population-level surveillance, and structured EWS. One family physician reflected on their limited familiarity,

> *I might have to downgrade my other response… not as knowledgeable as I thought I was in terms of specific early warning systems.* [P08, Family physician]

There was a perceived lack of well-developed national surveillance systems, with some participants stating that provincial-level wastewater surveillance was the only system they had direct experience with. One participant explained,

> *National surveillance is not really yet fully developed… at the provincial level, we have wastewater surveillance, but we don’t have experience with a better EWS.* [P01, Infectious disease physician]

XSL•FO
RenderX

A participant with public health training described the disconnect between EWS and clinical practice, stating,

> *I have training in public health… worked in low-income settings and infectious disease control … so I have some concept of what they are. If this question is about how it's relevant to my current practice, I don't think I truly understand how the early warning or early detection systems work and maybe that's because they don't work or don't exist in our current clinical environment.* [P07, ED physician]

Participants' self-reported familiarity with early warning systems was collected descriptively and was not a primary analytic focus.

### *Insights and Tools Learned From the COVID-19 Pandemic*

Participants referenced machine learning, artificial intelligence, and electronic communication as tools that could be integrated into EWS for ARI, although discussions on these technologies were brief. COVID-19 was frequently mentioned as a turning point in EWS discussions, highlighting both challenges and innovations. The complexity of SARS-CoV-2, particularly its "asymptomatic transmission" and "atypical symptoms," was noted as an obstacle to outbreak surveillance and management (P02, ED physician). However, the pandemic also led to rapid adoption of new technologies and scaling of public health interventions.

> *The wastewater surveillance is … a novel approach. We did not do this prior to COVID-19, at least in a widespread way. So, the lessons learned were adopt new technology, do it quickly and we can scale it up during the high-pressure pandemic situation.* [P01, Infectious disease physician]

Four participants also indicated that public health agencies played a crucial role in providing outbreak updates and disseminating information during COVID-19. One participant noted,

> *We would rely on public health to tell us … there's an outbreak… then we… institute… more formal screening process at triage so that we are isolating people quickly…It would be public health looking at the collective data… to let us know that they're starting to see something new come up and to be on the lookout.* [P07, ED physician]

### *Role of EWS in ARI Management*

Participants identified 3 key functions of EWS in ARI control and management:

First, most participants highlighted the role of EWS in detecting early signals of outbreaks, particularly by identifying rising case numbers or unusual clusters of symptoms before formal confirmation. As a primary care scientist explained:

> *I think it has tremendous potential to… policymakers… public health authorities aware of what's happened on the ground… (if) we have noticed … cluster of patients who are showing up with … not part of the usual respiratory group of symptoms, and they are all associated with this mutation… this variant, so heads up* [P05, Primary care scientist]

Second, some participants described EWS as supporting the screening and triage process by helping identify individuals at higher risks early in the care pathway, particularly in EDs. This was often discussed in relation to flagging symptoms or recent travel history associated with affected areas, enabling timely isolation and infection control measures. As an ED physician explained,

> *Screen specifically for symptoms and travel exposures at triage in the Emergency Department… usually have a system… to isolate individuals who might be coming from affected areas… where new and emerging diseases have been flagged, it then gets flagged at triage, and then to help tell us whether people have to be isolated and then we very quickly get… the Infection Prevention and Control involved.* [P07, ED physician]

Finally, some participants described EWS as supporting informed clinical decision-making and outbreak preparedness by aggregating data across sources and helping anticipate which infections may be circulating in the community. As one infectious disease physician explained,

> *We're watching the respiratory tract infection epidemiology so we can predict what may be presenting in the clinic based on what is circulating in the community… We are in a pertussis epidemic in [province name]… cases are higher than baseline and when patients present with a cough, we consider that they have pertussis based on the epidemiology. So, this is highly relevant to my clinical practice.* [P01, Infectious Disease physician]

## Theme 2: Desired Attributes of EWS for ARI

Participants identified 4 key attributes essential for an effective EWS for ARI, including accuracy, timeliness, integration, and equity. These qualities were viewed as critical for ensuring that the system reliably detects outbreaks, provides timely alerts, seamlessly integrates into clinical workflows, and addresses disparities in health care access.

### *Accuracy*

Most participants emphasized that an effective EWS must balance sensitivity and specificity, often describing this balance in practical terms. Participants highlighted the importance of detecting "clear signals" of emerging outbreaks early (P02, ED physician), while avoiding frequent false alarms that could overwhelm clinicians or reduce confidence in the system. Concerns were raised that over-reliance on an inaccurate or overly sensitive system could erode trust and limit its usefulness in clinical practice.

> *Doesn't shoot out red flags constantly leading to alarm fatigue, but it also needs to be calibrated so that real early warnings that need to be warned about get the appropriate thought and reaction from policymakers and the public.* [P04, Infectious disease and critical care physician specialist]

XSL•FO
RenderX

To enhance accuracy, participants favored a multifactorial approach rather than reliance on a single metric, such as swab testing. A more comprehensive surveillance system was suggested to reduce biases and improve reliability.

> *would have a multi-factorial kind of approach and wouldn't rest on a single metric. Because these things are complex, the health system … and people…and communities…, I don't think there is a silver bullet warning system like only swabs. Because if you pick one thing, it may have blind spots or biases baked into that particular approach. I would advocate a more holistic multi-factorial kind of approach for surveillance to recognize the complexity of the challenge of the problem we're trying to solve.* [P10, Family physician]

### *Timeliness*

A key expectation was that an EWS should detect potential outbreaks in "Real-time" (P02, eED physician) and alert health care providers "within 24 to 72 hours" (P06, family physician). The ability to rapidly disseminate information was seen as critical for early clinical and public health interventions:

> *Timeliness… that it could impact clinical care at the frontline* [P08, Family physician]

> *It would be timely in terms of getting the information out to the providers. And I would think within…short days. Ideally 48, 72 hours… would be helpful especially with respiratory illnesses that have potential to impact morbidity and mortality and impact kind of the need for healthcare providers that are looking after patients. So, timeliness would be the biggest one probably from the surveillance system perspective.* [P08, Family physician]

### *Integration*

Seamless integration into existing clinical systems was highlighted as a fundamental requirement. Participants stressed that the EWS should draw from multiple data sources, including electronic health records, swab testing data, wastewater surveillance, and self-reported symptoms, while minimizing disruptions to workflow.

> *It's ideally integrated into the electronic health records, so they only have to log into one system… I think a few things are ideal… everything from social media, wastewater, slight patterns, prescription medication use, symptoms that are recorded in health records and also people's own self-reporting.* [P06, Family physician]

### *Equity*

Equity emerged as a core and widely emphasized attribute of an effective EWS across participants. Participants emphasized that an effective EWS must prioritize equity, ensuring equal access to testing and surveillance across urban and rural areas and marginalized populations. Key concerns included representation of "Indigenous and newcomer communities" (P03, Family physician), "equitable geographic coverage" (P04, Infectious disease and critical care physician specialist), and strict data privacy safeguards to prevent misuse.

> *It would be really important that particular vulnerable groups that have been marginalised by the healthcare system over the last few decades were incorporated into the decision making around this so that an early warning system doesn't further stigmatise them and that they would be wanting to participate. And… they could provide guidance on how it would need to be designed and implemented. So…our Indigenous communities… the example of having these separate TB clinics that did create a lot of inequities in the past. So, just being thoughtful about that piece. Because then we risk developing something that doesn't actually help support the individuals that may be greatest risk for contracting respiratory illnesses.* [P11, Family Physician]

Across practice contexts, participants consistently identified accuracy, timeliness, integration, and equity as core attributes of an effective EWS.

## Theme 3: Anticipated Challenges in EWS Implementation

Participants identified challenges at 4 key stages of EWS development, including initiation, implementation, use, and evaluation. While multiple concerns were raised for each stage, only the most predominant issues are reported below.

### *Initiation*

Three primary challenges were highlighted regarding the initiation of an EWS for ARI: (1) lack of long-term commitment and high costs, (2) complexity of ARI mutations, and (3) public resistance due to data privacy concerns.

The lack of sustained commitment and financial investment was a major concern. Participants noted that enthusiasm and perhaps funding for pandemic-related technologies peaks during crises but diminishes between pandemics.

> *One of the main lessons learned in the pandemic is everyone is interested during the pandemic, but no one is interested in the pandemic between the pandemics…you get all kinds of government funding and interest and global engagement when there is the threat but when there is no threat nobody wants to fund pandemic technology.* [P01, Infectious disease physician]

The complexity of ARI mutations also raised concerns about the system's practical utility. Participants questioned how an EWS could detect novel pathogens that had never been identified before.

> *Now, there is new technology that might help us with PCR, and gene sequencing, and maybe we can hope to detect viruses that are previously unidentified more easily, but that stuff is really difficult… to then think about translating that at a clinical level, I mean, I don't know what to say about that… you can't detect anything that hasn't been detected before.* [P02, ED physician]

XSL•FO
RenderX

Finally, public trust and concerns about data misuse were seen as potential barriers to initiating an EWS.

> *The governance of these types of systems, because… we've seen lots of concerns about corporations or others sucking up this type of data. So, it would need to be governed in a way that actually serves the people and the public and is not just generating profit.* [P06, Family physician]

### *Implementation*

Challenges related to data system incompatibility and lack of legislation on data sharing were emphasized as major barriers to implementation.

Participants described fragmentation across electronic health records and data systems, with different provinces and organizations using incompatible platforms.

> *Different provinces have different electronic medical records. And a system would have to synchronize data from a variety of different sources so if it required a lot of tuning to the local electronic medical record, that would delay implementation.* [P01, Infectious disease physician]

In addition, the absence of clear legislation on data sharing was noted as a challenge. The lack of standardized protocols for tracking and tracing infections during COVID-19 was cited as an example of system limitations.

> *The contact tracing was non-existent in Ontario for the most part. It failed dramatically …restaurant sign up…(were) not be used by anyone. So, when people would test positive, there was no way to then see where they've been or anything… being able to contact trace better, that probably requires some sort of work from legislations at the legislation level.* [P02, ED physician]

### *Use*

Challenges related to workforce shortages, system capacity, and public engagement were the most frequently discussed barriers to EWS functionality. Almost all participants explicitly expressed their concerns related to the "administrative and workload burden" (10) associated with having a new EWS, especially given the chronic "human workforce shortage" (11). In one Canadian province, "2.5 million residents don't have a primary care doctor" (11), and many rely on EDs, which are "typically really busy" (09). A participant stressed that,

> *It's hard for folks (in the ED) to add something else onto their busy list. They see so many people with very vague symptoms, it can be difficult to I think nail that down within say the triage or the first encounter with the patient.* [09, Critical care physician]

Concerns were also raised about Canada's ability to sustain robust testing and surveillance.

> *If you have an atypical presentation and people do not have RSV (respiratory syncytial virus), flu, or COVID, then that might lead you down the road of trying to investigate and discover that we're dealing with something new. So, my worry is that our systems currently are not robust in terms of testing and isolating people with respiratory illness for the things that are circulating.* [P07, ED physician]

Participants also noted that public trust and willingness to engage would influence the success of an EWS.

> *We don't have the greatest track record of using data in that equitable manner… so there is going to be an inherent amount of distress of the system because of our inability to really respond to data with high quality equitable interventions.* [04, Infectious disease and critical care physician specialist]

Additionally, screening for travel history was seen as a critical function of EWS but also a potential source of discrimination.

> *Everyone from Senegal is isolated for Ebola even though they're presenting with they hurt their leg or something. I'm exaggerating, but so it can lead to a sense of discrimination when we're making this based on where people have travelled from.* [07, ED physician]

### *Evaluation*

Discussions on evaluation focused less on challenges and more on suggested methods for assessing EWS effectiveness. Participants proposed that evaluation should consider data synchronization across sources, ease of use, and sensitivity and specificity of screening.

> *A participant envisioned an easy-to-use EWS that "communicates with the EMR" that "flags" warning as they "input data", so they can perform "point-of-care testing".* [P11, Family physician]
>
> *Another participant suggested evaluation through "simulations and screening at airports… the evaluation happens frequently by people trying to get through and seeing if you pick that up through simulated events."* [P09, Critical care physician]

## Discussion

### Principal Findings

This qualitative study explored the perspectives of frontline clinicians and researchers involved in pandemic response on the role of EWS in monitoring and managing ARI in Canada. Three key themes emerged, including general knowledge of EWS, desired attributes, and anticipated challenges. While participants recognized the potential benefits of EWS, the absence of a widely recognized and established EWS for ARI in Canada limited their ability to engage in in-depth discussions about specific platforms. Participants identified accuracy, timeliness, integration, and equity as essential attributes of an effective system and highlighted challenges at each stage of development, including initiation, implementation, use, and evaluation. These findings underscore the complexities of designing and implementing a robust, sustainable, and equitable EWS for ARI in Canada. Including participants from diverse specialties and practice settings strengthened the relevance of our findings across varied clinical and health system contexts.

XSL•FO
RenderX

Our findings align with existing literature emphasizing that EWS primarily serves to detect outbreaks, guide clinical decision-making, and inform public health responses [36,37]. EWS has been shown to support real-time tracking of disease trends, early identification of emerging risks, and allocation of health care resources [38]. Similar to our participants' perspectives, previous reviews highlight that effective EWS must be timely, accurate, and seamlessly integrated into existing health care workflows to maximize their utility [39]. Participants' references to a 24 - 72 hour alert window reflect the need for timely situational awareness to support public health and clinical response, rather than a specific evidence-based mortality threshold. Previous studies further suggest that "accuracy" in EWS reflects trade-offs between sensitivity and specificity. For example, increasing sensitivity can reduce missed events but often results in more false-positive alerts and greater alert burden, whereas prioritizing specificity may lower alert frequency but increase the risk of delayed detection of deterioration [39]. Participants' concerns about alert fatigue and missed signals are consistent with these documented trade-offs.

In Canada, multiple surveillance systems monitor respiratory infections, including FluWatchers [17], TARRANET [18], and SPSN [19]. However, these systems primarily function as population-level surveillance tools and are not designed to provide real-time clinical decision support at the point of care. In contrast, several countries, including Australia, China, and parts of Europe, operate more integrated national respiratory infection surveillance systems that combine data from multiple sources, such as laboratory, syndromic, and sentinel surveillance [40,41]. In addition, some international EWS frameworks have begun integrating machine learning and artificial intelligence approaches to enhance early signal detection, identify high-risk populations, and support timely public health alerts [42,43]. Potential reasons for the disparity in EWS for respiratory infection between Canada and other countries may reflect a combination of system-level factors. First, Canada's health system is highly decentralized, with responsibility for health care delivery and public health surveillance largely residing at the provincial and territorial levels. This governance structure can present challenges for the development of a unified, nationally integrated EWS. Second, ongoing variation in data infrastructure, as well as differences in privacy legislation and data-sharing agreements across jurisdictions, may limit the timely integration of surveillance data at a national level. Finally, persistent gaps in access to primary care in Canada, including a substantial proportion of individuals who are unattached to a regular primary care provider, may further constrain surveillance capacity. Individuals experiencing socioeconomic marginalization are disproportionately represented among this population, which may contribute to gaps in population-level monitoring. These findings point to the need for implementation-focused research to design and evaluate integrated EWS that link surveillance, clinical care, and public health decision-making in real time while minimizing alert fatigue and inequitable coverage.

## Challenges in EWS Development and Implementation

Participants identified challenges across all 4 stages of EWS development (initiation, implementation, use, and evaluation), with challenges at the initiation stage emerging as the most pressing concern. In particular, participants emphasized the lack of sustained investment and policy commitment to pandemic preparedness outside of crisis periods. While funding and interest peak during outbreaks, maintaining long-term support for EWS was viewed as difficult, a concern that aligns with prior research describing intermittent funding in surveillance infrastructure [44]. Participants noted that challenges during the initiation phase, such as limited sustained investment and unclear long-term priorities, often shaped downstream issues related to implementation, system fit, and long-term use.

Challenges related to implementation and use were also frequently discussed. Participants highlighted the fragmentation of electronic health records across provinces and the absence of standardized data-sharing protocols as major barriers to integrating EWS into clinical workflows. These issues are consistent with broader challenges observed in decentralized health care systems, where data silos and variable policies limit timely information exchange and generate real-time decision support [45]. In addition, workforce shortages, increased administrative burden, and limited system capacity were seen as factors that could further impede the adoption and effective use of EWS, reflecting system pressures that have been widely documented in the Canadian health context [46]. Prior studies of digital surveillance and decision-support implementation have shown that workforce shortages and competing clinical demands can limit engagement with alerting systems and reduce their effective use [39].

Public trust and engagement were identified as critical to the effectiveness of EWS, particularly in relation to data governance and equity. Participants emphasized concern that poorly designed or inadequately governed systems could exacerbate existing health disparities or undermine public confidence. Similar concerns have been noted in the digital health literature, where issues related to data validity, transparency, and legal framework have been shown to influence the utility and acceptability of surveillance technologies [47]. Prior Canadian and international studies have identified equity-related challenges in EWS implementation, including limited applicability to Indigenous, rural, and remote contexts and concerns around data governance and trust [48]. Participants raised similar issues, emphasizing Indigenous leadership, community-specific needs, and contextual relevance. To address these concerns, participants advocated for the importance of co-designing EWS with communities, particularly Indigenous and marginalized populations. Participants described co-design as involving early engagement with community leadership, shared decision-making around data governance and system priorities, and ongoing feedback during pilot testing and implementation. Evidence from disaster management and health equity suggests that co-design approaches can enhance cultural responsiveness and system relevance, supporting more equitable and effective implementation of digital surveillance tools [49,50].

## Opportunities and Future Directions

Despite these challenges, there is growing global momentum toward strengthening respiratory surveillance. Many countries

XSL•FO
RenderX

have adopted disease-specific and syndromic surveillance models that rely on real-time data collection and clinical case reporting [51]. For example, the RESP-NET in the United States and Canada's FluWatchers program demonstrates the feasibility of large-scale respiratory surveillance [52,53]. However, our findings suggest that existing surveillance efforts in Canada are not yet configured as a unified system that can support both public health monitoring and real-time frontline clinical decision-making. Moving forward, efforts should focus on designing an EWS that bridges these domains. Key considerations include improving interoperability between electronic health records, laboratory networks, and syndromic surveillance tools; establishing clear and consistent frameworks for data governance, privacy, and equitable access; and involving key stakeholders in system design to support cultural safety and equity in implementation.

In the Canadian context, advancing transparent governance and equitable data use will require clearer coordination across federal, provincial, and territorial jurisdictions. Participants' emphasis on trust also points to the importance of embedding equity considerations early in system design, including meaningful engagement with communities that experience greater social and structural barriers. Together, these considerations may help enable Canada's future EWS to be perceived as legitimate, trustworthy, and responsible to the needs of its diverse population.

### Limitations

This study has several limitations. First, we did not include policymakers, public health officials, and data scientists involved in the design and governance of EWS, whose perspectives may have provided additional insights for policy development, data integration strategies, and long-term sustainability. Second, interviews were conducted between August and October 2024, outside peak winter respiratory virus season. Participants' perspectives may therefore reflect experiences during relatively stable surveillance periods rather than peak seasonal demand; however, discussions frequently drew on pandemic-era and outbreak experiences. Finally, patient perspectives were not included, limiting our understanding of public engagement and trust in EWS adoption.

### Conclusion

This study explored health care providers' and researchers' perspectives on EWS for ARI in Canada. Participants highlighted the potential of EWS to support outbreak detection, clinical decision-making, and pandemic preparedness, while also identifying persistent system-level challenges related to data integration, governance, and trust. These findings underscore the need for accurate, timely, integrated, and equitable systems that meaningfully bridge public health surveillance and clinical decision-making. Future research should incorporate policymaker and patient perspectives and examine how emerging digital and AI-enabled approaches can be responsibly integrated into EWS. With sustained investment and inclusive system design, Canada has the opportunity to strengthen its EWS capacity and improve preparedness for future respiratory outbreaks.

## Funding

This project was supported by funding from EPIC-IfP initative at the University of Toronto. Author BH is supported as a Research Scientist by the Upstream Lab at the MAP center forUrban Health Solutions, at the Li Ka Shing Knowledge Institute. The opinions, results andconclusions reported in this article are those of the authors and are independent from any fundingsources.

## Disclaimer

The authors declare the use of generative AI in the research and writing process. According to

the GAIDeT taxonomy (2025), the following tasks were delegated to GAI tools under full human

supervision:

- Proofreading and editing

The GAI tool used was: ChatGPT 5.

Responsibility for the final manuscript lies entirely with the authors.

GAI tools are not listed as authors and do not bear responsibility for the final outcomes.

Declaration submitted by: JQ

## Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

## Abstract

**Background:** By 2015, the emergence and dissemination of multidrug-resistant *Plasmodium falciparum* in the Greater Mekong Subregion threatened regional and global malaria control efforts. In response, Greater Mekong Subregion countries committed to malaria elimination by 2030, with strengthened surveillance as a strategic pillar. In 2017, Cambodia introduced an elimination-oriented digital Malaria Information System (MIS). Its health center app enables real-time, geo-located, case-based malaria reporting across primary health centers, and is fully integrated with the MIS.

**Objective:** This study aimed to evaluate the real-world national implementation of Cambodia's Android-based health center app, considering coverage, fidelity, timeliness, and data use, and their effects on malaria surveillance performance, case management, programmatic response, and public health outcomes.

**Methods:** System performance and public health use were assessed using system-generated metadata, national surveillance data, and user surveys. Operational indicators included technical performance, data completeness, and reporting timeliness, alongside surveillance outcomes such as case notification, classification, reactive case detection, and foci investigation. Nationwide user experience was measured via a survey of 761 health centers across 21 provinces, with in-depth structured surveys at 9 health centers in 3 provinces. Descriptive analyses evaluated system functionality, contribution to malaria surveillance and response, and usability among frontline health workers.

**Results:** The health center app demonstrated strong technical performance, with rapid loading and resilient data transmission under low-bandwidth conditions, supporting reliable reporting in resource-constrained settings. Integrated real-time dashboards provided analytics for case management, surveillance monitoring, risk stratification, and targeted public health interventions. Data completeness remained high (99%, 89/90 fields in 2024), demonstrating consistent routine use even as case incidence declined. Between January 1, 2025, and July 31, 2025, 69 malaria cases were reported nationally (23 locally acquired, 7 domestically imported, and 39 internationally imported). Of these, 95.7% (66/69) were notified and classified within 1 day. Reactive case detection was completed within 3 days for all 21 eligible cases, and 16 of 19 eligible foci received a response within 7 days, indicating strong operational responsiveness. User surveys showed 96.3% (733/761) of health centers were satisfied or very satisfied, 90.1% (686/761) reported rare or no technical issues, and 91.7% (698/761) found the app easy to navigate. Operational challenges included limited internet connectivity, transport to remote areas, and electricity interruptions. In-depth surveys confirmed high uptake, confidence in reporting, and routine use of surveillance data, although gaps in local analytical capacity were identified.

**Conclusions:** Developed and managed locally to enhance sustainability, the MIS drove significant reductions in malaria case incidence, with the health center app contributing timely, complete, structured reporting at the point of care. Public health responses were facilitated by real-time analysis, targeted interventions, and decentralized decision-making. User engagement was sustained as malaria cases declined, and further enhancements are planned to ensure seamless transition to postelimination surveillance, reducing the risk of malaria reestablishment in Cambodia.

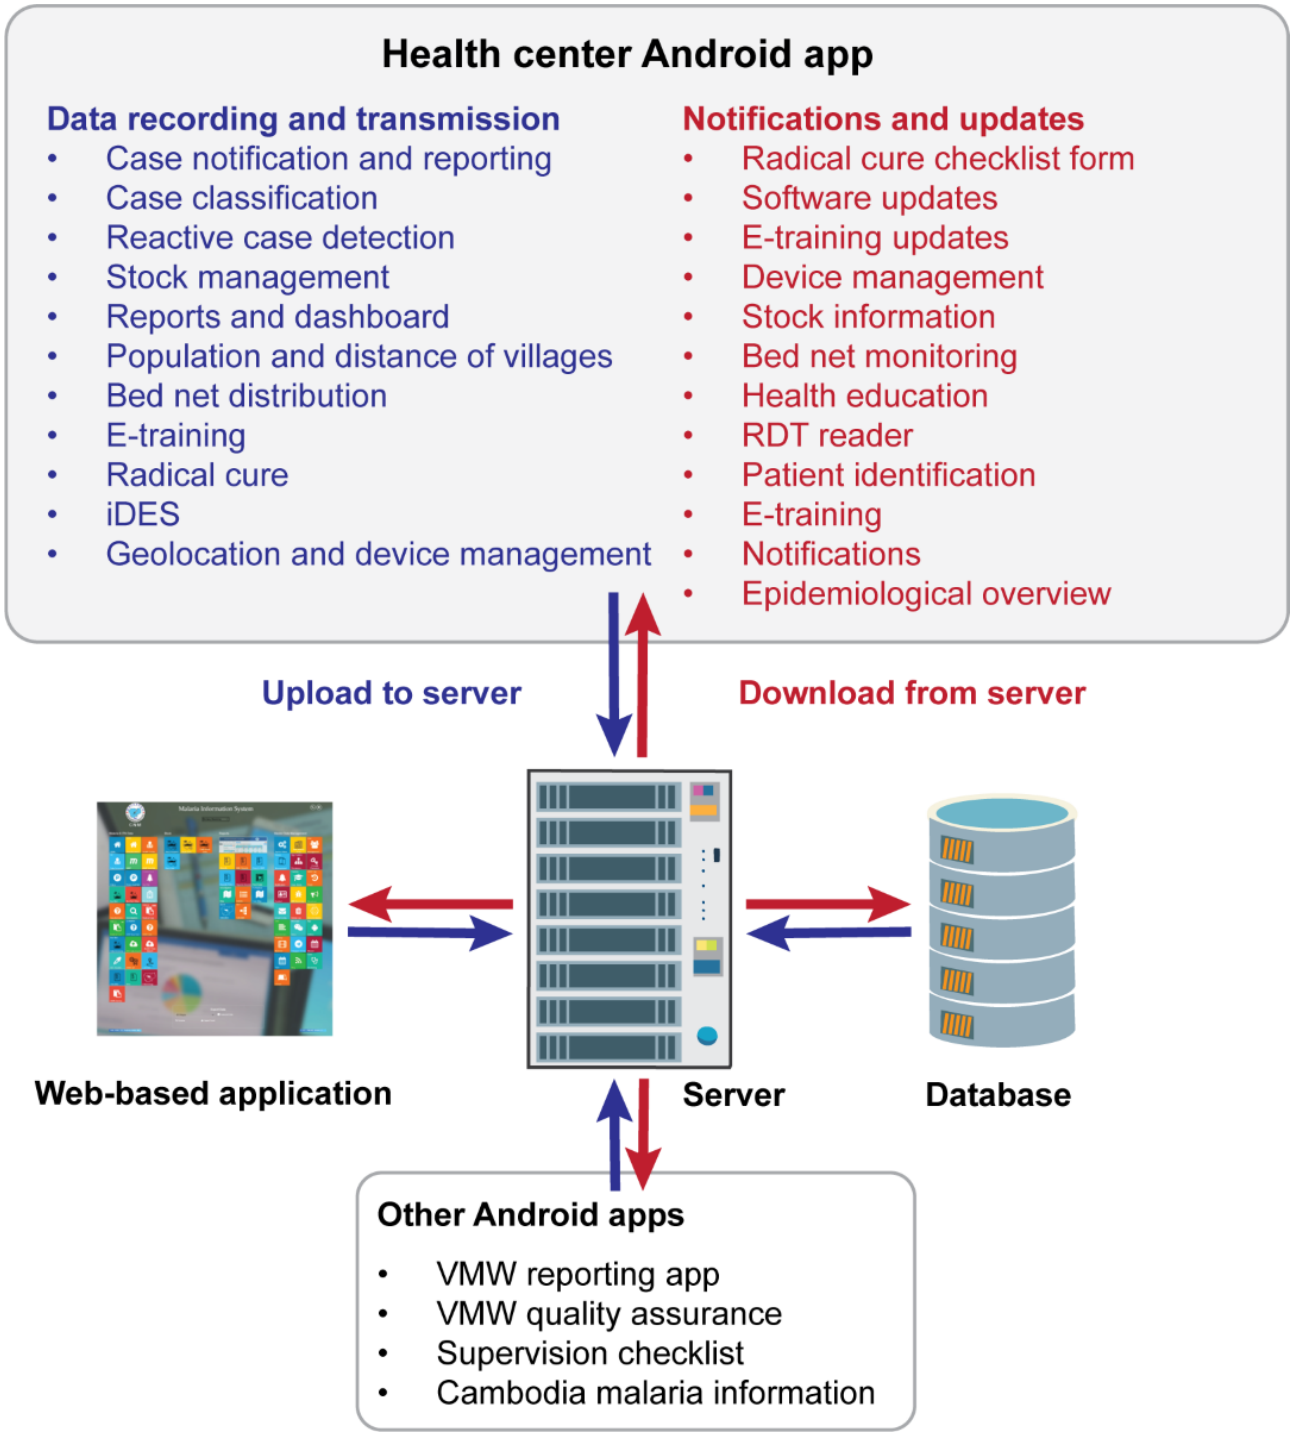
## Introduction

Malaria is a life-threatening parasitic disease caused by *Plasmodium spp*., transmitted to humans through the bites of infected *Anopheles* mosquitoes. Malaria continues to pose a major global health challenge, causing significant morbidity and mortality [1].

The Greater Mekong Subregion (GMS) has been a focus for the development of parasite resistance to antimalarial drugs. In the late 1950s, chloroquine-resistant *Plasmodium falciparum* emerged in the GMS, and over the following 2 decades disseminated worldwide [2]. This led to extensive treatment failures and significantly undermined malaria control programs globally [3,4]. Similarly, the GMS was the source of pyrimethamine-resistant parasites which quickly spread to Africa [5]. The introduction of artemisinin-based combination therapy (ACT) in 2001 marked a turning point in malaria control, restoring treatment efficacy and becoming the cornerstone of global treatment strategies. Consequently, reports in 2008 of the emergence of *P. falciparum* artemisinin partial resistance on the Thai-Cambodia border generated considerable concern. The subsequent evolution of multiresistant parasites and their rapid proliferation across the GMS complicated efforts to treat and contain the disease [6-8]. There was a considerable risk that these multiresistant parasites would spread globally, causing malaria to become untreatable [9]. This led to urgent and coordinated regional efforts to contain malaria [10], which by 2015 had evolved into a commitment to attain malaria elimination in the entire GMS by 2030 [11].

Malaria elimination is the interruption of local transmission in a defined geographical area [12]. It is an ambitious objective that is complex to achieve. Elimination is pursued in phases [11,12]. In the transmission-reduction phase, broad interventions are applied to reduce disease burden, such as widespread vector control, including the distribution of insecticide bed nets, and strengthening malaria services to deliver effective medicines. Once case incidence is low (typically below 1 case/1000 people/year), the elimination phase begins, and surveillance becomes the primary intervention [11,12]. The aim is to systematically drain the human transmission reservoir by finding and eliminating all parasites and interrupting transmission. To achieve this, a strong and responsive surveillance system is needed, capable of promptly detecting and treating every case, determining the origin of each case, triggering a timely and appropriate public health response, and detecting any changes in therapeutic drug efficacy or transmission patterns. This is generally achieved via one or more of three main surveillance strategies:

1. The 1-3-7 strategy: supporting malaria elimination in China and elsewhere, each case is reported within 1 day, investigated within 3 days, and followed by a targeted response within 7 days to prevent onward transmission [13-15].
2. Integrated drug efficacy surveillance (iDES): an early warning of drug resistance to ensure effective treatment; follow-up is extended to Day 42 for *P. falciparum* and Day 90 for *P. vivax* cases to identify treatment failures; blood spot samples are also collected for molecular analysis of known drug resistance markers [16-19].
3. Stratification of malaria risk: detailed epidemiological and ecological data at a high level of granularity are used for targeting to ensure effective deployment of essential resources.



Although these strategies can be implemented independently, their integration strengthens malaria surveillance and response systems by linking timely case detection, investigation, targeted intervention, and drug efficacy monitoring. This ensures good patient outcomes, reduces transmission potential, and maximizes the public health benefit. A coordinated approach also reduces duplication of effort, improves the efficiency of resource use, and enhances the sustainability of malaria elimination programs.

In Cambodia in 2008, malaria surveillance was severely limited and ineffective malaria treatments were commonly prescribed, deepening the public health impact and fueling transmission. Initial efforts to contain artemisinin resistance included banning artemisinin monotherapies in favor of more effective ACTs, phasing out the private sector, deploying insecticide-treated bed nets, facilitating information sharing across borders, and introducing malaria surveillance using a Microsoft Access Database. As the regional response pivoted to target malaria elimination, Cambodia implemented a National Strategic Plan for Malaria Elimination (2011 - 2025). This included substantial investments in surveillance infrastructure by the Cambodian Ministry of Health, led by the National Center for Parasitology, Entomology and Malaria Control (CNM) [20,21]. These efforts expanded surveillance activities via the Malaria Information System (MIS), which was migrated to a web-based platform in 2015 [22,23]. However, data were still collected on paper forms, with aggregation at the operational district level and monthly reporting. This process was slow, data were often incomplete, and outputs lacked the required granularity to support elimination efforts within an increasingly heterogeneous and fragmented transmission landscape [22-24]. To overcome these limitations, a fully digital system was launched in 2017, combining web-based analytics on the MIS, with 2 mobile apps enabling digital real-time reporting from health workers in the field, one for village malaria workers (VMWs) and another for staff at health centers (Figure 1) [24,25]. The MIS thereby supports the 1-3-7 strategy, iDES, and malaria risk stratification within one fully integrated platform extending throughout the public health system and the community.

XSL•FO
RenderX

**Figure 1.** Overview of health center app within the Cambodian malaria surveillance system. iDES: integrated drug efficacy surveillance; RDT: rapid diagnostic test; VMW: village malaria worker.

Cambodia's national malaria surveillance system has been widely recognized internationally as a model for digital transformation in elimination settings [26-31]. Efficient surveillance has supported an extraordinary decline in malaria cases from over 66,000 in 2018 to 355 in 2024, with no deaths from malaria recorded over this period [1,25,32]. Given that malaria elimination remains a priority for the World Health Organization and the Global Fund to Fight AIDS, Tuberculosis and Malaria, documentation of a fully implemented, nationally integrated digital surveillance platform has substantial global relevance. The broader surveillance architecture and its evolution have been described in recent publications [24,25]. This study extends that work by documenting the integration of the health center-level digital surveillance application into the country's malaria surveillance architecture. Operationalization of the system at the primary health care level is essential, as real-time case reporting, treatment verification, and response coordination directly influence elimination outcomes. This implementation case study focuses on a snapshot of recent data to highlight both the strengths and limitations of the health center app as Cambodia strives to complete the "last mile" to malaria elimination. The architecture and implementation principles are directly transferable to other malaria-endemic countries transitioning from control to

XSL•FO
RenderX

elimination, focusing on practical insights for national-level digital health surveillance planning and sustainability in preelimination settings.

## Methods

### Ethical Considerations

This work was conducted as part of CNM's ongoing efforts to strengthen routine surveillance, drawing on existing program data and surveys with VMWs about their professional use of a government-supported malaria reporting system. All respondents were public health personnel acting in their official roles, and participation in the surveys was voluntary and anonymous. No information that could identify individual patients or reveal personal health details was collected or assessed. Under national guidelines, the activities did not require formal ethics committee review or written informed consent. All procedures complied with relevant institutional, national, and international standards for data protection. No formal ethics committee approval was sought for this work because the project constituted a service implementation and evaluation activity using routinely collected, fully anonymized patient data, with no direct patient contact or intervention. Staff participants contributed only in their professional capacities as employees of the digital health service. Guidance from the University of Cambridge Research Ethics framework states that ethical review is not normally required for the secondary use of robustly anonymized data where individuals are not identifiable to the research team. Relevant guidance is available from the University of Cambridge Research Ethics Handbook [33] and associated ethics review guidance: University of Cambridge Ethics Review Flowchart [34]. Cambodian national health research ethics oversight information is available from the Cambodian National Ethics Committee for Health Research [35].

### Malaria Surveillance in Cambodian Health Centers

Health centers serve as the primary formal health care contact for rural populations, offering essential diagnosis, treatment, and referral services for common illnesses. Each center covers a defined catchment area, typically including 8000 - 12,000 persons, and operates under Ministry of Health guidelines. For malaria, health center staff use rapid diagnostic tests (RDTs), prescribe ACTs, and record clinical and epidemiological details of each case. Health centers also provide support for VMWs, compile routine reports, and conduct follow-up investigations to direct local malaria responses.

Since 2017, health centers have conducted real-time case-based reporting via a dedicated digital application (Figure 1). Health center participation is mandatory in endemic districts, with malaria designated as a notifiable disease, supporting broad coverage and adherence to reporting requirements. Consequently, health center data form a core component of Cambodia's malaria surveillance infrastructure, contributing to individual case management, targeted local responses, and national-level monitoring and elimination planning.

### App Development

The health center mobile app was developed in-house by CNM, with support from the Global Fund, to strengthen malaria elimination activities. Its primary aim is to enable timely, accurate, standardized malaria case reporting from public health centers, aligning with national strategy [20,21].

Built as a native Android app using Java, the app was designed for frontline health staff, considering feasibility, usability in low-connectivity settings, and compatibility with Ministry of Health workflows. Supporting Android versions 5.0+, this platform was selected over iOS and web-based alternatives due to its affordability, flexibility, offline functionality, and compatibility with the low-cost, older smartphones and tablets available within the public health system.

Recognizing the limited network access in rural areas, the app features offline-first functionality with local SQLite data storage, synchronizing automatically to the central MIS (Microsoft SQL Server) when internet becomes available (Figure 1). This integration supports near real-time data consolidation with other sources (eg, VMW app). The MIS also automatically shares data with the National Health Information System and the Malaria Reference Laboratory, with population information maintained through the Ministry of Planning Commune Database.

A user-centered design approach guided development. The interface uses icons to enhance usability and organizes functions into distinct modules (Figure 2). The system brings together a comprehensive suite of malaria surveillance and management functions, beginning with patient reporting, which captures essential epidemiological case data at the point of care. Additionally, the system supports detailed case classification, distinguishing local from imported cases and further categorizing indigenous, induced, recrudescent, and relapsing infections. It supports timely reactive case detection to actively identify additional infections around confirmed cases that might otherwise be missed and enables effective management of radical cure for *P. vivax* malaria, including tracking treatment eligibility and implementation across health facilities. Demographic insights are strengthened through population data that help determine accurate incidence rates, complemented by bed-net status features that record distribution dates, coverage, and expiry alerts. An iDES module is included to provide early warning signals of emerging drug resistance through extended follow-up of *P. falciparum* and *P. vivax* cases. Operational efficiency is supported by stock management tools that monitor commodity levels, expiry dates, and re-ordering needs, while an offline mode ensures continuous data capture in low-connectivity settings. The platform also offers robust reporting capabilities through automated and customizable analytics and facilitates oversight of VMWs by tracking their locations, training, reporting performance, and supervision. A centralized dashboard synthesizes key indicators to present a clear picture of the local malaria situation with precise village location mapping assigned using standardized GPS-based codes.

Prototypes underwent scenario-based testing at CNM with iterative refinement involving health staff, CNM surveillance officers, and district managers, ensuring usability and relevance. Updates continue based on input from subnational teams and evolving program needs. A dedicated 7-member CNM team manages maintenance, updates, training, and technical support.

XSL•FO
RenderX

A custom device management module enables remote software updates, monitors device use, and helps resolve hardware issues. Health centers can also report lost or damaged devices directly to CNM.

**Figure 2.** Health center app graphical user interface home screen. Top right: E-training – online resources and training materials and courses. (1) Patient reporting; (2) Integrated drug efficacy surveillance (iDES); (3) Reactive case detection; (4) Stock management; (5) Offline mode – management of data transfer offline and online; (6) Reporting; (7) Village malaria workers; (8) Population; (9) Bed-net status; (10) Dashboard; (11) Village location; (12) Case classification; (13) *P. vivax* radical cure. The figure was derived with permission from CNM's online malaria information system available via their website [36].

## Data Processing

To facilitate adoption and reduce training needs, the app replicates the national paper-based malaria reporting forms used at health centers, aligning with national surveillance standards. Structured digital forms feature drop-down menus, prepopulated fields, and built-in logic to minimize errors and ensure consistency. This familiar design supports harmonized data collection, standardized case classification, and seamless analytics for trend monitoring and outbreak detection. Automated data quality checks verify completeness and internal consistency. In-app alerts notify users of missing fields or late submissions, while recent entries can be reviewed for prompt correction, reinforcing accountability. Entries are time-stamped and geotagged using built-in GPS functionality, enabling fine-scale spatial mapping, real-time risk stratification, and targeted response activities.

Once uploaded, case data feeds into the MIS, which applies validation checks and flags cases requiring follow-up. The MIS generates visual outputs, including time-series graphs, incidence maps, and summary tables, accessible to national and subnational teams via a secure online interface to track surveillance quality, treatment timelines, and emerging hotspots. To enhance performance in low-bandwidth areas, the MIS uses pregenerated dashboards and analytics that refresh hourly. Visuals are cached and compressed for fast access on both desktop and mobile devices, even with limited connectivity.

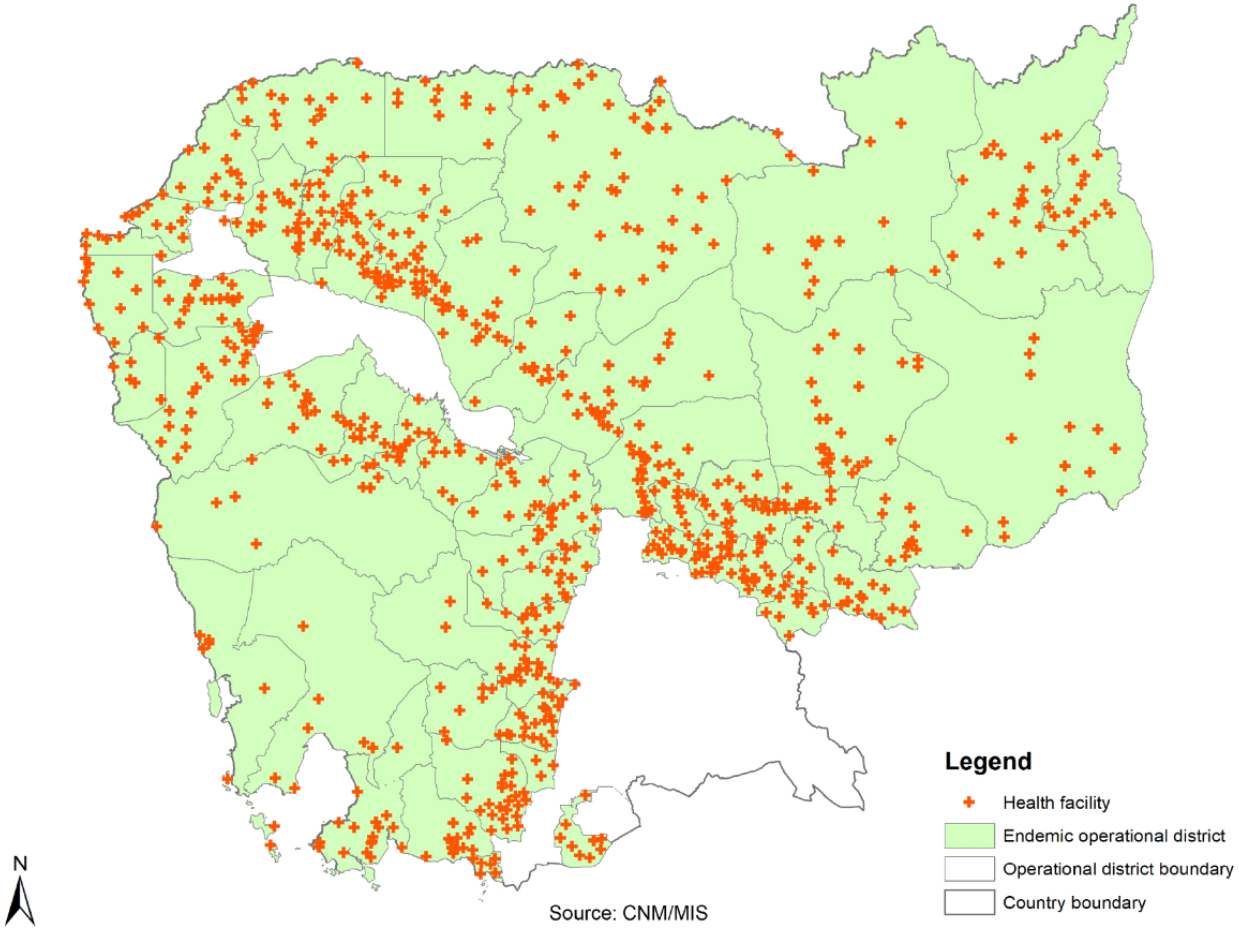
## Data Security

Security and data protection were integrated from the design stage. Data transmitted between the app and MIS server is encrypted via HTTPS, with user access controlled through unique logins authenticated against CNM's central system. To safeguard patient confidentiality, personally identifiable information is minimized and retained only at the local level for follow-up care. Each case is assigned a unique identifier, and data access is role-based. CNM uses basic pseudonymization for national reporting, aligning with international standards for data minimization and secure storage.

## Implementation

In 2017, CNM procured 800 tablets for distribution to health facilities across 21 provinces, completing rollout by early 2018. Since 2021, the app has been running on general-use health center devices, improving sustainability. As of June 2025, there are 977 devices active across 871 health centers, recognizing that most health centers now have more than one device (Figure 3).

Initial deployment included in-person training, followed by field visits for reinforcement and troubleshooting. New staff are onboarded through a similar process, with training typically



XSL•FO
RenderX

requiring 2 hours. Annual refresher sessions are held to maintain user skills. CNM also provides ongoing support via phone or Telegram, with on-site visits for unresolved issues.

To enhance continuous learning, the app includes an embedded e-training module offering videos, slides, checklists, and quizzes. This enables staff to troubleshoot issues independently and assess their knowledge. CNM can remotely update training materials and send reminders to ensure compliance. For example, during the COVID-19 pandemic, the e-training module allowed uninterrupted training while supporting infection control. In particular, advice could be updated on how to continue to deliver malaria services effectively during the pandemic and differential diagnosis of fever. Additionally, an in-app messaging feature enables health workers to submit questions directly to CNM, which also helps identify broader knowledge gaps.

**Figure 3.** Distribution of health centers using the mobile app in 2024. The figure was derived with permission from CNM's online malaria information system available via their website [36].

## Monitoring and Evaluation

A comprehensive evaluation and monitoring framework assesses the performance, usability, and programmatic use of the health center app. This framework combines continuous system-generated monitoring, routine surveillance validation, user feedback mechanisms, and periodic in-depth assessments to ensure the system remains aligned with malaria elimination requirements and responsive to user needs.

Technical performance is monitored continuously using automated metadata collected through the app and the MIS. Key performance indicators include app launch time, data upload and download success rates, synchronization times under varying network conditions, and crash frequency. A third-party monitoring service (Firebase Crashlytics) generates real-time alerts enabling rapid identification and rectification of technical issues. Timing logs capture request–response durations, supporting evaluation of system resilience under low-bandwidth conditions. These real-time indicators allow the CNM to assess system reliability, detect emerging technical constraints, and prioritize software improvements.

Routine monitoring includes tracking the completeness, accuracy, and timeliness of case-based reporting. Data submitted through the app are automatically transferred to the MIS, where automatic validation checks assess internal consistency, missing data, and unusual entries. Unusual or inconsistent patterns are flagged and followed up with field visits. Health center participation rates, frequency of app use, and completeness of mandatory fields are also monitored. Evaluation of case form content includes verification of demographic, diagnostic, and treatment variables. Malaria elimination surveillance performance is assessed through real-time longitudinal monitoring of the 1-3-7 framework, iDES, and foci clearance.

XSL•FO
RenderX

The app also supports risk stratification at the village level, a key programmatic tool.

Ongoing evaluation of the health center app's usability and contextual performance is essential. Real-time feedback is routinely collected, and user surveys are conducted periodically to check alignment between the app functionality, user experiences, and programmatic objectives. More in-depth surveys are conducted to obtain fine-grained information on potential app improvements and training needs.

## Results

### Data Collection for Case Management

Data submitted through the health center app are automatically transmitted to the MIS, where they undergo routine validation and analysis. These data underpin surveillance outputs guiding malaria elimination across all health system levels. In 2024, 99% (871/882) of endemic-area health centers used the app, logging an average of 4 visits per month. Data quality was high, with 99% (89/90) of submitted records complete and accurate.

The malaria case form captures all essential data, including demographics, diagnostic methods and results, treatment regimens, and epidemiological risk factors such as travel, forest exposure, or occupation to inform accurate case classification (Figure 4A). Each patient has a unique code, confirmed with fingerprint identification, allowing linked interactions for follow-up and retreatment (Figure 4A). Accurate time and location information allows cases to be tracked in real-time and supports the deployment of rapid responses to prevent or contain outbreaks.

XSL•FO
RenderX

**Figure 4.** Examples of reporting workflow on the health center app. A: Case reporting workflow on the health center app. Starting from the health center app main menu health center form (1), the menu for data entry is selected (2), the month is selected and patient details are entered, including demographic and clinical characteristics, diagnostic test results, treatment and referral details (3); data can be linked to previous records using the patient code, name, sex, age, or contact details (3.1) and patient details can be viewed (3.2) with any additional patient details completed (4), and further details on treatment, referrals, and pregnancy, hemoglobin, and glucose-6-phosphate dehydrogenase test results as well as drug doses recorded (5). B: Follow-up schedule for *P. vivax* radical cure on the health center app. Starting from the health center app home menu health center form (1), the data entry menu is accessed, including *P. vivax* radical cure follow-up (2). Year and month are used to search for patient information (3) and follow-up is scheduled depending on treatment regimen (3.1). At follow-up, the date and time are noted and the patient asked about possible signs of hemolysis (paleness, yellow skin and eyes, shortness of breath, etc) (4). Treatment follow-up by the village malaria worker is detailed in section (5), providing information on adherence, recovery, and adverse events. The figure was derived with permission from CNM's online malaria information system available via their website [36].

As malaria elimination has progressed in Cambodia, the epidemiological context has shifted from a high burden of *P. falciparum* malaria to most cases now caused by *P. vivax*. The treatment protocol for *P. vivax* is complex, requiring prior testing to determine glucose-6-phosphate dehydrogenase (G6PD) activity before treatment with an ACT for 3 days plus daily primaquine for 7 days for patients with normal or intermediate G6PD activity, or weekly primaquine for 8 weeks for patients with G6PD deficiency. Therefore, a specific workflow is incorporated to support efficient case management of *P. vivax* malaria cases, including follow-up and adherence (Figure 4B).

The app also provides individualized patient tracking, highlighting follow-up needs and adherence checks to support quality case management and programmatic objectives. Automatic reminders for follow-up interventions (phone calls

XSL•FO
RenderX

or in-person visits) are generated, for example, to track patients enrolled in iDES or to support *P. vivax* radical cure adherence.

## Data Analytics for Malaria Elimination

To support immediate data use by frontline staff, the app includes an integrated dashboard showing key indicators by catchment area. Performance against the 1-3-7 framework is tracked with visualizations of cases disaggregated by *Plasmodium spp*., age, and sex using time-series graphs. Comparative summaries with peer facilities promote data use and performance monitoring. Automated flags identify cases for investigation. For example, delayed treatment suggesting access issues, retreatment possibly due to drug resistance, or cases in elimination zones triggering outbreak responses.

In addition to case data, the dashboard tracks preventive measures. Bed-net distribution status, including maps and expiry dates, supports redeployment planning. Also, procurement is guided by commodity stock level monitoring, with analytics identifying overstocked, adequate, or depleted sites. By delivering timely, accessible, and actionable insights, the dashboard transforms surveillance into a 2-way process, embedding data-driven decision-making into routine care and elimination activities.

## System Performance

In terms of technical operation, the system is robust, with key technical performance indicators shown in Table 1. The app opens rapidly, typically within 3 seconds. This ensures that the app is available at the time of patient consultation and is quickly accessible given the workload and time pressure that health staff often face. Data uploads and downloads are resilient, even on older 2G and 3G networks. Success rates for uploads (95%) and downloads (98%) are high, providing reassurance that the design of the system has been optimized for a low-bandwidth setting.

**Table .** Key indicators of health enter app technical operation.

| Indicators | Outcomes |
|---|---|
| Time between app data submission and updated dashboard analytics availability, median (IQR)[a] | 3 (3 - 20) |
| Time taken for the app to launch and become usable after being opened, median (IQR)[a] | 3 (3 - 20) |
| Data uploads and downloads that were successful without errors or retries (%) | |
| Upload success rate | 95 |
| Download success rate | 98 |
| Proportion of attempts that required retries due to network failure, timeouts, or other issues (retry rate per 1000 operations) | 50 |
| Interactions that occurred in offline mode and later synchronized successfully (%) | 10 |
| Number of crashes (per 1000 active user-days) | 20 - 30 |
| Time taken for synchronization segmented by network, median (IQR)[a] | |
| 2G | 13 (13 - 30) |
| 3G | 10 (7 - 30) |
| 4G | 3 (4 - 20) |
| Wi-Fi | 3 (4 - 20) |

[a]Measured in seconds.

## Surveillance Performance

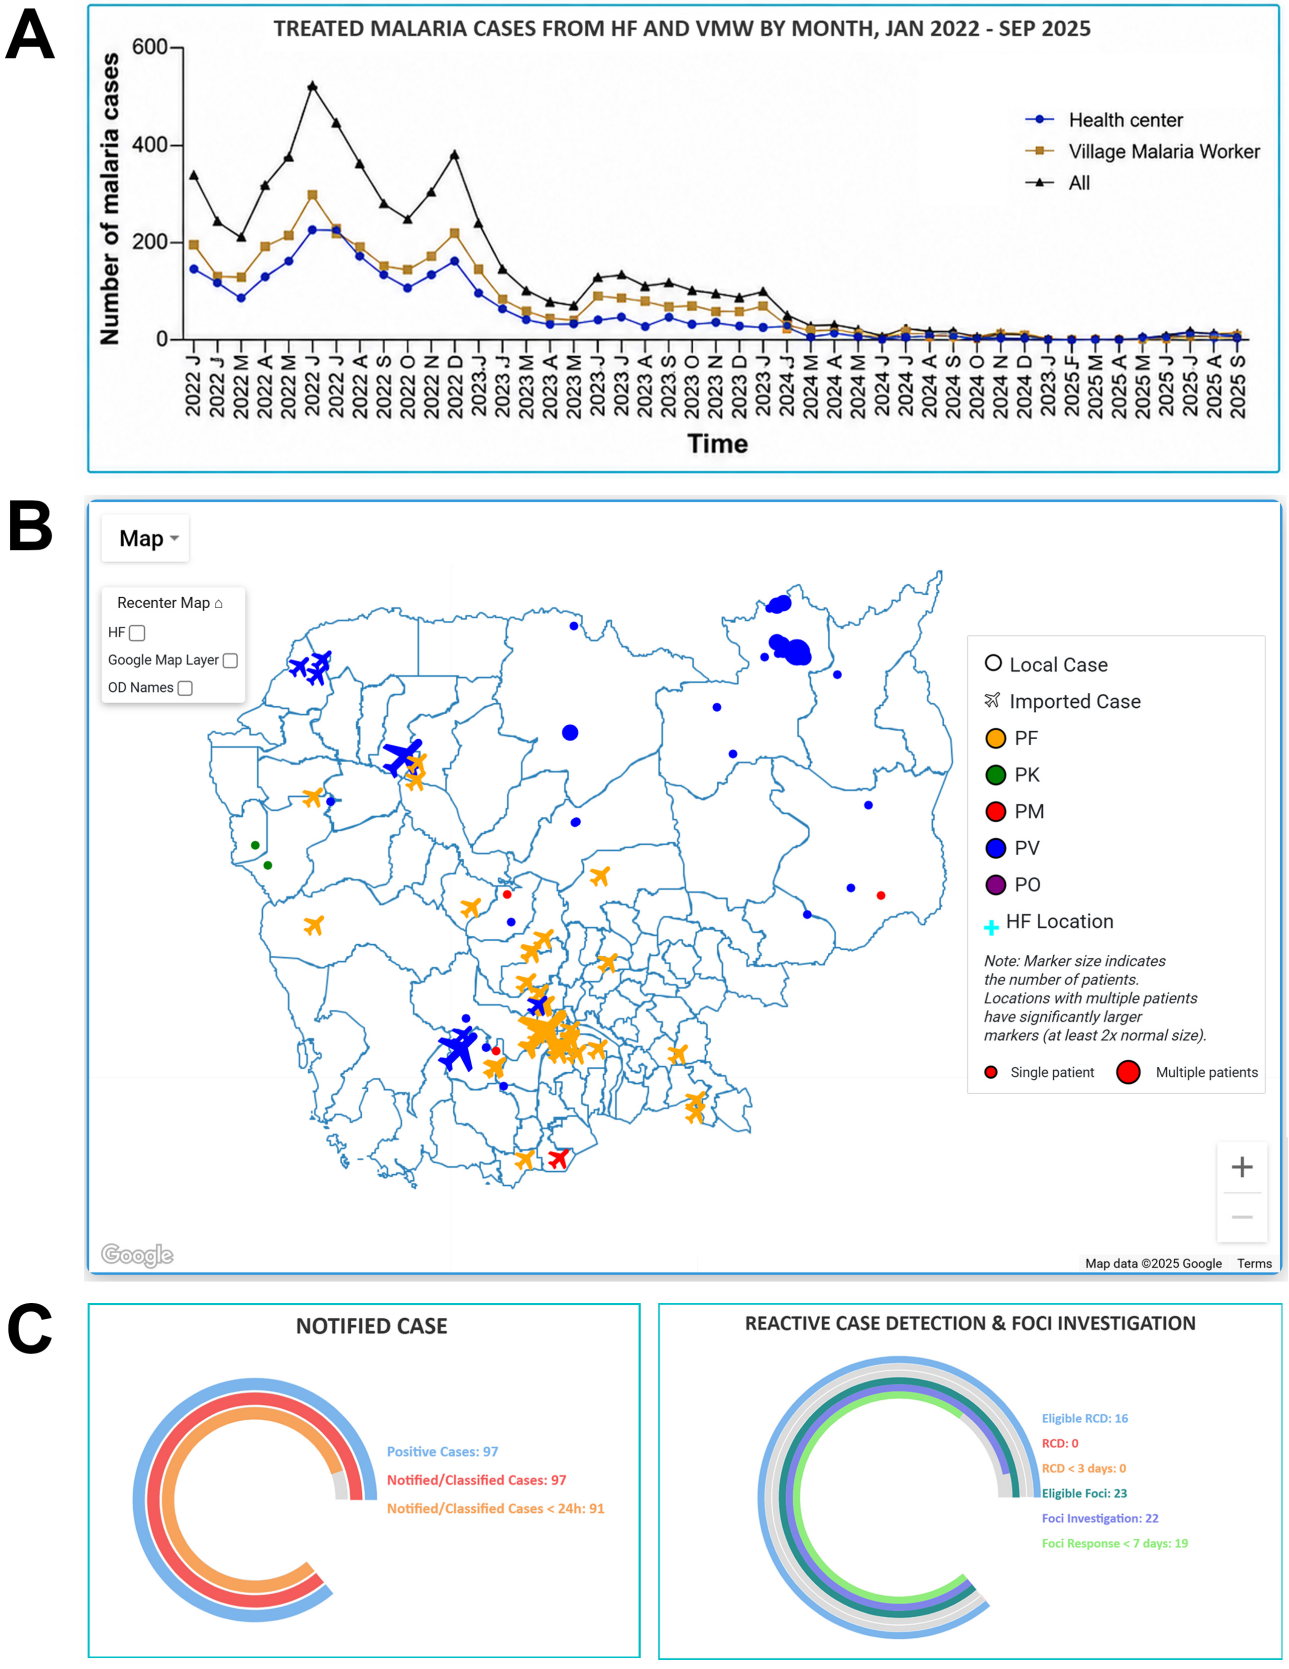
The MIS aggregates case data for all reported malaria cases in Cambodia. Malaria cases continued to decline in 2025 compared to previous years (Figure 5A), with no malaria deaths since 2018. Between January 1, 2025, and July 31, 2025, 69 cases were reported: 23 locally acquired, 7 domestically imported (from other districts), and 39 internationally imported (Figure 5B). Of these, 16 were reported via the health center app, 14 via the VMW app, and 39 internationally imported cases were added by MIS staff as these cases occurred in non-endemic areas.

Among the 69 cases, 95.7% (66/69) were notified and classified within 1 day. Reactive case detection was completed within 3 days for 21 of 21 eligible cases. Of 19 eligible foci, a foci response was initiated within 7 days for 16 (Figure 5C), reflecting strong adherence to the 1-3-7 framework.

National roll-out of iDES was completed in 2020. In 2024, 91.3% (173/186) of eligible cases were enrolled. Follow-up was completed to Day 28 for 99.4% (172/173) of cases and for *P. vivax* cases 92.9% (158/170) completed Day 90 follow-up. In 2024, dried blood spots were collected on Day 0 for 80.9% (140/173) of cases and on Day 28 for 77.5% (134/173) of cases permitting later analysis for molecular resistance markers. Declining case numbers reduce the sensitivity of clinical outcome data for detecting resistance, increasing the importance of molecular resistance markers [37].

Real-time foci identification classifies villages as active (≥1 indigenous case in the current year), residual (cases within the

XSL•FO
RenderX



past 1 - 3 years), or cleared. As of August 2025, there were 27 active and 70 residual foci. Foci are prioritized for intensified elimination efforts, including increased testing, behavior change interventions, bed-net distribution, and forest pack allocation (eg, hammock nets, repellents, and educational materials) [32].

Risk stratification ensures efficient resource allocation. In 2025, of 9.8 million residents in endemic areas, 22,119 were high risk, 147,602 medium risk, 2.8 million low risk, and 6.8 million at no risk. Stratification relies on the annual blood examination rate (ABER) and annual parasite index (API), both requiring comprehensive reporting and accurate population data. These metrics are automatically generated on the dashboard to the village level (Figure 6).

XSL•FO
RenderX

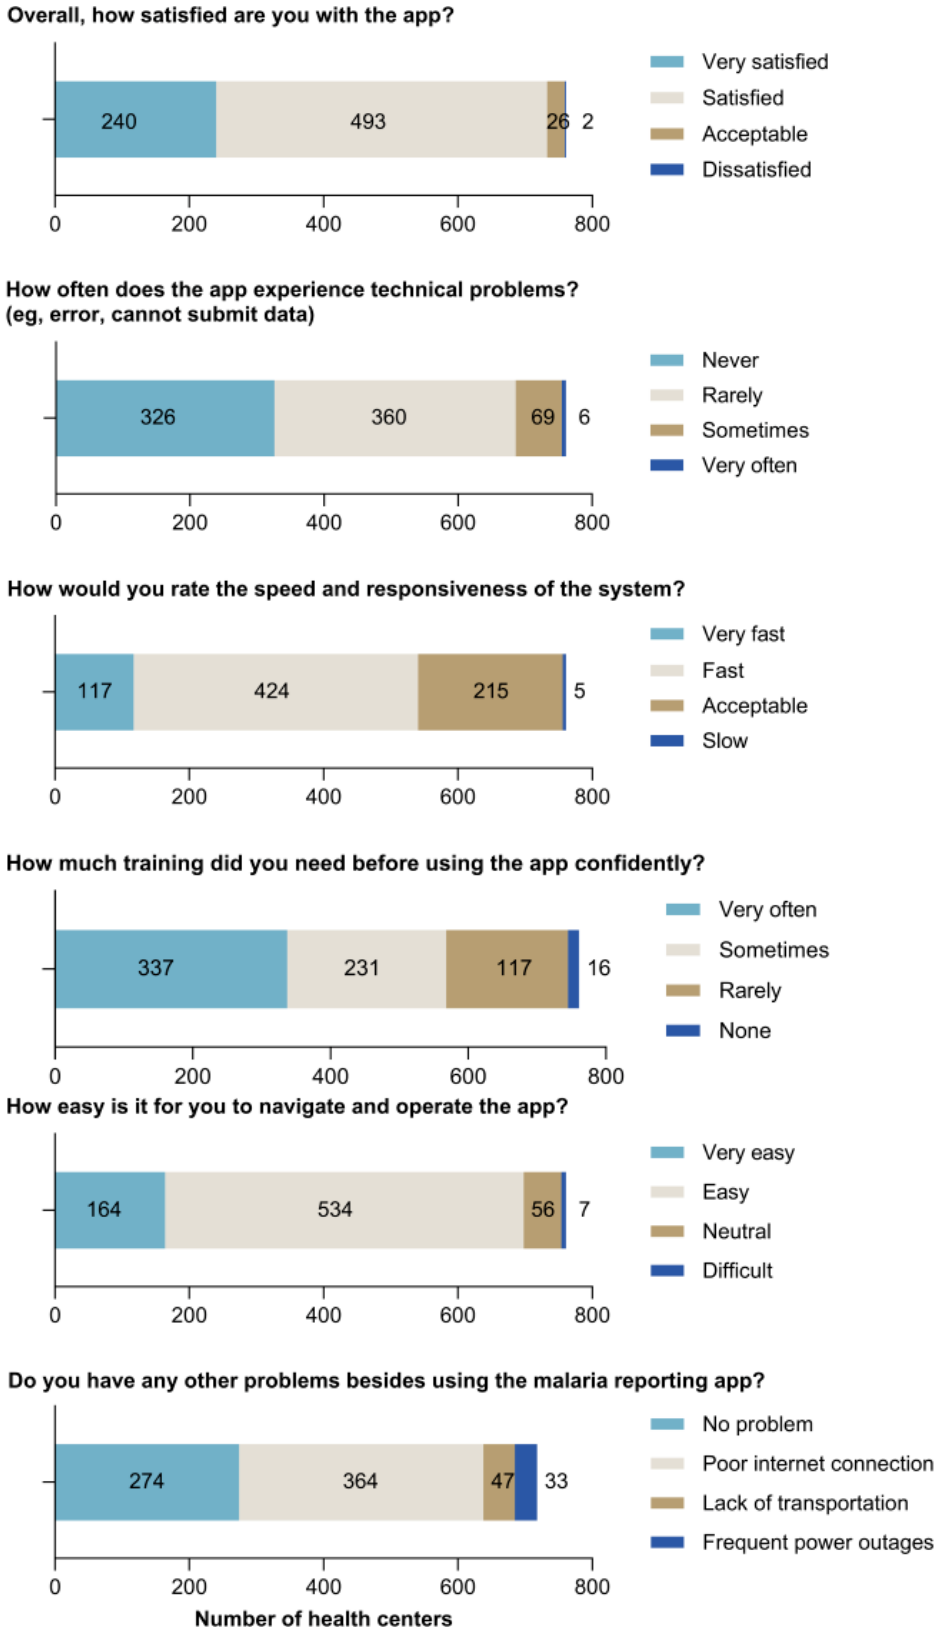
**Figure 5.** Snapshot of indicators of surveillance performance from the Malaria Information System dashboard. (**A**) Number of malaria cases and reporting route (January 2022 to September 2025). (**B**) Status of malaria cases in Cambodia (January to September 2025). (**C**) Performance against 1-3-7 targets (January to September 2025). These outputs are automatically generated from data submitted via the health center and VMW apps and included on the dashboard. The figure was derived with permission from CNM's online malaria information system available via their website [36].

XSL•FO
RenderX

**Figure 6.** Core surveillance indicators for malaria stratification from the Malaria Information System dashboard. (**A**) Annual blood examination rate (ABER) (January to September 2025), defined as the number of blood samples tested, divided by the total population, then multiplying by 100. (**B**) Annual parasite index (API) (January to September 2025), defined as the number of confirmed malaria cases per 1000 people within a specific geographic area and time period. These outputs are automatically generated from data submitted via the health center and VMW apps and included on the dashboard. The figure was derived with permission from CNM's online malaria information system available via their website [36].

XSL•FO
RenderX

For ABER (Figure 6A), the proportion of the population tested annually indicates surveillance coverage. While ≥10% is recommended in control settings, elimination contexts require more targeted approaches, such as reactive testing and screening high-risk groups. Therefore, high ABER is expected in high-risk areas and lower in areas where risk is minimal. For API (Figure 6B), confirmed cases per 1000 people; measures transmission intensity and guides intervention focus. In elimination settings with low incidence, uneven surveillance can distort API, so village-level granularity is critical. Cambodia's low API supports readiness for national elimination.



### User Feedback

A usability and satisfaction survey conducted in July 2025 of all health centers received responses from 86.3% (761/882) of facilities within 1 month (Figure 7). Overall, 96.3% (733/761) of health centers were satisfied or very satisfied with the app, 90.1% (686/761) found that technical issues were rare or absent, and 71.1% (541/761) thought that system speed was fast or very fast. Although 44.3% (337/761) of centers confirmed that they needed regular training on the app, 91.7% (698/761) found navigating the app easy or very easy. Other common issues that impacted surveillance activities were poor internet connection, a lack of transportation to reach remote locations, and frequent power outages (Figure 7). This highlights the infrastructure constraints that had to be considered during the MIS system design.

XSL•FO
RenderX

**Figure 7.** Health center user feedback on app technical performance and usability. The figure was derived with permission from CNM's online malaria information system available via their website [36].

The most recent in-depth survey was conducted in 9 randomly selected health centers across Battambang, Kampong Speu, and Mondul Kiri provinces (August-November 2024). Responses were obtained from the designated malaria focal person at each health center, all of whom had received standardized training on the use of the health center app and surveillance.

All 9 centers were aware of malaria reporting mandates, the requirement for case-based data submission, and national surveillance guidelines, demonstrating strong procedural awareness. All used both the health center app and CNM-issued paper forms (not processed, retained for audit purposes). All health centers confirmed immediate case reporting and

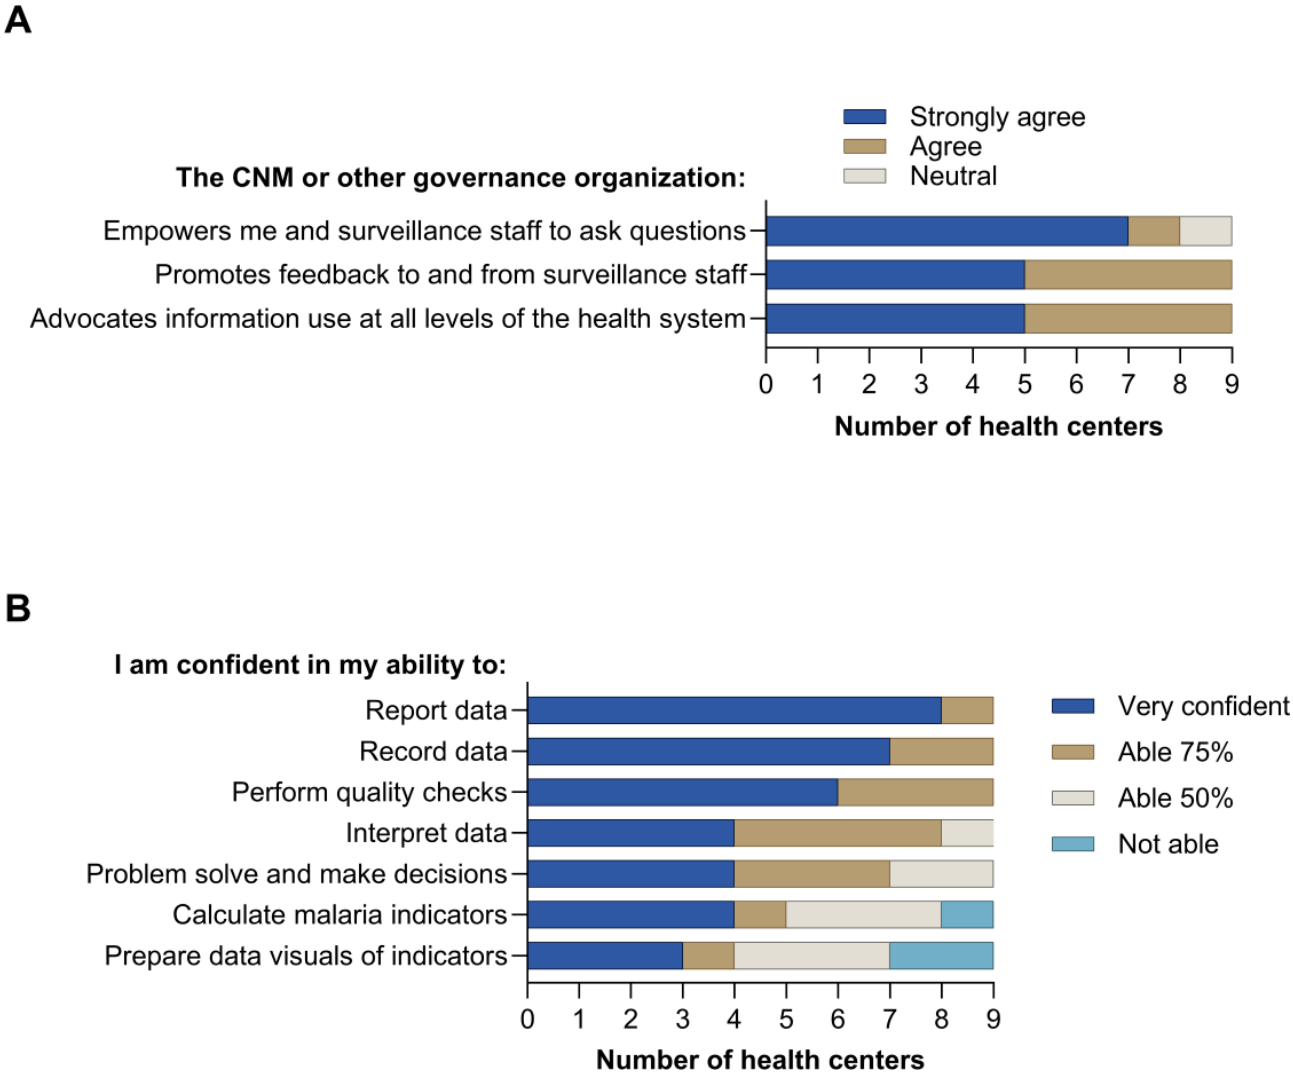
XSL•FO
RenderX

compliance with WHO recommendations, including reporting zero cases, demonstrating high uptake and process adherence. Their understanding of surveillance objectives showed alignment with programmatic goals (Textbox 1) [20,21].

**Textbox 1.** Summary of health center perceptions of the purposes of surveillance.

- The system is designed to monitor malaria trends and track the number of tests conducted, regardless of whether they are few or many.
- It serves as a reminder and alert to keep health workers aware of the current malaria situation, helping them understand fluctuations over time.
- By tracking malaria cases, it enables identification of areas at risk and provides real-time data, making it easier to generate timely reports.
- Reports can be accurately managed at the health center level and efficiently shared with higher levels of the health system.
- The data are valuable for understanding where malaria cases are concentrated, whether in villages with many or few cases, and supports planning for the following month or year.

Self-reported comprehension of surveillance data was high: 100% at 3 centers, 80% at 6 centers. All found job-aids and SOPs clear, although one center noted complexity requiring further training. All centers knew where to seek support, indicating adequate system support. Eight of 9 centers conducted monthly data quality checks, all had supervision records; recent supervisory visits included data quality assessments, corrective actions, and written feedback, with standardized checklists used in 8/9 cases.



Staffing was adequate, with 6 centers reporting the correct number of staff (between 1 and 5 persons), 2 centers needed an additional staff member each, and 1 center had 1 more member of staff versus requirements. All centers had patient record books and tablets, with all tablets operational over the previous 30 days. This probably reflects the app's device management module which supports a high level of functionality by quickly identifying technical issues. Three centers had computers and 5 had printers, with 1 computer and 2 printers fully functional for the last 30 days. Printers and computers are maintained locally, often with limited technical support. Infrastructure challenges persist: 4 centers experienced power issues, 3 had internet disruptions, and 2 had temporary system failures in the past 4 weeks. However, all centers reported access to troubleshooting support. Stock-outs pose a risk to elimination efforts and one Mondul Kiri center experienced a stock-out of RDTs and ACTs, highlighting the need for responsive surveillance systems in the preelimination phase.

All centers accessed dashboard visualizations and 4 downloaded data for further analysis. All held data review meetings, with bulletins produced in 6 centers. However, only 5/9 could calculate key indicators, with gaps in training and data availability reported in several centers. Despite this, 8 centers accessed data daily or weekly, and all at least monthly, and feedback on CNM and partner support was positive (Figure 8A). Consistent with the annual training cascade, all health centers received surveillance training in the previous 12 months on case notification, supervision, case data review, case report compilation, and recording of patient information. Six centers also received training on report preparation and 8 on data analysis and use. While confidence was high for data entry and quality checks, staff were less confident in calculating indicators and preparing visual outputs (Figure 8B).

XSL•FO
RenderX

**Figure 8.** Health center user feedback on surveillance activities supported by the health center app. (**A**) Feedback on the supportive supervision of CNM (the National Center for Parasitology, Entomology and Malaria Control) regarding surveillance. (**B**) Confidence of users in their ability to conduct core surveillance activities, analyze data and interpret and use data. The figure was derived with permission from CNM's online malaria information system available via their website [36].

## Discussion

### Study Findings and Generalizability

The Cambodian health center app constitutes a pivotal component of the national malaria surveillance system, enabling real-time, case-based data capture from endemic districts. By facilitating structured digital reporting at the point of care, the system improves the timeliness and completeness of malaria case notification, supports treatment adherence, and permits granular analysis of clinical and epidemiological data, enhancing case classification accuracy and enabling faster public health responses.

Effective surveillance prevents delayed treatment and onward transmission. The key strength of case-based data are alignment with the 1-3-7 surveillance framework [13,14]. This strategy contributed to malaria elimination in China, and similar approaches have been adopted in Cambodia, Thailand, Lao PDR, Myanmar, Viet Nam, India, Tanzania, and Zambia [13,14,38]. In Cambodia, digital surveillance at the point-of-care enables timely case management and follow-up, meeting 1-3-7 targets while integrating drug efficacy surveillance to ensure that treatments remain effective. At the same time, the Cambodian MIS fulfills WHO requirements for malaria elimination certification, ie, the surveillance system must be able to detect, investigate, and classify cases as locally acquired or imported [39]. Thus, no additional systems are required, avoiding duplication of effort in preparing for malaria certification.

While grounded in a specific country context, the challenges addressed by the health facility app are common across malaria-eliminating countries globally; malaria becomes increasingly spatially and temporally heterogeneous, focused in hard-to-reach communities. In Cambodia, geolocated case data have revealed persistent transmission in border and forested regions despite low overall case numbers, allowing tailored vector control and community engagement strategies [32,40]. Without sufficiently sensitive and sustainable surveillance, hard-won gains can be quickly lost following the withdrawal of control measures, as outbreaks in at-risk communities spread unchecked [41]. For example, in Sri Lanka in the 1960s, the Huai River basin in China in the 1960s and 1970s, and more

XSL•FO
RenderX

recently in Thailand in 2017 [42-44]. Sub-national tailoring of interventions based on risk stratification informed by real-time surveillance allows targeting of residual foci and prompt identification and control of outbreaks, preventing resurgence [45].

As Cambodia moves toward a postelimination phase, emphasis will shift from local transmission detection to identifying imported cases, especially across porous international borders. Vigilance must be maintained and malaria should still be perceived as a threat both in terms of the risk of resurgence and for individual patients who may be at risk of poor outcomes if presentation, diagnosis and treatment are delayed [43,46]. The health facility app is integrated with complementary tools such as the VMW app, allowing detection in both formal health facilities and community settings. This digitally integrated approach allows the surveillance system to transition seamlessly from elimination to postelimination activities.

Sustainability is essential. Global funding is contracting, and as malaria cases decline, there is a risk of de-prioritization within national health budgets. The sustainable design principles applied to the Cambodian MIS and mobile reporting apps have broad applicability: national ownership, low recurrent costs, offline-first functionality, integration with routine workflows, efficient training requirements, and the ability to adapt rapidly to evolving epidemiological and programmatic needs while avoiding duplication. By contrast, a mobile case-based surveillance system in Myanmar struggled with long-term sustainability due to heavy reliance on external support, duplicated systems, and dependence on internet access [47-49].

In a broader context, the Cambodian MIS is an example of a successful digital health system implemented in a low-resource setting. Digital health tools show potential to widen care access and improve service quality, but in many low-resource countries progress has stalled at brief pilot stages with limited scale-up and unclear long-term viability [50]. A systematic review of digital health interventions in low-and middle-income countries identified barriers relating to infrastructure, equipment, internet access, electricity, and the nature of the intervention [51]. Facilitators were associated with stakeholder commitment and participation [51]. The experience of Cambodia illustrates that meaningful local involvement in design, deployment, and ongoing development is fundamental to context-specific problem solving and ensuring that systems remain flexible and robust in the face of evolving operational demands [52].

## Limitations

Despite the system's strengths, challenges persist. While reporting and data entry have been widely adopted, gaps remain in health center staff's capacity to analyze, interpret, and act on data. Although the dashboard offers summary indicators, users often lack the skills to conduct more complex analyses, even when data are exportable to Excel. Limited digital literacy and a lack of tailored analytic tools at the local level restrict the full use of surveillance data for decision-making.

Connectivity remains another constraint, particularly in remote areas. Although the system supports offline data entry, delayed synchronization still occurs, potentially affecting real-time response and 1-3-7 targets. Despite the expansion of internet access in Cambodia, this issue is clearly still impacting day-to-day surveillance, with most health centers reporting poor internet connectivity. Similar challenges are a common issue for digital health interventions in low-resource settings [51].

## Future Directions

Expanding the analytical capacity of the app to address evolving user needs represents a key area for development. As malaria transmission becomes increasingly isolated, analytics must become more specialized. Centralized generation of customized reports or automated analytics tailored to specific settings could enhance data use at health centers. Additionally, broadening the training curriculum to emphasize data interpretation and visualization skills would strengthen local decision-making.

Future system upgrades could include integration with other data sources, such as population mobility, environmental data, and socioeconomic indicators. Linking health and geospatial data with climate datasets may allow more accurate prediction of transmission risk and better outbreak preparedness [53].

Post-elimination, the ability to rapidly stratify malaria risk in terms of environmental receptivity, historical transmission, and importation rate is required for the prevention of reestablishment of malaria transmission. Incorporating machine learning and predictive analytics could enhance early warning capabilities, automate anomaly detection, and support more targeted public health interventions [54]. Given the existing integration of the MIS with the National Malaria Laboratory, there is also potential for further molecular surveillance to discriminate between local and imported infections [55].

Finally, expanding the platform to support surveillance for other diseases or syndromic conditions typically encountered at health centers may increase long-term sustainability, reduce duplication within the health system, and build broader public health resilience in Cambodia.

## Conclusions

Without urgent commitments from the GMS countries, resistant *P. falciparum* could have spread globally, leading to a resurgence in the disease. The considerable investment in surveillance and its contribution toward malaria elimination in the GMS requires greater examination and recognition. Also, the experience of Cambodia and other GMS countries provides valuable learnings and templates for designing flexible surveillance systems which are applicable in other malaria endemic settings transitioning from burden reduction to targeting malaria elimination. This is particularly relevant given the emergence of artemisinin partial resistance in Africa [1].

This report showed that strengthening the functionality and reach of Cambodia's health center malaria surveillance app enhanced the efficiency and responsiveness of the national malaria elimination program. The app's integration of case-based reporting, interactive dashboards, and training modules supports data timeliness, completeness, and use, transforming surveillance from a passive reporting task into an active, data-driven tool for decision-making.

XSL•FO
RenderX

The system's national coverage and strong uptake among frontline health workers aim to capture every malaria case. Its open-source, in-house development model ensures adaptability to evolving operational needs, including new features for treatment adherence monitoring and foci response. Real-time data collection has facilitated high adherence to the 1-3-7 framework and informed targeted responses in residual transmission zones.

To ensure continued success and sustainability, future efforts should focus on strengthening analytic capacity among health center staff, addressing infrastructure limitations such as connectivity, developing predictive capabilities, and further integrating the app with other health and environmental information systems. Long-term sustainability will depend on continued political commitment, integration with surveillance for other health priorities, and active engagement of internal and external stakeholders. As Cambodia moves into the postelimination phase, a robust digital surveillance infrastructure is essential for protecting the population from malaria resurgence.

## Acknowledgments

Technical support was provided by the Mahidol Oxford Tropical Medicine Research Unit. Naomi Richardson (Magenta Communications Ltd) provided writing, editorial, and graphical services.

## Funding

Funding was provided by the Global Fund to Fight AIDS, Tuberculosis and Malaria, the World Health Organization, the U.S. President's Malaria Initiative, the United Nations Office for Project Services and the Bill and Melinda Gates Foundation (OPP1193472_2018). This publication was funded in whole, or in part, by the Wellcome Trust [220211/Z/20/Z]. ## Abstract

**Background:** Injuries are a major cause of death and disability, but cities often lack surveillance systems that can monitor injury burden across mechanisms, severity levels, and population groups. In Spain, no comprehensive city-level injury surveillance system routinely captures the full spectrum of injuries. The Barcelona Injury Surveillance System (BISS) was developed to address this gap by integrating routine health and police data.

**Objective:** This study aims to describe the BISS, including its scope, data sources, and public health rationale, and illustrate its utility through the analysis of recent injury data in Barcelona.

**Methods:** We conducted a descriptive study using routinely collected emergency department, hospital discharge, mortality, and police data integrated into the BISS. We analyzed nonfatal injuries in 2024, fatal injuries in 2023, and trends from 2018 onward. Injury indicators were examined by sex, age, mechanism, type, and severity. Crude and age-adjusted rates per 100,000 residents were calculated.

**Results:** In 2024, BISS recorded 123,420 emergency department injury episodes and 18,749 injury-related hospitalizations; among residents, these figures were 99,379 and 14,319, respectively. In 2023, 695 injury-related deaths were recorded among residents. Nonfatal injuries were slightly more frequent in females, especially at older ages, whereas injury-related mortality was higher in males. Falls were the leading specified mechanism and were concentrated among older females, particularly those aged ≥75 years. Self-harm hospitalization rates were highest among females aged 15 years to 24 years, whereas self-harm mortality was higher in males. Road traffic injury and overall mortality rates were also higher in males. From 2018 to 2024, most nonfatal injury indicators increased after the decline observed in 2020, while road traffic injuries declined overall.

**Conclusions:** BISS demonstrates the value of integrating routine health and police data to generate actionable urban injury intelligence. The findings highlight priorities for prevention, particularly falls in older females, self-harm in young females, and the persistently higher fatal injury burden among males. Integrated city-level surveillance systems such as BISS can support monitoring, equity-oriented prevention, and data-informed public health policy.

**KEYWORDS**

injury; surveillance; monitoring; inequalities; evaluation; injury severity

## Introduction

Injuries are a leading cause of death and disability worldwide and remain a major public health challenge across the life course [1,2]. Beyond fatalities, millions of nonfatal injuries require care in emergency departments (EDs), hospitals, and other health services, often resulting in long-term physical, psychological, and social consequences [2]. Injury burden is not evenly distributed: Marked differences are observed by age, sex, and socioeconomic status as well as by injury mechanism. Young men are disproportionately affected by road traffic injuries and interpersonal violence, whereas falls account for a substantial and increasing burden among older adults, particularly women [1,2]. These patterns underscore that injuries are not random

XSL•FO
RenderX

events but largely predictable and preventable outcomes shaped by social, environmental, and policy contexts [3].

Effective prevention requires timely, valid, and policy-relevant information on the frequency, characteristics, mechanisms, and severity of injuries as well as on the population groups most affected. Public health surveillance has been defined as the continuous and systematic collection, analysis, and interpretation of health-related data for the planning, implementation, and evaluation of public health practice [4]. Applied to injuries, surveillance systems can support prevention by identifying priorities, monitoring trends, detecting inequalities, and informing the design and evaluation of interventions [5,6]. Because injury risks and consequences differ by sex and intersect with other axes of inequality, injury surveillance should also support an equity-oriented perspective [5,6].

International organizations have long emphasized the importance of standardized injury surveillance. The World Health Organization (WHO) and the US Centers for Disease Control and Prevention (CDC) developed guidance on the establishment, coding, and use of injury surveillance systems [6,7]. In Europe, injury surveillance has also been promoted through harmonized initiatives such as the European Injury Database, which supports the production of comparable indicators across countries [8-10]. Together, these initiatives have highlighted the value of routine, standardized data from health services for understanding injury burden and guiding prevention policies.

In Spain, however, there is no comprehensive injury surveillance system routinely monitoring the full spectrum of injuries at the national, regional, or city level. Existing systems have been limited in scope, with the most established example being the Barcelona Traffic Injury Information System, which has monitored road traffic injuries using multiple sources since the late 1990s [11], or fatal injuries or injury discharges at the national level reported via Eurostat [10]. At the same time, other routine data sources—such as ED records, hospital discharge data, mortality registers, and police records—offer an important but underused opportunity to build broader injury surveillance capacity particularly at the local level, where prevention can be implemented. Integrating these sources is essential to moving beyond a fragmented understanding of injuries and toward a more complete picture of their magnitude, mechanisms, severity, and social patterning.

The Barcelona Injury Surveillance System (BISS) was developed by the Public Health Agency of Barcelona to address this gap. BISS brings together existing routine health and police data to support the epidemiological surveillance of injuries in the city, including road traffic injuries, falls, violence, self-harm, and other external causes treated in health services or recorded in mortality data. By generating standardized indicators and enabling analyses by sex, age, injury mechanism, severity, and other axes of inequality, BISS aims to support priority setting, prevention planning, monitoring, and evaluation from an urban and equity-oriented public health perspective.

This study aimed to describe the BISS, including its scope, data sources, and public health rationale, and illustrate its utility through the analysis of recent injury data in Barcelona.

## Methods

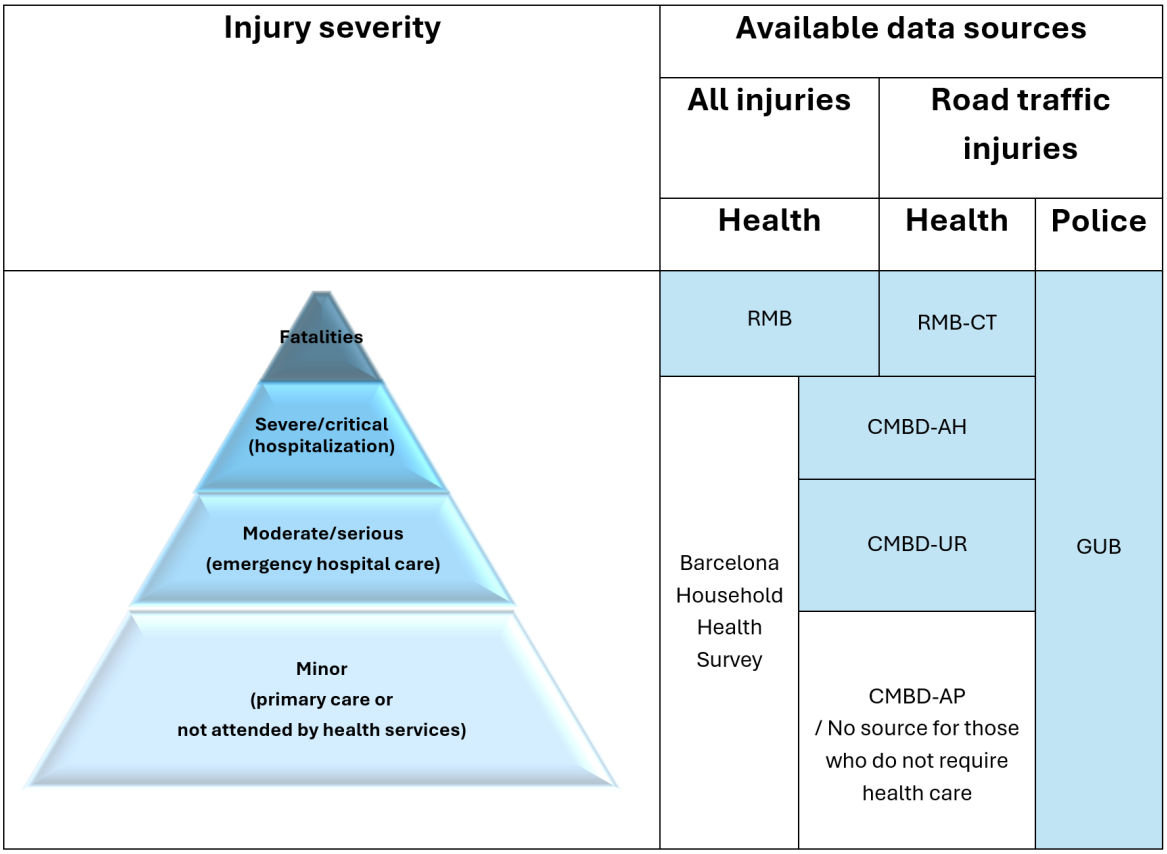
### Study Design

This observational, descriptive study of injury epidemiology used routinely collected health data in Barcelona integrated into a city-wide injury surveillance system. The BISS compiles and analyzes data on injuries from multiple existing databases (health, administrative, and police records) in a continuous manner. The study design was cross-sectional and retrospective, using pre-existing data. Key elements of the design include the integration of an established road traffic injury registry (the Barcelona Traffic Injury Information System, now a subsystem called BISS-RTI for road traffic injuries) into a broader all-injury surveillance framework. The analysis presented focused on injury data from the year 2024 for emergencies and hospitalizations, 2023 for mortality, and 2018 onward for trends.

### Setting

The study was set in the city of Barcelona, Spain, an urban area with approximately 1.6 million residents within a larger metropolitan region. The BISS covers injuries occurring among all persons in Barcelona, including residents, workers, visitors, and commuters within the city. We report on injuries that occurred or were treated in Barcelona during 2024 (with trend analyses from 2018 onward), encompassing incidents across the entire city.

### Participants and Study Population



The BISS does not enroll participants directly but instead includes all injury cases meeting specific criteria from each data source. The target population for surveillance is everyone who lives, works, or spends time in Barcelona—effectively the entire population at risk in the city. We included injury episodes (events) rather than unique individuals because one person may suffer multiple injuries over time.

We provide a visual overview of the data and inclusion process: Figure 1 illustrates the “injury pyramid” for Barcelona, showing all levels of injury severity, the available data sources at each level, and the portion covered by BISS multiple (not linked) databases (shaded in the figure). At the base, there are minor injuries, which are the most common and are either treated in primary care or do not require medical attention. The next level consists of moderate to severe injuries, which are typically treated in EDs. Serious or critical injuries, although less common, require emergency medical attention and frequently lead to hospital admission for further treatment. At the top of the pyramid are fatal injuries, some of which are treated in health services (emergency care and hospitalization), while others result in death at the site of the injury before medical help can be provided.

XSL•FO
RenderX

**Figure 1.** Pyramidal distribution of injuries due to external causes according to severity and available data sources for all injuries and specifically for traffic collision injuries; blue shading shows the coverage of the Barcelona Injury Surveillance System (BISS). CMBD: Register of the Minimum Basic Data Set in Spain; CMBD-AH: CMBD of hospital discharges; CMBD-AP: CMBD of primary care visits; CMBD-UR: CMBD of hospital emergency department visits; GUB: Register of Accidents and Victims by the Barcelona City Police, which does not include information on the nature and severity of injuries; RMB: Barcelona Mortality Register; RMB-CT: Barcelona Traffic Collision Mortality Register.

BISS covers moderate to fatal injuries by leveraging existing routine data sources in Barcelona, primarily health-related records that document injury diagnoses and mechanisms but also health surveys (no data included here). It includes moderate to critical injuries due to external causes using data from the Register of the Minimum Basic Data Set in Spain (CMBD; acronym in Catalan) for hospital emergencies and discharges. Additionally, fatalities resulting from external causes among Barcelona residents are recorded through the Barcelona Mortality Register (RMB; acronym in Catalan). Currently, milder injuries are not included, despite the availability of CMBD data for primary care, as the quality of injury coding from this source has not yet been assessed. However, this may be considered in future phases of the system.

In the specific case of BISS-RTI, in addition to moderate to critical injuries from the CMBD of emergencies and hospital discharges, there are 2 sources for traffic injuries: the Barcelona Traffic Collision Mortality Register (RMB-CT; acronym in Catalan), which provides information on all individuals who have died from traffic-related incidents in Barcelona including injury diagnoses, and the Road Traffic Collisions Register from the Municipal Police (GUB; acronym in Catalan), which is an exhaustive record of all traffic collisions in Barcelona and the individuals injured, ranging from minor to fatal. Although the GUB does not include injury diagnoses, it provides detailed information on the circumstances of each collision.

Eligibility criteria were defined by injury mechanism and severity using diagnostic codes and external cause codes. In general, BISS covers injuries requiring medical attendance up to fatalities, while minor injuries not requiring medical attention (or only primary care) are not yet captured. Specifically, to be included in BISS analyses, a case had to satisfy the data inclusion criteria for one of the BISS databases as outlined in Table 1. Table 1 also details the algorithms and codes used to identify eligible injury records from each source, such as *International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM)* external cause codes indicating injuries due to external causes, and location filters (eg, resident of Barcelona for mortality data). When there was an injury-related fatality at the ED or during hospitalization, records were classified according to the outcome (fatal vs nonfatal) to avoid double-counting deaths. In contrast, ED and hospitalization databases were not linked at the person level due to the lack of a personal identifier; consequently, some cases initially treated in the ED and later hospitalized may be counted in both sources.

## Data Sources

Multiple data sources were used to construct the BISS databases, each providing information on different segments of the injury pyramid. All sources consist of routinely collected administrative or medical records (and police records for road traffic injuries). The sources and their use in BISS are described in the following sections.

### *Hospital Emergency Department Data (CMBD-UR)*

The Urgencies Register (CMBD-UR) is a component of the regional CMBD and captures all ED visits in hospitals and emergency centers. For BISS, we extracted all ED records with an injury-related diagnosis or external cause code representing moderate or serious nonfatal injuries that received medical treatment. Each ED record includes up to 8 *ICD-10-CM* diagnosis codes and corresponding external cause codes for the injury. These data were considered comprehensive for hospital-attended injuries in the city, as the CMBD covers all public and most private hospitals in Catalonia.

### *Hospital Discharge Data (CMBD-AH)*

The Hospital Discharge Register, another part of the CMBD, records all inpatient admissions in Catalonia's hospitals. We included records of patients hospitalized for injury (again identified via *ICD-10-CM* external cause and diagnosis codes). These represent serious-to-critical injuries requiring admission. Each record can contain up to 15 diagnosis codes. By using both ED and admission data, BISS distinguishes injuries treated and released from the hospital versus those severe enough to require hospitalization.

### *Mortality Register (RMB)*

The RMB collects data on all deaths of Barcelona residents, with cause of death coded in *ICD-10*. For BISS, we extracted injury-related deaths (external cause of mortality codes V01-Y89). The RMB data ensure coverage of fatal injuries among city residents, whether the death occurred in Barcelona or elsewhere. However, the mortality database does not provide detailed injury diagnoses (beyond the underlying cause of death), which limits certain indicators (eg, we cannot identify trauma subtype for all fatalities).

### *Traffic Fatalities Register (RMB-CT)*

The RMB-CT is a specialized subset of the mortality data focusing on road traffic injury–related deaths in Barcelona. It is compiled by deterministically linking multiple sources: the general mortality data, records from the Institute of Legal Medicine and Forensic Sciences of Catalonia (ie, autopsy and forensic reports), civil death certificates, and police reports. This person-level data linkage allows the collection of detailed information on each traffic fatality, including injury diagnoses from an autopsy, circumstances of the crash, and victim details. The RMB-CT thus provides rich verification of road traffic death cases beyond the death certificate alone. Data from RMB-CT feed into the BISS MORTAL-RTI database (fatal road traffic injuries). The RMB includes all deaths of individuals residing in Barcelona, regardless of whether the death occurred within the city or elsewhere (manual available at [12]).

### *Police Traffic Injury Database (GUB)*

The GUB records all traffic collisions in Barcelona that result in personal injury (from minor to fatal). This source does not include medical information like injury diagnoses, but it captures the context of each collision (eg, date, location, types of vehicles, road conditions) and basic information on persons injured (age, sex, road user role). The police criteria consider a [13] person injured if they require any form of medical attention at the scene or afterward. The GUB data are used for the BISS INJURED-RTI database (nonfatal traffic injuries, including minor injuries not seen in hospital records) and for calculating total collisions and total injured persons in traffic (indicators 54 - 60). Police data were not directly linked to hospital records at the individual level for this analysis (ie, we did not attempt to deduplicate police-reported injuries against hospital-treated injuries) but were rather analyzed as a complementary dataset to provide information on minor injuries and collision circumstances [14].

Therefore, the BISS-RTI is fed by the 3 data sources from the Barcelona Traffic Injuries and Accidents Information System [14-17]:

- The CMBD-AH and CMBD-UR, using an injury definition for traffic-related incidents established by the "Working Group of the Spanish Society of Epidemiology on the measurement of the health impact of injuries in Spain" [18]
- The GUB, which is based on traffic collision reports from the Barcelona City Police, providing comprehensive information on the circumstances of collisions that occur within the city
- The RMB-CT

## BISS Databases and Injury Subsets and Surveillance Indicators

Based on the data sources from the CMBD-UR, CMBD-AH, RMB, RMB-RTI, and GUB and applying the data inclusion criteria outlined in Table 1, 5 databases were generated for the BISS: ED: emergency department visit data; HOSP: hospital discharge data; MORTALITY: injury-related mortality data; MORTAL-RTI: road traffic injury–related mortality data; and INJURED-RTI: data for people with a road traffic–related injury.

From these 5 databases (ED, HOSP, MORTALITY, MORTAL-RTI, and INJURED-RTI), 8 subsets of injuries to be monitored were generated (one for general injuries and another for traffic collision injuries) and labeled as A, B, C, D, E, F, G, and H.

Table 1 presents the data sources feeding into the BISS, the 5 derived databases, and the 8 resulting injury subsets. They further list the selection criteria applied to each data source and subset, along with the corresponding surveillance indicators used for monitoring. An episode of injury refers to an incident that, due to an external cause, results in harm to an individual. For nonfatal injuries, we referred to episodes rather than individuals, as a single person may experience multiple injury episodes throughout their lifetime.

XSL•FO
RenderX

## Variables

The primary outcomes of interest were counts and rates of injury cases across various categories (nonfatal injuries treated in EDs, nonfatal injuries requiring hospitalization, and fatal injuries). Rather than traditional "exposures" and "confounders" as in an etiologic study, this surveillance system tracked descriptive variables such as demographics, injury mechanisms, and severities for each case. Key variables included in BISS databases are listed in Table 2. These include basic demographics (sex, age, and country and municipality of residence), injury descriptors (date of injury or admission, diagnosis codes, and external cause codes specifying mechanism and intent), clinical outcomes (hospital discharge disposition, such as survival or death, and injury severity), and traffic-specific variables for road traffic injuries (eg, road user type, collision circumstances from police records). Table 2 displays which variables are available in each of the 5 BISS databases: ED (ED visits), HOSP (hospital admissions/discharges), MORTALITY (fatal injuries among Barcelona residents), MORTAL-RTI (fatal road traffic injuries in Barcelona), and INJURED-RTI (police-reported traffic collision injuries). A "✓" indicates the variable is present in a given database. For example, injury diagnosis codes (*ICD-10-CM*) are recorded in the health databases (ED, HOSP) with multiple diagnosis fields available and in the forensic mortality data (MORTAL-RTI) but are not recorded in the police injury database. External cause codes (*ICD-10-CM*) for the injury mechanism are captured in ED and HOSP records but not in mortality data. The severity of injuries is determined differently in police records versus medical records: Medical records allow derivation of severity via the Maximum Abbreviated Injury Scale (MAIS; from *ICD-10-CM* diagnoses), whereas the police database (INJURED-RTI) uses its own criterion of whether an injury required medical attention (not anatomic severity score). All coding frameworks (*ICD-10-CM* for diagnoses and external causes and *ICD-10* for causes of death) and classification schemes (eg, CDC's injury matrices for intent and mechanism) used to define variables are consistent with international standards.

Table 3 provides a description of the variables considered in the BISS, including the possible values assigned to each. A more detailed description of each variable is provided in Multimedia Appendix 1.

### Selection and Definition of Indicators

In addition to these variables, the BISS defines a set of surveillance indicators. Each indicator corresponds to a specific subset of injuries (eg, by severity, mechanism) and a measure (number of cases, rates). For example, indicators include counts of nonfatal hospital-treated injuries, counts of traffic-related injuries, counts of severe injuries, mortality counts by cause, and population-based rates for these events. These indicators were carefully selected to ensure comparability at the international level, aligning with global standards. The system relies on standard classifications, as outlined in the previous section, to provide a consistent and reliable framework for injury surveillance and analysis.

The selection of the indicator package for the BISS was conducted through an extensive review of scientific literature and official sources. The process involved searches in PubMed, as well as portals of the Spanish Ministry of Health, the European Commission, and the US CDC. Key reference publications included the report by the Spanish Ministry of Health, *Indicators of Morbidity and Mortality of Injuries Due to Traffic Accidents* [22], and the European Core Health Indicators proposal [23].

Additionally, publications and tools from the European Injury Database of the European Commission [24] were considered, as well as the CDC's *State Injury Indicators Report: Instructions for Preparing 2020 Data* [7] and associated tools [25]. These references provided a robust basis for selecting internationally aligned and evidence-based indicators.

The BISS compiles a comprehensive set of 60 indicators organized into 5 categories to monitor the morbidity and mortality associated with injuries from external causes and to track their temporal evolution (Table 4):

1. Nonfatal injury indicators (indicators 1 - 22): These indicators track nonfatal injury episodes based on the type of health care required (eg, hospital emergency or hospitalization departments), the mechanism and intentionality of the injury, and the severity.
2. Traffic collision nonfatal injury indicators (indicators 23 - 38): This subset includes 16 indicators specific to nonfatal injuries resulting from traffic collisions and classified by health care requirements (eg, hospital emergency or hospitalization), severity, and user type (eg, pedestrian, cyclist, driver).
3. Mortality indicators for external causes (indicators 39 - 48): These 10 indicators focus on mortality caused by external factors and are categorized by the mechanism of the basic cause of death.
4. Traffic collision mortality indicators (indicators 49 - 53): This set includes 5 indicators specific to traffic collision–related mortality distinguished by the type of user involved.
5. Traffic collision and injury indicators (indicators 54 - 60): These 7 indicators measure the total number of traffic collisions where medical assistance was required and the total number of injured persons without differentiating severity or type of assistance but classified by the type of user.

Table 4 provides a comprehensive overview of the 60 indicators used by the BISS, detailing their corresponding data sources, databases, and injury subsets from which they are derived. It also specifies the inclusion and definition criteria applied to each database, ensuring clarity and consistency in categorization and monitoring. Complementing this, Table 4 outlines the specific definition criteria for each indicator, offering a detailed account of how they are constructed and classified, including any known limitations. This table serves as key references for understanding the methodological framework and scope of the BISS injury surveillance system.

## Quantitative Variables

Several continuous or quantitative variables in the dataset were categorized or summarized for analysis.

Age was analyzed in age groups rather than as a continuous variable. We used the following standard age bands: 0 - 14 years, 15 - 24 years, 25 - 44 years, 45 - 64 years, 65 - 74 years, and ≥75 years. These groupings align with public health reporting standards and facilitate age-specific rate calculations and comparisons across demographic subpopulations.

Injury severity (as derived from *ICD-10-CM* diagnoses using Abbreviated Injury Score [AIS] or MAIS scores) was dichotomized into severe/critical versus nonsevere. Specifically, injuries with MAIS≥3 were considered “severe” (including critical injuries), while those with MAIS<3 were considered moderate (or minor) injuries. This threshold is commonly used in injury epidemiology to identify serious injuries and was chosen based on international definitions. Some indicators (eg, indicators 2, 12, 24, 32) specifically track the subset of cases meeting this MAIS≥3 criterion.

Time variables such as dates (admission date, discharge date, and collision date) were mainly used for record criteria and calculating durations (eg, length of hospital stay, time trends by year). For annual surveillance reporting, we aggregated data by calendar year. No seasonal nor monthly analyses are presented in this paper, so dates were not explicitly categorized by month or season in this analysis.

Population denominators for rate calculations (number of residents of Barcelona) were treated as continuous counts but were effectively fixed values for each year and each demographic stratum. For standardization, we used the average population of Barcelona across the analysis period as a standard population.

All other variables (eg, sex , mechanism categories, intent) were analyzed as categorical variables, with categories as defined in Table 3. For instance, mechanism of injury has categories like traffic, falls, and burns; intentionality has categories such as unintentional, assault, and self-harm. These categorizations were predetermined based on public health definitions and the coding structure. Grouping of continuous data (eg, age, injury severity scores) was done to enhance interpretability and align with existing frameworks for injury surveillance.

## Bias

Because this study was based on routinely collected data, we considered several potential sources of bias and took steps to address them where possible.

### *Selection Bias*

The BISS was designed to be population-based and exhaustive for the defined inclusion criteria, minimizing selection bias. All eligible injury events recorded in the source databases were included (no sampling). However, by design, we excluded minor injuries not captured in hospital or police records, which could bias the overall injury counts toward more severe cases. We acknowledge that the current system underrepresents minor injuries (those only seen in primary care or not treated), an issue

XSL•FO
RenderX

we plan to address in future expansions of BISS. In terms of geographic inclusion, hospital records included injuries treated in Barcelona hospitals even if the injury occurred outside the city; thus, there was potential overinclusion of cases not actually stemming from Barcelona incidents. To mitigate this, for mortality, we restricted to city residents, and for nonfatal indicators, we interpreted results with caution, noting that some hospital-treated injuries might be from outside incidents (this is listed as a limitation in relevant indicators, and population rate denominators use city residents who could slightly overestimate true incidence). Conversely, some injuries that occurred in Barcelona may have been treated outside the city (eg, in neighboring municipalities), leading to underascertainment of certain cases. This was likely minimal for serious injuries given the concentration of tertiary hospitals in Barcelona.

### *Information Bias (Misclassification)*

We relied on coding in administrative data, which could have led to misclassification of injuries or causes (eg, errors in *ICD-10* coding). To address this, we used previously validated coding algorithms and standard definitions for identifying injury mechanisms and outcomes, and we referenced validation studies of *ICD* coding in Spain when available. For example, the definition of traffic injury cases was based on a published algorithm [26], and all cause-of-death coding followed official mortality coding standards, reducing misclassification of injury deaths. Still, coding inconsistencies were possible (eg, variation in external cause coding practices between hospitals). The inclusion of multiple sources and the focus on broad categories of injuries (rather than single *ICD* codes) helped dilute some random misclassification. We did not have access to independent verification of each case's details, so some misclassification bias (in injury mechanism or severity) may remain.

### *Confounding*

Since this was primarily a descriptive study, confounding (as in risk factor/outcome relationships) was not a major concern. We were not examining an exposure-outcome causal hypothesis but rather summarizing injury occurrence. Therefore, we did not need to control for confounders via stratification or modeling. However, when comparing subgroups (eg, injury rates by sex), we used age-standardized rates to account for confounding by age structure in sex comparisons.

### *Summary of Bias*

In summary, the design inherently covered the population of interest and used robust data sources, which helped mitigate selection bias. We made efforts to ensure consistency and accuracy in case definitions to minimize information bias.

## Study Size

No a priori sample size calculation was needed because this study included the entire target population of injury events meeting the inclusion criteria in 2018 through 2024. The effective sample size was determined by the number of eligible injury cases recorded in the data sources. By leveraging whole-population data, the study aimed for comprehensive coverage rather than a targeted enrollment number. The study size was thus fixed by data availability: All relevant records for the year were included. This yielded sufficient numbers to produce stable estimate rates for most indicators at the city level. Where certain subcategory counts were small (for rare causes of injury or specific subpopulations), the results were still reported but interpreted with caution.

## Statistical Methods

All statistical methods applied in this study were descriptive and were planned with the goal of comprehensive surveillance reporting. We did not use inferential statistical tests or complex models; instead, we produced frequency distributions and rate calculations as described in the following paragraphs.

We generated annual summary tables of injury counts and proportions stratified by key variables. For example, we tabulated the number of injury cases by sex, age group, injury mechanism, and injury severity. In these tables, each cell shows the absolute number of cases and its percentage of the column or row total (eg, the proportion of all injuries that falls represent or the percentage of injuries occurring in a given age group). Separate tabulations were done for males and females to facilitate sex-specific insights.

For each of the defined indicators, we calculated the annual incidence rate per 100,000 population. The population denominators were drawn from the Barcelona Municipal Register of Inhabitants (Padron) for the corresponding year. We produced two main types of rate tables for each indicator: (1) overall and sex-specific rates (including crude and age-standardized rates for males and females) and (2) age-specific rates by sex. Age standardization was done using the direct method and the combined 2018‐2024 Barcelona population as the standard, to adjust for differences in age distribution when comparing sexes.

There were very few missing data for core variables due to the nature of the sources (eg, age and sex are almost always recorded in administrative data). If any key variable was missing, those records were still included in overall counts but excluded from stratified analyses requiring that variable. We did not need to apply any imputation, as missingness was minimal and not central to the indicators.

We did not perform analyses of subgroups or interactions beyond the stratifications by sex and age already described. The design of the indicators inherently stratified certain subgroups. We did not explicitly test interactions or perform subgroup hypothesis tests, since our focus was on reporting descriptive metrics rather than estimating effect sizes.

Given that our study was descriptive, we did not conduct formal sensitivity analyses. However, we did examine whether results were consistent over the time series (2018‐2024) as an informal check.

All analyses were performed using Stata 16 statistical software. Data cleaning and rate calculations were done using standard Stata procedures and validated by cross-checking selected results with an independent calculation. The statistical outputs (tables and figures) were then compiled for reporting, with no adjustments for multiple comparisons and no derivation of *P* values.

## Ethical Considerations

This study was based exclusively on anonymized secondary data collected within the routine mandate of public health authorities, which did not require review by a research ethics committee. All data were processed in compliance with applicable data protection regulations.

## Data Access and Cleaning Methods

Access to the underlying data was governed by institutional agreements, but within the research team, the investigators had full access to all relevant de-identified records used to create the study datasets. Specifically, the Public Health Agency of Barcelona has authorized access to the CMBD and mortality databases for surveillance purposes as well as to the police collision database through a collaboration with the city police. All data were handled in compliance with privacy regulations. Therefore, although raw data cannot be made public, the authors (analysts) could use the complete datasets for the purposes of this study. We also note that details on how to access supplemental materials (eg, coding lists or aggregate data tables) are provided in the manuscript or Multimedia Appendix 1 as needed.

Data cleaning procedures were carried out to ensure a high-quality analytic dataset. Key steps included filtering and case selection, merging and deduplication, coding harmonization, missing or inconsistent values, and linkage quality (if applicable).

For filtering and case selection, we applied the inclusion criteria algorithms (per Table 1) to each source to extract injury cases. This involved querying diagnosis and external cause code fields for relevant *ICD-10-CM* codes, selecting only Barcelona residents for the mortality dataset, and selecting only traffic-related cases for the BISS-RTI subsets using cause codes. We verified that these filters were correctly implemented by cross-checking data.

For merging and deduplication, records are uniquely identified within each data source. In the health datasets (ED and HOSP), it is possible that the same patient's care could generate multiple records (eg, an ED visit followed by an admission). Currently, due to the unavailability of a common patient ID, it was not possible to avoid double counting. We treated ED and HOSP data as separate strata and did not merge them at the patient level; an ED visit that became an admission would appear in both ED and HOSP databases. It was expected that, in the future, patient ID will be available for BISS and consequently, no double-counting would occur across ED versus HOSP indicators, making them mutually exclusive. In contrast, we ensured that deaths were only counted in the mortality datasets and not simultaneously in ED or HOSP (for example, if a person died in hospital, that case is recorded in the mortality register and in the HOSP data; for BISS reporting, we counted it as a death, not a nonfatal hospitalization). In the police data, each injured person in a collision is a separate record; if one person had multiple injury-causing collisions, they would appear multiple times, but each corresponds to a distinct event (this is consistent with the definition of counting episodes, not unique individuals).

Regarding coding harmonization, we standardized variable coding across data sources. For instance, we created common categorical variables for mechanism and intent of injury using *ICD* codes from health data and analogous categories from police data. We also mapped the police-defined road user categories to match the categories used in health data where possible. All *ICD-10* and *ICD-10-CM* codes were checked against their descriptions to confirm they were correctly grouped under each mechanism or intent category.

We also performed checks for impossible, inconsistent, or missing values (eg, negative ages, admission dates after discharge dates). No systematic issues were found; any obvious data errors were minimal, and those records were either corrected if possible or excluded if not critical. For example, if an ED record was missing age or sex, it would not contribute to age- or sex-specific analyses but would still be counted in total injuries.

Regarding linkage quality, in the RMB-CT (traffic fatality), data linkage between sources (forensic, police, and death certificate) is managed by a deterministic match (using identifiers like national ID, name, date of birth, and date of incident). The quality of these linkages is maintained by the Public Health Agency's longstanding procedures; for this study, we did not perform independent linkage, but we trusted the quality control in the existing RMB-CT process. All traffic deaths included have been vetted through that system. We did not link the police nonfatal records with hospital records due to lack of identifiers; thus, no probabilistic linkage procedure was required beyond what is done within the RMB-CT for fatalities.

Throughout, the data cleaning process was thoroughly documented. The code used for data processing and analysis is available upon request, and the study protocol and variable code lists are provided in Multimedia Appendix 1. These steps ensured that the final analytical datasets were accurate representations of the source data, with a harmonized structure and ready for calculating the injury indicators.

## Stakeholders Involved in the Injury Surveillance System

A wide range of stakeholders were involved in the development, implementation, and use of the injury surveillance system. These included public health officials, hospital and emergency care providers, epidemiologists, injury prevention specialists, data analysts, policy-makers, researchers, and representatives from affected communities. Each stakeholder group played a critical role in ensuring that the system generates accurate, relevant, and timely data to inform prevention strategies and health policies. Their active engagement enhanced the system's relevance, facilitated data interpretation, and support the translation of findings into effective public health action.

## Evaluation of the Surveillance System

The surveillance system will be evaluated following CDC guidelines to assess its performance and alignment with public health objectives. Key attributes—such as usefulness, simplicity, flexibility, data quality, acceptability, sensitivity, predictive value, representativeness, timeliness, and stability—will be

XSL•FO
RenderX

analyzed to identify strengths and areas for improvement. Evaluation findings will guide targeted recommendations, developed in consensus with stakeholders, and communicated in formats adapted to relevant audiences to support system enhancement.

### Dissemination of Surveillance System Results

The dissemination of results from the BISS is a critical step to ensure that collected data translate into effective public health action. Results will be shared systematically with key stakeholders. The planned dissemination includes a web-based dashboard featuring indicators displayed in tables, graphs, and maps across multiple years; reports, infographics, and policy briefs; peer-reviewed publications; and oral and poster presentations, including those at individual, community, and professional meetings. Efforts will be made to ensure that the results are communicated in a timely, accessible, and actionable manner, facilitating data-driven decision-making and strengthening injury prevention strategies across sectors.

## Results

### Age and Sex Distribution

Overall, 123,420 nonfatal injury episodes were recorded in 2024 in hospital EDs, of which 99,379 (80.5%) occurred among Barcelona residents. ED episodes were slightly more frequent in females than in males, both in total episodes (63,108 vs 60,312) and among residents (52,323 vs 47,056). A total of 18,749 nonfatal hospitalized injury episodes were recorded in 2024, of which 14,319 (76.4%) were among Barcelona residents. Hospitalized episodes were also somewhat more frequent in females than in males, both in total episodes (9645 vs 9104) and among residents (7916 vs 6403). In contrast, mortality data (year 2023) included 695 fatal injuries, all among Barcelona residents, of whom 388 were males and 307 were females (Table 5).

[a]For residents of Barcelona, the sex of 14 injured people was unknown, and the ages of 7 females and 65 males were also unknown. For nonresidents of Barcelona, the sex of 5 injured people was unknown, and the ages of 3 femals and 5 males were also unknown.

[b]Emergency department visit data.

[c]Hospital discharge data.

[d]Injury-related mortality data.

[e]Rates were calculated using as the numerator only men and women for whom age information was available.

[f]N/A: not applicable.

[g]AR: age-adjusted rate.

By sex, crude resident rates for nonfatal injuries were slightly higher for females than for males for both ED episodes (5854.2 vs 5743.9 per 100,000) and hospitalized episodes (885.8 vs 782.7 per 100,000). However, age-adjusted rates were higher for ED episodes in males younger than 45 years and hospitalized episodes in males younger than 75 years. For mortality, both crude and age-adjusted rates were clearly higher in males than in females (47.9 vs 34.6 per 100,000 and 55.6 vs 30.0 per 100,000, respectively), indicating a greater fatal injury burden among males.

Injury rates varied markedly by age. ED rates were higher in males at younger ages but higher in females at older ages, especially from the age of 65 years onward. Hospitalized injuries showed a similar pattern, with the highest rates in the oldest age groups, particularly among females. Fatal injury rates increased sharply with age in both sexes and were highest among adults aged 75 years or older.

## Injury Mechanism

Table 6 shows the distribution of injury episodes and deaths by injury mechanism in the ED, hospitalized, and mortality data sources. Missing or unspecified information was substantial, particularly in the ED database, where episodes without an external cause code accounted for 63.6% (38,337/60,312) of records for males and 62.8% (39,662/63,108) for females; the

XSL•FO
RenderX

corresponding proportions in hospitalized episodes were 20.4% (1854/9104) and 16.5% (1591/9645), respectively, while nonspecific mechanisms also represented a relevant share across all sources, especially mortality records. Among specified mechanisms, unintentional falls were the most frequent in both ED and hospitalized data and were consistently more common in females than in males (ED: 7052/63,108, 11.2% vs 4761/60,312, 7.9%; hospitalized: 4583/9645, 47.5% vs 2890/9104, 31.7%). Intentional self-harm was also frequent and occurred at higher proportions for females in the nonfatal data (ED: 2260/63,108, 3.6% vs 1515/60,312, 2.5%; hospitalized: 508/9645, 5.3% vs 311/9104, 3.4%), whereas males more often presented with aggression, motor vehicle traffic injuries, and several other unintentional mechanisms. In the mortality data, unintentional asphyxia was the leading specified mechanism and was more frequent for females (113/307, 36.8% vs 114/388, 29.4%), while intentional self-harm had the largest sex difference in the opposite direction, with markedly higher proportions among males than females (75/388, 19.3% vs 31/307, 10.1%).

## Nature of Injury, Anatomical Region, and Injury Severity

Table 7 shows the distribution of nonfatal injury episodes in 2024 by type of injury, anatomical region, and injury severity, separately for ED and hospitalized episodes and for males and females. In both care settings, substantial proportions of cases were coded as unspecified injury, particularly in ED episodes, where this category accounted for 37.3% (22,417/60,312) of episodes in males and 40.4% (25,470/63,108) of episodes in females, compared with 4% (362/9104) and 4.3% (411/9645), respectively, among hospitalized episodes. Among specified injury types, fractures were more frequent in females than in males and were especially prominent among hospitalized episodes (4855/9645, 50.3% in females vs 3812/9104, 41.9% in males), whereas open wounds were more common in men in both the ED and hospitalized data. Extremities and head and neck were the most frequently affected anatomical regions in both sexes, although trunk injuries represented a larger proportion of hospitalized episodes in males than in females.

XSL•FO
RenderX

Regarding injury severity, most episodes were classified as nonsevere, but severe injuries accounted for a considerable proportion of hospitalized episodes and were slightly more frequent in females than in males (4540/9645, 47.1% vs 4025/9104, 44.2%), while the proportion of episodes with unknown severity remained notable in both data sources.

**Table .** Nature of injury, anatomical region, and injury severity for episodes treated in hospital emergency services and discharged after hospitalization, by sex in the Barcelona Injury Surveillance System (BISS).

[a]ED: emergency department.

[b]Emergency department visit data.

[c]Each category of type of injury and anatomical region shows the number of people with an injury of that type or in that anatomical region; therefore, percentages sum to more than 100%, as one person may have multiple injuries affecting multiple regions.

[d]Hospital discharge data.

[e]Amputation, blood vessel, crushing, sprains and strains, injury to nerves, injury to muscles and tendons, other injury.

[f]MAIS: Maximum Abbreviated Injury Score.

[g]Includes episodes with diagnosis codes considered traumatic injuries according to the study definition and Centers for Disease Control and Prevention criteria but not mapped by the ICD Programs for Injury Categorization in R (ICDPIC-R) [27] because they do not correspond to anatomical injuries.

## Indicators

Table 8 shows a selection of indicators included in the BISS. Age-adjusted rates of all injuries, severe injuries, and traumatic brain injury were higher in males than in females in both the ED and hospitalization data. In the ED data, males had higher rates of all injuries (5873.1 vs 5619.6), severe injuries (1896.6 vs 1691.3), and traumatic brain injury (1120.8 vs 917.0).

XSL•FO
RenderX

However, mechanism-specific ED indicators (indicators 3 - 9) should be interpreted with caution because of the high proportion of missing values. In hospitalized episodes, males also had higher age-adjusted rates of all injuries (875.0 vs 788.5), severe injuries (283.0 vs 258.6), and traumatic brain injury (230.9 vs 187.3), whereas females showed higher rates of fall-related injuries (401.8 vs 341.4), long-bone fractures (253.5 vs 181.0), fall-related hip fractures among people aged ≥65 years (115.6 vs 69.5), and self-harm (50.4 vs 30.5). In contrast, assault-related hospitalization rates were higher in males (19.7 vs 4.8). Mortality rates were consistently higher in males, both overall (55.6 vs 30.0) and for specific causes, particularly unintentional suffocation (17.9 vs 10.8), self-harm/suicide (9.4 vs 3.3), falls (5.7 vs 3.4), drug poisoning/overdose (2.8 vs 0.9), and traffic-related injuries (2.1 vs 0.3).

[e]Data not available in the mortality register.

[f]TBI: traumatic brain injury.

Self-harm rates were highest among females aged 15 years through 24 years, who showed the greatest burden of all age-sex groups. In contrast, unintentional falls increased steeply with age and were particularly concentrated among older females, with the highest rates observed in those aged ≥65 years, especially among females aged ≥75 years (Table 9).

**Table .** Number of nonfatal episodes discharged after hospitalization and age-specific rates by sex for unintentional falls and self-harm related injuries in the resident Barcelona population, as recorded in the Barcelona Injury Surveillance System (BISS) in 2024.

| Mechanism by age group (years) | Males | | Females | |
|---|---|---|---|---|
| | Episodes, n | Episodes, age-specific rate × 100,000 population (residents) | Episodes, n | Episodes, age-specific rate × 100,000 population (residents) |

### Trends

From 2018 through 2024, nonfatal injury rates showed a dip in 2020 followed by a sustained increase in both sexes. Overall, ED-treated injuries rose slightly for males (+3.4%) and females (+3.2%), whereas severe ED-treated injuries increased markedly (+54.5% and +49.1%, respectively). Discharged injuries also increased in both sexes, with females consistently showing higher rates than males. Fall-related injuries rose sharply and remained substantially higher in females, while self-harm injuries increased in both sexes but increased more among females. In contrast, road traffic injuries declined overall, although rates remained consistently higher in males. Fatal injury rates (2018 - 2023) increased in both sexes, especially in males, who also had persistently higher mortality than females throughout the period (Table 10).

## Road Traffic Injuries

Table 11, which includes data from the road traffic injury subsystem and police records (GUB), shows a consistently higher burden of traffic-related injuries among males than among females across most indicators and data sources. All rates were calculated using the resident population as the denominator; therefore, the analysis was restricted to residents. For all injuries combined, males had higher numbers and crude rates than females for nonfatal ED episodes, nonfatal hospitalized episodes, fatalities, and injured people recorded in police data. Severe injuries (MAIS≥3) were also more frequent among males in both ED and hospitalized episodes. Motorcyclist injuries accounted for a substantial share of the burden, particularly among males, with markedly higher counts and rates across all available sources. Cyclist injuries and injuries

XSL•FO
RenderX

among users of personal transport devices were also more common in males. In contrast, pedestrian injuries showed a more balanced sex pattern: Although hospitalized pedestrian injuries were more frequent in males, police data recorded more injured female pedestrians than male pedestrians, and pedestrian fatalities were slightly higher among females. Car user injuries had smaller sex differences in the ED and hospitalized data, although police records still indicated higher numbers among males. Finally, traumatic brain injury was more frequent among males than females across ED, hospitalized, and fatal cases. Importantly, these resident-based estimates do not capture the full number of traffic-injured people occurring in the city, as many additional injured individuals were also recorded by the Guàrdia Urbana but were not included in the analytical rates because the denominator was restricted to residents only.

## Discussion

This study provides a comprehensive assessment of the burden of nonfatal and fatal injuries in Barcelona using an integrated injury information system based on ED, hospitalization, mortality, and, for road traffic injuries, police data. Several findings deserve emphasis. First, nonfatal injuries were slightly more frequent among females, particularly at older ages, whereas fatal injuries were clearly more frequent among males. Second, falls were the leading specified mechanism in nonfatal care and were concentrated among older females, while self-harm represented a marked burden among young females in hospitalization data but a higher mortality burden among males. Third, from 2018 through 2024, most nonfatal injury

XSL•FO
RenderX

indicators increased after the decline observed in 2020, whereas road traffic injuries showed an overall downward trend. Taken together, these findings highlight the heterogeneous distribution of injury burden by sex, age, mechanism, and severity and show the added value of combining multiple routine data sources to identify prevention priorities at the city level.

Our findings also underline the public health relevance of integrated injury surveillance. Surveillance has been defined as the ongoing, systematic collection, analysis, interpretation, and dissemination of health data needed for prevention and control, and WHO injury surveillance guidance similarly emphasizes that the ultimate purpose of injury data collection is to support prevention strategies that reduce death and disability. In this context, this study showed that a multisource system can do more than quantify service use: It can identify high-risk population groups, characterize the severity and mechanisms of injury, and monitor trends over time. This is particularly important in urban settings, where injury risks are shaped by mobility, aging, social context, and health care use and where prevention requires coordinated action across sectors [6,28].

The predominance of falls, especially among older females, is one of the most relevant findings of this study. Falls were the leading specified mechanism in both ED and hospitalized injury data, and rates increased sharply with age, with the highest burden observed in females aged ≥65 years, particularly those aged ≥75 years. This pattern is consistent with previous evidence showing that falls are a major cause of injury-related morbidity and mortality in older adults worldwide. WHO identifies falls as a major public health problem in older populations, and recent studies have shown that frailty substantially increases the long-term risk of fall- and fracture-related hospitalization, particularly among older women. Our findings therefore support the need to frame injury prevention in cities not only around transport safety but also around healthy aging, fall prevention, and the prevention of severe consequences such as fractures, loss of autonomy, and institutionalization [29,30].

Self-harm emerged as another key priority. In our data, hospitalization rates for self-harm were highest among females aged 15 years to 24 years, whereas mortality from self-harm was substantially higher among males. This distinction between nonfatal and fatal burden is important because it suggests that mortality data alone provide an incomplete picture of self-harm epidemiology. The findings are consistent with recent European evidence. In France, hospitalizations for self-harm have increased sharply among adolescent girls and young women since late 2020, and a nationwide registry-based study in Spain reported rising hospitalization rates for nonlethal intentional self-harm between 2018 and 2023, particularly among young women. This pattern is also supported by meta-analytic evidence showing a higher prevalence of self-injurious behaviors among adolescent females. Together, these findings reinforce the need for sex- and age-sensitive prevention strategies that connect injury surveillance with youth mental health services and suicide prevention policies [31,32].

The temporal trends observed in this study are also informative. The decline in nonfatal injuries in 2020 followed by a sustained increase is consistent with evidence from other settings showing reduced injury-related emergency visits during the first phase of the COVID-19 pandemic, likely reflecting both changes in exposure and changes in care-seeking behavior. After 2020, however, most nonfatal injury indicators, including severe injuries, falls, and self-harm, increased in Barcelona. In contrast, road traffic injuries declined overall. Although our study does not permit causal attribution, this decline is consistent with the long-standing urban mobility and road safety policies implemented in Barcelona and with previous evaluations showing that sustained interventions were associated with substantial reductions in traffic-related injuries over time. Recent work from Barcelona estimated that more than 34,800 road traffic injuries may have been prevented between 2008 and 2023, including approximately 1000 severe injuries. These contrasting trends suggest that, although progress may have been made in road safety, other injury mechanisms are emerging as equally important or growing priorities for urban public health action [13,33].

The Barcelona system provides actionable local evidence across multiple sectors, including health, mobility, mental health, and social care. At the same time, the results make clear that improvements in data quality remain essential. In particular, the high proportion of missing external cause coding in ED data, together with the share of unspecified injury diagnoses and unknown severity, limits the precision of mechanism-specific analyses in nonadmitted cases. In addition, because the system is primarily episode-based, repeated contacts related to the same injury event may not always be distinguishable in the absence of full linkage across all sources. Regarding harmonization, linkage and the potential for double counting are essential in multisource systems. Although previous work in Barcelona demonstrated the feasibility of probabilistic linkage between police and hospital ED data for road traffic injuries, this has not yet been adopted routinely within the surveillance system, partly because of data protection constraints [34]. Future development should therefore prioritize improved external cause coding, harmonized data standards, and secure linkage capacity across health and nonhealth data sources. Recent work on digital injury surveillance platforms and data science strategies for injury prevention suggests that these steps are critical to move from fragmented routine data to robust prevention intelligence [28,35]. Several limitations should be considered when interpreting these findings. First, missing or unspecified external cause information in ED data limits mechanism-specific interpretation for nonfatal injuries treated without admission. Second, differences in coding practices, completeness, and purpose across emergency, hospitalization, mortality, and police data sources may affect comparability. Third, because the system is largely episode-based, some repeated contacts may not be fully distinguishable without individual-level linkage across all sources. Finally, although the study provides a detailed and policy-relevant picture of injury burden in Barcelona, the findings are most directly applicable to this urban context and should be generalized cautiously to settings with different health systems, coding practices, or mobility patterns.

In conclusion, this study showed that an integrated city-level injury information system can provide a substantially richer picture of injury burden than isolated routine data sources. In

XSL•FO
RenderX

Barcelona, the current burden of injury is characterized by a high and increasing burden of falls among older females, an important burden of self-harm among young females, and persistently higher injury mortality among males alongside an overall decline in road traffic injuries. These findings suggest that urban injury prevention should now be framed more broadly than road safety alone and should incorporate healthy aging, fall prevention, and youth mental health as central priorities. More broadly, they support the role of integrated injury intelligence systems as essential public health tools for identifying priorities, monitoring change, and informing equitable prevention policy in cities.

## Acknowledgments

The authors declare the use of generative artificial intelligence (GAI) in the research and writing process. According to the GAIDeT taxonomy (2025), the following tasks were delegated to GAI tools under full human supervision: proofreading, editing, and translation. The GAI tool used was Microsoft Copilot with OpenAI GPT 5.4. Responsibility for the final manuscript lies entirely with the authors. GAI tools are not listed as authors and do not bear responsibility for the final outcomes. Declaration submitted by collective responsibility.

## Funding

The authors declare that financial support was received for the research, authorship, and/or publication of this article. Support was received from the Department of Research and Universities of the Generalitat de Catalunya (AGAUR), N. 2021 SGR 01462 and Partnership for Healthy Cities, Bloomberg Philanthropies, Vital Strategies.

## Data Availability

The injury datasets analyzed during this study were obtained from Agència de Salut Pública de Barcelona (ASPB; health data) and the Barcelona City Council (police data) under data use agreements and are not publicly available. Aggregated data tables are available from the corresponding author on reasonable request. The authors are committed to open science and will consider sharing de-identified individual data in accordance with privacy regulations and with permission of the source agencies.

## Conflicts of Interest

Department of Infectious Diseases Epidemiology, Robert Koch Institute, Seestr. 10, Berlin, State of Berlin, Germany

## Abstract

**Background:** Automated outbreak detection can enhance infectious disease surveillance by enabling early identification of outbreaks and supporting timely public health measures. However, information on its current use by national public health institutes remains limited.

**Objective:** This study aimed to provide an updated and extended overview of automated outbreak detection use in the European Union and the United Kingdom by (1) assessing current demand, (2) examining the availability of key prerequisites within existing surveillance systems, and (3) identifying challenges and requirements for implementation.

**Methods:** A mixed methods approach was applied as part of the Joint Action UNITED4Surveillance. Data were collected between April 2023 and January 2024 through an online survey sent to 25 countries, an in-person workshop with experts from 16 countries, and follow-up meetings with participating national public health institutes. Additional information for selected countries was obtained from the literature. Data were analyzed descriptively.

**Results:** Twenty-one countries completed the survey. In total, 33.3% (n=7) of the countries had established automated outbreak detection systems, 19% (n=4) were planning implementation, and 47.6% (n=10) participated in a pilot project. All surveyed countries reported acting on detected surveillance signals. Most had suitable surveillance infrastructure, including case-based data (n=20, 95.2%), daily reporting (n=21, 100%), and at least 3 years of historical data (n=21, 100%). Main barriers to implementation included limited funding (n=15, 71.4%), insufficient IT capacity, and data quality issues (n=9, 42.9%). Despite heterogeneity in methods and system design, outputs and user requirements were largely similar across countries, with needs for flexible outputs, stratification, and user-friendly interfaces.

**Conclusions:** While the specific methods in existing automated outbreak detection systems differ, overall demands and outputs are similar, suggesting that a single tool could serve multiple countries. European Union–funded Joint Actions may help address some of these barriers by supporting collaborative tool development and knowledge exchange.

public health surveillance; communicable diseases; disease outbreaks; algorithms; public health informatics

## Introduction

Timely detection of infectious disease outbreaks, enabling targeted investigations and control measures, is a core objective of public health surveillance [1,2]. Outbreak detection relies on identifying case numbers that exceed the expected threshold, typically recognized through accumulated case reports of notifiable diseases or outbreak notifications from reporting entities. With the growing availability of electronic case reports, automated outbreak detection has gained significant importance, offering a systematic approach to identify outbreaks [1,3,4].

Outbreak detection refers to the process of identifying unusual increases in case numbers by comparing the current epidemiological situation with a baseline, usually established from historical or geographical data. Statistical methods estimate the expected number of cases and compute a threshold. When observed values deviate significantly from these expectations, surpassing the threshold, signals are generated and often presented in tables, visualizations, or descriptive reports. These signals necessitate epidemiological investigations to determine whether they represent potential outbreaks or false positives [5].

XSL•FO
RenderX

Various methods for outbreak detection exist and have evolved over time [6-8]. Among the most widely used are the method by Farrington et al [9] and adaptations by Noufaily et al [10], which use generalized linear models to predict the expected number of cases accounting for seasonality, time trend, and overdispersion. Building on these methods, we can distinguish a hierarchy of components: statistical methods underlie tools that operationalize them, and some of these tools allow for the automated analysis of complete surveillance datasets. Here, automation means performing outbreak detection across relevant dimensions such as region, age, or subtype rather than sequentially inspecting individual strata and time series. Together with the necessary infrastructure, standard operating procedures, and trained personnel, these tools constitute comprehensive automated outbreak detection systems (AODSs).

Despite methodological advances, information on AODS implementation in the European Union (EU) is limited. The most recent overview from 2010 reported 6 institutes in 5 countries (Denmark, Germany, the Netherlands, Sweden, and the United Kingdom) using automated detection for routine surveillance. On the basis of the existing AODSs and practical experiences, recommendations were drawn, including the regular evaluation of AODSs and aiming for a user-friendly approach directed at epidemiologists [11,12]. Additionally, a 2017 workshop involving stakeholders from 17 institutions across the EU emphasized the exchange of data and experiences across countries, the need for visual outputs for users, and assessment and comparison of detection methods [13].

The EU4Health program is the EU's funding instrument for strengthening public health systems and preparedness. Within this program, Joint Action UNITED4Surveillance (U4S) brings together national public health institutes (NPHIs) across Europe to improve integrated infectious disease surveillance, including strengthening capacities for outbreak detection and response. One aim of U4S was to identify the requirements of EU countries for effective outbreak detection [14]. Understanding these needs and current practices is a necessary first step before developing and implementing new AODSs. While the project also involved developing and piloting an open-source R Shiny app for automated outbreak detection by multiple NPHIs, this study provides an updated and extended overview of automated outbreak detection use in EU countries and the United Kingdom. The analysis encompassed (1) assessing current demand for automated outbreak detection, (2) examining the availability of necessary prerequisites of surveillance systems, and (3) identifying challenges and requirements for running AODSs.

## Methods

### Overview

A mixed methods approach was used, combining a survey, a workshop, and online meetings as part of the U4S project. The United Kingdom and France did not participate in the survey but were included as additional case studies because the 2010 overview and the workshop described in the Introduction section identified these countries as operating relevant AODSs [11,13]. In the 2010 overview, UK systems were reported separately for England, Wales, and Northern Ireland. Therefore, our analysis distinguishes these jurisdictions where relevant. Reporting of this work followed the SRQR (Standards for Reporting Qualitative Research) [15].

### Questionnaire Development

A questionnaire was drafted with the goal of identifying gaps and needs from the perspective of epidemiology and data science. Respondents were asked to select one national surveillance system either in current use or considered most suitable for automated outbreak detection. The questionnaire had two sections: (1) description of public health surveillance systems, including types, legal frameworks, disease groups, data sources, aggregation level, reporting frequency, indicators, geographical resolution, and historical data availability; and (2) automated outbreak detection capacities, covering resource availability; signal follow-up; and details of existing methods, resources, and outputs.

The draft was reviewed by 6 project partners and a contact point at the European Centre for Disease Prevention and Control and revised accordingly. The final version (Multimedia Appendix 1) contained 33 questions, of which 22 were mandatory, primarily single- or multiple-choice rankings and free-text fields.

### Survey Administration

The survey was created using the EUSurvey platform and distributed on April 17, 2023, by the U4S coordinator to designated contact points of the 25 countries participating in the project. These contact points were representatives of the participating NPHIs or partner institutions and served as the official coordinators for project activities within their respective countries. They were asked to coordinate questionnaire completion with relevant national experts, including epidemiologists and data scientists, where necessary, and submit one consolidated response describing the national surveillance system considered most suitable for automated outbreak detection.

### Workshop

An on-site workshop was held in May 2023 at the Robert Koch Institute in Berlin, Germany, as part of the U4S project. Participants were invited from institutions participating in the U4S project, with active partners involved in the outbreak detection work package encouraged to attend in person. To ensure balanced representation across participating institutions, attendance was limited to a maximum of 2 representatives from active outbreak detection partners and 1 representative from other beneficiary institutions. In total, 30 public health experts, epidemiologists, and data scientists from NPHIs representing 16 EU countries participated. The workshop aimed to discuss survey findings, identify relevant use cases, and plan the pilot phase. Participating countries presented existing AODS and surveillance system overviews. Participants were divided into 2 breakout groups. Data scientists worked on defining outbreak detection tools achievable within the following 12 months, including requirements, vision, data input and output, and handling (operation, users, interfaces, and reporting). Epidemiologists, as future tool users, worked on outlining the ideal tool, specifying intended functionality, data sources, pathogens, use cases, and operational aspects.

XSL•FO
RenderX

### One-on-One Meetings and Calls

In January 2024, structured one-on-one meetings were conducted with the 10 piloting countries participating in the tool implementation phase. Between April 2024 and November 2024, these countries piloted the outbreak detection tool by integrating their national surveillance data into the required input format, using the tool in routine surveillance, providing feedback, reporting bugs, suggesting additional requirements, and participating in the tool evaluation. Meetings included the national project representatives and technical experts involved in surveillance and data management. Discussions followed a predefined agenda covering country-specific surveillance structures, administrative divisions, data availability, and functional requirements for the outbreak detection tool. Additional informal online meetings conducted between 2023 and 2024 further supported the collection and clarification of tool requirements.

### Data Analysis

Survey responses were exported from EUSurvey and analyzed using R (version 4.4.0; R Foundation for Statistical Computing) [16]. As this study aimed to describe the characteristics of national surveillance systems and automated outbreak detection capacities across participating countries, analyses were descriptive. Categorical variables are presented as counts and percentages where appropriate, whereas free-text responses were reviewed and summarized thematically to capture common approaches and country-specific characteristics.

### Data Verification

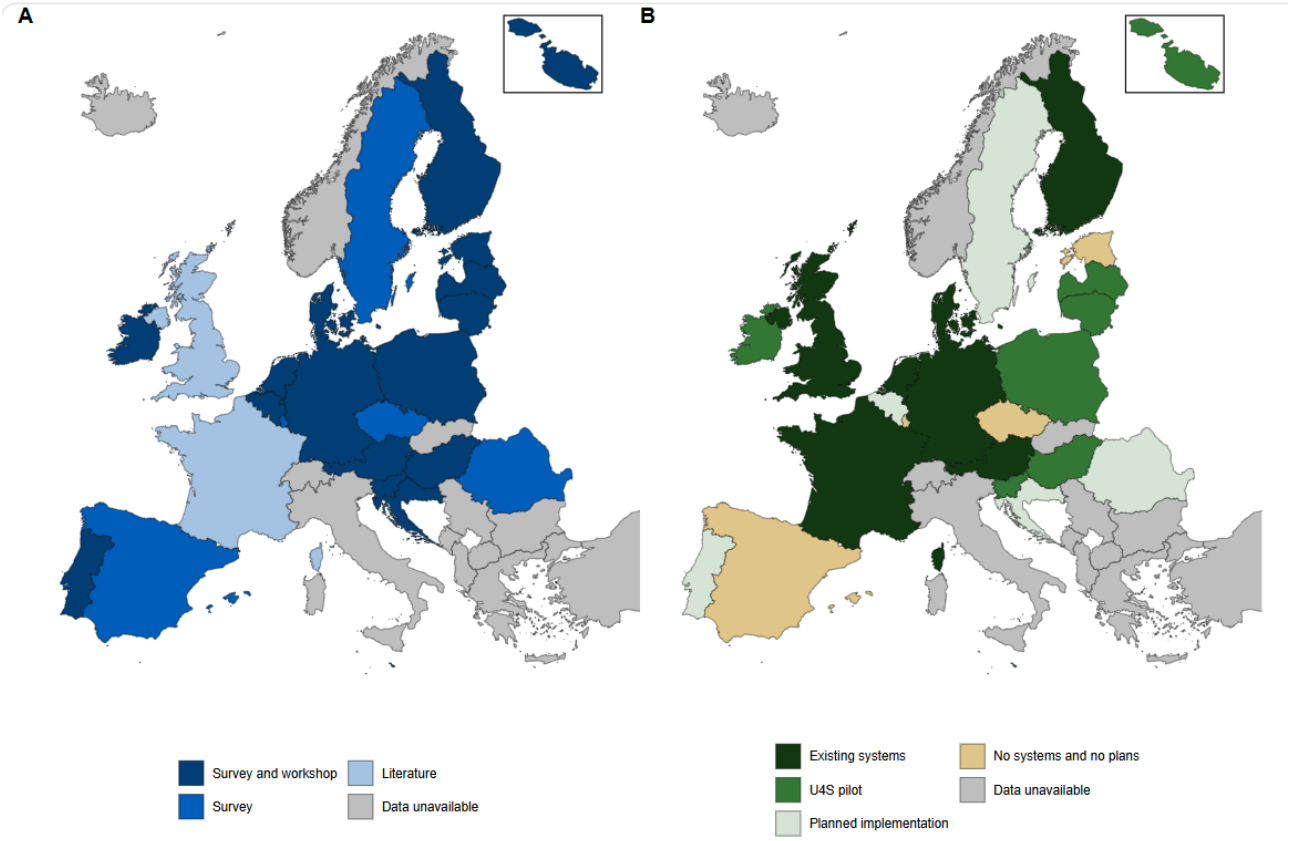
Survey results were first presented during the workshop in May 2023, allowing participants to review and validate the data. During a project webinar in June 2023, the survey and workshop results were shared with the entire project consortium, giving all survey respondents the opportunity to verify their data.

### Ethical Considerations

No formal ethics committee approval was sought because this study did not involve patients, clinical interventions, or the collection of sensitive personal data, and findings were analyzed and reported only in aggregated country-level form. The processing of participants' contact information was reviewed in consultation with the Robert Koch Institute's Data Protection Office and conducted in accordance with the General Data Protection Regulation (Regulation [EU] 2016/679) and the German Federal Data Protection Act (*Bundesdatenschutzgesetz*).

Participants provided electronic informed consent before completing the survey. Names and email addresses were used solely for study administration and were not included in the analysis. All results are presented in aggregated form, ensuring that individual participants cannot be identified.

## Results



### Overview

The analysis included 26 countries, comprising 25 (96.2%) EU member states and the United Kingdom. Of the 25 U4S consortium members invited to participate in the survey, 21 (84%) completed it. France did not respond. The United Kingdom was not invited because it was not part of the U4S consortium. The largest group of countries (16/26, 61.5%) contributed data through the survey and participation in the workshop. A total of 19.2% (5/26) of the countries participated in the survey only; data for 7.7% (2/26) of the countries were obtained solely from the literature; and for 11.5% (3/26) of the countries, no data were available (Figure 1). Most survey respondents (19/21, 90.5%) were associated with NPHIs, and the remainder were associated with ministries of health (2/21, 9.5%).

XSL•FO
RenderX

**Figure 1.** Map showing the current status of automated outbreak detection systems (AODSs) in the European Union (EU) and the United Kingdom and the corresponding source of information (2024). (A) Source of information used to assess the status of AODSs across the EU and the United Kingdom. All countries that participated in the workshop also completed the survey. The upper right inset shows Malta. (B) Countries are categorized by their current level of implementation of AODSs. In cases in which countries meet the criteria for multiple categories (eg, Finland, Denmark, and the Netherlands, which have existing AODSs and are also UNITED4Surveillance [U4S] pilot partners), the higher level of implementation is displayed. "U4S pilot" refers to those countries that used the automated outbreak detection tool developed within U4S in a pilot phase from April 2024 to December 2024. The upper right inset shows Malta.

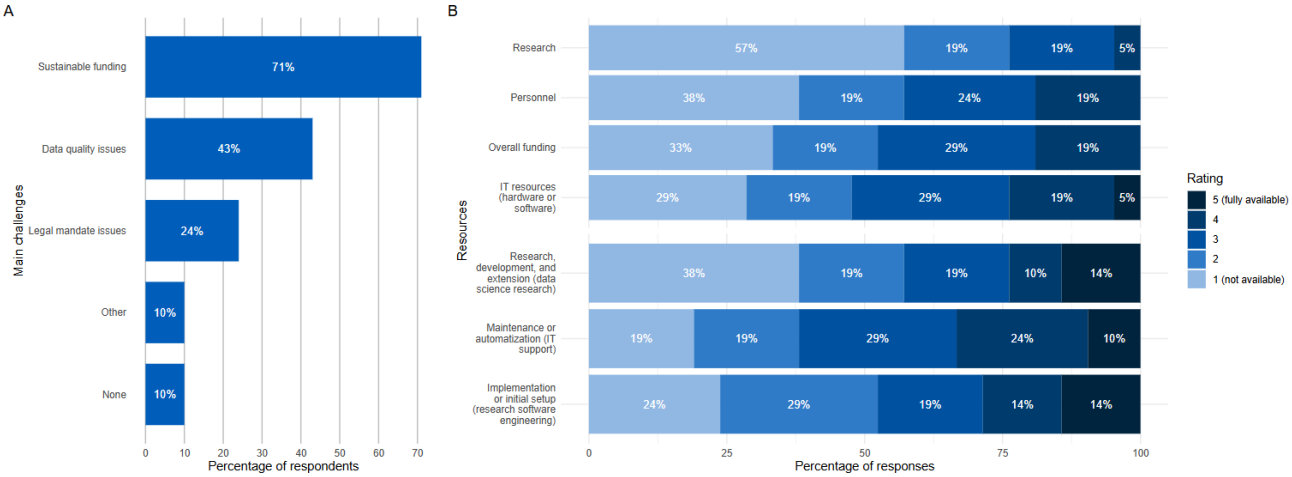
## Current Use of AODSs in EU Countries

On the basis of the data collected from EU countries and the United Kingdom, 26.9% (7/26) of the countries had existing AODSs in place. A total of 38.5% (10/26) of the countries participated in the U4S pilot project, whereas 15.4% (4/26) were planning to implement such AODSs. Another 15.4% (4/26) had neither AODSs nor plans for implementation, and for 11.5% (3/26) of the countries, no data were available (Figure 1). Country-specific information on data sources and implementation status for each of the 26 countries is also provided in Multimedia Appendix 2.

## Identified Need for Outbreak Detection

Beyond the current level of implementation, our survey examined how countries responded to signals generated from surveillance data, whether detected manually or automatically. While a diverse level of implementation across the EU was observed, all countries that completed the survey (21/25, 84%) stated that they would act on a signal identified through their surveillance data, whether from manual inspection or automated analysis. Typically, this response involved verification of the signal, followed by the initialization of an investigation, a risk assessment, further communication, and introduction of measures if needed. In most cases (14/21, 66.7%), the corresponding NPHI received feedback on actions triggered by a signal via outbreak reports (6/14, 42.9%), via direct communication with the investigation authorities (3/14, 21.4%), or by observing the performed public health action (2/14, 14.3%). In one case, investigations were conducted directly by the NPHI. In many countries (11/21, 52.4%), feedback on actions was collected systematically and often also used for evaluation (8/11, 72.7%). In addition, piloting countries grew from initially 7 to 10, reflecting the high interest in the tool.

## Identified Challenges to Implementing AODSs



When asked about main challenges in implementing AODSs, lack of sustainable funding and resources was indicated as the primary obstacle (15/21, 71.4%). This was followed by data quality (9/21, 42.9%) and legal mandate issues (5/21, 23.8%). In one country, data quality specifically referred to limited data availability and reporting delays. A total of 9.5% (2/21) of the countries reported no barriers, whereas another 9.5% (2/21) reported "other" issues. Of these countries, one respondent (Sweden) noted that an automated detection system had previously been implemented in the surveillance system but had not yet been reimplemented following a system upgrade in 2022. The other country (Lithuania) cited concerns about potential functional incompatibilities between systems, referring to technical issues that can cause delays or inconsistencies when data are synchronized across platforms before integration into the national eHealth system.

XSL•FO
RenderX

Regarding funding, respondents reported particularly limited funding for research capacity, specifically staff knowledge and time for research activities (12/21, 57.1%), personnel (8/21, 38.1%), overall funding (7/21, 33.3%), and IT resources such as hardware and software (6/21, 28.6%). Similarly, no funding was available for IT competences, including research software engineering for implementation (6/21, 28.6%), IT support for maintenance and automatization (6/21, 28.6%), and data science expertise for development and extension (8/21, 38.1%; Figure 2).

**Figure 2.** Reported challenges and resources for implementing automated outbreak detection systems (AODSs) in the European Union based on a survey of national public health institutes in 2023. (A) Main challenges reported by countries in implementing AODSs. Multiple answers per respondent were possible. (B) Aggregated ratings (1-5) of funding availability and IT competences to run and support implementation. Higher scores indicate greater perceived availability.

## Surveillance System Prerequisites

Despite these implementation barriers, many countries already possessed surveillance infrastructures that provided favorable conditions for AODS implementation. The performance of AODSs primarily relies on the information available in the surveillance system, including historical data used to establish baselines, detect trends, and adjust for seasonality [5]. Almost all respondents stated that data were reported in a case-based format (20/21, 95.2%) and on a daily basis (19/21, 90.5%) at the national level. A total of 57.1% (12/21) stated that additional personally identifiable data (eg, addresses, date of birth, and personal identity number) were available. Furthermore, all countries (21/21, 100%) had at least 3 years of historic data available, and 38.1% (8/21) had historic data for 20 years or more.

All countries (21/21, 100%) received information on age, region, pathogen, and sex of infectious disease cases through their surveillance systems at the national level. These are the most common stratification dimensions in AODSs and allow for extensive investigation. Most countries also had additional information on outcomes such as death (19/21, 90.5%), hospitalization (17/21, 81%), and date of symptom onset (17/21, 81%) or specific symptoms (14/21, 66.7%), which would allow for further assessment of signals regarding the severity or even outbreak detection on different indicators (eg, number of hospitalizations). In many countries, information on vaccination status (15/21, 71.4%), risk factors (11/21, 52.4%), or exposures (15/21, 71.4%) was available, which would enable further disease-specific analyses.

## Identified Use Cases for AODSs

Given these surveillance capacities, we next explored the disease areas and scenarios in which countries saw the greatest potential for AODSs. Identifying potential use cases for automated outbreak detection is essential for designing an effective and widely used AODS. This includes specifying data input formats, defining user-configurable input options such as filters and parameters, and ensuring that analysis and outputs are actionable and relevant for various disease surveillance systems [17].

The survey collected information on disease groups targeted by the surveillance systems, revealing potential use cases for AODSs and groups that could benefit the most from these systems. Food- and waterborne diseases (19/21, 90.5%), airborne diseases (18/21, 85.7%), and vector-borne and zoonotic diseases (17/21, 81%) were the most common disease groups. At the workshop, gastroenteritis and respiratory diseases emerged as the main use cases, with stronger interest in gastroenteritis. Accordingly, pilot use cases focused mainly on gastrointestinal pathogens, with one other country selecting group A streptococci.

## Identified Requirements for AODSs

The identified requirements for AODSs drawn from one-on-one meetings and calls with the piloting countries showed significant overlap despite different organizational and geographical structures. Key needs included flexible output formats, adaptability for pandemic periods, and various filtering and stratification options. The systems should also provide information on cases related to already known outbreaks; enable extraction of detailed case line lists; support different temporal aggregations, such as daily, weekly, and monthly; and offer multiple language options. Several countries also highlighted the need to accommodate whole-genome sequencing data within future outbreak detection tools. The workshop discussion highlighted that signals were managed by different experts across countries with varying levels of IT expertise, underscoring the need for user-friendly, accessible, and

XSL•FO
RenderX

adaptable tools. These requirements highlight the need for a flexible system that can accommodate diverse user needs effectively.

### Current AODSs Implemented by Countries

Table 1 presents an overview of current AODSs implemented in 26.9% (7/26) of the countries. The results are presented in 2 sections highlighting the differences in type and depth of information between countries that participated in the U4S project and France and the United Kingdom, for which only literature-based data were available.

XSL•FO
RenderX

**Table .** Characteristics of automated outbreak detection systems for infectious disease surveillance in 5 countries from the UNITED4Surveillance project (survey data) and France and the United Kingdom (literature; 2024).

| Country | Pathogens and surveillance data | Methods | Implementation and automation | Reporting and frequency | Remarks |
|---|---|---|---|---|---|
| Austria | *Campylobacter* and *Salmonella*; case data from the national reference laboratory | Farrington Flexible algorithm and CUSUM[a] | R, *surveillance* package; fully automated | Weekly report | COVID-19–era hiring added data scientist capacity; plan to use data from the national electronic reporting system and extend to all notifiable diseases |
| Denmark | Approximately 20 assorted notifiable diseases, *Campylobacter*, and COVID-19; laboratory data from the national microbiology database | Threshold rules for approximately 20 diseases; Farrington Flexible algorithm; in-house method for COVID-19 prevalence levels | SQL+R+SAS; *surveillance* package; automation varies | Daily automatic email alerts (approximately 20 diseases); weekly ad hoc R reports or web figure | No single framework; evaluation pending; initiative to unify |
| Finland | Influenza; cases from Register of Primary Health Care Visits | MEM[b] | R, *mem* package; fully automated | Daily website updates on case numbers, thresholds, and epidemic levels | MEM since 2015; focused on influenza; plan to monitor other infectious diseases with data from the National Infectious Diseases Register |
| Germany | Approximately 30 diseases; national case reports from German surveillance database | Farrington Flexible algorithm | R pipeline, *surveillance* package; fully automated | Comprehensive weekly report (maps, charts, and tables) | Extensive coverage of notifiable pathogens |
| The Netherlands | Approximately 40 diseases; case-based data in the RIVM[c] database | HMM[d]+spline seasonality [18] | R Shiny dashboard ("survboard"); ad hoc computation during use of dashboard | Interactive dashboard; frequency dependent on use | Real-time geographic, temporal, and demographic views; plan to use WGS[e] data for outbreak detection with the new Shiny app |
| France (SurSaUD)—syndromic | Influenza+11 other syndromes; ED[f] and SOS Médecins visits+mortality (approximately 700 EDs and 60 GP[g] units); >90% ED coverage | Ensemble of GLMs[h], robust GLMs (weighted), and HMM [19] | Daily R scripts at Santé publique France; alarms fully automated; human validation of alert levels | Daily national dashboard and weekly reports | Performance benchmarked comparing ensemble vs individual methods and application to different data sources |
| United Kingdom—England (syndromic) | Comprehensive coverage of syndromes; NHS[i] 111 calls, GP consultations, and ED attendances | RAMMIE[j] [20] | Automated Stata script; daily | Daily internal alerts and public weekly bulletins | RAMMIE demonstrated high sensitivity (approximately 92%) and specificity (approximately 99%); adjusts for weekday and holiday effects |
| United Kingdom—England and Wales (laboratory isolates) | >3300 distinct organisms; HPA[k] surveillance data | Farrington Flexible algorithm (quasi-Poisson GLM) | R scripts (*surveillance* package); fully automated | Weekly reports emailed to national and regional epidemiologists | One of Europe's oldest automated systems; continuously refined |

The 19.2% (5/26) of countries participating in the U4S project (Austria, Denmark, Finland, Germany, and the Netherlands) all used routinely collected notifiable infectious disease surveillance data and made use of R-based workflows, including the *surveillance* R package [21]. They differed, however, in the number and type of pathogens monitored, the specific outbreak detection method applied, the degree of automation, and the type of reporting. While some countries used their AODSs for individual pathogens, others covered a broad range of notifiable diseases. Despite this heterogeneity, all systems generated near–real-time outputs. Several countries were currently working to expand pathogen coverage, integrate national surveillance data, or harmonize their workflows.

France and the United Kingdom operated long-established R-based AODSs across diverse national data streams and used established R-based analytic frameworks. Both countries had comprehensive coverage of syndromes (France and the United Kingdom) or pathogens (United Kingdom) and automated R scripts run daily or weekly, producing internal alerts, dashboards, and bulletins. The systems in France and the United Kingdom have been established for many years; reflect a high level of methodological maturity, including systematic evaluations; and offer guidance for further development and application of AODSs in other countries.

## Discussion

### Principal Findings

This study provides an updated overview of the current landscape of AODSs in the EU and the United Kingdom by assessing current demand for automated outbreak detection, evaluating the availability of surveillance system prerequisites, and identifying barriers and requirements for implementation. Our findings reveal a heterogeneous state of implementation, with only 26.9% (7/26) of the countries included in the analysis operating AODSs. However, our results also highlight important opportunities for broader adoption, as surveillance systems in many countries already meet key data-related prerequisites for automated outbreak detection, including the availability of case-based, frequently reported, and sufficiently extensive historical surveillance data.

Compared to the 2010 overview, which outlined AODSs in Denmark, England, Germany, the Netherlands, and Sweden, our findings show that the overall landscape has changed little [11]. Most of these countries continued to operate AODSs, except Sweden, which discontinued its system following the implementation of a new surveillance system. Austria and Finland were the only countries that had introduced new systems: Austria's enhanced capacities during the COVID-19 pandemic may reflect increased prioritization of AODSs enabled by the additional resources made available during the pandemic. In contrast, Finland's adoption using the moving epidemic method focused more on retrospective trend analysis than on real-time signal detection. The findings also suggest that high-resource countries are more likely to establish outbreak detection systems but maintaining them can become challenging when substantial changes in surveillance systems occur. This limited progress appears to reflect persistent structural barriers rather than a lack of demand as respondents consistently identified sustainable funding, IT capacity, data quality, and legal mandates as the main obstacles to implementation.

Deficits in software engineering, IT support, and data science restrict the ability of NPHIs to develop and sustain systems. These constraints help explain why, despite clear interest, only a minority of countries currently operated AODSs. Similarly, the 15.4% (4/26) with neither an operational AODS nor plans for implementation reported barriers including limited funding, data quality, legal mandates, and IT capacity, with 2 also citing low political priority or a limited need due to a small number of notifications. At the same time, surveillance environments are evolving. An increasing number of countries are routinely generating whole-genome sequencing data as part of surveillance activities, which introduces new requirements for outbreak detection tools, particularly with regard to data input formats, interoperability, and the ability to integrate sequencing information alongside epidemiological data.

Our survey and pilot project further indicate growing momentum toward automation. In total, 38.5% (10/26) of the countries actively piloted the developed tool, demonstrating both the technical feasibility of implementation and the willingness of NPHIs to integrate methods into routine practices. In parallel, all survey respondents (21/21, 100%) confirmed that they would act on signals detected in their surveillance data. This finding indicates that the principle of responding to signals is firmly embedded in national public health practice. Structured procedures for response were in place in most countries (18/21, 85.7%), yet the way feedback was collected and integrated varied considerably. Reliance on manual verification may cause delays and inconsistencies, whereas greater automation could enable timelier signal identification, more consistent risk assessment, and systematic feedback.

Moreover, the results show significant potential for implementing new outbreak detection systems as many countries reported having extensive historical data, often exceeding 8 years, which is crucial for establishing baselines and trend analysis. Identifying specific use cases such as gastrointestinal pathogens highlighted the practical value of AODSs in routine surveillance tasks. Another potential application of new methods such as spatial clustering at the address level arises from the availability of certain personally identifiable data. The ability to incorporate such data allows for more precise mapping and detection of patterns.

Experience from pilot and established systems showed substantial alignment in outbreak detection needs across the EU. Despite differences in epidemiological contexts and

XSL•FO
RenderX

organizational structures, system requirements showed considerable overlap. Pilot countries highlighted needs such as flexible output formats, temporal aggregation, filtering, and multilingual support, whereas established systems used different statistical methods and infrastructures yet generated largely comparable outputs. The convergence of outputs despite methodological differences suggests that key outputs, including signals, visualizations, maps, and reports, could be standardized. These shared requirements indicate that a single flexible tool could accommodate diverse national contexts, meeting practical needs without requiring separate systems for each country. The widespread use of the *surveillance* package is a good example of the utility of open-source tools developed by the public health community.

### Limitations

Our study has some limitations. First, the survey focused on one surveillance system per country, which might not fully capture the use of AODSs across all national surveillance systems. Second, varying interpretations of automated outbreak detection could have influenced reported use, including differences between signal detection and data visualization. Third, reliance on self-reported data may have introduced bias or overestimation, with response depth varying by how extensively experts were consulted. Fourth, workshop participation was limited to 30 experts from 16 countries, not representing all EU contexts. Fifth, while the systems in the United Kingdom and France were still operational, the data may not reflect all subsequent updates. Sixth, saturation was not formally assessed or used as a criterion for determining the extent of data collection. Countries were predefined by their involvement in their respective U4S project activities. The qualitative components were used to complement and contextualize the country-level survey findings and further explore requirements for AODSs. Despite these limitations, this study provides valuable insights into existing practices and priority areas for improvement.

### Future Perspectives and Conclusions

AODSs offer the potential to enhance routine surveillance of infectious diseases across EU countries. However, the results of this study indicate that resource limitations and technical barriers continue to hinder their wider implementation. Broader adoption of flexible, open-source solutions could accelerate cross-country collaboration and promote more harmonized outbreak detection in the EU. The experience across countries with different surveillance capacities further suggests that AODSs can be adapted to diverse settings, although their implementation in more resource-limited contexts will depend on the availability of reliable surveillance data, digital infrastructure, and sustained technical support.

These findings have broader implications for infectious disease surveillance within the EU. Increasing harmonization of outbreak detection approaches could facilitate knowledge exchange between countries, support more comparable surveillance practices, and reduce duplication of effort through the shared development and maintenance of open-source tools. Collaborative initiatives such as U4S may help bridge existing implementation gaps by bringing together expertise, building technical capacity, and fostering collaboration across countries.

Future work should focus on integrating the R Shiny app within the U4S project into local systems; expanding its use beyond the project phase; and refining methods, interfaces, and data integration. Broader adoption of such flexible, open-source solutions could accelerate cross-country collaboration and promote more harmonized outbreak detection in the EU. As automated systems can generate large numbers of signals with varying specificity, systematic evaluation in routine public health practice will be essential to assess their accuracy, usability, workload implications, and overall added value for infectious disease surveillance.

## Acknowledgments

The authors sincerely thank the UNITED4Surveillance consortium for their participation in the survey and acknowledge their project partners at the Austrian Agency for Health and Food Safety; Statens Serum Institut, Denmark; the Finnish Institute for Health and Welfare; the National Institute for Public Health and the Environment, the Netherlands; the Infectious Disease Prevention and Control Unit at the Health Promotion and Disease Prevention Directorate, Malta; the Health Promotion and Disease Prevention Directorate, National Public Health Center, Hungary; the National Institute of Public Health, Slovenia; the Latvian Centre for Disease Prevention and Control; the Health Protection Surveillance Centre, Ireland; the National Centre for Communicable Diseases, Lithuania; and the Directorate-General of Health, Portugal, for their collaboration, expertise, and ongoing support throughout the project. The authors used ChatGPT (GPT-5.2) from OpenAI (2026) under full human supervision to assist with linguistic editing of the manuscript, refinement of the code used to generate figures, and support the preparation of a summary table. All AI-generated outputs were reviewed and verified by the authors, who take full responsibility for the final content of the manuscript.

## Funding

The research activities reported in this paper were conducted as part of the UNITED4Surveillance project cofunded by the European Union under the EU4Health program (project ID 101102070). The positions of PvFgI and ACV were funded through this project. The funder had no role in the design or conduct of the research, analysis or interpretation of the data, preparation of the manuscript, or decision to submit the manuscript for publication. The views and opinions expressed are, however, those of

## Abstract

**Background:** Hypertension is a key driver of multimorbidity; however, its role in shaping dynamic disease progression, especially in rural populations, remains underexplored.

**Objective:** This study aimed to characterize temporal patterns of multimorbidity progression among inpatients with a recorded hypertension diagnosis and to examine whether these patterns differed by sex, age, insurance type, and county.

**Methods:** We analyzed electronic health record data from 34,099 inpatients with a recorded hypertension diagnosis across 3 rural counties in Henan, China (2019 - 2023), constructing a temporal comorbidity network of 250 disease nodes and 1512 disease transitions. Statistical validation was performed using bootstrap resampling, case-dropping, and permutation tests. Subgroup analyses were conducted by sex, age, insurance type, and county.

**Results:** The temporal comorbidity network revealed a densely interconnected core involving hypertension, atherosclerotic heart disease, and cerebral infarction, with type 2 diabetes occupying a bridging position between cardiovascular and multisystem disease clusters. The ordering of dominant recorded pathways differed by sex (earlier coronary involvement among female inpatients vs more direct progression to stroke among male inpatients), was more complex in inpatients older than 70 years of age, and was more diffuse among those covered by urban-rural resident insurance compared with urban employee insurance.

**Conclusions:** Multimorbidity among inpatients with recorded hypertension followed structured and heterogeneous temporal patterns that differed by sex, age, insurance type, and county. Cardiovascular and cerebrovascular conditions formed the principal recorded progression pathways, while type 2 diabetes connected cardiovascular pathways with broader multisystem complications. These findings support further evaluation of risk-stratified and locally adapted approaches to chronic disease prevention and longitudinal care.

## Introduction

Hypertension is a major modifiable risk factor for cardiovascular diseases (CVDs) and a dominant contributor to global multimorbidity. In China, over 270 million individuals live with hypertension, with the burden particularly concentrated in rural areas where health care infrastructure, health literacy, and early screening are limited [1]. This condition rarely occurs in isolation. Instead, it often initiates a cascade of comorbidities, including stroke, ischemic heart disease, diabetes, and chronic kidney disease, leading to premature mortality, disability, and catastrophic health expenditures [2]. Multimorbidity, typically

XSL•FO
RenderX

defined as the presence of 2 or more chronic conditions, has become a central challenge in population health and health system sustainability. In the European Union alone, over 50 million people are affected, and projections suggest that complex multimorbidity (≥4 conditions) will increase from 10% in 2015 to 17% by 2035 [3]. The implications are profound: multimorbidity is associated with reduced quality of life, functional decline, and substantial health care costs [3].

Despite its significance, most research on multimorbidity has employed cross-sectional approaches, capturing only static disease clustering rather than dynamic disease progression. This limits the ability to identify early transitions, turning points, or critical intervention windows [4]. In recent years, there has been a shift toward longitudinal frameworks and data-driven disease trajectory models that can track the accumulation, ordering, and evolution of chronic conditions over time [4,5]. These include techniques such as trajectory modeling, latent class analysis, and, increasingly, temporal network analysis (TNA), which conceptualizes disease interactions as evolving networks [6]. Hypertension is recognized as a key initiating node in these networks. Longitudinal simulations have shown that individuals with hypertension have significantly higher lifetime risks of progressing to diabetes, heart failure, and cerebrovascular events, with variability by age, sex, and socioeconomic status [4,7]. In particular, trajectory simulations from Chinese population data demonstrate that hypertension precedes and predicts a broad spectrum of multimorbidity profiles, underscoring its centrality in disease evolution [7].

Hypertension frequently coexists with cardiovascular, metabolic, cerebrovascular, and kidney-related conditions, and the burden of multimorbidity substantially increases with age [8]. Previous studies have documented the prevalence, clustering, and clinical consequences of multimorbidity among people with hypertension across different populations [9]. Longitudinal investigations have further shown that multimorbidity dynamically evolves through heterogeneous sequences of disease emergence and accumulation, rather than as a simple increase in disease counts [10]. However, existing research has largely focused on prevalence, cross-sectional co-occurrence, or static clustering patterns, and relatively few studies have examined the temporal ordering of diagnoses across repeated health care encounters [11,12]. Characterizing these temporal patterns may complement conventional measures by revealing which conditions are repeatedly recorded earlier or later in longitudinal clinical records and whether these patterns vary across population subgroups.

However, most trajectory research has been conducted in high-income countries [4]. There is a critical lack of evidence from low- and middle-income settings, especially in rural counties of China, where occupational exposures (eg, pesticides), local dietary customs, and unequal health resource allocation create unique risk structures [3,4]. Furthermore, within-country heterogeneity—between counties, economic strata, and health insurance groups—has been underexplored.

To address this evidence gap, this study aimed to characterize temporal patterns of multimorbidity progression among inpatients with a recorded diagnosis of hypertension and to examine whether these patterns differed by sex, age, insurance type, and county across 3 socioeconomically diverse counties in Henan Province, China. We used TNA to reconstruct statistically supported, temporally ordered disease transitions from longitudinal inpatient records. By identifying common progression structures and subgroup-specific patterns, the study sought to provide evidence to support more risk-stratified and context-sensitive approaches to chronic disease prevention and management in underserved rural populations.

## Methods

### Data Source and Study Design

This retrospective observational study was conducted using inpatient electronic health records (EHRs) collected from 6 local hospitals across 3 counties in Henan Province, China, covering the period from January 1, 2019, to December 31, 2023. The dataset comprised 300,241 inpatient visits, including inpatient identifiers, admission dates, discharge diagnoses, and *ICD-10* (*International Classification of Diseases, 10th Revision*) codes.

Hypertension was treated as the index condition, given its recognized role as a central initiating disease in multimorbidity trajectories [1,12]. The present analysis was based on inpatient EHR data because these records provided patient-linked diagnostic information across repeated hospital admissions, allowing the temporal ordering of recorded chronic conditions to be reconstructed. Hypertension was used as a cohort-defining recorded diagnosis and was not necessarily the primary reason for hospitalization. Accordingly, the study was designed to characterize temporal multimorbidity patterns among hospitalized patients with a recorded hypertension diagnosis rather than to represent all individuals with hypertension in the underlying county populations. The study design followed a population-level, longitudinal disease trajectory framework, consistent with established approaches in multimorbidity trajectory research and temporal disease network construction [3-5]. This ensures that the evolution of comorbidity patterns analyzed thereafter accurately reflects the disease progression in hypertensive inpatients. Because this study used the complete set of eligible inpatient EHR records available from the 6 participating hospitals rather than data obtained through a probability-based survey design, survey sampling weights were not applicable. All analyses were therefore conducted using the unweighted analytical cohort. This study was reported in accordance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology; Checklist 1) statement for cohort studies and the RECORD (Reporting of Studies Conducted Using Observational Routinely Collected Health Data; Checklist 2) statement.

### Ethical Considerations

This study was approved by the Ethics Committee of Research and New Technology/New Business of Fuwai Central China Cardiovascular Hospital (approval number 2025; ethics review number 25). Owing to the retrospective study design and the use of routinely collected inpatient EHR data, the requirement for individual informed consent was waived by the ethics committee.

XSL•FO
RenderX

The source data received by the research team contained direct inpatient identifiers, including names and ID numbers. Before the construction of the analytical dataset, these direct identifiers were removed and replaced with encrypted inpatient identifiers, which were used solely to link multiple inpatient admissions belonging to the same inpatient. All statistical analyses were conducted using the resulting deidentified analytical dataset, and no directly identifying information was included in the reported results.

Because this study involved the secondary analysis of existing inpatient records and no inpatients were directly recruited or contacted, participant compensation was not applicable.

## Data Preprocessing

Raw EHR data underwent standardized preprocessing procedures to ensure data integrity and analytical reproducibility. Specifically, this procedure included inpatient identity harmonization, diagnostic code standardization, temporal normalization, and record exclusion. Encrypted inpatient identifiers were harmonized across records to enable the longitudinal linkage of multiple admissions belonging to the same inpatient. All diagnoses were mapped to the National Clinical *ICD-10* version 2.0 standard, following recommended practices for multimorbidity research [2,3]. Admission dates were converted to a unified format (“yyyy-mm-dd”) to enable precise temporal ordering. A total of 4300 inpatient records were excluded due to missing critical fields (patient ID, diagnosis code, or admission date), consistent with data quality control strategies in large-scale EHR studies [4]. No imputation was applied to missing diagnostic or temporal variables, as incomplete records could compromise disease sequencing accuracy.

## Cohort Selection Criteria

Cohort selection was carried out according to predefined inclusion and exclusion criteria. To ensure that the comorbidity patterns analyzed would accurately reflect the disease progression of hypertensive inpatients, the inclusion criteria were (1) inpatients with at least 2 inpatient records during the study period, (2) each inpatient record must include at least 2 diagnoses, (3) at least one diagnosis classified as a CVD, and (4) at least one admission containing a hypertension diagnosis (*ICD-10*: I10.x). The exclusion criteria were (1) inpatients with only one inpatient record; (2) inpatients without any hypertension diagnosis; (3) records with missing key identifiers or temporal information such as inpatient ID, diagnosis, or date; and (4) duplicate inpatient records. After applying the predefined inclusion and exclusion criteria, 34,099 inpatients with at least one recorded hypertension diagnosis during the study period were included in the final analytical cohort.

## Baseline Comorbidity Pattern Analysis

To characterize coexisting disease patterns at cohort entry, chronic conditions recorded during each inpatient’s first admission in the study dataset were aggregated into inpatient-level transactions. The number of distinct chronic conditions was calculated after deduplicating diagnosis codes within the cohort-entry admission, with hypertension included in the condition count. Frequent disease combinations were identified using the Apriori algorithm with a minimum support threshold of 0.01. Itemset length was not restricted during the mining process; for readability, only the top-ranked 2-, 3-, and 4-itemsets are presented in Table 1.

XSL•FO
RenderX

**Table .** Top-ranked baseline disease combinations identified by association rule mining among 34,099 inpatients with at least one recorded diagnosis of hypertension across 6 hospitals in 3 counties in Henan Province, China, 2019 - 2023, based on chronic conditions recorded during each inpatient's first admission (support ≥0.01).[a]

| Length and *ICD-10*[b] code | Itemsets | Support |
|---|---|---|

[a]Only the top-ranked 2-, 3-, and 4-itemsets are displayed for readability; itemset presentation was not used as an inpatient-level exclusion criterion.

[b]*ICD-10*: *International Classification of Diseases, 10th Revision*.

## Construction of the Temporal Comorbidity Network

To characterize statistically robust disease progression patterns, we constructed a temporal comorbidity network (TCN)—a weighted, directed network representing population-level disease evolution, following established disease trajectory modeling frameworks [5,6,12,13]. In the TCN, nodes represent distinct *ICD-10* disease categories, and directed edges represent statistically significant temporal transitions between diseases. Across the cohort, 24,959 unique, temporally ordered disease diagnosis pairs were identified and used as candidate temporal comorbidity pairs for statistical inference.

## Network Construction Procedure

For each inpatient, chronic disease records were chronologically ordered according to admission dates. Only the earliest recorded occurrence of each disease within the study dataset was retained, and subsequent records of the same disease were excluded to reduce repeated-counting bias associated with recurrent hospitalizations. The date assigned to each disease, therefore, represents its first recorded occurrence in the available inpatient EHR data rather than the true date of disease onset or initial clinical diagnosis.

The retained disease records were then grouped by inpatient admission to generate an inpatient-specific longitudinal sequence of effective admission time points. Conditions first recorded during the same admission were assigned to the same time point, and no temporal direction was inferred between them. For each pair of consecutive effective admissions, all eligible disease pairs were generated by linking a disease first recorded at admission $t$ to a different disease first recorded at the immediately subsequent admission $t$+1. Thus, each inpatient contributed a sequence of temporally ordered disease pairs derived from successive inpatient admissions.

XSL•FO
RenderX

As a hypothetical example, consider an inpatient with hypertension (I10.X) and atherosclerotic heart disease (I25.1) first recorded during admission 1, type 2 diabetes (E11.9) first recorded during admission 2, and cerebral infarction (I63.9) first recorded during admission 3. Because hypertension and atherosclerotic heart disease were first recorded during the same admission, no temporal direction was assigned between them. The consecutive-admission procedure generated the pairs I10.X→E11.9 and I25.1→E11.9 between admissions 1 and 2, and E11.9→I63.9 between admissions 2 and 3. Repeated recordings of previously observed conditions during later admissions were ignored. This hypothetical example is provided solely to illustrate the sequence-generation procedure and does not represent an actual patient record.

Patient-level disease pairs were subsequently aggregated across the cohort. A chi-square test was first used to determine whether the observed co-occurrence frequency of each disease pair exceeded that expected under independence. A significance level of $\alpha$=.05 was used, and pairs with $P$<.05 were retained. For each retained pair, a binomial test was then used to determine whether one temporal direction occurred more frequently than the reverse direction under a null probability of 0.5. Pairs with $P$<.05 in both tests were represented as directed edges in the population-level TCN, with edge weights corresponding to the observed frequency of the temporal transition among inpatients.

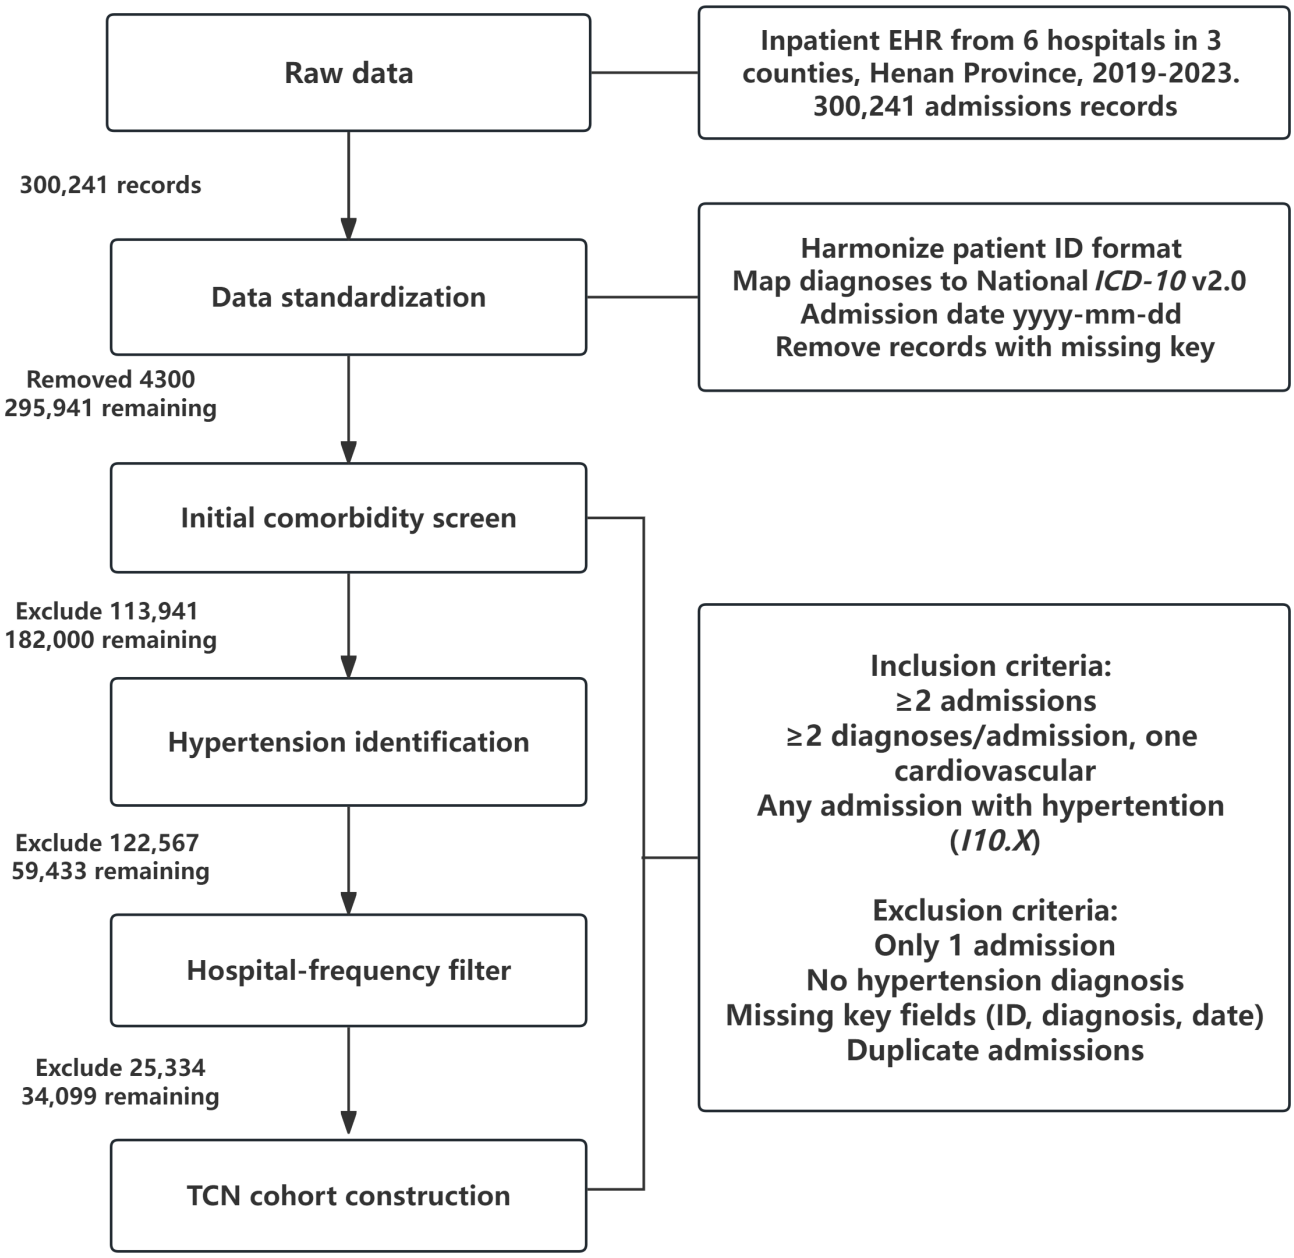
### Robustness and Validation Analysis

To evaluate the stability and reliability of the inferred TCN, 3 complementary robustness analyses were conducted, following best practices in network epidemiology [3,5]. First, bootstrap resampling with replacement was performed 1000 times. The TCN was reconstructed in each bootstrap sample, and the proportion of bootstrap networks in which each edge reappeared was calculated. Edges reproduced in at least 95% of the bootstrap samples were retained to form the Stable Network, representing the most reproducible core subnetwork of the original TCN.

Second, a case-dropping sensitivity analysis was conducted to assess the robustness of the network to changes in cohort composition. In each of the iterations, 3410 of 34,099 (10.0%) inpatients were randomly excluded, and the TCN was reconstructed. Similarity between the edge sets of each reduced network and the original TCN was quantified using the Jaccard similarity coefficient.

Third, a permutation-based null-network analysis was performed to determine whether the observed network topology exceeded that expected by chance. The temporal order of recorded disease diagnoses was randomly permuted for each inpatient, and the TCN was reconstructed using the same analytical procedure for each of the 1000 permutations. The number of nodes and edges, network density, and average clustering coefficient of the original TCN were compared with the corresponding null distributions.

For clarity, the original TCN refers to the full network constructed from all statistically significant temporal disease transitions identified in the observed cohort. The Stable Network is a bootstrap-derived subnetwork of the original TCN comprising edges reproduced in at least 95% of the bootstrap samples. The permutation-based null model refers to the distribution of randomized networks generated by disrupting the observed temporal ordering of diagnoses and serves as a chance-expectation benchmark for the original TCN.



## Results

After applying the predefined eligibility criteria, 34,099 inpatients with at least 1 recorded hypertension diagnosis during the study period were included in the final analytical cohort (Figure 1). Baseline demographic and clinical characteristics were derived from each inpatient's first inpatient record in the study dataset (Table 2). The cohort included 17,071 (50.1%) male inpatients and 17,028 (49.9%) female inpatients.

[a]SMD: standardized mean difference.

Patients aged 70 years or older constituted the largest age group (14,990/34,099, 44.0%), followed by those aged 60 to 69 years (9848/34,099, 28.9%). The standardized mean difference in age-group distribution between male and female inpatients was 0.096.

Geographically, 62.5% (21,305/34,099) of inpatients resided in Jia County, 29.5% (10,047/34,099) in Yiyang County, and 8.1% (2747/34,099) in Mianchi County. Health insurance data indicated that 82.0% (27,975/34,099) of inpatients were covered by Urban and Rural Resident Basic Medical Insurance, with a higher proportion of women (14,987/17,028, 88.0%) than men (12,988/17,071, 76.1%) under this scheme (standardized mean difference=0.375). Conversely, a greater proportion of men (2718/17,071, 15.9%) were covered by Urban Employee Insurance than women (796/17,028, 4.7%).

Based on the distinct chronic conditions recorded during each patient's first inpatient admission in the study dataset, out of 34,099 inpatients, 4499 (13.2%) had one recorded chronic condition, 9777 (28.7%) had two, 9402 (27.6%) had three, 5769 (16.9%) had four, and 4652 (13.6%) had five or more recorded chronic conditions. Overall, 29,600 (86.8%) inpatients had at least 2 recorded chronic conditions at cohort entry.

All 34,099 inpatients contributed at least 2 effective inpatient admission time points, with only the earliest recorded occurrence of each chronic disease retained. Of these inpatients, 27,381 (80.3%) contributed 2 effective time points and 6718 (19.7%) contributed 3 or more, with a range of 2 to 11 time points per inpatient. The median interval between each inpatient's first and last effective admission was 738 (IQR 526 - 856) days.

Collectively, the inpatient-specific longitudinal sequences consisted of 44,524 intervals between consecutive effective admissions. Disease pairs were generated from these consecutive intervals and aggregated at the population level, yielding 24,959 unique candidate temporally ordered disease pairs for statistical testing. These candidate pairs formed the longitudinal basis for the construction of the TCN.

Table 1 displays only the top-ranked 2-, 3-, and 4-itemsets for readability. This presentation does not indicate that inpatients with more than 4 recorded chronic conditions were excluded. At cohort entry, 4652 out of 34,099 (13.64%) inpatients had 5 or more recorded chronic conditions, and these inpatients were retained in the subsequent analyses. The TCN was constructed from pairwise, temporally ordered disease transitions and therefore incorporated eligible transitions irrespective of the total number of chronic conditions recorded for an individual inpatient.

Following statistical testing of the 24,959 candidate temporally ordered disease pairs, the original TCN comprised 250 disease nodes and 1512 directed edges. Of the 1512 edges in the original TCN, 682 (45.1%) were reproduced in at least 95% of the 1000 bootstrap samples and were retained in the Stable Network. The Stable Network comprised 189 nodes and represented the most reproducible core subnetwork of the original TCN. The 682 stable edges accounted for 2.73% of all 24,959 candidate temporal disease pairs.

In the case-dropping sensitivity analysis, the mean Jaccard similarity between the edge sets of the reduced networks and the original TCN was 0.8587 (SD 0.0075) across 1000 iterations,

XSL•FO
RenderX

with a coefficient of variation below 1%, indicating limited sensitivity to the random exclusion of 10% of the cohort.

The permutation-based null model generated networks with a mean of 117.50 (SD 6.62) nodes and 134.30 (SD 11.51) edges. Compared with the null-network distributions, the original TCN had greater network density (0.0243 vs mean 0.0098, SD 0.0008) and a substantially higher average clustering coefficient (0.6557 vs mean 0.0124, SD 0.0108). The clustering coefficient of the original TCN exceeded the null mean by more than 50 SDs, supporting the conclusion that the observed network structure was unlikely to have arisen from random temporal ordering (Table 3).

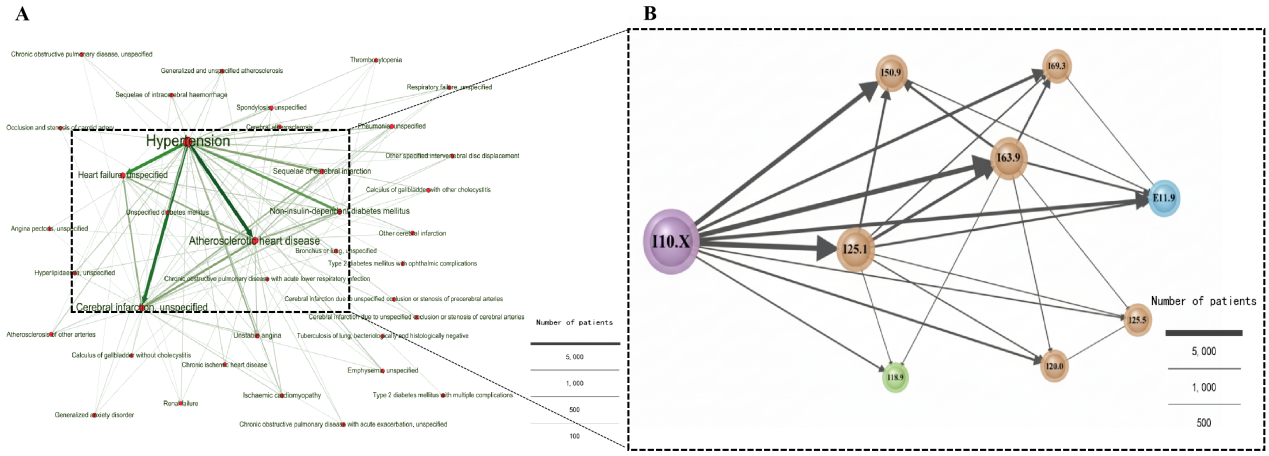

**Table .** Robustness validation and topological characteristics of the original temporal comorbidity network (TCN), its bootstrap-derived Stable Network, and permutation-based null networks among 34,099 inpatients with at least one recorded hypertension diagnosis across 6 hospitals in 3 counties in Henan Province, China, 2019 - 2023.[a]

| Metric | Original TCN | Stable Network | Null networks, mean (SD) |
|---|---|---|---|
| Number of nodes | 250 | 189 | 117.50 (6.62) |
| Number of edges | 1512 | 682 | 134.30 (11.51) |
| Network density | 0.0243 | 0.0192 | 0.0098 (0.0008) |
| Average clustering coefficient | 0.6557 | 0.5791 | 0.0124 (0.0108) |

[a]The original TCN comprised all statistically significant temporal disease transitions identified in the observed cohort. The Stable Network was a subnetwork of the original TCN containing edges reproduced in at least 95% of 1000 bootstrap samples. Null-network values are the mean and SD from 1000 networks generated by randomly permuting the temporal order of recorded diagnoses within each inpatient.

The original TCN exhibited a hub-and-spoke structure, with hypertension (I10.X), atherosclerotic heart disease (I25.1), cerebral infarction (I63.9), and heart failure (I50.9) occupying central positions. The most prominent directed pathways originating from hypertension were those to atherosclerotic heart disease and to cerebral infarction. Hypertension, atherosclerotic heart disease, and cerebral infarction also formed a densely interconnected region within the network (Figure 2).

**Figure 2.** (A) Population-level temporal comorbidity network among 34,099 inpatients with at least one recorded diagnosis of hypertension across 6 hospitals in 3 counties in Henan Province, China, 2019 - 2023, with an enlarged view of the densely connected core region of (B) core comorbidity transition network.

Type 2 diabetes (E11.9) occupied a bridging position between cardiovascular and metabolic disease clusters. Recorded transitions connected type 2 diabetes with hypertension and diabetes-related renal, neurological, and ophthalmic complications, including E11.4, E11.7, and E11.3. This network position indicates that type 2 diabetes connected otherwise distinct groups of recorded cardiovascular and multisystem conditions.

Additional recorded transitions from hypertension included carotid artery stenosis and systemic atherosclerosis. Downstream nodes in the network included chronic obstructive pulmonary disease (J44.0), emphysema (J43.9), renal failure (N18.9), and sequelae of cerebrovascular disease (I69.X). Renal failure and cerebrovascular sequelae received directed edges from multiple upstream nodes, indicating that they occurred as common downstream recorded conditions in several network pathways.

Subgroup-specific TCNs were constructed by sex, age group, county, and insurance type. The dominant core chains and corresponding path lengths are summarized in Table 4, and subgroup-specific inpatient flows are presented in Figure 3.

**Figure 3.** Inpatient flows in recorded comorbidity progression pathways originating from hypertension (I10.X) among 34,099 inpatients across 6 hospitals in 3 counties in Henan Province, China, 2019 - 2023, stratified by sex, insurance type, county, and age group: (A) sex; (B) insurance type; (C) county; and (D) age group.

Sex-stratified networks were constructed for 17,071 male and 17,028 female inpatients. The dominant male core chain began with hypertension (I10.X) followed by cerebral infarction (I63.9), heart failure (I50.9), and type 2 diabetes (E11.9), with additional downstream cardiovascular and cerebrovascular conditions. In the female network, the dominant core chain began with hypertension, followed by atherosclerotic heart disease (I25.1), cerebral infarction, and heart failure. These results indicate that the ordering of the principal recorded cardiovascular conditions differed between the male and female networks.

Age-stratified networks were examined for inpatients aged <30 years (n=77), 30 to 39 years (n=424), 40 to 49 years (n=2101), 50 to 59 years (n=6,659), 60 to 69 years (n=9848), and ≥70 years (n=14,990). Because the subgroup aged less than 30 years contained only 77 inpatients and did not yield a sufficiently stable core chain, its pathway was not reported in Table 4. Therefore, the age-specific core chains presented below refer to inpatients aged 30 years or older.

In the 30 to 40 age group, the predominant comorbidity pathway was from hypertension to unstable angina. The 40 to 50 age group exhibited a relatively limited range of downstream recorded conditions following hypertension. Cerebral infarction (I63.9) was one of the principal downstream recorded conditions in this age group. Type 2 diabetes (E11.9) also appeared as a downstream recorded condition in this age-group network. The networks for inpatients aged 50 to 69 years included transitions involving heart failure (I50.9), Alzheimer disease (G31.9), and diabetes complications (E11.X). The network for inpatients aged ≥70 years included a broader range of recorded conditions across multiple disease systems, and it included recorded transitions involving ischemic heart disease (I20.0), chronic kidney disease (N18.9), hyperlipidemia (E78.1), and cerebrovascular disorders (I64.X).

Using health insurance type as a proxy for socioeconomic status, the study found disparities in recorded comorbidity transition patterns. The largest group, covered by the urban and rural residents' health insurance, displayed a complex and extensive disease network with transitions to J44.9, D61.9, E14.2, and I50.0. A distinctive feature in this group was the early and common progression from hypertension to atherosclerotic heart disease (I25.1). Their recorded downstream conditions were more limited, with fewer types and quantities of downstream end-point diseases.

In terms of county distribution, inpatients from Jia County exhibited the overall trends observed in the study cohort, with a core progression pathway from hypertension (I10.X) to cerebral infarction (I63.9), followed by type 2 diabetes (E11.9) and ischemic heart disease (I20.0). Inpatients from Yiyang County exhibited a different pattern, with a more prominent intermediate disease stage of atherosclerotic heart disease (I25.1). After progressing through the pathway centered on atherosclerotic heart disease (I25.1), a higher proportion of inpatients progressed to hyperlipidemia (E78.0) and other cerebral infarction sequelae (I69.8). Inpatients from Mianchi County were characterized by their later-stage disease progression. Compared with other counties, these inpatients had a higher risk of progressing to atherosclerosis (I70.2) and cerebral infarction sequelae (I69.3) after experiencing cardiovascular and cerebrovascular events. Furthermore, the transition to emphysema (J43.9) was more prominent in the Mianchi County network than in the other county-specific networks.

## Discussion

### Principal Findings

TNA represents a substantive methodological advancement over traditional cross-sectional multimorbidity analyses by explicitly modeling directionality and the temporal ordering of diagnoses recorded across successive inpatient admissions. Most conventional multimorbidity studies have focused on static disease clusters or coprevalence matrices, which obscure the sequential nature of chronic disease accumulation [3,4]. Consistent with population-wide disease trajectory studies using Danish registry data, which demonstrated that disease pairs exhibit nonrandom and directional progression patterns over time [12], our TNA results reveal statistically significant and reproducible transition pathways rather than mere co-occurrence. In contrast to earlier hospital-based studies that relied on undirected comorbidity networks [13], our directed framework captures how diseases are temporally ordered in the available inpatient records, rather than only which conditions coexist. Notably, hypertension occupied a central upstream position in the network, with strong directed edges toward atherosclerotic heart disease and cerebral infarction. This finding corroborates large-scale temporal trajectory analyses, showing hypertension as a common upstream condition preceding ischemic heart disease and stroke [6,12]. By explicitly modeling directionality, our study extends prior work by identifying a densely interconnected temporal pattern involving hypertension, atherosclerotic heart disease, and cerebral infarction, which would remain indistinguishable in undirected network models. These directed associations reflect the temporal ordering of diagnoses in the available inpatient data and should not be interpreted as proof of causal disease progression.

Our subgroup analyses revealed pronounced sex-specific progression pathways. Male inpatients showed a more direct transition from hypertension to cerebral infarction, whereas female inpatients were more likely to progress first to atherosclerotic heart disease before subsequent cerebrovascular events. This pattern is consistent with epidemiological evidence, indicating that women experience adverse cardiovascular outcomes at lower blood pressure thresholds than men [14] and that hypertension-related vascular remodeling differs by sex [15]. Furthermore, estrogen-related mechanisms provide biological plausibility for our observed pathways. Sabbatini and Kararigas [16] demonstrated that postmenopausal estrogen decline exacerbates endothelial dysfunction, inflammation, and oxidative stress, accelerating coronary and vascular damage in women with hypertension. Our network-level finding of earlier coronary involvement among women empirically supports these mechanistic insights at the population level. In contrast to studies that report higher overall hypertension prevalence among men in early adulthood [14], our findings suggest that progression severity and pathway structure, rather than prevalence alone, differ substantially by sex—an aspect often overlooked in prior cross-sectional analyses.

Age-stratified analyses showed broader and more multisystem recorded pathways in the older age groups. Inpatients aged 40 to 49 years exhibited relatively constrained cardiovascular trajectories, whereas those aged 50 to 70 and particularly ≥70 years developed complex, multisystem disease networks involving metabolic, respiratory, and neurocognitive conditions. This observation is consistent with longitudinal evidence from the English Longitudinal Study of Aging, which showed that multimorbidity burden increases not only in prevalence but also in systemic complexity with advancing age [17]. Importantly, Bendayan et al [17] reported that specific multimorbidity patterns, including hypertension combined with diabetes and CVD, were associated with accelerated functional decline in older adults. Our findings extend this work by describing the temporal ordering of diagnoses within these patterns, rather than treating them as static states. Moreover, the prominence of diabetes as a transitional node from midlife onward aligns with MorbiNet findings, where type 2 diabetes was shown to connect CVD to multiple downstream complications despite moderate overall centrality [13]. This supports the interpretation that diabetes functions as a bridge disease within multimorbidity trajectories.

Our comparison across health insurance types revealed that the network for inpatients covered by Urban Resident Basic Medical Insurance contained a longer and more diverse dominant recorded pathway than that for inpatients covered by Urban Employee Basic Medical Insurance. The less extensive downstream patterns observed among inpatients covered by Urban Employee Basic Medical Insurance may reflect differences in population characteristics, continuity of care, preventive service use, or diagnostic opportunities across insurance groups. However, these factors were not directly measured in this study. More broadly, these insurance-related differences should be considered alongside nationwide evidence, showing that hypertensive inpatients with multimorbidity face significantly higher risks of catastrophic health expenditure, particularly among socioeconomically disadvantaged and nonemployee insurance groups [2]. Fu and Chen [2] demonstrated that multimorbidity increased the odds of catastrophic health expenditure by over 20% and that insurance protection was insufficient to offset this risk. Our temporal findings provide a disease-mechanistic explanation for these economic outcomes: more complex and accelerated multimorbidity trajectories likely translate into higher cumulative treatment costs and health care use. In contrast to studies focusing solely on expenditure outcomes [2], our work provides complementary information on the recorded disease pathways that may accompany such financial vulnerability.

County-level analyses revealed substantial heterogeneity in disease progression patterns, even within the same province. These findings are consistent with prior evidence that multimorbidity patterns vary by geographic and socioeconomic context [13,17] but extend the literature by showing that the order and speed of disease accumulation also differ across counties. For example, counties with higher progression toward peripheral vascular disease may reflect differential lifestyle exposures or health care accessibility, whereas elevated emphysema transitions following CVD may indicate environmental or occupational risks. Such place-based heterogeneity reinforces calls for localized public health

XSL•FO
RenderX

strategies rather than uniform chronic disease management frameworks.

The temporal organization of the observed disease network has important implications for prevention-oriented hypertension management. The prominent transitions linking recorded hypertension with atherosclerotic heart disease, cerebral infarction, and heart failure suggest that hypertension management should be considered within a broader cardiovascular risk framework rather than focusing exclusively on blood pressure levels [18]. Rather than treating each subsequently recorded condition as an isolated event, clinicians and chronic disease management programs may benefit from considering these conditions as components of an evolving multimorbidity profile. The bridging position of type 2 diabetes between cardiovascular and multisystem disease clusters further supports integrated cardiometabolic and kidney risk assessment, including the appropriate evaluation of glycemic status and renal function [19,20]. Nevertheless, these network-defined transitions represent population-level temporal associations and should not be interpreted as deterministic or causal pathways for individual inpatients.

From a public health perspective, the heterogeneity observed across sex, age, insurance type, and county provides evidence for evaluating more risk-stratified and context-sensitive approaches to chronic disease prevention. Older inpatients, whose networks involved a broader range of metabolic, respiratory, renal, and neurological conditions, may benefit from more comprehensive, individualized care and improved coordination across clinical services [21]. County-level variation may also help identify communities in which screening, longitudinal follow-up, and integrated chronic disease services require further evaluation or prioritization. This interpretation is consistent with place-based chronic disease prevention frameworks that use local population data to inform priority setting, program planning, and resource allocation [22]. Differences across insurance groups may similarly identify populations facing greater challenges in continuity and coordination of care; however, insurance type may reflect multiple unmeasured socioeconomic and health care access factors and should not be interpreted as a causal determinant of disease progression. Therefore, the subgroup patterns identified in this study can inform local needs assessment and the development of targeted pilot strategies, but specific resource-allocation decisions would require external validation and evaluation of feasibility, effectiveness, and cost.

From a health data science perspective, this study demonstrates the value of integrating longitudinal EHR data with temporal network analytics to move beyond static descriptive analyses toward the characterization of population-level temporal patterns. Similar to prior trajectory-based frameworks [6,12], our approach enables early identification of high-risk transitions, supporting anticipatory intervention rather than reactive care. Importantly, by incorporating demographic, socioeconomic, and geographic stratification into the network analysis, our framework is consistent with precision public health approaches that use population-level data to identify groups that may benefit from more targeted and timely preventive strategies [23].

## Limitations

This study has several limitations. First, the retrospective observational design precludes causal inference. The directed edges in the TCN represent the temporal ordering of diagnoses recorded across successive inpatient admissions, rather than confirmed biological disease progression. Moreover, the earliest recorded occurrence of a condition in the study dataset may not correspond to its true onset or initial clinical diagnosis.

Second, the use of inpatient EHR data introduces selection considerations. Individuals whose hypertension and other chronic conditions were managed exclusively in outpatient or primary care settings were not captured, and people with limited access to hospital services may be underrepresented. Conversely, hospitalized patients may have greater morbidity or more intensive health care use and therefore more opportunities for additional conditions to be recorded. The observed temporal patterns should, consequently, be interpreted as patterns among inpatients with a recorded hypertension diagnosis at the participating hospitals and should not be generalized directly to the broader population of individuals with hypertension. Future studies integrating inpatient, outpatient, primary care, and community-based data would be valuable for assessing whether similar temporal patterns are observed across the broader hypertension population.

## Conclusion

This study identified structured and heterogeneous temporal patterns of multimorbidity among inpatients with recorded hypertension across 3 counties in rural Henan Province. Cardiovascular and cerebrovascular conditions formed the principal recorded progression pathways, with atherosclerotic heart disease, cerebral infarction, and heart failure occupying prominent positions in the network. Type 2 diabetes appeared to connect cardiovascular pathways with broader metabolic, renal, and other multisystem complications. Differences by sex, age, insurance type, and county further indicated that recorded multimorbidity progression was not uniform across population groups.

These findings highlight the potential value of incorporating longitudinal disease patterns into hypertension-related chronic disease prevention and management. Population-specific network patterns may help identify priorities for risk assessment, continuity of care, and locally adapted service planning. However, the observed transitions represent population-level temporal associations in inpatient records rather than causal or deterministic disease pathways, and their application to specific prevention strategies requires external validation.

## Abstract

**Background:** Facing the threats of emerging and reemerging health issues requires One Health surveillance systems to provide information for integrated responses. Malawi started enhancing the electronic integrated disease surveillance and response (eIDSR) system in 2015, progressing with the aim of developing a One Health Surveillance Platform (OHSP) using District Health Information Software 2 (DHIS2) as its technical backbone, thereby supporting the COVID-19 pandemic response more resiliently and impacting the integrated disease surveillance and response (IDSR) performance. Digital solutions are critical components of One Health surveillance; however, evidence of the successful establishment and implementation of adaptive digital One Health surveillance systems is scarce.

**Objective:** This study aims to report on the establishment of the OHSP in Malawi and how an adaptive digital health solution contributed to strengthening and impacting the country's eIDSR during the COVID-19 pandemic and beyond the pandemic.

**Methods:** The establishment of Malawi's OHSP was based on the action design research methodology with a transdisciplinary approach. The core team reflected the multiple iterative processes of building the OHSP and formalized its impact on IDSR reporting quality.

**Results:** The OHSP core team conducted multiple iterative cycles to build the platform, leveraging lessons from previous eIDSR pilots, reusing digital health infrastructure, and developing DHIS2 digital solutions in 2019, right before the COVID-19 pandemic. The initial establishment was to cover 48.3% (14/29) of the country's health districts. Pivoting from the initial plan as the COVID-19 pandemic emerged, the core team swiftly adapted the OHSP to scale up nationwide and assisted the health system in responding to the pandemic. The pandemic shock resulted in a national scale-up of the OHSP and impacted the national weekly IDSR reporting quality from nonexistence in 2015 to 97.8% and 74.5% for completeness and timeliness, respectively, in 2024.

XSL•FO
RenderX

**Conclusions:** The establishment of the OHSP significantly bolstered the surveillance function for weekly IDSR reporting. Government leadership and good coordination were key to success. Continuous capacity building, enhancement of community-level surveillance with digital innovations, adaptable technical infrastructure, and a reuse strategy can provide long-term sustainability for One Health surveillance. Malawi's experience may apply to other countries with demonstrated value of resilient, government-led digital health interventions. Future efforts should focus on improving interoperability with other One Health domains and investing in infrastructure upgrades with local leadership and domestic funding to prepare for future emergencies.

## Introduction

Emerging and reemerging health threats, coupled with the complexity of modern health systems, underscore the need for an integrated approach to health surveillance and response, known as the One Health approach [1-3]. Leveraging the One Health approach, the One Health surveillance system emphasizes intersectoral and multidisciplinary collaboration and integrated surveillance of human, animal, and environmental health, which offers promising avenues for strengthening public health management and pandemic preparedness [2,3]. The recent COVID-19 pandemic highlights the critical need to adopt and realize the One Health approach–aided surveillance systems to foster the health system's resilience and reduce disease risks [1,3]. However, given the broad scope of One Health, a proper implementation model for examining the One Health surveillance system and resilient health systems has yet to be fully developed [1,4].

In strengthening health system resilience, surveillance is essential for enhancing the health system's governance function during the shock onset, alert, and impact management stage [5]. Considering health system resilience and recent COVID-19 pandemic experience, effective information and communication systems and digital technologies–empowered surveillance can aid health authorities in responding more resiliently [5-7]. The "One Health surveillance system" is considered a collaborative surveillance system that provides the systematic collection, validation, analysis, and interpretation of data, and dissemination of information collected from humans, animals, and the environment to inform decisions for more effective, evidence-based health interventions [2,8]. By linking surveillance data across different sectors and applying a transdisciplinary approach, One Health surveillance can help different health-related actors address the full spectrum of disease and outbreak detection, emergency preparedness, response, management, and global health security and health system resilience [2,4].

However, establishing, realizing, and implementing a functional One Health surveillance system has proven challenging, with findings showing that the absence of a clear vision for the future of One Health is a barrier to interdisciplinary collaboration and that siloed approaches by different sectors restrict the ability of professionals to work collaboratively across disciplines [9,10]. At the policy level, political will and legal basis are essential for integrating surveillance systems yet remain difficult to attain the collaborative goal [2,8,10]. At the institutional level, establishing a formal governance body with representatives from each sector could assist in overcoming long-standing barriers of privacy and distrust, where sociopolitical factors were considered as organizational attributes contributing to establishing a One Health surveillance system [2,8-10]. At the operational level, technical barriers highlight that the requirements for a successful One Health surveillance system should include understanding disease transmission and the importance of domain experts' knowledge as scientific support, as well as technical mechanisms to support collaboration [2,10].

Malawi adopted the integrated disease surveillance and response (IDSR) system as its national surveillance system for human health and recognized the need for improvements through advanced information technologies [11]. The latest IDSR technical guidelines highlight the importance of using electronic and digital tools to strengthen its function, known as electronic integrated disease surveillance and response (eIDSR) [12]. Countries are urged to implement electronic tools with an interoperable approach to fortify the eIDSR system and information-sharing platforms between various health units to expedite data transmission and enable a swift response to public health threats [12].

In 2014, the Ministry of Health (MoH) sought to enhance the nation's health emergency preparedness plan and piloted an in-house–developed eIDSR system for the first time [13]. After the World Bank–funded eIDSR pilot project, the Public Health Institute of Malawi (PHIM) of the MoH carried out another pilot by using SMS text message technology—Argus—to aid periodic eIDSR reporting [14]. However, these 2 pilots could not be sustained and scaled up. Meanwhile, Malawi recognized the importance of adopting a One Health approach and leveraging digital tools for surveillance by strengthening the eIDSR system as a starting point for the human health domain in the country [11,15,16].

After Cyclone Idai in 2019, the postdisaster needs assessment revealed the urgent need for strengthening and sustaining epidemiological surveillance and emergency preparedness for overall health system resilience [17]. As Malawi has responded continuously to numerous health disasters, including floods, droughts, and disease outbreaks, the idea of the One Health Surveillance Platform (OHSP) originated amidst the pilots of eIDSR, a successful response to an animal-originated anthrax outbreak and the postdisaster period learning [18]. As a result, the MoH chose the District Health Information Software 2

XSL•FO
RenderX

(DHIS2), a technology that has been used for Malawi's health management information system (HMIS) with a successful nationwide scale-up [16,19], as the technical backbone to establish the OHSP.

Health system resilience is the ability of the system to prepare for and respond to sudden shocks and everyday challenges, and its capacity to absorb deteriorations, adapt, and transform to cope with them [5,20]. It requires strong leadership, political will, a collaborative and coordinated governance structure, and robust surveillance systems to detect shocks and their impact in a timely manner [5,6]. In response to the emerging challenges posed by the COVID-19 pandemic, the MoH decided to accelerate the speed of the establishment of the OHSP to accommodate emerging needs. Malawi was able to use the OHSP as one of the digital health innovations, thereby bouncing forward resiliently during the COVID-19 pandemic [21]. This study aims to report on the establishment of OHSP in Malawi and how an adaptive digital health solution contributed to strengthening and impacting the country's eIDSR during the COVID-19 pandemic and beyond the pandemic.

## Methods

### Overview

The establishment of Malawi's OHSP for eIDSR started in 2015 based on the action design research (ADR) methodology [22] with the initial intention to strengthen the country's IDSR system. The ADR method has four stages: (1) problem formulation; (2) building, intervention, and evaluation (BIE); (3) reflection and learning; and (4) formalization of learning [22]. We chose this method to ensure that practical insights, stakeholder feedback, and emerging needs were continually incorporated into the platform's development.

### Context of the Public Health Surveillance System in Malawi

Malawi is a landlocked country situated in southeastern Africa with a population of almost 16 million. It borders Tanzania, Zambia, and Mozambique [23]. Administratively, the country is divided into 3 regions—northern, central, and southern—with further demarcation into 5 zones, 29 health districts, and 4 major cities. The epidemiology department of the PHIM within the MoH is the main custodian of the IDSR system.

Malawi adopted the IDSR strategy in 2002, and the third edition technical guidelines were published in May 2014 with incremental notifiable diseases and health conditions to fulfill the International Health Regulations (IHR) 2005 and public health needs [24]. Malawi conducted a nationwide assessment of the IDSR system in 2017 [11] and found that the IDSR system showed relatively good completeness but poor timeliness of monthly reports nationwide and zero weekly reports. The use of IT to overcome challenges and improve the surveillance system to have better timeliness for IDSR reporting was proposed [11]. Ever since the assessment, PHIM has been working on strengthening the nation's IDSR system activities with electronic and digital solutions, and later on added the One Health surveillance vision after successfully responding to a hippopotamus' original anthrax outbreak in 2019 [18].

### Research Materials and Analysis Methods

Our analysis centered around various documents, including policies, meeting minutes from focus group meetings and key informant interviews, field notes, technical documentation, and digital health products used during the establishment of the OHSP. The OHSP is a digital health innovation accelerated during the COVID-19 pandemic for resilient responses [21] and was sustained for eIDSR functions beyond the pandemic. We summarize the findings from the current establishment to fill the existing knowledge gaps in the implementation of the digitalized OHSP. The impact of the OHSP digital health innovations on the weekly IDSR reporting quality was analyzed using 2024 weekly IDSR reporting quality data with the built-in function of the Reporting Rate Summary in the DHIS2, using the same approach as applied in the previous study [11].

### Reflection and Learning Analytic Tool for OSHP and Impact on IDSR System

In order to rigorously reflect on how the OHSP establishment, and the use in responding to the COVID-19 pandemic resiliently, an analytic tool against the resilience framework was synthesized from the available literature, covering the One Health surveillance systems establishment, attributes of engineering resilient information systems for emergency response, strengthening health systems resilience, and known challenges of implementing DHIS2 [2,5,6,9,10,25,26]. Based on the synthesized findings, we first defined the following five analysis domains: (1) One Health surveillance characteristics, (2) addressing known DHIS2 challenges, (3) health system resilience phases, (4) health system resilience attributes, and (5) health system resilience tools [2,5,6,25]. We then identified thematic areas [2,5,6,25,26] and their corresponding establishment level of a One Health surveillance system, namely policy, institutional, and operational levels, based on Bordier et al [2]. Key attributes and challenges were identified from the reviewed literature [1,2,5,6,9,10,25-28]. We selected the relevant strategies and principles applied to the thematic areas and finally selected attributes for our analysis. The high-level analytic tool is shown in Table 1, and the indicators are detailed in Multimedia Appendix 1 [1,2,5,6,9,10,25,26].

In the One Health surveillance characteristics domains, we focused on analyzing the One Health surveillance–related policies, legal instruments, governance, and leadership in Malawi, reflecting on the known characteristics of setting up and sustaining a One Health surveillance at the policy and institutional levels [2,9,10]. We further analyzed the stakeholders' engagement processes and strategy for data integration and the technical infrastructure of the OHSP to see if it fulfills the One Health surveillance needs at the operational level [2,9].

[a]DHIS2: District Health Information Software 2.

Since the DHIS2 was chosen as the backbone technology for the OHSP, we applied the Addressing Known DHIS2 Implementation Challenges domain for analysis [25]. Among the 11 themes, we selected 4 relevant themes, focusing on analyzing the infrastructure issues, the data pipeline, and the workforce to provide technical support, as well as education and training to implement the OHSP, and synthesized the rest in other domains.

For the health system resilience phases and attributes, adaptive resilience was selected to assess the ability of the OHSP and development team to swiftly adjust to immediate challenges with flexibility while continuously evolving and improving based on past experiences and new information. Resilient digital health systems should be designed to adapt and maintain functionality, as well as enable smooth recovery and reintegration amid changing circumstances to accommodate new requirements, emerging threats, or evolving user needs. The practice of adaptability includes integrating new business requirements and new technologies, scaling up or down as necessary, and supporting interoperability with other systems [1,9,27,28].

Finally, since the OHSP is now institutionalized in Malawi and clearly stated in Malawi's Health Sector Strategic Plan III 2023-2030 (HSSP III) [29], we applied the same reporting quality indicators, completeness, and timeliness, to assess the OHSP's preliminary impact on weekly IDSR reporting at the national level [11]. Completeness was measured using the number of actual reports received against the number of expected reports from health facilities according to the health system level. At the same time, the timeliness of reporting was calculated based on the proportion of health facilities submitting surveillance reports on time to the district, with a national target of 80% for both indicators [11].

## Ethical Considerations

This study was approved by the Malawi National Health Science Research Committee with approval number 16/4/1563 and the Regional Ethics Committee, Regionale Komiteer For Medisinsk

XSL•FO
RenderX

Of Helsefaglig Forskningsetikk sør-øst, with approval number 2015/2441/REK sør-øst A for its ethical conduct as part of the first author's PhD study. The establishment of the OHSP was conducted under the supervision of the MoH to strengthen the country's surveillance system in accordance with the relevant guidelines and regulations. All key informants were informed and obtained their verbal consent to provide information. The policies for analysis are publicly available. The meeting minutes from focus group meetings and key informant interviews, and field notes are kept safely by the first author and restricted access unless approval is obtained from the MoH. PHIM and the Digital Health Division of the MoH keep the technical documentation and digital health products. No compensation or reimbursement was provided to the meeting participants and key informants.

## Results

The observable implementation activities and outputs, including the establishment, implementation, and experience of the OHSP with the COVID-19 pandemic shock, and the post–COVID-19 pandemic impact on the IDSR reporting, are presented in this section based on the ADR method.

### Constitution of the OHSP Development Team

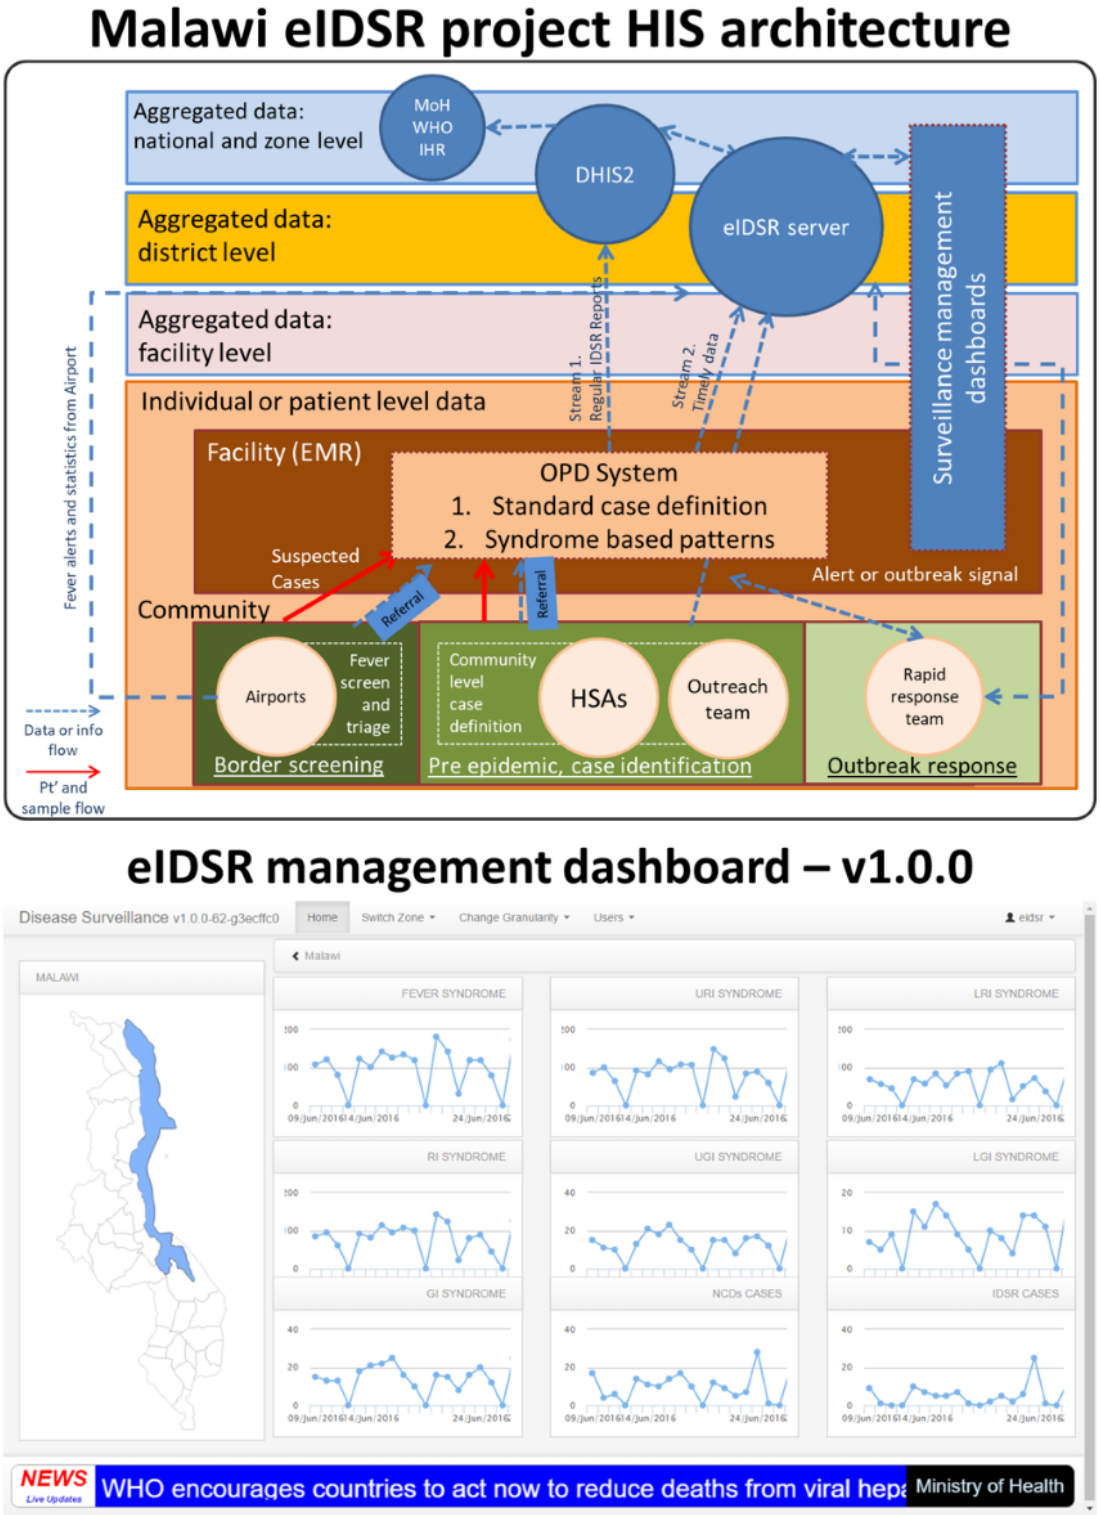
At the beginning of the study, the first author, TSJW, fulfilled his roles as an ADR researcher and practitioner in his capacity and was deeply immersed in the country's digital health development context. He facilitated the constitution of the OHSP core team with the MoH leadership. The OHSP core team (n=12) comprises 2 government officials responsible for the nation's IDSR system, 3 epidemiology unit and institution leaders at the PHIM, 5 digital health and IT staff from the Digital Health Division and Information Communication Technology Division of the MoH, a coordination officer, and a technical advisor. TSJW, the first author and technical advisor who was involved in the 2017 IDSR performance assessment, executed eIDSR pilots and provided technical inputs and guidance on developing the OHSP throughout the BIE stages. The extended OHSP development team consists of government technical officers from different sectors, in their role as the IHR focal person in the respective departments. The OHSP core team inherited technical officers supported by partners and sustained the institutional memories within the government from the previous eIDSR pilot projects by integrating them into the OHSP core team, and started working on establishing the OHSP technical solutions in 2019.

### Problem Formulation Stage

The establishment of the OHSP to support the eIDSR function was inspired by surveillance practices in the country and international recommendations, aligning with the third edition of the IHR 2005. The initial problems of the IDSR system were identified, highlighting the lack of technological solutions for weekly IDSR reporting. In order to tackle this problem, the first author, TSJW, continuously engaged the MoH and development partners to strengthen the IDSR system with 2 eIDSR pilots conducted from 2015 to 2018.

The World Bank supported the first pilot for the post-Ebola era with the aim of developing and implementing an eIDSR system at all levels of the health system in 2015. The following three main activities were conducted: (1) development of a comprehensive eIDSR system architecture and system logical design, (2) software development, and (3) system deployment and field support. During the first eIDSR pilot, we managed to develop the architecture design, establish a border health fever screening system, and develop the IDSR immediate notifiable disease reporting and syndromic reporting automated functions in the outpatient module of a partner-funded electronic medical record system (EMRS). The eIDSR architecture design used the organizational architecture level to guide respective information product developments and information flow; at the same time, the dashboard was designed to enable monitoring of the diseases and syndromic patterns of the outpatient visits together with a geographic information system and global health news Really Simple Syndication feeds function, as shown in Figure 1.

The following two main problems were identified based on the eIDSR pilot implementation results:



1. Sustainability: most of the project team members were dismissed after the project, leaving a minimal capacity within the MoH to maintain the developed systems. The management dashboard and eIDSR central database were designed in-house without the full transition of the source codes to the ministry, and the eIDSR functions in the EMRS were removed after the pilot due to a lack of funding for continuous support.
2. Technical infrastructure: the eIDSR pilot at the facility level was implemented in 59 health facilities with EMRS; however, it covered only 3.2% (59/1849) of the total public health facilities in the country at that time. By the time the pilot ended, the eIDSR pilot also did not cover the whole country for the needed periodic IDSR reporting (weekly and monthly) and community-level case detection.

In order to continue the eIDSR enhancement, the MoH obtained support from the United Nations International Children's Emergency Fund (UNICEF) to pilot the World Health Organization (WHO) Argus solution and facilitate system integration for the country in mid-2017. The UNICEF support was to address the need for a timely weekly IDSR report using the technology. The solution was built and deployed to 220 health care workers for weekly IDSR reporting. However, sustainability and technical infrastructure challenges remained, with no subsequent financial resources and inadequate coverage of the facilities. During the pilot, an additional need was identified to have interoperability between the WHO-Argus solution and the nation's HMIS, which uses DHIS2 technology. The 2 pilots provided lessons for the subsequent establishment of the OHSP. The prevention of the hippopotamus' original anthrax outbreak in late 2018 inspired the MoH to decide to build a suitable digital system to accommodate the One Health surveillance needs and serve the eIDSR functions with the DHIS2 as the technological backbone support.

## BIE Cycles

### *Pre–COVID-19 Pandemic BIE Cycle*

The OHSP establishment formally started in September 2019. Based on the pilot experience, the OHSP core team identified sustainability and technical infrastructure as the 2 key problems to be addressed in the forthcoming OHSP. In addition, previous core team members studied IDSR implementation gaps and community-level surveillance barriers in relation to technology for timely reporting; inadequate training, limited resources, and health-seeking behaviors affecting surveillance capability were also taken into consideration when the team started the OHSP establishment, as summarized in Textbox 1.

XSL•FO
RenderX

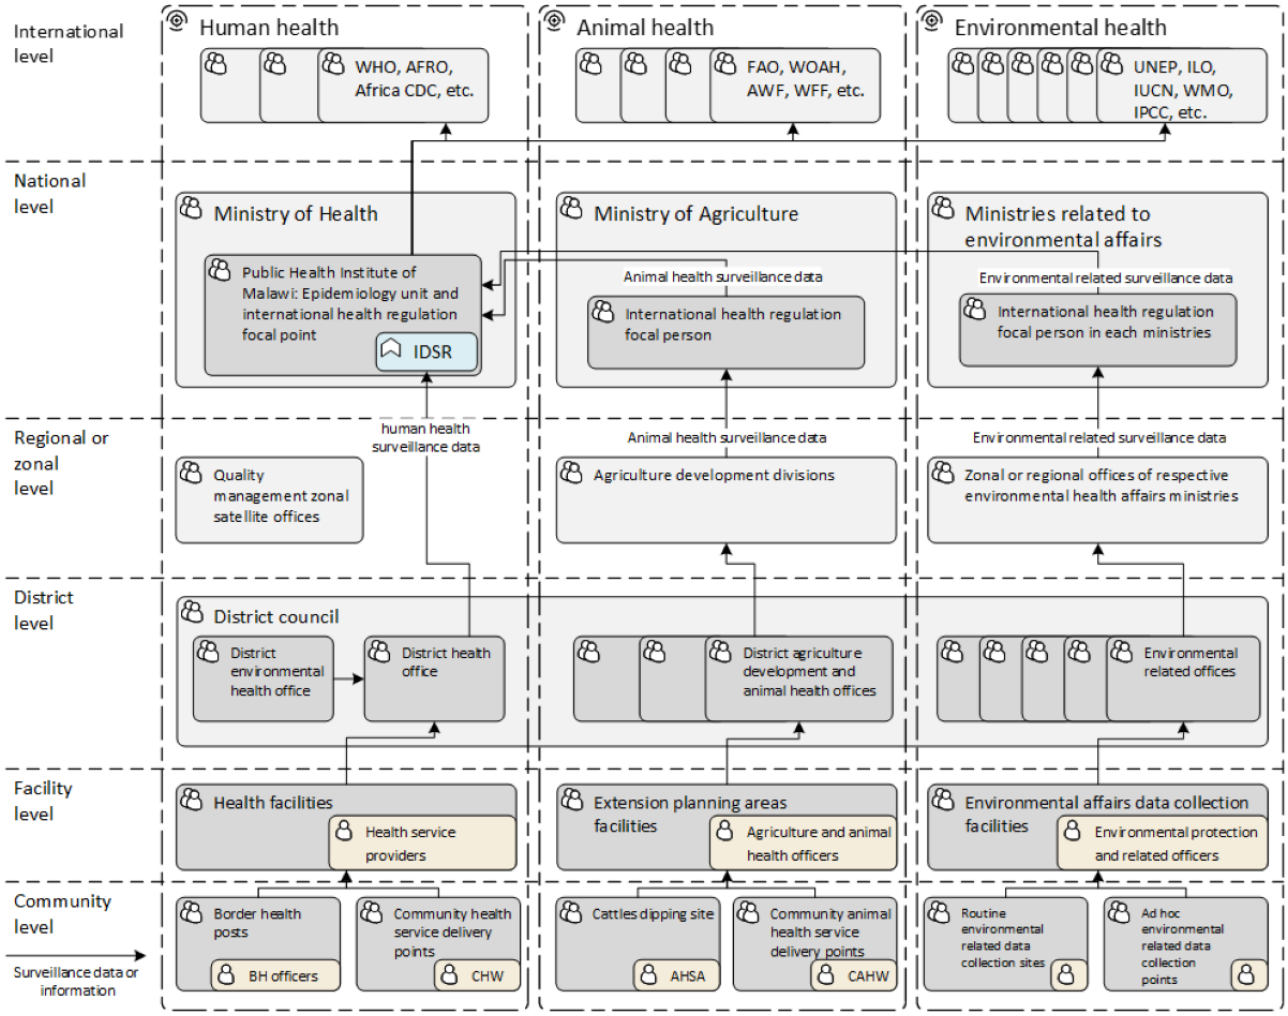
**Textbox 1.** Problems identified from the Malawi electronic integrated disease surveillance and response (IDSR) pilots and previous studies during 2015-2019.

**Sustainability**

- Organizational sustainability
  - Lack of coordination leading to duplication of efforts
  - Lack of engagement from key personnel
  - Unavailability of key Ministry of Health (MoH) staff
  - Coordination issues for systems deployment
  - Conflicting project schedules with some implementing partners
- Human resource sustainability
  - User non-compliance with system usage
  - Technical staff were dismissed without a full transition
  - Inadequate technical personnel in the MoH to continue the development and maintenance
- Financial sustainability
  - Unforeseen communication expenses
  - Cash flow issues are delaying hardware procurement
  - Lack of financial resources for scale-up and sustainability

**Technical Infrastructure**

- Incomplete functionality for the full IDSR system needs, including the community-level surveillance
- Low coverage of the solution
- Extended power outages are affecting deployment
- Connectivity issues affecting system functionality
- Labor-intensive setup process for the terminal device (smartphone)
- Congestion and delivery failures of the SMS service



The OHSP core team initiated the BIE stage to address organizational sustainability issues by reviewing the organizational structure across One Health domains, government documents, and literature to inform the design of the OHSP organizational architecture to accommodate One Health surveillance's needs and the IDSR weekly electronic reporting function. Addressing the coordination and leadership issue was the first step. The core team conducted technical meetings with MoH leadership and learned that the One Health task force was formed during the anthrax response. Through these iterative meetings, we transparently communicated the governance concerns and affirmed that the ownership and leadership of the OHSP belong to PHIM within the MoH. PHIM's leadership then led the core team to further engage with stakeholders to contribute to the architecture design of the OHSP. The OHSP core team began engaging with the animal and environmental sectors, with the animal health domain, represented by the Ministry of Agriculture, being fully consulted. While for the environmental domain, due to its vast fields, the team decided to engage further in the next phase of the OHSP implementation after the consultation with relevant stakeholders.

The core team developed a high-level business process architecture of the OHSP (Figure 2), and aligned information flows based on the identified organizational units, surveillance personnel, and studied data collection tools. The hierarchy of the surveillance units is similar across domains but still shows differences at the subnational level across the 3 One Health domains, as listed in Table 2.

XSL•FO

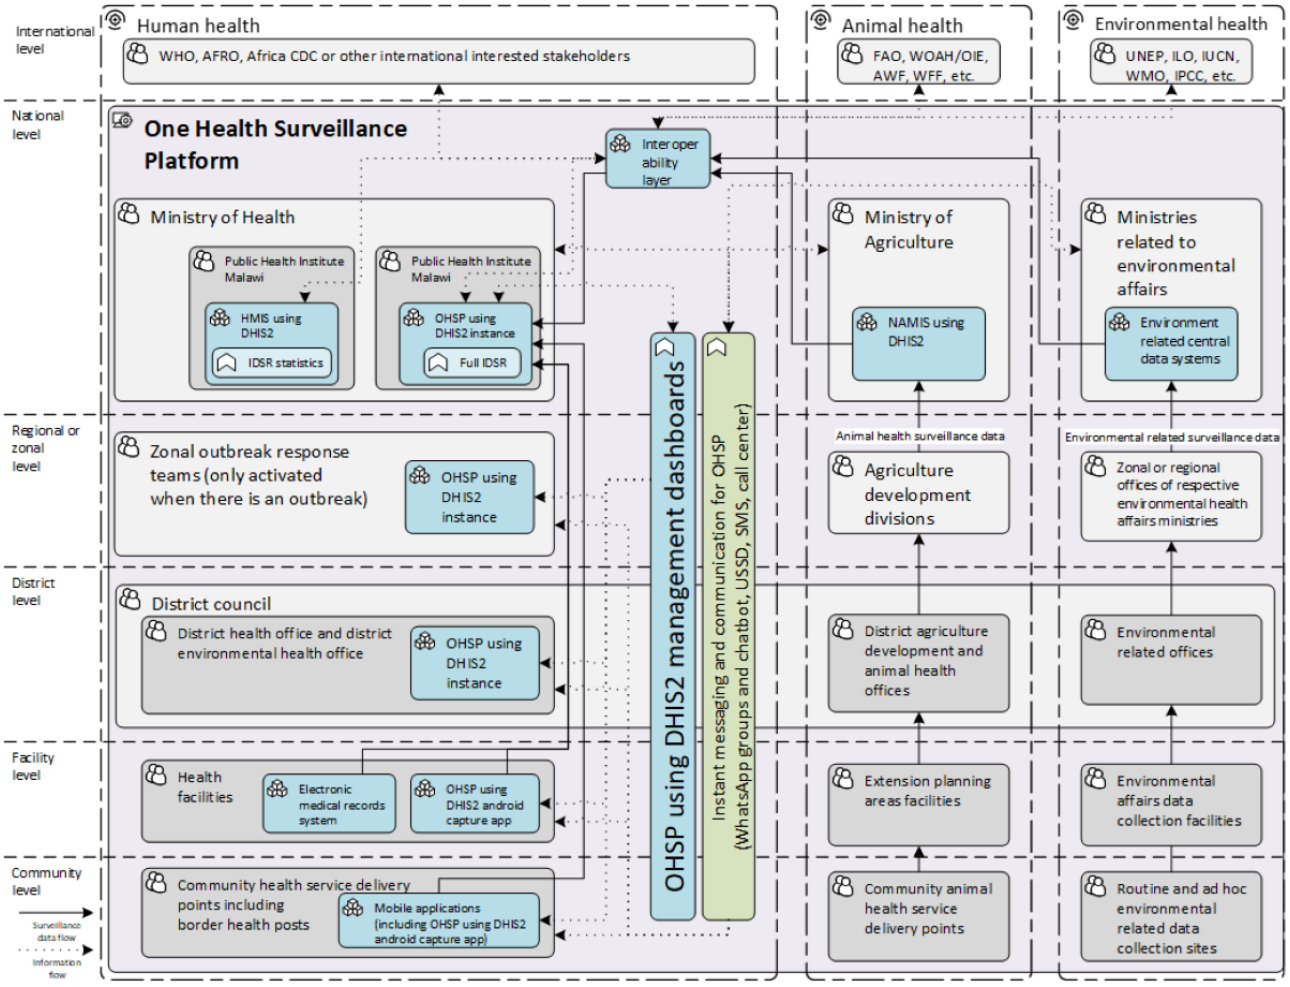
**Table 2.** Organizational units mapping between the 3 One Health domains in the context of Malawi.

| Administrative level | Human health | Animal health | Environmental health |
|---|---|---|---|
| National level | • Ministry of Health | • Ministry of Agriculture | • Ministries of Water and Sanitation, Natural Resources and Climate Change, Mining, Labour, and Land |
| Subnational level: region, zone, or division | • 3 regions, 5 health zones | • 8 agricultural development divisions | • Different from each ministry |
| District level | • 29 health districts with district health offices | • 28 administrative districts with district agricultural development offices | • 28 administrative districts |
| Facility level | • Central hospitals<br>• District hospitals<br>• Rural and community hospitals<br>• Health centers | • Extension planning areas and sections where agriculture extension development officers work | • Different from each ministry |
| Community level | • Health post<br>• Village clinic<br>• Outreach clinic<br>• Village health committees (operated by community health workers) | • Area development committees<br>• Village development committees (operated by animal health surveillance assistants | • Different from each ministry |

Upon stakeholder engagement, we noticed that only the human health surveillance system had standardized reporting and data collection tools using IDSR technical guidelines. Animal health surveillance has a reporting structure, but the standardized reporting forms and tools have yet to be updated and made available. Environmental health surveillance encompasses an even larger degree of complexity, including climate change, weather forecasts, air and water quality monitoring, waste management, pollution incident surveillance, occupational hazards, and risk surveillance.

After the high-level business process architecture was developed, the core team focused on establishing the main data repository to enable facility-level periodic IDSR reporting and to prepare for integrating animal and environmental health surveillance data pipelines in the next phase. The core team developed a strategy to mobilize future surveillance-related investment for human resource retention and to continue the enhancement of the OHSP to anchor and align the One Health surveillance architecture and existing solutions. At the beginning of the OHSP establishment, UNICEF supported the initial OHSP development and committed to initial implementation covering 48.3% (14/29) of the country's health districts.



Once the high-level OHSP architectures were designed, the core team started working on the technical infrastructure for the establishment of the OHSP. Technical factors were considered to favor collaboration and integration of data from different domains, including DHIS2, as an existing national DHIS2-enabled digital health infrastructure used in HMIS, and an interoperability layer (IL), as an existing national information exchange infrastructure, to address these needs.

The core team started the development of the OHSP in November 2019. In terms of roles, the technical staff were responsible for software development and deployment. The first author worked as a technical advisor serving leading and mediating functions in the communication between different stakeholders, including the requirements and limitations from different disciplines to the technical staff. Using a transdisciplinary approach, he translated the business process, information flow, and available tools into programmable technical requirements for developers. After the technical execution, the core team designed the technical architecture for the OHSP, as shown in Figure 3.

XSL•FO
RenderX

**Figure 3.** Technical architecture of the One Health Surveillance Platform (OHSP) after the transdisciplinary translation from public health needs to programmable digital health solutions in Malawi, 2019. AFRO: World Health Organization Regional Office for Africa; AWF: African Wildlife Foundation; CDC: Centers for Disease Control and Prevention; DHIS2: District Health Information Software 2; FAO: Food and Agriculture Organization; HMIS: health management information system; IDSR: integrated disease surveillance and response; ILO: International Labour Organization; IPCC: Intergovernmental Panel on Climate Change; IUCN: International Union for Conservation of Nature; NAMIS: National Agriculture Management Information System; UNEP: United Nations Environment Programme; USSD: unstructured supplementary service data; WFF: World Wildlife Fund; WHO: World Health Organization; WMO: World Meteorological Organization; WOAH: World Organisation for Animal Health.

Based on the architectural design, the core team technical staff applied the Agile method, executing Scrum sprints to build the OHSP digital products. An instant messaging and communication collaboration mechanism was established and included in the OHSP. The One Health forum WhatsApp group was created for all IHR focal persons from different ministries to collaborate on health emergency preparedness and responses for real-time communications during the 2018-2019 anthrax outbreak response and was managed by the MoH. The functional One Health forum WhatsApp group served as one of the digital solutions in the OHSP, providing alerts to the group members. Similar WhatsApp groups have existed to facilitate IDSR coordination and collaboration since 2018. The experts in the One Health forum WhatsApp group anticipated that COVID-19 would become a great threat to the nation's public health in mid-January 2020. The signal was provided to the core team for the team to focus on leveraging available infrastructure resources and reusing technologies from previous eIDSR pilots to develop the following three DHIS2-related digital products: (1) a national DHIS2 instance for the OHSP, (2) a DHIS2 Android Capture app for OHSP, and (3) an interoperability mediator between HMIS and OHSP.

The primary focus during January 2020 was setting up the national DHIS2 instance, especially the metadata design for weekly, monthly, and quarterly IDSR reporting. The core team paid attention to building the OHSP with integration and interoperability infrastructure, especially in relation to the HMIS. The IDSR periodic report and case-based surveillance form were standardized to provide appropriate data and replicated on the OHSP to match those in the HMIS to maintain data integrity. The integration was done by first matching the data element IDs, including the data field IDs and the dataset IDs. The organizational unit IDs were mapped and aligned with national standards using a master health facility registry. The team cloned existing facility mappings and data element mapping identification from the existing HMIS instance and registered the OHSP as a client in the nation's IL so that it could recognize the OHSP instance as a source for data exchange.

Technical solutions were applied to ensure graceful degradation and seamless reintegration, including the DHIS2 features of PostgreSQL (PostgreSQL Global Development Group) performance tuning to improve query performance and scalability. The MoH-owned Proxmox (Proxmox Server

XSL•FO
RenderX

Solutions GmbH) cluster was created to tolerate server downtime without affecting user access through multiple web servers. Load balancing within Nginx (F5 Inc) was configured to distribute load evenly across server instances and to detect any unavailable instances and reroute traffic as needed. The core team applied the "sticky sessions" solution of the DHIS2 to help maintain user session continuity by routing requests from the same client to the same server. The core team configured daily data backups of the OHSP to ensure data restoration capabilities. Fire and water safety controls and a continuous power backup supply at the national digital health server room were applied for the OHSP to operate continuously with minimal downtime. For security, the OHSP DHIS2-related products used password protection and controlled access.

In February 2020, the team concentrated on ensuring HMIS-OHSP interoperability. When building the interoperability, an initial script was created to directly transfer the IDSR data from the HMIS instance into the OHSP. However, when running the script, there was a time-out due to the huge payload that was being sent from HMIS to OHSP; hence, the team decided to use the IL for chunking functionality. Process-wide, the IDSR periodic reporting process was not standardized; some facilities reported in HMIS, while some reported in the OHSP. The MoH leadership addressed the issue by disseminating an internal memo to regulate all surveillance data to be entered in OHSP. The core upgraded the HMIS and OHSP instance, so the payload was channeled through the IL to use the chunking of the payload when sending it from the OHSP to the HMIS.

Simultaneously, the team worked on the integration and user interface design of the DHIS2 Android Capture app to interact with the OHSP instance for data collection and reporting. Also, the team worked on obtaining additional public IP addresses with the government domain for OHSP to facilitate Secure Sockets Layer acquisition and deployment of the solutions through the internet. By March 2020, OHSP was tested by PHIM and was fully ready for implementation to support Malawi's surveillance and response needs.

### *During the COVID-19 Pandemic BIE Cycle*

Right before the core team was ready to deploy the OHSP products, new requests emerged as the country faced the impending threats from the COVID-19 pandemic. According to the original plan, the first release of the OHSP products was to facilitate timely IDSR periodic aggregated data reports. However, with the emergency, the MoH and the national COVID-19 response team at the emergency operation center raised requests and digital health solutions needs, which required additional functions, integration, and interoperability between the OHSP products and other digital health solutions.

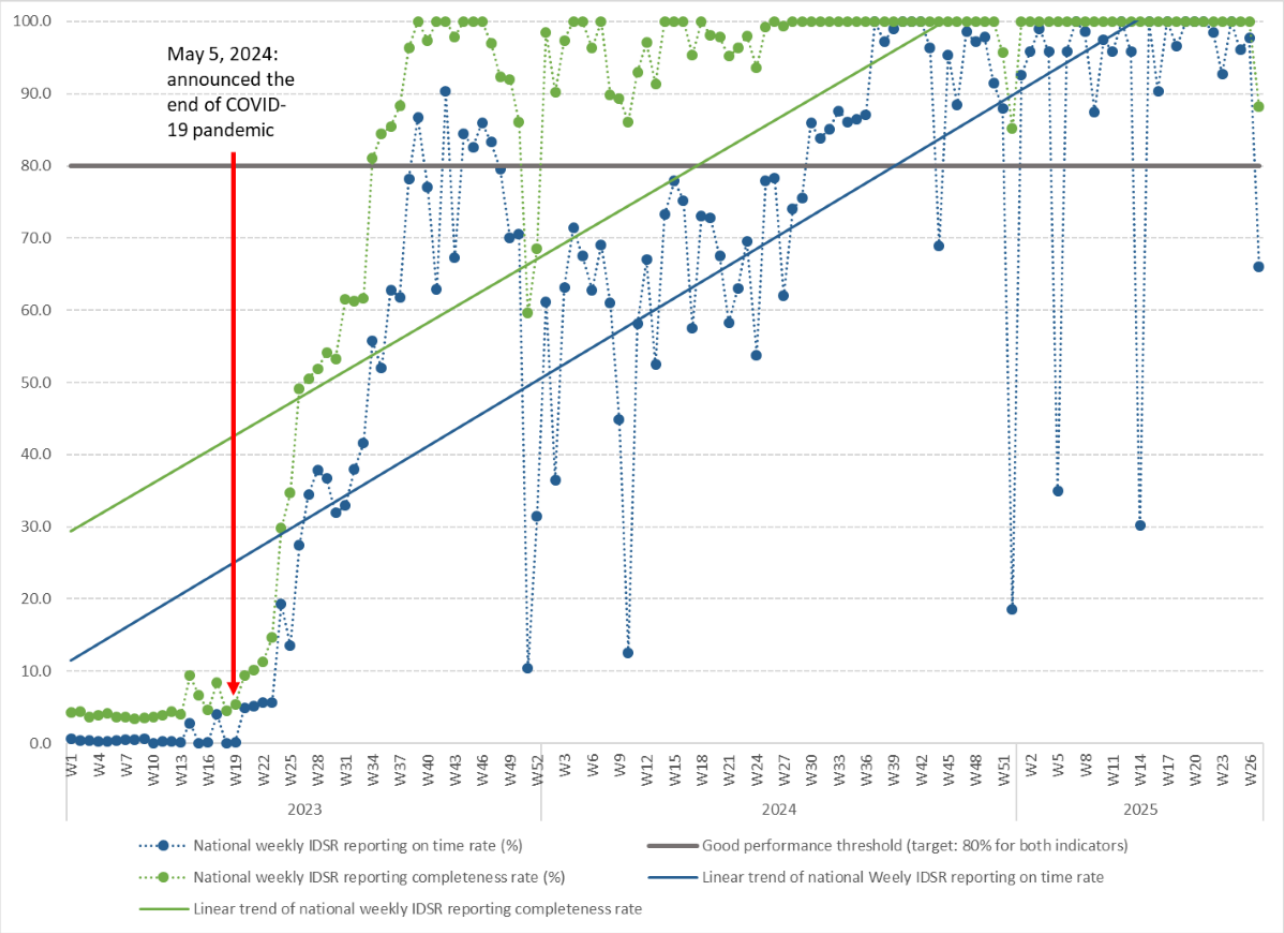
The COVID-19 response emergency operation center was formed according to the Africa Centres for Disease Control and Prevention recommendations in April 2020. The first author, TSJW, was appointed acting manager at the COVID-19 emergency operation center that same month, supporting response activities while continuing to serve on the core team for OHSP development. The core team responded to the requests raised and prioritized them according to the consensus and guidance from the government by leveraging available digital solutions and the IL. The case-based surveillance form of the IDSR system in OHSP was harmonized and standardized with various stakeholders' expectations and updated with COVID-19 conditions in May 2020. Additional forms for border health declaration and contact tracing were developed and added to the OHSP during May-June 2020. The validation rules for mandatory data entry were programmed in the OHSP to ensure data quality at the same time. After the new features of OHSP products were developed, they were included in the new national emergency preparedness and response plans to support the response from May 2020.

The core team applied the agreed strategy to mobilize resources for the national scale-up of OHSP instead of only implementing it in 14 districts when funders and partners showed interest in investment resources for pandemic response. Through the government leadership and collaboration mechanism, multiple funders accepted the advocacy at the beginning of the COVID-19 pandemic, and the core team secured access to additional technical infrastructure resources, especially the server, terminal devices (tablets), and reverse billing approach of connectivity, for deploying the OHSP products countrywide since June 2020. However, the team was unable to mobilize adequate resources for comprehensive redundancy and backup servers of OHSP DHIS2-related products till the end of the pandemic in May 2024.

During the national rollout, all partners followed the MoH leadership to provide standardized training, follow-up supervision, and refresher training. A training program for OHSP products users was designed and implemented comprehensively with user manuals, standardized presentations, a deployment checklist, and detailed schedules, covering computer literacy from the beginner level. A centralized digital health helpdesk at the Digital Health Division was established to provide support to OHSP users. The core team members received further education and training for their DHIS2-related capacity building through online and in-person participation in DHIS2 academies from 2021 to 2023.

A national OHSP enhancement plan was developed to institutionalize OHSP, and a dedicated technical working group was established to facilitate One Health surveillance and regular updates and the One Health bulletin at PHIM in 2023. A comprehensive capacity-building plan and a system infrastructure enhancement plan of OHSP were developed to integrate animal health and environmental health data pipelines in 2024. After the deployment, the OHSP core team has constantly collected the needs and feedback from relevant stakeholders through the established collaboration mechanism. Since then, the OHSP digital products have been sustained and continue to be used for IDSR reporting to date.

### *Post–COVID-19 Pandemic OHSP's Impact on IDSR Reporting*



The OHSP became the main digital data repository for all IDSR surveillance periodic reports after the pandemic. The interoperability mediator is functioning with the MoH as the custodian, ready for reuse and tapping into other One Health surveillance domains' data. The One Health forum WhatsApp

XSL•FO
RenderX

group is still functioning to facilitate the ongoing One Health surveillance activities. The completeness and timeliness of IDSR periodic reports' data quality indicators were defined according to the national guideline and configured in the OHSP's national DHIS2 instance. The MoH continuously provides appropriate feedback on data quality issues through the dashboards, bulletins, and WhatsApp groups to reporting facilities to ensure data quality, with the OHSP core team maintained within the MoH governance structure. The OHSP dashboards developed provide functionality to monitor the epidemiological patterns of notifiable diseases routinely for outbreak detection. As a result, the weekly IDSR reporting transformed from nonexistence in 2015 to a state where the nation reached 97.8% and 74.5% reporting quality for completeness and timeliness, respectively, in 2024. The secular trends and weekly IDSR reporting rate quality are illustrated in Figure 4.

**Figure 4.** The integrated disease surveillance and response (IDSR) weekly reports completeness and timeliness indicators from January 2, 2023, (epidemiological week 1) to June 29, 2025, (epidemiological week 26) in Malawi.

## Discussion

### Summary of Main Findings

This study aims to report on the establishment of the OHSP in Malawi and how an adaptive digital health solution contributed to strengthening and impacting the country's IDSR system during the COVID-19 pandemic and beyond the pandemic. Our findings show that Malawi successfully established a government-led digital tools–aided OHSP right before the COVID-19 pandemic, building on the ongoing effort and further strengthening the country's IDSR system. The OHSP was built corresponding to the characteristics of One Health surveillance systems across policy, institutional, and operational levels [1,2]. Amid the COVID-19 pandemic, the MoH evidently used the OHSP to mitigate the spread and impact of the pandemic [21], and the weekly IDSR reporting improved significantly after the pandemic, from zero reporting in 2015 [11] to 97.8% completeness and 74.5% timeliness by 2024, while PHIM is currently undertaking a full impact assessment of the OHSP.

Findings from this study indicate that the alignment of the national health policies and the establishment of a formal coordination body with government leadership were essential to the One Health surveillance governance. The government-owned and government-led strategy was useful for communicating with all potential funders to invest in the OHSP and align with the government's direction.

The developed holistic OHSP architecture guided the data and information integration design, especially on organizational units and reporting tools standardization. The mapping of the corresponding organizational units with the human health system hierarchy at each administrative level for animal and environmental domains, and having standardized data elements, was a complex task. Considering the complexity, the OHSP core team sensitized all stakeholders engaged in helping with the proper mapping of the units and understanding of the

XSL•FO
RenderX

importance of the data standards for future One Health surveillance data exchange and interoperability.

The reuse of the eIDSR pilots' hardware and available digital solutions provided adequate hardware, software, and communication infrastructure for the initial establishment of the OHSP and accelerated in responding to the COVID-19 pandemic needs. Several known DHIS2 implementation challenges were addressed during the establishment of the OHSP. The OHSP anticipation and adaptive resilience abilities were observed in the study. A detailed discussion, comparison, and contrast of findings with existing literature is followed.

## Interpretations and Implications of Lessons Learnt

### *One Health Surveillance Characteristics*

Our findings were reflected based on four thematic areas using the analytic tool developed (Table 1) under the One Health surveillance characteristics domain, corresponding to the policy, institutional, and operations levels according to the One Health surveillance framework developed by Bordier et al [2].

### *Policy and Governance at the Policy and Institutional Levels*

As known challenges, robust policy frameworks and governance structures are essential factors toward a successfully integrated One Health surveillance system [2,8-10]. The third edition of the IHR 2005 [30] was the main international legal instrument used to justify the One Health surveillance initiative in Malawi. The Joint External Evaluation conducted in Malawi in 2019 highlights the importance of operationalizing and strengthening the One Health platform, improving surveillance systems, and enhancing the data-sharing platform [15], providing an operational framework for Malawi to take action.

The Public Health Act (1948) [31] and the Control and Diseases of Animals Act (1967) [32] provide legal frameworks for disease surveillance, reporting, and control in both human and animal health sectors in Malawi. The Environment Management Act (2017) [33] complements the One Health approach by promoting environmental protection, monitoring, reporting, and public participation in decision-making processes. Malawi's health sector policy, especially the HSSP III [34], highlights the adoption of the One Health approach and OHSP, particularly in areas of antimicrobial resistance and climate change, echoing the One Health surveillance focuses found by Bordier et al [2] and Malawi's emerging needs [17]. At present, the OHSP is institutionalized at PHIM in Malawi to strengthen the IDSR reporting quality, avoiding potential abandonment of the digital health initiative after the COVID-19 temporary use [29]. The developed OHSP enhancement plan and HSSP III [34] guide the gradual integration of different One Health domain data pipelines using the OHSP digital tools. These are useful legal instruments that solidify the government-led coordination mechanism at the policy and institutional level, as advocated in relevant literature [2,5,6], and may be applied in other settings.

Concerning the governance and operation of collaborative surveillance across different sectors, the political will is essential in establishing a One Health surveillance system and may foster its success [2,9,10,35]. Our findings clearly indicated that Malawi showed strong political will, solidified soon after the successful anthrax outbreak response, and gained momentum from the resilient response to the COVID-19 pandemic. The 2 instances affirmed the leadership role of PHIM and strengthened the commitment of the government to take the same One Health approach for future health emergencies. As advocated, government-owned and led digital health interventions offer an opportunity to strengthen health systems and attain health-related goals on the continent [36]. The reinforced government commitment to OHSP's development had effectively reduced the creation of "silos" in the health surveillance system. Political will and leadership are the two key enabling factors contributing to the sustainable operation of the One Health surveillance system, echoing the findings from Vietnam and Australia's experience [10,35]. Coordinated implementation with government leadership maintained continuity and OHSP ownership, further ensuring financial and organizational sustainability in Malawi at the institutional level [2,26].

### *Sustainability for All Levels*

The affirmation of the One Health leadership, established coordination mechanisms, and policy alignment secured the organizational sustainability of Malawi's One Health surveillance initiatives, reflecting the advocacies from others [2,9,10]. The government officials at the forefront led the implementation and delivery of the OHSP digital products to avoid district and facility health care workers conceiving the OHSP as an external system. This approach further reduced operational costs and silo creation, ensuring long-term sustainability as argued by academics in the same field [2,8,10,35]. Meanwhile, the reuse of technology strategy with open-source digital solutions, such as the global DHIS2 and Open Health Information Exchange communities [25,37], provides technical advancement and long-term software sustainability, coupled with the ongoing maintenance by the core team, making the OHSP a resilient information system [26].

Concerning financial sustainability, the strategy of advocating and lobbying for surveillance-related investment to anchor and align the One Health surveillance architecture was a useful approach for the OHSP to scale up nationwide, with the COVID-19 pandemic providing the MoH with an opportunity to align and direct partners' investment to support it. Government ownership and leadership of the OHSP avoid the potential interruption, silos, or hiccup of funding availability, responding to the challenges observed and concepts reported before [2,5,9,10,35]. The OHSP, as a government system, with or without external financial support, requires all civil servants to commit to making it work.

### *Data Integration at the Operational Level*

Most of the One Health surveillance systems in action are focused on zoonotic diseases [38,39] for data to be integrated with human surveillance. The established OHSP can swiftly connect with animal and environmental health surveillance data with its adaptability. In fact, the recent development of the National Agriculture Management Information System (NAMIS) in Malawi also uses the same DHIS2 technology to support the

XSL•FO
RenderX

Ministry of Agriculture in improving livestock production, enhancing herd health, and addressing transboundary animal diseases [40]. The OHSP can provide its affordance to interoperate with NAMIS for surveillance needs. Environmental health, by the nature of its vast domain, has more work to do. Therefore, the OHSP enhancement plan focuses on climate change in alignment with HSSP III can be supported by the same DHIS2 solutions [41]. However, as per our findings, the standardization of organizational units to cover all One Health surveillance domains will be a key issue that needs to be addressed, ideally using a similar master facility registry for animal and environmental surveillance sites.

### *Technical Infrastructure Reuse at the Operational Level*

The functional OHSP, as an effective information system, addressed Malawi's Joint External Evaluation report issues and lack of weekly IDSR reporting by operationalizing and strengthening the One Health platform [11,15]. The high-level architecture, inspired by the concept of the integrated health information system architecture [42] and its alignment with IDSR processes, supported the design of OHSP and the strategy to reuse the existing infrastructure. Although the collaboration with stakeholders during the COVID-19 pandemic secured adequate technical infrastructure for the nationwide OHSP scale-up; however, the current collaborative modalities and technical support mechanisms are still limited in the human health domain, similar to other settings' One Health surveillance progress [38,43,44], where investment will be needed in other domains.

Digital health tools have proven instrumental in improving resilience and maintaining essential health services during crises [21]. However, the challenges noted in the infrastructure, particularly the lack of comprehensive redundancy and the limitations of the server room, point to the need for continuous investment, as highlighted by engineering resilience [26], to have a robust technical infrastructure to ensure OHSP's scalability and reliability.

### *Corresponded to Known DHIS2 Implementation Challenges*

Findings were mainly reflected and compared with Dehnavieh et al [25].

#### Political, Cultural, Social, and Structural Infrastructure

The legal instruments, MoH's leadership, and institutionalization of the OHSP at PHIM addressed known politically related challenges [25]. However, as discussed earlier, sustaining stable financing for technical infrastructure remains a challenge.

#### Appropriate Data—Quality and Standards

The standardized IDSR data collected through the OHSP—including updates and additions introduced during the COVID-19 pandemic—along with validation rules for mandatory data entry, defined data quality indicators, data quality monitoring dashboards, and a weekly epidemiological bulletin ensured appropriate surveillance data supplies. These results directly addressed the challenges identified in Dehnavieh et al [2,25].

#### Workforce and Capacity Building

Malawi has a relatively adequate workforce for the development and implementation of OHSP DHIS2-related products, as evidenced by the constitution of the core team consisting of government officials and technical support officers from partner organizations who programmed the DHIS2 solutions locally. The OHSP enhancement plan, capacity-building plan, and online DHIS2 academies [45] addressed the human resource challenges [25].

### *Health System Resilience—Anticipation and Adaptive Resilience*

Concerning the health system resilience, Malawi's health emergency awareness capacity was enhanced through real-time communication using WhatsApp groups for timely information sharing and decision-making. The use of such a digital solution with the One Health approach corresponds to the Riyadh Declaration to improve preparedness and response to future pandemics [46]. However, although the MoH manages these WhatsApp groups, risks remain for intentional information leakage by group members.

The adaptability of the OHSP was evident in the rapid response to COVID-19, with adjustments made to the system based on emerging needs. This finding echoes the recent organizational resilience studies during COVID-19 about adaptation, innovation, capabilities, and the use of new technology [47]. The Agile software development method, a skilled and committed core team, and affordable digital tools made the success possible.

The result demonstrated that Malawi's OHSP is a resilient system with high adaptability that supports the surveillance goals during the COVID-19 pandemic [21]. The OHSP core team consistently managed to build effective governance with strong government leadership to provide clear policy directions, which are essential for building resilient health systems [1,4]. The government's strong leadership in the establishment of the OHSP paved the way for OHSP digital health solutions to be developed with resilience and rapidly scaled nationwide, echoing conclusions on Africa's digital transformation [36].

## Remaining Gaps and Future Directions

The OHSP addressed some identified barriers to support the IDSR system [11]; however, the current functionality has yet to address the community-level surveillance gaps fully [48]. Event-based surveillance (EBS) is one of the recommended surveillance methods to support community-level surveillance, as stated in the recent IDSR technical guidelines [12]. Other countries' EBS implementation experiences and practices encountered some challenges, including the trade-off between sensitivity and specificity, low awareness of EBS, and inadequate infrastructure [49,50]. The role of middle-layer actors in participating in community-level surveillance, community engagement, and additional digital solutions should be considered as the OHSP is enhanced to support the EBS in the country, not only for human health but also animal, including wild and domestic, and the surrounding environment as a whole [1,48,50]. Engagement with stakeholders using existing coordination mechanisms and applying the participatory

XSL•FO
RenderX

approach should be encouraged for future OHSP enhancement [35]. Despite Malawi managing to address the OHSP establishment challenges through strategic planning and implementation, continuous capacity building, training, supervision, and retaining skilled personnel for the OHSP to be resilient still exist in Malawi with constrained resources, similar to the challenges that Tanzania encountered trying to establish a similar platform [51]. Mobilizing and lobbying resources to fully operationalize the OHSP enhancement plan, with highlighting multisectoral benefits as argued by Fasina et al [44], is the recommended direction.

### Limitations

Our study focused on the establishment experience of the OHSP in Malawi; despite its impact on the weekly IDSR reporting quality, its further use, linkage to other One Health domains, and its impact on the overall One Health surveillance are limited. Regarding the health system resilience, although the frameworks were developed [5,6], they are limited to emergency management and health care systems, with none specifically for One Health surveillance systems [26,52,53]. The synthesis analytic tool we developed for the OHSP establishment analysis can be used in similar settings for assessing the One Health surveillance system, despite the fact that our analysis was limited to the One Health surveillance system establishment stage; further use of the tool is encouraged.

### Conclusions

The success of Malawi's OHSP establishment highlights the importance of government leadership and coordination in ensuring financial and organizational sustainability. Key findings informed the need for continuous capacity building, adaptable technical infrastructure, and enhanced community-level surveillance in the long run.

As global health systems continue to face emerging threats to respective contexts, Malawi's experience demonstrates that a well-integrated, government-led digital OHSP can enhance resilience and preparedness to these health challenges. Amid the dynamic of the global development policy changes and complex human-animal-environmental interactions, findings from this study can be applied to broader audiences to enhance their surveillance and health systems in combating the pandemics to come.

Future investments, with emphasis on local leadership and domestic financial resources, in interoperability, infrastructure, and community engagement, will be essential for maximizing the impact of OHSP and similar initiatives worldwide.

## Acknowledgments

We acknowledge support from multiple funding and implementing partners whose contributions supported the establishment of the One Health Surveillance Platform in Malawi before and during the COVID-19 pandemic; including United Nations International Children's Emergency Fund, the Gates Foundation through Kuunika Data for Action Project via Cooper/Smith, United States Agency for International Development/United States President's Emergency Plan for AIDS Relief through Elizabeth Glaser Pediatric AIDS Foundation, Management Sciences for Health, International Training and Education Center for Health, World Bank, and the Global Fund. We also acknowledge the useful and resourceful technical support and contribution from the District Health Information Software 2 global community and the Health Information Systems Programme Centre at the University of Oslo. We extend our sincere gratitude to the senior management team of the Ministry of Health for their strong leadership and unwavering commitment to realizing the establishment of the One Health Surveillance Platform.

The authors declare that Grammarly was used as a machine tool to suggest language improvement within the language. No other generative AI tools were used in this manuscript.

## Funding

The funding support to this study of the One Health Surveillance Platform establishment and learning was supported by the Pingtung Christian Hospital (grants PS-IR-109001, PS-IR-111001, and PS-IR-111001), Taiwan, through Luke International, Norway, as part of the first author's PhD work.

## Data Availability

All meeting minutes and internal notes are available upon request. The One Health Surveillance Platform–related source codes and documentation, for public access according to the Ministry of Health regulations, are available in the following GitHub repositories: (1) Ministry of Health of Malawi in production services GitHub repository [54] and (2) Ministry of Health of Malawi Project-Based GitHub repository [55].

## Conflicts of Interest

None declared.

## Abstract

**Background:** Public health surveillance (PHS) systems are essential for routine disease monitoring, early outbreak detection, and emergency response. Although many studies focus on system development and implementation, less attention has been given to factors that sustain surveillance systems over time.

**Objective:** This study aimed to identify stakeholder-perceived conditions associated with the sustainability of PHS systems in Thailand by examining stakeholder experiences across 2 operational national surveillance platforms.

**Methods:** A comparative qualitative case study was conducted using evidence from the Malaria Surveillance System (MIS) and Digital 506 (D506), the national notifiable-disease surveillance platform. In total, 6 individual interviews and 4 small-group interviews were conducted using semistructured guides with 17 participants: IT personnel, project managers, public health officers, and policymakers and funders. Audio recordings were transcribed and analyzed using a deductive-dominant hybrid thematic approach combining deductive and inductive coding, with explicit within-case and cross-case comparison.

**Results:** Thematic analysis identified 7 themes reflecting stakeholder perceptions of PHS sustainability: user needs, collaboration and partnership, human resources, infrastructure, financial sustainability, ownership, and system adaptability. Participants associated continued use with systems that fit routine workflows, reduced duplicate work, and produced actionable outputs. MIS findings highlighted context-adapted design in remote settings, donor transition, and reluctant ownership, while the D506 findings emphasized interoperability, near real-time national reporting, and constraints in domestic budgeting and specialized technical capacity. Shared challenges included infrastructure maintenance and recurrent staffing and financing needs. Participants also distinguished digitization from digital transformation intended to improve efficiency, decision-making, and adaptability to changing needs.

**Conclusions:** Stakeholder perspectives suggest that sustaining PHS systems requires more than technical deployment. For comparable national surveillance systems, the findings suggest prioritizing clear operational ownership and recurrent resources to support routine workflows, maintain human and infrastructure capacity, and enable continuous adaptation to changing public health and technological needs.

## Introduction

Public health systems worldwide continue to face emerging health threats that require timely detection and response. Traditional paper-based surveillance systems, which depend on manual reporting and delayed data collection, are increasingly inadequate for addressing the challenges of modern public health. These limitations have driven the adoption of health information systems (HISs) within public health surveillance (PHS) to facilitate timely monitoring, efficient data management, and evidence-based decisions in public health practice [1,2]. By improving data timeliness, PHS systems can enhance public health readiness and support faster responses to outbreaks and emergencies, making them important components of modern public health infrastructure.

As health care demands rise, the importance of sustainable PHS systems has become increasingly apparent. Public health organizations worldwide have implemented PHS systems to address diverse and evolving health risks [3,4]. The integration of PHS systems into the existing HIS framework enables more efficient data collection, analysis, and dissemination, improving disease surveillance and enabling more effective public health responses [5].

Sustainability, which has been conceptualized in environmental science as "meeting present needs without compromising future generations," has been extended to IT topics to describe the ability of systems to remain functional and practical over time despite technological, organizational, or financial changes [6]. In the context of PHS, sustainability refers to the system's capacity to maintain surveillance activities to support continuous disease monitoring and public health decision-making [7,8].

Despite the growing adoption, the long-term sustainability of PHS systems remains a significant challenge and an underexplored area of research. As with other software systems, their viability depends not only on their initial development but also on technical infrastructure, organizational support, and management processes. Without adequate support for sustainability, PHS systems risk becoming inefficient or even obsolete over time [9]. Examining sustainability challenges in operational PHS systems can provide valuable insights into system implementation and maintenance processes throughout their lifecycle to support long-term use.

Studies in Thailand have described the development, implementation, and performance of individual surveillance systems [10-14]. However, comparative qualitative evidence on the sustainability of national PHS platforms with contrasting development, governance, and financing pathways remains limited in the Thai context. Consequently, little is known about which sustainability concerns are shared across systems and which are shaped by their operational contexts.

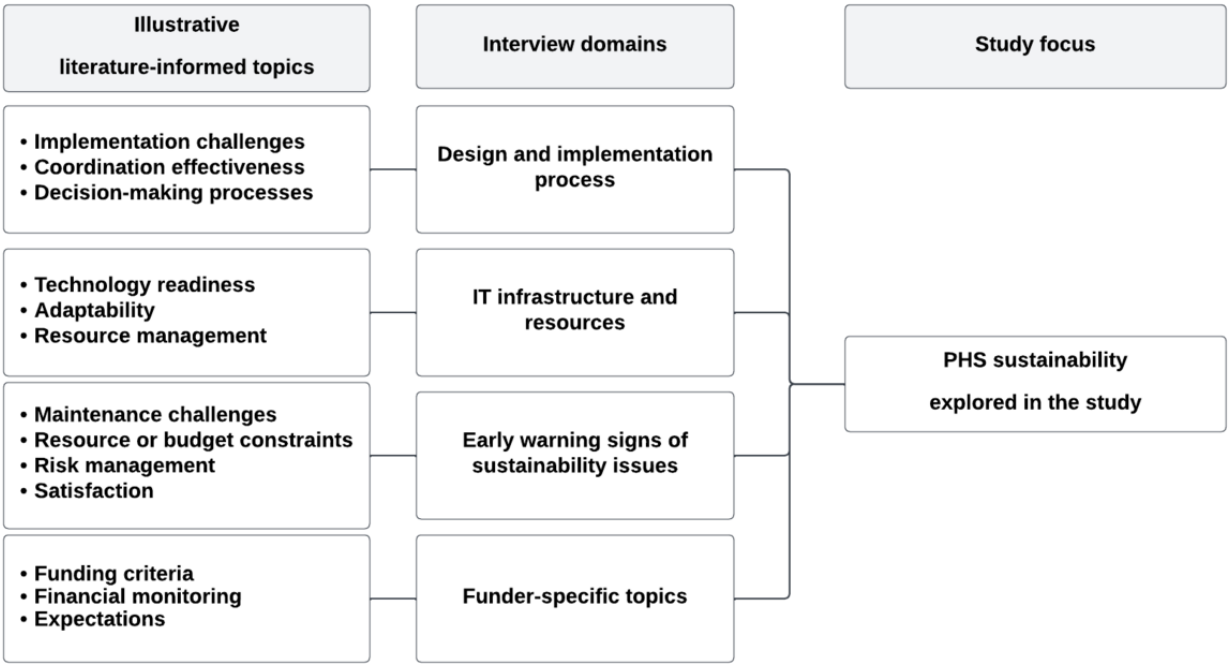
Accordingly, this study aimed to identify stakeholder-perceived conditions associated with the sustainability of PHS systems in Thailand through a comparative qualitative case study of the Malaria Surveillance System (MIS) and Digital 506 (D506), the national notifiable-disease surveillance platform. These systems were selected as deliberately contrasting cases because they differed in disease scope, development pathways, operational contexts, governance, and financing arrangements, allowing shared and context-specific sustainability concerns to be examined. The study drew on the perspectives of individuals directly involved in system development, implementation, management, routine use, policymaking, or funding. By focusing on sustainability as a central yet underexplored dimension of PHS, this study contributes to understanding how surveillance systems can remain functional and responsive in dynamic public health environments.

## Methods

### Study Design

The study used a comparative qualitative case-study design to investigate stakeholder perceptions of the sustainability of PHS systems in Thailand [15,16]. Semistructured interviews and small-group interviews were used to gather in-depth insights into the experiences and perceptions of stakeholders involved in the development, implementation, routine use, management, policymaking, or funding of these systems. The MIS and D506 were intentionally selected before data collection, with each surveillance system serving as a bounded case and primary unit of analysis. Their contrasting disease scope, development pathways, operational contexts, and funding arrangements were prespecified as the basis for cross-case comparison. This purposeful contrast allowed the study to examine which perceived sustainability conditions were shared across 2 operational systems and which were specific to their institutional, technical, and financing contexts.

Both systems were selected for their continued operation through changes in technology, organizational arrangements, and public health requirements, providing information-rich insights into adaptation and ongoing challenges. Although discontinued systems were not included, these cases allowed examination of difficulties encountered during continued operation.



For this study, sustainability was operationalized as the ability of a PHS system to continue functioning and supporting routine surveillance over time despite changes in technology, funding, organizational arrangements, and public health requirements. This included continued routine use, maintenance and support, clear responsibility for ongoing operation, and the capacity to adapt to changing needs [8,17].

An interview guide was developed to ensure consistency across data-collection sessions while permitting open-ended responses. The guide was structured using a literature-informed framework developed by the research team from recurring sustainability considerations reported in HIS and PHS literature [6-8,17]. These considerations were organized into 4 domains: design and implementation process, IT infrastructure and resources, early warning signs of sustainability issues, and funder-specific topics (Figure 1). The framework was used as an organizing structure for data collection and the deductive component of initial coding while allowing additional concepts to emerge from participants' accounts.

XSL•FO
RenderX

**Figure 1.** A literature-informed interview framework. PHS: public health surveillance.

## Ethical Considerations

The study received approval from the ethics committee of the Faculty of Tropical Medicine, Mahidol University (MUTM2025-015-01). Before participation, participants reviewed the study information and were informed of the study objectives, procedures, rights, and confidentiality risks, including the limits of confidentiality in small-group interviews. Written informed consent was obtained from all participants. Direct identifiers were removed from transcripts before coding. Audio recordings, transcripts, and study materials were stored, with access restricted to the research team. Each participant received THB 500 as compensation for their time. For reporting, quotations and supplementary materials were deidentified and reviewed to reduce the risk of deductive identification for national-level stakeholder groups.

## Study Setting

The study focused on 2 PHS systems in Thailand: the MIS and D506, the national notifiable-disease surveillance platform. MIS is used nationwide for malaria surveillance and supports monitoring and management of malaria transmission, with particular operational requirements in malaria-endemic and border settings. Its development grew from electronic and mobile malaria-surveillance initiatives introduced in 2009 and subsequently expanded in provinces along Thailand's international borders. MIS has been supported by international funding sources, including the World Health Organization, the Bill & Melinda Gates Foundation, and the Global Fund, and received technical support from the Center of Excellence for Biomedical and Public Health Informatics (BIOPHICS), Faculty of Tropical Medicine, Mahidol University [10,11].

D506 evolved from the legacy Report 506 (R506) weekly reporting structure, which has supported national notifiable-disease reporting since 1967. D506 was developed domestically using national budget allocations in 2022 to support more timely electronic reporting and was later incorporated into the broader Digital Disease Surveillance framework in 2024 [12-14].

## Study Population

Participants were selected using purposive sampling to include individuals with relevant roles and experience in PHS systems and the capacity to provide in-depth insight into their long-term sustainability [18]. Eligibility required at least 6 months of relevant involvement in system development, implementation, operation, management, policymaking, or funding. Formal invitations were sent directly to the designated leads responsible for MIS or D506 within participating organizations. These leads were asked to identify and nominate staff whose functional involvement met the eligibility criteria. The recruitment process therefore reflects nominated and participating individuals rather than all staff who may have been considered within each organization.

The study population was categorized into 4 key stakeholder groups based on functional roles. The first group comprised IT personnel, including developers, system analysts, and administrators, responsible for the technical design, deployment, and maintenance of PHS systems. The second group included project managers (PMs) who oversee system planning and implementation and coordinate between technical teams and public health stakeholders. The third group consisted of public health officers (PHs), such as epidemiologists and field practitioners, who are responsible for routine data collection, verification, and the application of surveillance data for disease monitoring. The fourth group included policymakers and funders (PFs), encompassing senior officials and representatives who provide strategic direction, governance, or financial support for PHS systems.

XSL•FO
RenderX

These categories were selected to capture complementary responsibilities across the surveillance-system lifecycle: technical development and maintenance, implementation coordination, routine public health use, and policy or financial governance. Stakeholder categories were assigned according to participants' primary functional responsibilities in the surveillance system rather than formal organizational job titles.

The initial recruitment plan allowed for up to 10 participants associated with each PHS system and up to 5 policy or funding participants. The plan was informed by the range of technical, operational, governmental, and partner perspectives included in comparable qualitative research on HIS sustainability [19] and by the stakeholder functions relevant to the present study. Final recruitment was guided by informational redundancy in the accumulating interview data rather than by statistical calculation [20].

## Data Collection

Participants took part in either an individual interview or a small-group interview based on their responsibilities, involvement, and availability. Participants involved in closely coordinated technical or operational activities were generally included in small-group interviews to capture shared experiences and complementary perspectives, whereas those with strategic, supervisory, policy, or funding responsibilities were generally interviewed individually to support more detailed insights into governance and decision-making. Small-group interview composition was arranged around related responsibilities and participant availability while seeking to limit hierarchy effects where possible.

Two role-adapted semistructured interview guides were used. The surveillance-system stakeholder guide was used for participants directly involved in MIS or D506, including technical, public health, management, and policy roles. The funder participant was interviewed using a separate guide focused on funding criteria, monitoring, expectations, and sustainability beyond the funding period. Before data collection, WP pilot-tested the interview guides internally with CR and SL through mock administration of the questions. Based on this process, the research team refined the wording and sequencing of questions and incorporated relevant follow-up probes to improve clarity and suitability for the intended participant groups. The pilot testing was conducted as an internal research-team procedure, and no pilot-test data were included in the analysis. The complete English interview guides are provided in Multimedia Appendix 1.

Sessions were conducted in either Thai or English, depending on participants' preferences, and took place on-site or online through the Mahidol University password-protected Zoom environment. CR and WP participated in all data collection sessions as an interviewer or comoderator, asked follow-up and clarification questions, and supported session recording and observation. All sessions were audio-recorded with participants' consent, and recordings were stored, with access restricted to the research team. Handwritten notes were used to capture key points and preliminary observations and to support postsession discussion within the research team.

Data saturation was assessed iteratively during data collection as redundancy in the accumulating information [20]. WP and CR reviewed the accumulating interview content and the evolving codebook as data collection progressed and considered whether subsequent sessions contributed substantively new information relevant to the study objectives. Recruitment concluded when subsequent interviews largely repeated issues already represented in the codebook, while also considering the availability of eligible participants and organizational access. Data collection was completed in a single session per participant; no repeat interviews were scheduled, and transcript return and participant member checking were not part of the study procedures.

## Researcher Characteristics and Reflexivity

The research team was based at an academic institution, with backgrounds in epidemiology and health informatics and experience in PHS and digital health systems. The team has established academic and professional collaborations with the Ministry of Public Health and relevant stakeholders in Thailand. CR and WP led the individual and small-group interviews; CR had formal qualitative research training and interviewing experience, and WP conducted data collection under CR's supervision.

The researchers' familiarity with PHS facilitated access and understanding of the study context. However, none had a direct supervisory relationship with participating PHS personnel or operational responsibility for either surveillance platform. Although the MIS was developed by BIOPHICS within the broader institutional environment, the researchers were not involved in its day-to-day operation or staff supervision. Following each session, CR and WP conducted reflective debriefings to compare interpretations, consider how their assumptions or experiences might influence interpretation, and discuss alternative or divergent perspectives to ensure that findings remained grounded in participants' accounts.

## Data Analysis

Audio recordings were transcribed verbatim in the language used in each session. WP transcribed Thai-language recordings word for word in Thai and used ChatGPT (OpenAI) as a translation-support tool to prepare English translations, whereas English-language recordings were transcribed directly in English. WP checked every English translation against the corresponding Thai transcript and audio recording. CR and SL reviewed the translated material and its use throughout the analysis. The English translations also enabled PH, an English-speaking coauthor, to participate in analytic review and validation. Unclear or culturally and technically specific wording was resolved by replaying the recording, returning to the Thai transcript, and discussing the intended meaning within the research team. Coding and analysis were conducted in English.

Data were analyzed using a deductive-dominant hybrid thematic approach combining deductive and inductive coding [21,22]. Initial coding was structured by the 4 literature-informed framework domains and 13 predefined working codes documented in the qualitative codebook. A common coding framework was used across MIS and D506, with codes applied

XSL•FO
RenderX

where relevant to each participant's interview material. WP performed the primary coding in Microsoft Excel and recorded material not adequately captured by the initial categories as emerging concepts. WP, CR, and SL iteratively reviewed coded excerpts, emerging concepts, category organization, and candidate themes. Interpretive differences raised during review were addressed by returning to source excerpts and revising category or theme boundaries through discussion. This process consolidated the predefined codes and emerging concepts into the 7 final themes reported in the Results section.

Following theme development, evidence was reviewed within MIS and D506 and compared across the 2 systems to identify convergent, divergent, and case-specific patterns. A structured cross-case evidence matrix was prepared from the existing coded dataset to make these comparisons explicit. The supplementary materials include participant and session characteristics (Multimedia Appendix 2), the qualitative codebook with theme definitions, distinctions, and illustrative coding (Multimedia Appendix 3), and the cross-case evidence matrix (Multimedia Appendix 4). The SRQR (Standards for Reporting Qualitative Research) checklist is provided in Multimedia Appendix 5.

# Results

## Participant and Session Characteristics

Data collection was conducted between February and July 2025 and included 17 unique participants from organizations involved in the development, funding, and implementation of the 2 PHS systems. Participants represented 4 stakeholder categories: IT personnel (n=6), PMs (n=3), PHs (n=4), and PFs (n=4). No participant contributed to more than 1 data collection session.

Data were collected through 6 individual interviews and 4 small-group interviews. The small-group interviews included 2-4 participants. In total, 3 sessions were conducted online via Zoom, and the remaining 7 were conducted onsite. Session durations ranged from approximately 33 to 90 minutes. Participant- and session-level characteristics are provided in Multimedia Appendix 2.

Most participants had substantial experience in PHS systems, with 13 of 17 reporting at least 10 years of relevant experience. Notably, IT personnel were involved in both the development and maintenance phases, providing insights into the full technical lifecycle from system design to long-term sustainability. A summary of participant characteristics is presented in Table 1.

**Table 1.** Participant and session characteristics.

| Session ID | Participant ID[a] | PHS[b] experience (years)[c] | Interview type | Session duration (minutes:seconds)[d] |
|---|---|---|---|---|
| MIS-1 | MIS-PM-01 | 10-15 | Small group | 33:24 |

## Summary of the Themes

### Overview

The 4 literature-informed interview domains shown in Figure 1 structured data collection and initial deductive coding but were not treated as final themes. Through iterative review, the predefined codes and emerging concepts were consolidated into 7 final themes reflecting participants' perceptions of PHS sustainability: user needs, collaboration and partnership, human resources, infrastructure, financial sustainability, ownership, and system adaptability. These themes describe technical, organizational, and policy dimensions of continued surveillance-system operation. Table 2 summarizes the principal cross-case findings.

**Table 2.** Summary of final theme findings and cross-case interpretations.

| Theme | Key findings | Cross-case interpretation | |
|---|---|---|---|
| | | MIS[a] | D506[b] |
| User needs | Participants associated continued use with systems that fit routine workflows, reduced reporting burden, and provided immediately useful outputs. | Emphasis on field usability despite unstable connectivity and on case follow-up. | Emphasis on timeliness, dashboards, interoperability, and national-scale information use. |
| Collaboration and partnership | Participants described sustainability as requiring ongoing coordination among technical, public health, managerial, vendor, and policy stakeholders. | Long-term collaboration between malaria staff and developers. | Broader network with greater interoperability and vendor-coordination demands. |
| Human resources | Continuity was perceived as vulnerable when technical or operational knowledge depended on a small number of people and more resilient when internal capability and training were strengthened. | Emphasis on field training and transfer of system-specific technical knowledge. | Emphasis on recruitment and retention of specialized engineering capability. |
| Infrastructure | Infrastructure was described as a lifecycle issue involving connectivity, maintenance, capacity, upgrading, procurement, and continuity. | Emphasis on resilience to weak connectivity and older hardware. | Emphasis on centralized processing, interoperability, and increasing data volume. |
| Financial sustainability | Participants described sustainability financing as extending beyond development to recurrent personnel, infrastructure, maintenance, training, and governance costs. | Donor-to-domestic transition concerns. | Domestic budgeting and procurement constraints despite stronger institutional embedding. |
| Ownership | Participants associated continued operation with a responsible entity that had authority, resources, and accountability for system continuity. | Reluctant or nominal ownership emerged most explicitly in MIS. | More institutionalized government responsibility through departmental roles and budget allocation. |
| System adaptability | Participants viewed sustainability as dynamic and dependent on continued relevance under changing epidemiological, organizational, technological, policy, and user conditions. | Adaptability to disease context, organizational change, remote operations, and technology. | Adaptability through interoperability, evolution from prior reporting systems, and broader digital transformation. |

[a]MIS: Malaria Surveillance System.

[b]D506: Digital 506.

### User Needs

Participants associated the perceived sustainability of PHS systems with their ability to meet user needs by integrating into routine workflows and providing immediate, tangible value. Across both cases, continued use was associated with whether the system supports daily operations rather than imposing additional reporting burdens. Participants perceived that useful tools for decision-making and service delivery encouraged continued engagement and long-term use.

Despite this shared principle, user needs differed according to the operational context of each system. In the MIS, the primary requirement was to facilitate the transition from paper-based and spreadsheet-based processes to a digital platform suitable for use in remote and resource-constrained settings. MIS participants highlighted the importance of retaining functionality that accommodates unstable internet connectivity, such as offline data entry and delayed synchronization:

> *... Users often said their internet was unstable ... so we switched to an online-offline model ... which allows users to input data offline and then syncs it to the central system when internet is available.* [MIS-IT-03]

> *... They had specific workflows, including report forms, data collection templates, and required reporting formats ... We used them to design the computerized system accordingly ...* [MIS-PM-01]

In contrast, D506 participants described how the COVID-19 pandemic increased demand for timely, useful outputs, prompting a shift from legacy weekly reporting (R506) to near real-time data availability. They described the development of

XSL•FO
RenderX

interoperable components, including APIs and dashboards, to support timely monitoring and national-level decision-making. These developments were accompanied by consultation with field users about which information to display:

> *The factor that led from R506 to D506 came during the COVID period. ... We realized we needed real-time data ... to get timely information ... During COVID, we were using Excel to report daily data and were still struggling with just Excel.* [D506-PH-03]

> *If we only develop based on what we want to see, without actually asking field users what they need, then it is not useful.* [D506-PH-01]

Across both systems, participants associated immediate, actionable outputs for routine supervision and decision-making with motivation to continue using the system. Thus, both cases emphasized practical fit and visible value, while the specific user requirements differed: MIS centered on field usability under unstable connectivity, whereas D506 centered on timeliness, dashboards, interoperability, and national-scale information use.

### *Collaboration and Partnership*

Across both systems, participants emphasized that sustainability depends on continuous coordination to align system design and implementation with routine public health practices. They described collaboration as a way to integrate policy priorities, technical requirements, and field realities into usable digital workflows and resolve problems as the systems evolved. They perceived that systems developed without such alignment, particularly those driven solely by central-level requirements, were less likely to be sustained.

> *There were so many stakeholders involved, and even gathering requirements was tough. We came from the center and did not really know how they operated in practice, ... we had to go into the field ... so they could explain what they encountered and how things worked.* [MIS-PM-02]

> *... If the system is designed only for central programs, it won't be sustainable. If it's designed to be used by the field, for real work, it becomes sustainable.* [PF-01]

In the MIS, participants described a focused, long-term partnership between disease control programs, subnational implementation teams, and an academic development partner. This relationship was described as complementary, combining domain-specific expertise in malaria elimination with technical capacity for system development. They associated continued collaboration with mutual trust, shared problem-solving, and a strong understanding of local workflows and operational contexts:

> *The disease program has elimination expertise, while the development partner has developer and digital expertise ... we both have something the other lacks. When we come together, it works.* [MIS-PH-01]

In contrast, D506 participants described coordination across a broader and more complex institutional network, including multiple disease programs, regional health offices, public and private health facilities, and HIS vendors. They identified a key challenge in achieving interoperability across diverse systems while transitioning from weekly reporting to near real-time, API-based data exchange. They described ongoing engagement with vendors, structured technical guidance, and collaborative problem-solving intended to support consistent data reporting nationwide:

> *... we organize meetings ... with vendors and provide development guidelines on how they need to develop, what user and password they'll need, what kind of access rights to use, and how to send data ...* [D506-PM-01]

Although MIS relied on a more concentrated partnership with accumulated domain knowledge, D506 required sustained coordination across a larger and more heterogeneous interoperability network. Across both systems, participants nevertheless emphasized the importance of continuous communication and practical support rather than one-time agreements. Participants described mechanisms such as standard operating procedures, data standards and mappings, help-desk services, messaging platforms, and routine review processes as important for maintaining alignment as systems evolved.

### *Human Resources*

Human resources were described as a key constraint affecting the sustainability of both PHS systems. Participants emphasized that sustainable operation depended not only on system design but also on the availability and continuity of personnel capable of developing, maintaining, and adapting the systems over time. A common concern was the gap between workforce capacity and the increasing technical and operational demands of modern surveillance systems.

> *I think training people within the organization to sustain it is very important ... Having in-house people who can solve these issues makes the system more user-centric and ... move much faster.* [PF-02]

In the MIS, participants described challenges in building operational capacity among field staff, supporting the transition from paper-based to digital workflows and transferring technical knowledge to the institutions expected to maintain the system. Participants highlighted the need for iterative, task-based training to address varying levels of digital literacy and ensure routine system use after handover:

> *... They do not really have people who specialize in databases or development ... taking over this system requires them to look into the database and development side.* [MIS-IT-02]

> *... the core was still the same ... just converted into electronic format ... so the learning curve took quite a while to overcome.* [MIS-PM-02]

In contrast, D506 participants described difficulties in recruiting and retaining specialized technical personnel, particularly shortages in data engineering and system integration. These challenges were linked to public-sector compensation constraints, limiting the ability to attract highly skilled staff:

XSL•FO
RenderX

> *The challenge is about personnel ... We need people with additional knowledge in computer engineering ... each person is basically handling one dashboard on their own.* [D506-PH-03]

> *... we are really lacking in Data Engineers ... we cannot hire them due to budget constraints.* [PF-03]

Across both systems, participants perceived continuity as more vulnerable when important knowledge or technical capacity depended on a small number of people. MIS emphasized training and handover of system-specific knowledge, whereas D506 emphasized recruitment and retention of specialized technical capability for a national data platform.

### *Infrastructure*

Infrastructure was described as one factor shaping the extent to which PHS systems could support routine operations. Across both systems, participants emphasized that infrastructure must enable continuous functionality without disrupting surveillance workflows. This included not only software capabilities but also reliable systems for data synchronization, server management, and user support.

> *... If we have the right tools for data entry, everything will be faster ... and help us clean up data more efficiently.* [D506-IT-03]

In the MIS, participants linked infrastructure challenges to hardware limitations and the operational realities of remote settings. Participants highlighted the need for systems that support offline functionality and reliable synchronization under unstable connectivity. They also described delays in hardware procurement and server replacement under complex administrative processes as a concern for continued operation:

> *... they're trying to replace the server ... it's been a year, and they still haven't finalized it ... there are many issues with procurement ...* [MIS-IT-03]

In contrast, D506 participants emphasized centralized infrastructure to support nationwide interoperability, including data pipelines, dashboards, and integration across multiple reporting platforms. Participants also described how reusing the underlying infrastructure developed during the COVID-19 response made D506 development easier and faster:

> *... we already have a model from COVID-19 reporting ... we used this system to build upon for the new system ... helped us develop and build further.* [D506-PM-01]

Whereas MIS participants emphasized connectivity resilience and legacy hardware constraints, D506 participants focused on centralized processing, interoperability, and increasing data volume. Across both systems, participants associated continued operation with maintaining core system components and minimizing disruption to users.

### *Financial Sustainability*

Participants across both systems described a financial sustainability challenge in the mismatch between short-term development funding and the recurrent costs of operating and maintaining a surveillance platform. These costs extended beyond initial development to include infrastructure, personnel, system upgrades, training, technical support, and governance. Participants noted that budgets often prioritized system development, while long-term operational needs were addressed through ad hoc solutions rather than structured financial planning.

> *Sustainability is really about who supports [financially] the work moving forward ... because these systems don't run for free. Someone has to take responsibility for funding it.* [PF-04]

In the MIS, financial sustainability was closely tied to reliance on external donor funding, particularly from the Global Fund. Participants identified this as a key vulnerability, as future continuity was linked to a credible pathway for transferring financial and operational responsibilities to domestic structures beyond grant periods. This included sustaining technical personnel and disease-specific expertise beyond externally funded positions:

> *... if the Global Fund didn't support it, this project would have failed ... What we really need are personnel and funding ...* [MIS-PM-02]

In contrast, D506 was supported by domestic government funding, providing a different initial financial foundation. However, participants noted ongoing constraints in allocating limited resources across competing priorities, such as staffing, infrastructure, and system improvements, which affected long-term planning:

> *The real challenge is: how do we use this money in a sustainable way?... Most of the time, we have to find funding on our own because the internal budget is not sufficient.* [PF-02]

MIS faced a clear donor-to-domestic transition challenge, whereas D506 faced constraints within domestic budgeting and procurement despite stronger institutional embedding.

> *... If they don't value the system, it ends. But now they realize it's essential and necessary. When they realize that, it will keep going even without money ... In the end, a way will be found ...* [MIS-PH-01]

Participants also reported that continued funding was more likely when systems demonstrated clear value and operated within well-coordinated organizational structures. These descriptions suggest that financial sustainability depended not only on the available resources but also on credible pathways for ongoing funding, capacity transfer, and gradual system scaling.

### *Ownership*

Ownership emerged most explicitly in the MIS case. Participants indicated that the central ownership challenge was not simply identifying a responsible organization, but ensuring that the designated owner had the authority, resources, and willingness to manage the system throughout its lifecycle. They associated effective ownership with decision-making authority and dedicated resources for ongoing functions such as system maintenance, monitoring, and upgrades. Participants noted that when ownership was perceived as unclear or weak, systems

XSL•FO
RenderX

would be vulnerable to delayed updates, reliance on workarounds, and declining user trust over time.

> *One of the biggest challenges ... is ownership—who takes responsibility.* [MIS-PM-02]

MIS participants also described a "reluctant ownership" dynamic as a challenge, in which organizations recognized the benefits of the system but were hesitant to assume full operational responsibility. They linked this reluctance to limited technical capacity, procurement constraints, and concerns about accountability for system performance. They described a gap between nominal ownership and responsibility for continued operation:

> *We're the developers but not the owners of the systems or the data. ... once it's handed over, there isn't always clear responsibility for ongoing maintenance ...* [MIS-IT-02]

Perceptions of ownership were also shaped by funding and governance structures. In the MIS, participants described challenges in transferring financial responsibility and technical expertise from external partners to domestic institutions. In D506, participants used the language of ownership less directly, discussing institutionalized government responsibility and the allocation of departmental roles and budgets. Across both cases, participants associated continued operation with a responsible entity that had the authority and capacity to assume long-term accountability:

> *... if funding ends, it comes down to ownership ...* [MIS-PM-02]

> *Instead of just one division being responsible, since this is a national task, we assign it to the department so the budget and data can be shared across divisions.* [PF-03]

Beyond institutional responsibility, MIS participants also highlighted the importance of developing a sense of shared ownership among users. They described actively involving users in providing feedback and adapting the system to reflect their field workflows and operational needs. Participants noted that when users saw that their input led to practical system improvements, they were more likely to regard the system as a tool developed with them rather than merely a reporting requirement imposed on them. Participants associated this sense of involvement with active engagement, routine use, and perceived long-term sustainability:

> *... we try to make users ... feel like they own the system ... that's why it has been sustainable ...* [MIS-IT-02]

### *System Adaptability*

Participants described sustainability as dynamic rather than as the preservation of a static system. They associated continued relevance with the ability of surveillance platforms and their governance arrangements to respond to changing epidemiology, organizational structures, reporting requirements, technology, and user needs.

In MIS, participants linked the system's continued relevance to changing disease patterns and surveillance needs. They also noted that, as disease burdens changed, surveillance data could retain value for future research and that the platform would need to adapt to organizational and technical changes:

> *... if the disease is gone ... the data may still be useful for something else ... I believe it will still be valuable for future research.* [MIS-IT-02]

For D506, participants described adaptability as requiring more than the electronic reproduction of legacy reporting processes. They emphasized that changes were intended to improve reporting timeliness, workflows, interoperability, data use, and decision-making. One participant summarized this broader pattern by distinguishing simple digitization from meaningful digital transformation:

> *The goal is to truly transform the system and the efficiency of the work, not just to store things digitally ... that's not enough.* [PF-03]

Across both cases, participants therefore viewed adaptability as the capacity to remain useful as conditions changed. MIS findings centered on disease context, organizational change, remote operations, and technology, whereas D506 findings centered on interoperability, reuse of earlier reporting infrastructure, and broader digital transformation.

## Discussion

### Principal Findings

This study suggests that stakeholders perceived PHS sustainability as depending not only on technical design but also on the extent to which systems were embedded within real-world implementation contexts. Prior research has examined surveillance-system integration, development, and implementation [23-25]; however, sustaining routine use remains a complex implementation challenge. The findings suggest that participants understood sustainability through interacting technical, organizational, and governance factors, consistent with established health information and surveillance frameworks [26,27]. The results particularly highlight operational ownership and the capacity for continuous adaptation to evolving technologies. The cross-case comparison showed that these dimensions took different forms: MIS findings emphasized online-offline field functionality, donor-to-domestic transition, and reluctant ownership, whereas D506 findings emphasized nationwide interoperability, specialized technical capacity, and domestic budgeting and procurement constraints. These findings reflect participant perceptions rather than objectively measured or causal determinants of sustainability. The contribution lies in explaining how shared sustainability concerns take different forms across 2 Thai platforms with contrasting development and financing pathways.

In many countries, multiple PHS systems operate across different contexts. While standard system architectures may provide a common foundation, identifying context-specific users and functional requirements is critical for sustainability [27,28]. Participants associated long-term system use with how well systems integrate into existing operational practices without increasing user burden and frustration. MIS participants emphasized resilient design for remote settings with unstable connectivity, consistent with evidence from southern Africa

XSL•FO
RenderX

that infrastructure constraints affect system use [17,24,28]. In contrast, D506 participants emphasized workflow redesign to support near real-time reporting and interoperability across multiple platforms, with integration into existing HISs to reduce duplicated workload. At the national level, aligning stakeholder interests, roles, and responsibilities remains a key challenge [6,17,29]. Our findings also suggest that sustained collaboration, supported by continuous communication and practical coordination mechanisms rather than one-time agreements, is important for long-term system continuity. The comparison suggests that a common commitment to user-centered design can require different technical and organizational responses rather than a single architecture for every setting.

Participants associated long-term PHS sustainability with how financial, infrastructure, and human resources are managed across the system lifecycle. Prior work similarly identified limited technical capacity and staff turnover as common challenges in sustaining surveillance systems [17,23,25]. Although participants did not describe turnover as a uniformly high concern, they emphasized the need for continuous skill development to keep pace with evolving technologies and increasing system complexity [25]. Participants also associated reliable IT infrastructure with the ability to sustain routine surveillance workflows. These findings suggest that incremental adaptation and reuse of existing infrastructure can support continued operation and development. In MIS, this involved connectivity resilience and the modernization of legacy components, whereas D506 participants emphasized scalable data pipelines, interoperability, and capacity for increasing national data volumes.

Financial factors were prominent in participants' descriptions of sustainability. Participants described budgets that prioritized system development, while long-term operational needs were addressed through ad hoc solutions rather than structured planning. This concern is consistent with prior research on sustaining donor-supported HISs [17]. These findings suggest that sustainability depends not only on resource availability but also on establishing credible pathways for ongoing funding, capacity transfer, and gradual system scaling. Clear postgrant transition plans were also highlighted as critical for maintaining long-term value within national health systems. The comparison nevertheless indicated that domestic funding did not remove perceived sustainability concerns: MIS faced uncertainty during donor-to-domestic transition, while D506 participants described constraints in routine budgeting, procurement, infrastructure, and technical staffing.

These findings also draw attention to the political economy of surveillance systems. Participants' descriptions suggest that the organizations and users who benefit from timely, decision-useful information are not always the same actors who bear the costs of hosting, maintenance, technical personnel, training, and future upgrades. In MIS, donor-supported development and external technical expertise were expected to transition toward domestic responsibility. In D506, government responsibility was more institutionalized, but central teams continued to manage resource competition and coordination with other divisions and vendors. Sustainability therefore involves not only the amount of funding available but also how costs, authority, expertise, and accountability are distributed over time. This interpretation suggests that assigning responsibility without corresponding budget authority and technical capacity may leave the receiving organization reluctant or unable to assume operational commitments. Political economy was therefore an important cross-cutting consideration connecting financial sustainability with operational ownership in both cases.

The ownership findings highlighted a gap between formal designation and operational capacity. Participants described functional ownership as requiring institutions to have the authority, resources, and willingness to undertake system maintenance, monitoring, and continuous improvement. In this interpretation, ownership identifies who can authorize and resource continued operation, while collaboration describes how the relevant actors coordinate, and adaptability concerns how the system responds to change. This challenge was particularly evident in MIS, where participants described reluctant or nominal ownership during handover, while D506 reflected more institutionalized departmental responsibility.

In this context, D506 participants collectively described digital transformation as improving reporting workflows, efficiency, interoperability, data use, and decision-making, rather than simply converting paper-based processes into electronic storage. These findings suggest that sustainable systems should remain adaptable and capable of supporting emerging health threats or broader public health needs.

Leadership and legal constraints were less prominent in the interviews. This may reflect the established institutional settings of the 2 systems, although limited emphasis in these interviews does not establish that these factors were unimportant. Compared with the emphasis on enduring champions in the proposed genomic-surveillance operating model [25], these findings suggest that the salience of leadership may differ by institutional context and system maturity.

In resource-constrained settings, we suggest first addressing the most immediate threat to routine surveillance by aligning operational responsibility, recurrent resources, and technical support. For MIS, priorities could include maintenance responsibilities and knowledge transfer during donor transition; for D506, specialized integration capacity and support for data exchange. Expanding system functions may provide additional value but also increase maintenance and staffing demands. A staged approach could therefore protect essential operations while revisiting longer-term financing and development. These are author-derived implications of the 2 cases rather than an empirical ranking of the 7 themes.

## Strengths and Limitations

This study has several strengths. First, it examined 2 operational national PHS systems with different development histories, technical architectures, financing pathways, and operational demands. This enabled the study to examine stakeholder perspectives on sustainability over time and to compare how similar concerns were expressed in different implementation contexts. Second, many participants had been involved since the development phase and remained responsible for system maintenance, providing detailed insights across the system

XSL•FO
RenderX

lifecycle. Third, the qualitative design, using both individual interviews and small-group interviews, captured perspectives from technical, operational, managerial, and policy-level stakeholders. Finally, the study extends beyond broad technical and financial barriers by explaining how ownership, user-centered adaptation, collaboration, and system adaptability were experienced across the 2 cases. The explicit cross-case analysis and supplementary materials also increased the transparency of the study and strengthened the interpretation of the findings.

These strengths should be considered alongside several study boundaries. Purposive, organization-facilitated recruitment and the inclusion of 2 operational systems may have favored more engaged participants and relatively sustainable cases, while remote frontline users were less represented. Consequently, the findings may give greater prominence to managerial and technical concerns than to the everyday reporting burdens and support needs of remote frontline users. Data saturation was assessed through redundancy across the overall dataset rather than separately for every case-role subgroup. In addition, the findings reflect stakeholder perceptions rather than objective measures of system performance or sustainability. Transferability may therefore be greatest for comparable national surveillance systems. Application to decentralized, laboratory, event-based, community, or One Health surveillance requires consideration of their different governance and operational arrangements.

## Conclusions

Stakeholders across 2 operational national surveillance systems in Thailand perceived that sustaining PHS requires more than successful technical development or initial implementation. They associated long-term sustainability with the extent to which systems were aligned with user needs, embedded within routine workflows, supported by sustained collaboration, and backed by adequate human, financial, and infrastructure resources. Clear operational ownership and the ability to adapt to evolving technologies and public health priorities were also perceived as important for maintaining system relevance over time. The comparison showed that these dimensions were expressed differently across cases: MIS highlighted remote field operation, donor transition, and reluctant ownership, whereas D506 highlighted nationwide interoperability, specialized technical capacity, and constraints within domestic budgeting and procurement.

For comparable systems, these findings suggest that sustainability should be planned across the full system lifecycle, with operational ownership and recurrent resources considered during initial development, feedback and knowledge transfer supported during routine use, and technical and governance arrangements revisited as needs change. These implications are not tested prescriptions; they are context-sensitive lessons from 2 surviving systems that require examination in other surveillance models and in discontinued or less-sustained cases.

## Acknowledgments

The authors thank all study participants for generously sharing their time, experiences, and perspectives. Their contributions were essential to understanding the sustainability of public health surveillance systems in Thailand. This research was conducted as part of a thesis for the Master of Science Program in Biomedical and Health Informatics, Mahidol University.

## Funding

This study was supported by the Rockefeller Foundation (grant 2021 PPI 005). The grant supported this research and did not provide operational funding for the Malaria Surveillance System, Digital 506, or the participating organizations in relation to the surveillance systems examined. PH was partially supported by a fellowship from the Hanse-Wissenschaftskolleg Institute for Advanced Study. Neither the Rockefeller Foundation nor the Hanse-Wissenschaftskolleg Institute for Advanced Study had a role in the study design, data collection, analysis, interpretation of findings, or preparation of the manuscript.

## Data Availability

The datasets generated and analyzed during this study are not publicly available due to participant confidentiality and the potentially identifiable information about participants and their organizations. Requests for access to deidentified data may be directed to the corresponding author and will be assessed individually in accordance with the study's ethics approval, participant consent, and confidentiality requirements. Deidentified excerpts and supporting materials, including participant and session characteristics, interview guides, a qualitative codebook, and a cross-case evidence matrix, are included in this article and its multimedia appendices.

## Generative AI Use

The authors declare that generative AI was used in the creation of this manuscript. Generative AI (ChatGPT) was used for proofreading, editing, or language polishing, and reference formatting. The authors verified all outputs of the tool(s) used in the preparation of this manuscript. The authors used ChatGPT (OpenAI) to support Thai-to-English translation of interview transcripts, English language editing, wording refinement, and formatting support. Thai-to-English translations were reviewed by the authors against the original Thai transcripts and audio recordings to preserve the intended meaning. ChatGPT was not used to generate

XSL•FO
RenderX

data, conduct analysis, or interpret findings. All AI-assisted suggestions were reviewed and verified by the authors, who take full responsibility for the final manuscript.

## Authors' Contributions

WP contributed to conceptualization, data curation, methodology, formal analysis, visualization, and writing the original draft. CR contributed to conceptualization, data curation, methodology, formal analysis, and validation. PH contributed to conceptualization, methodology, formal analysis, and validation. TB contributed to conceptualization, methodology, and validation. SL contributed to conceptualization, methodology, validation, funding acquisition, supervision, and writing the original draft. All authors critically reviewed and approved the final manuscript.

## Abstract

**Background:** Cardiovascular disease (CVD) remains the leading cause of death. Primary prevention relies heavily on health risk assessments and lifestyle changes, which can reduce long-term risk and mortality. Digital health offers an accessible and cost-effective approach to support prevention, enabling data sharing and visualization of key indicators such as blood pressure and glucose fluctuations. These visual insights may help patients better understand the effects of lifestyle changes and enhance communication with health care providers.

**Objective:** This research aims to evaluate whether the use of CVD risk visualization (Petal-X) and continuous glucose monitoring (CGM), alone or in combination, is associated with lifestyle changes and the perception of person-centered care (PCC) among patients at increased risk of CVD.

**Methods:** We conducted a 4-arm, single-blind, 2×2 factorial randomized controlled feasibility trial in primary care. A total of 119 participants were enrolled, of whom 101 completed the 6-month follow-up. Participants were randomized to 1 of 4 arms: (1) Petal-X CVD risk visualization+CGM; (2) CGM only; (3) Petal-X only; or (4) standard care with routine lifestyle counseling and no digital tools. CGM was used for 10 days in the CGM arms. Since this was a feasibility trial, no formal sample size calculation was performed. Primary outcomes are healthy lifestyle (Health Lifestyle and Personal Control Questionnaire [HLPCQ]) and perception of PCC (Person-Centered Practice Inventory—Service User [PCPI–SU]), and secondary outcomes (Systematic Coronary Risk Evaluation 2 [SCORE2], anthropometrics, and biological age) were assessed at baseline and 6 months. Descriptive statistics and Kruskal-Wallis tests (*K* independent samples) were used for analyses.

**Results:** At baseline, mean SCORE2 values ranged from 3.84 (SD 2.08) in intervention group 3 to 4.87 (SD 2.61) in intervention group 1, with the control group having a mean value of 4.53 (SD 3.63). Regarding the assessment of a healthy lifestyle, the domain of daily routine had the highest baseline scores across all groups (eg, mean 19.24, SD 5.87 in intervention group 1), and these scores improved by the final evaluation, although there were no statistically significant differences ($P$=.42) in changes between the groups. The perception of PCC was rated highest across all groups in the domain of shared decision-making, with no statistically significant differences ($P$=.26) between the groups. Results indicated improvements in healthy lifestyle habits, but the impact of interventions on perceived changes remained insignificant.

**Conclusions:** Healthy lifestyle and perceived PCC scores improved, although no statistically significant between-group differences were found. Risk visualization appears to be a key tool for increasing CVD awareness and strengthening patient involvement in care planning. Longer interventions with larger samples are needed to clarify these effects and optimize digital tools for lifestyle change.

## Introduction

Chronic diseases are long-lasting and usually progressive in nature and not transmissible between people. They represent a major global health burden, both in terms of mortality and health care costs. There are 4 main types of chronic disease: cardiovascular disease (CVD), cancer, chronic respiratory diseases (such as chronic obstructive pulmonary disease and asthma), and diabetes. These chronic diseases are responsible for most deaths worldwide [1,2]. Importantly, these diseases share common modifiable lifestyle risk factors such as poor diet, physical inactivity, tobacco use, and harmful alcohol consumption [2-4]. In 2021, they were estimated to cause 20.5 million deaths, approximately a third of deaths worldwide, which affected more than half a billion people [5-8]. The prevalence of CVD is rising due to increases in obesity, hypertension, type 2 diabetes mellitus, and physical inactivity [5,9-12]. Given that unhealthy lifestyles are estimated to contribute to around 60% of chronic disease risk [3,5,13,14], managing behavioral and environmental risk factors remains one of the most effective approaches to alleviating the burden of CVDs. Targeted lifestyle interventions have been shown to reduce CVD incidence and related mortality over the long term [15,16]. According to Visseren et al [17], lifestyle improvement should be the first line of intervention, including dietary changes (eg, reducing salt, saturated fats, and alcohol) and physical activity. The guidelines divide patients into risk categories so that prevention can be targeted. The groups are: I-very high risk of CVD (>40% in the next 10 y), II-high risk of CVD (20% - 40% in the next 10 y), III-moderate risk of CVD (10% - 20% in the next 10 y), IV-low risk of CVD (<10% in the next 10 y) [18]. However, many individuals at risk for CVD do not understand their personal risk or the potential benefits of lifestyle change. Moreover, they may underestimate the consequences of inaction, which underscores the importance of interventions that enhance awareness and promote sustained behavioral change [19-21].

In this context, digital health has emerged as a promising tool. Technological innovations are increasingly being used to deliver scalable interventions aimed at improving health behaviors [22]. Smartphones, which are now owned by approximately 6.9 billion people worldwide (86% of the global population), have become a platform for delivering digital health interventions [23]. Evidence suggests that digital health applications can support lifestyle change, improve glycemic control [24,25], lower blood pressure (BP) [26], and even reduce hospitalizations when integrated into cardiac rehabilitation programs [27,28]. Digital technologies also offer new ways of presenting health information in an engaging and understandable way. Visual representations of risk (graphs, dendrograms, and interactive charts) can improve patients' understanding of their condition and motivate behavior change [8,29-31]. As noted by Visseren et al [17], absolute risk and risk reduction are more easily understood when presented visually, rather than numerically. Advanced tools such as decision support systems and continuous glucose monitoring (CGM) devices provide real-time, personalized insights into patient health. These technologies support prevention and treatment by integrating clinical data with evidence-based knowledge to enable personalized interventions [32]. For example, CGM systems not only help reduce the risk of hypoglycemia and hyperglycemia but also encourage behavior change by providing instant feedback on glucose levels [33-35]. However, the successful implementation of digital health tools depends on both patient engagement and health literacy [36]. Without the ability to understand and act on digital information, even the most advanced tools may have a limited effect. This is where person-centered care (PCC) becomes crucial. By involving patients as active partners in their own care and decisions, PCC has been shown to enhance outcomes across a range of conditions [37,38]. Research focuses on how risk for CVD can be effectively visualized using digital health tools, with a particular focus on CGM and its role in supporting lifestyle change. In line with the principles of PCC, the aim is to understand how these technologies can promote greater patient engagement and ultimately contribute to improved CVD outcomes. Simultaneously, the research recognizes the need for high-quality evaluations of the tools and visualization strategies used in clinical settings.

## Methods

The research used a quantitative, multiarm design with data collected through validated questionnaires and direct participant measurements to comprehensively assess behavioral changes as well as subjective and objective health outcomes.

### Study Design and Research Protocol

A quantitative research design was used to obtain measurable and generalizable data, which were collected using a combination of validated questionnaires and direct participant measurements, allowing a comprehensive assessment of both subjective experiences and objective health indicators. The trial followed a 4-arm 2×2 factorial design, and the research protocol was registered at ClinicalTrials.gov (NCT06226948). The primary objective was to compare changes in lifestyle behaviors across these 4 arms and to explore whether the combined use of CVD risk visualization and real-time CGM (intervention group 1) leads to greater improvements than standard care. Standard care consisted of routine clinical management at the primary care level, including regular check-ups with a family physician or nurse, brief lifestyle counseling (on diet, physical activity, smoking, and alcohol use) according to national guidelines, and access to general educational materials on CVD prevention. No additional digital tools or enhanced monitoring were provided to the control group.

The secondary objective was to compare changes in estimated CVD risk (SCORE2 [Systematic Coronary Risk Evaluation 2]) across the 4 groups. Additionally, we aimed to determine which lifestyle domains changed in patients at risk of CVD following

XSL•FO
RenderX

exposure to CVD risk visualization, real-time CGM, or their combination.

### Type of Study

This research was designed as a single-blind, 4-arm randomized controlled trial (RCT) and was conducted from May to December 2024. Participants were informed only about the intervention they received and were not informed about the full set of study arms or the interventions delivered in other groups (limited disclosure). This RCT was designed as a pragmatic feasibility study embedded in routine primary care. A formal sample size or power calculation was not performed, as this study was designed as a pragmatic feasibility trial. The primary aim was to evaluate feasibility, usability, and behavioral trends rather than to test definitive effectiveness. Therefore, the sample size was determined based on practical feasibility considerations, including the number of eligible patients available in primary care and the logistical capacity for conducting clinical and laboratory assessments. As a result, the study may have been underpowered to detect statistically significant between-group differences.

Participants were randomly assigned to 4 study arms:

- Intervention group 1: Petal-X CVD risk visualization+CGM
- Intervention group 2: CGM only
- Intervention group 3: Petal-X visualization only
- Control group: standard care

Participants were randomized in a 1:1:1:1 ratio into 4 arms using a computer-generated allocation sequence (RAND function in Microsoft Excel). The randomization sequence was generated by the study researcher. The same researcher enrolled participants and assigned them to the trial arms according to the generated sequence. Given the pragmatic feasibility design, formal allocation concealment procedures were not implemented; the enrolling researcher was aware of the upcoming assignment. Participants without a compatible smartphone were randomized only between the 2 non-CGM arms (Petal-X only vs standard care).

The study followed the intention-to-treat principle, whereby all participants were analyzed within the groups to which they were originally assigned, regardless of whether they completed the intervention [39]. This approach preserved the integrity of randomization and reduced bias.

The trial and its reporting were in accordance with the CONSORT (Consolidated Standards of Reporting Trials) 2010 flowchart and the CONSORT extension for pilot and feasibility RCTs (see *Results*), and the corresponding checklist has been completed and submitted (Checklist 1).

### Assessment Instrument

The primary outcomes (healthy lifestyle and perception of PCC) were assessed using 2 validated instruments: the Health Lifestyle and Personal Control Questionnaire (HLPCQ) and the Person-Centered Practice Inventory—Service User (PCPI-SU).

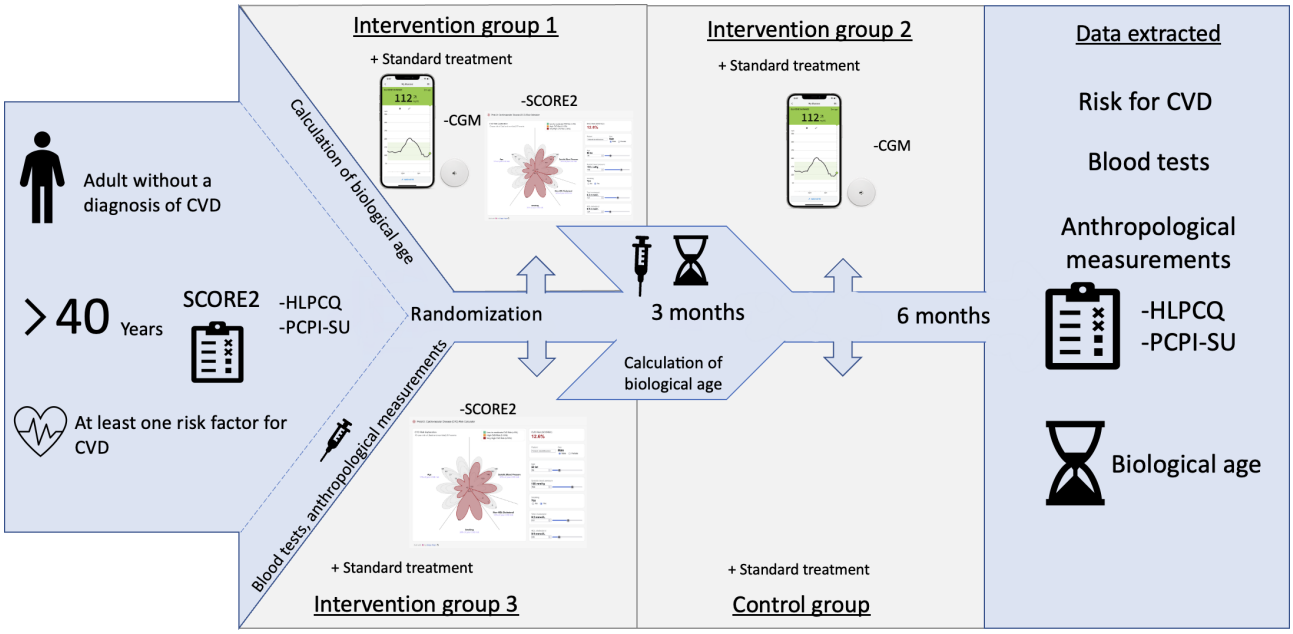
The following validated instruments were used in the research.

The HLPCQ [40] was used to assess lifestyle and perceived personal control. The questionnaire included demographic data (sex, age, marital status, number of children, smoking status, and education and employment status) and anthropometric measures (body weight and height). The HLPCQ consists of 26 items grouped into 5 domains. We used a validated Slovenian version of the questionnaire [41]. In the Slovenian validation study conducted among 666 adults at risk of CVD, the total scale showed good internal consistency (Cronbach $\alpha$=0.85), with subscale $\alpha$ coefficients ranging from 0.59 to 0.88, indicating acceptable to good reliability [41]. In the present feasibility trial, we therefore relied on these previously established psychometric properties and did not repeat internal consistency testing (eg, Cronbach $\alpha$) in our sample. The main aim of this questionnaire was to identify and quantify lifestyle patterns that reflect lifestyle change as reflected in stress levels and internal control over health. All domains were significantly positively related to each other, suggesting that people who adopt healthy eating habits and avoid harmful diets also follow a daily routine of activities, engage in organized exercise, seek social support, and take care of their mental health. Higher scores indicate a better lifestyle.

The PCPI-SU [42] was used to assess perceptions of PCC. It consists of 20 items and is designed to capture individuals' views on their perceptions of PCC. It covers 5 domains: working with the patient's beliefs and values (4 items), shared decision making (5 items), genuine collaboration (4 items), compassionate presence (3 items), and holistic action (4 items). The questionnaire was a 5-point Likert scale. Higher scores indicated better perceptions of PCC. In a Slovenian study among 426 adults with noncommunicable diseases, the PCPI-SU demonstrated good internal consistency, with Cronbach $\alpha$=0.82 for the total scale [43]. Consistent with our feasibility design and to avoid redundancy, we did not recalculate Cronbach $\alpha$ in the current sample and relied on these existing reliability estimates.

Participants were shown the Petal-X visualization [44] using a graphical tool that illustrated their current level of CVD risk in a visual representation. This tool was based on the SCORE2 prognostic model [45], which calculates an individual's 10-year risk of developing CVD. We then modified the parameters to reflect target values and used the visualization again to show how an individual's risk could potentially be reduced through lifestyle changes and adherence to the guidelines provided. The code of the Petal-X dashboard is publicly available on GitHub [46], and the English version of the dashboard as a web application is available on the internet [47]. The dashboard was developed using the Observable framework, with the Petal-X visualization [44] implemented using the Observable Plot system [48]. Petal-X was developed using a human-centered design process with iterative prototyping and expert review to ensure clarity and interpretability of the risk visualization [44]. In addition, the underlying surrogate model of SCORE2 was quantitatively validated and demonstrated high fidelity to the original SCORE2 equations, and a controlled experiment with 88 health care students showed that Petal-X supported more accurate interpretation of modifiable risk factor contributions than standard SCORE2 graphical score charts, without reducing perceived transparency, trust, or intention to use the tool [44]. Based on this prior evidence, we considered Petal-X to be of

XSL•FO
RenderX



sufficient quality and validity for use as an intervention tool in this feasibility trial. It is based on the validated SCORE2 prognostic model.

Biological age is calculated from plasma GlycanAge analysis [49] and is based on the algorithm developed by Levine et al [50], which incorporates 9 blood biomarkers most strongly associated with mortality: mean corpuscular volume, C-reactive protein, albumin, blood glucose, alkaline phosphatase, red cell distribution width, creatinine, lymphocyte percentage, and chronological age; CGM data is collected using the Dexcom system G7 [51], allowing for real-time monitoring of blood glucose levels.

## Description of the Research Process

All participants who met the inclusion criteria completed the HLPCQ and the PCPI-SU at baseline and at the 6-month follow-up, and were also assessed for CVD risk using the SCORE2 prognostic model, incorporating the following variables: age, sex, systolic BP, total cholesterol, high-density lipoprotein (HDL) cholesterol, and smoking status. Venous blood samples were collected at baseline and at 6 months to determine standard biochemical markers (including lipid profile and fasting glucose) and to calculate phenotypic and glycated biological age, with an additional blood sample taken at 3 months for biological age assessment only. The risk assessment using SCORE2 was repeated after 6 months to evaluate potential changes. Additionally, biological age was calculated at 3 and 6 months as a more precise indicator of lifestyle changes compared to chronological age. Two models were used: the model by Levine et al [50], based on blood biomarkers, and GlycanAge, based on glycan analysis, as defined by Lauc and Primorac [49]. Participants were allocated to the following 3 different intervention groups and 1 control group according to the quantitative research design, with the groups differing according to the type of intervention they received during treatment (Figure 1).

**Figure 1.** Intervention groups and research process. CGM: continuous glucose monitoring; CVD: cardiovascular disease; HLPCQ: Healthy Lifestyle and Personal Control; PCPI-SU: Person-Centered Practice Inventory—Service User; SCORE2: Systematic Coronary Risk Evaluation 2.

Intervention group 1 received both CGM for 10 days and the Petal-X CVD risk visualization tool [44]. Petal-X allowed for a visual presentation of the participant's current risk and an interactive simulation of how lifestyle changes could improve the risk profile.

Intervention group 2 used CGM for 10 days, without using the Petal-X CVD risk visualization tool.

Intervention group 3 received only the Petal-X risk visualization.

The control group received standard care without additional intervention and did not receive any of the digital interventions (Petal-X or CGM) after study completion, as the trial did not include a delayed-intervention phase.

At baseline and after 6 months, all participants underwent anthropometric and blood measurements, completed the HLPCQ and PCPI-SU questionnaires, and received updated CVD risk (SCORE2) and biological age assessments. These data allowed for comparisons between groups and evaluation of changes in lifestyle and CVD. The 6-month duration was selected based on previous studies demonstrating meaningful changes in health behaviors within this period [52,53]. Adverse events and device-related issues (eg, CGM-related problems) were monitored throughout the study. No serious adverse events were reported.

## Study Sample

Recruitment was open to individuals across Slovenia, but the promotional campaign and study implementation were concentrated in a Community Health Center in central Slovenia. Purposive sampling was used, and inclusion criteria included adults being 40 years or older with no previous diagnosis of CVD but with at least one of the following risk factors: elevated BP (systolic >140 mmHg), elevated fasting glucose (>6.1 mmol/L), abnormal lipid levels (total cholesterol >5 mmol/L, HDL <1.4 mmol/L for men and <1.6 mmol/L for women,

XSL•FO
RenderX

low-density lipoprotein >3.5 mmol/L, triglycerides >1.7 mmol/L), or BMI >30.

Preexisting CVD, being younger than 40 years, and the absence of risk factors were the exclusion criteria. The sample was selected using purposive sampling. In total, 119 participants were included at baseline: 30 in intervention group 1 (CGM and Petal-X), 24 in intervention group 2 (CGM only), 33 in intervention group 3 (Petal-X only), and 32 in the control group. At follow-up, 101 participants remained: 27 in intervention group 1, 22 in intervention group 2, 26 in intervention group 3, and 26 in the control group. Dropout reasons included newly diagnosed health conditions, inability to attend follow-up appointments, or personal commitments.

### Statistical Analysis

Descriptive statistics (means and SDs for continuous variables and absolute and relative frequencies for categorical variables) were used to characterize the sample and summarize outcome measures. Group differences in categorical baseline characteristics (eg, gender, smoking status, and education) were analyzed using chi-square tests. All statistical analyses adhered to the intention-to-treat principle. IBM SPSS Statistics 29.0 was used for all analyses, and statistical significance was set at $P \leq .05$.

For Hypothesis 1, differences in lifestyle change across the 4 randomized groups were analyzed using the Kruskal–Wallis test, with the HLPCQ total score as the dependent variable. For Hypothesis 2, changes in cardiovascular risk across the 4 groups were analyzed with SCORE2 as the dependent variable, also using the Kruskal–Wallis test, due to nonnormal distributions and modest cell sizes. HLPCQ and PCPI-SU scores were treated as continuous variables using their total scale scores.

Spearman's rank correlation coefficients were calculated to explore associations between healthy lifestyle (HLPCQ) and perceived PCC (PCPI-SU) [54].

To reduce detection and analysis bias, outcome data were handled using coded group labels during data cleaning and analysis, and laboratory assessments were performed according to standard procedures without reference to group allocation.

### Ethical Considerations

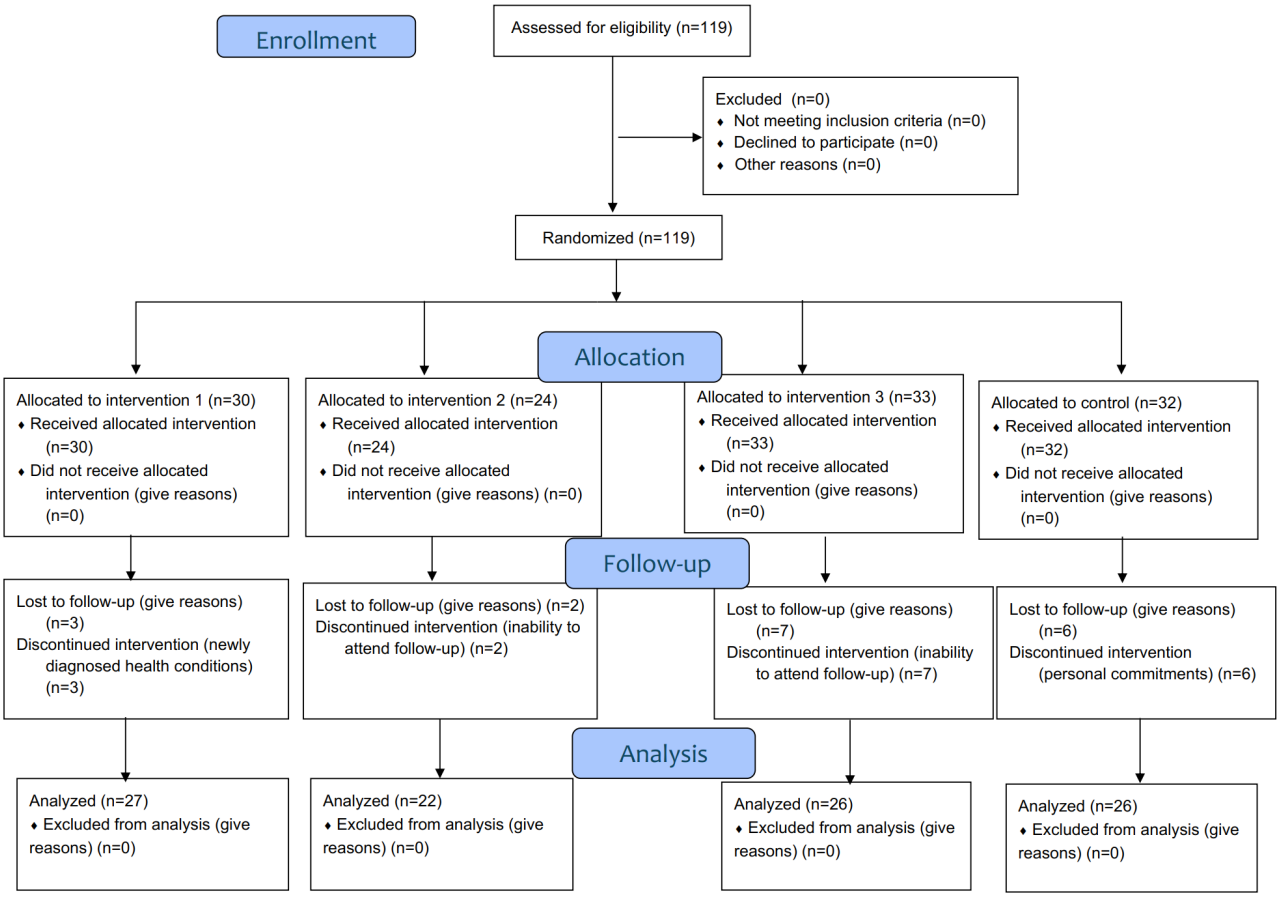
All data collection and intervention procedures were conducted at a community health center in Central Slovenia. The research was carried out by a researcher under the supervision of an associate professor and a physician.

Participants underwent venous blood sampling at baseline, 3 months, and 6 months. Appointment invitations included a brief personalized summary of test results, which served to further motivate participants. The study was single-blind at the participant level: participants were informed only about procedures in their allocated arm and were not informed about the full set of study arms. Due to the pragmatic implementation, study personnel were not blinded.

The study was approved by the Ethics Committee for Nursing Research at the Faculty of Health Sciences, University of Maribor (Approval No. 02/7K-2023), and the National Medical Ethics Committee of the Republic of Slovenia (Approval No. 0120-217/2023/4). We have also registered the research protocol in clinical trials (ClinicalTrials.gov NCT06226948) [55]. All participants were informed that their data would be used exclusively for research purposes.

Participants received written and verbal information about the study and provided written informed consent before any study procedures. Participation was voluntary, and participants could withdraw at any time without consequences for their usual care. To protect privacy and confidentiality, each participant was assigned a unique study identification code; identifiable information was stored separately from research data and was accessible only to authorized study personnel. Data were handled in accordance with applicable data protection regulations (eg, General Data Protection Regulation) and institutional policies, and were stored on password-protected systems with restricted access; only anonymized or aggregated data were used for analysis and reporting. No financial compensation was provided for participation.

## Results



### Participant Enrollment

Figure 2 presents the CONSORT participant flow diagram. In total, 119 participants were enrolled and randomized into 4 arms, and 101 participants completed the 6-month follow-up; dropouts were mainly due to newly diagnosed health conditions, inability to attend follow-up appointments, or personal commitments.

XSL•FO
RenderX

**Figure 2.** The CONSORT (Consolidated Standards of Reporting Trials) 2010 flowchart.

## Demographic Characteristics

Of the 119 participants, 71% (n=85) were women and 29% (n=34) were men. At the start of the study, most participants were married (n=56, 47%) and had children (n=107, 90%). Most participants had specialization in a professional higher education program, completed a university program or a master's degree (second degree; n=43, 36%), and were employed (n=110, 92%). Most participants did not smoke (n=82, 69%).

Table 1 shows the basic demographic characteristics of all intervention groups and the control group at baseline. The only demographic variable that differed significantly between the groups was educational level ($\chi^2_{15}$=37.15; *P*=.001). Participants in Intervention group 1 (13/30, 43.3%) and Intervention group 3 (15/33, 45.5%) more frequently reported holding a master's degree compared with the control group (6/32, 18.8%). No other demographic characteristics differed significantly across groups, including gender ($\chi^2_3$=3.15; *P*=.37), age ($H_3$=3.13; *P*=.37), marital status ($\chi^2_{12}$=9.22; *P*=.68), having children ($\chi^2_3$=0.71; *P*=.87), number of children ($H_3$=0.94; *P*=.82), employment ($\chi^2_6$=7.62, *P*=.27), smoking status ($\chi^2_6$=2.08; *P*=.91), and number of cigarettes smoked ($H_3$=3.18; *P*=.36). Any differences in the study were due to the interventions in the intervention groups and the level of education in the context of demographic characteristics.

## Evaluation of the Measurements of the Participants in the Main Research

Intervention group 1 had the highest mean SCORE2 at baseline (4.87, SD 2.61), followed by the control group (4.53, SD 3.63) and intervention group 2 (4.08, SD 2.42), while intervention group 3 had the lowest score (3.84, SD 2.08). This indicates that intervention group 3 had the most favorable CVD risk profile at baseline, as lower scores reflect lower risk. Intervention group 1 had the highest mean total cholesterol value at baseline (5.93, SD 1.10), while intervention group 2 had the lowest mean value (4.82, SD 1.51). Intervention group

XSL•FO
RenderX

3 had the highest mean HDL value, with a final value of 1.62 (SD 0.34), while intervention group 2 had the lowest mean value, with a baseline value of 1.28 (SD 0.31).

The highest mean systolic BP was measured in intervention group 1, with a baseline value of 129.23 mmHg (SD 16.76), while the lowest mean was in intervention group 3, with a final value of 119.69 (SD 11.58).

There were no statistically significant differences between groups in SCORE2 ($H_3$=3.269; *P*=.35), total cholesterol ($H_3$=2.402; *P*=.49), HDL ($H_3$=2.93; *P*=.40), systolic BP ($H_3$=3.346; *P*=.34), diastolic BP ($H_3$=2.588; *P*=.46), heart rate ($H_3$=2.170; *P*=.54), BMI ($H_3$=4.066; *P*=.25), phenotypic biological age ($H_3$=2.708; *P*=.44) and glycated biological age ($H_3$=0.261, *P*=.97). Statistical analysis showed no significant differences between groups. This means that the groups compared with respect to SCORE2, total cholesterol, HDL, BP, heart rate, BMI, phenotypic biological age, and glycated biological age were like each other. The baseline and final values for all measurements are presented in Table 2.

**Table .** Participant measurements by randomized groups.

| | Intervention group 1, mean (SD) | Intervention group 2, mean (SD) | Intervention group 3, mean (SD) | Control group, mean (SD) | Change in *P* value (SD) |
|---|---|---|---|---|---|
| SCORE2[a] | | | | | .35 |
| Baseline value | 4.87 (2.61) | 4.08 (2.42) | 3.84 (2.08) | 4.53 (3.63) | |
| Final value | 4.06 (2.71) | 3.53 (2.02) | 3.17 (1.99) | 4.36 (3.27) | |
| Total cholesterol | | | | | .49 |
| Baseline value | 5.93 (1.10) | 5.09 (0.66) | 5.68 (0.93) | 5.28 (1.12) | |
| Final value | 5.10 (2.26) | 4.82 (1.51) | 5.43 (0.99) | 5.44 (1.07) | |

| Value after 3 mo | 57.39 (16.53) | 53.23 (20.79) | 54.74 (16.00) | 49.37 (19.8) | |
| Final value | 56.04 (18.73) | 51.86 (20.95) | 54.96 (17.09) | 53.50 (15.76) | |

[a]SCORE2: Systematic Coronary Risk Evaluation 2.

[b]HDL: high-density lipoprotein cholesterol.

Based on the analyses of the data, we found that there were no significant differences in lifestyle changes between participants in the intervention groups and those in the control group.

XSL•FO
RenderX

### Healthy Lifestyle Assessment: HLPCQ

In all 3 intervention groups and the control group, the domain with the highest baseline score was daily routine. The mean scores for this domain were 19.24 (SD 5.87), 19.17 (SD 3.59), 19.93 (SD 5.18), and 17.61 (SD 5.82) for the first, second, and third intervention groups and the control group, respectively. However, the lowest-rated domain in all groups was organized exercise. The mean scores were 4.27 (SD 1.87), 4.00 (SD 1.78), 4.55 (SD 2.08), and 4.09 (SD 1.69).

At the end point, the highest and lowest rated domains remained unchanged but increased, indicating an improvement in HLPCQ scores. The mean scores for the highest-rated domain, Daily Routine, were: 21.27 (SD 4.94) for the intervention group 1; 21.50 (SD 4.30) for the intervention group 2; 21.25 (SD 3.90) for the intervention group 3; and 19.80 (SD 4.85) for the control group. However, organized exercise was the lowest rated domain in all groups. The mean scores were 5.31 (SD 1.67) in the first intervention group, 4.36 (SD 1.94) in the second intervention group, 4.54 (SD 2.00) in the third intervention group, and 4.88 (SD 2.01) in the control group.

Missing data were minimal across variables, with no missing values for healthy dietary choices at baseline (n=0), and only isolated cases for dietary harm avoidance (n=1), daily routine (n=3), organized physical activity (n=1), and social and mental balance (n=2); the highest number of missing values occurred in the total HLPCQ scores, with up to 5 in 1 group at final measurement.

There were no statistically significant differences in change in HLPCQ scores between groups ($H_3$=2.801; $P$=.42). Thus, the Kruskal–Wallis test showed that group had no significant effect on the change in HLPCQ (Table 3).

**Table .** Baseline and final HLPCQ[a] scores by randomized group.

| HLPCQ | Intervention group 1, mean (SD) | Intervention group 2, mean (SD) | Intervention group 3, mean (SD) | Control group, mean (SD) |
|---|---|---|---|---|
| Healthy dietary choices | | | | |
| Baseline value | 15.93 (3.50) | 14.79 (2.30) | 16.94 (2.57) | 15.25 (3.44) |
| Final value | 17.72 (4.08) | 16.64 (3.55) | 18.28 (3.39) | 16.42 (2.80) |
| Dietary harm avoidance | | | | |
| Baseline value | 10.40 (2.39) | 10.52 (2.25) | 11.31 (2.15) | 10.28 (2.73) |
| Final value | 11.08 (2.04) | 10.32 (2.23) | 11.88 (2.01) | 10.46 (1.94) |
| Daily routine | | | | |
| Baseline value | 19.24 (5.87) | 19.17 (3.59) | 19.93 (5.18) | 17.61 (5.82) |
| Final value | 21.27 (4.94) | 21.50 (4.30) | 21.25 (3.90) | 19.80 (4.85) |
| Organized physical activity | | | | |
| Baseline value | 4.27 (1.87) | 4.00 (1.78) | 4.55 (2.08) | 4.09 (1.69) |
| Final value | 5.31 (1.67) | 4.36 (1.94) | 4.54 (2.00) | 4.88 (2.01) |
| Social and mental balance | | | | |
| Baseline value | 14.10 (2.51) | 13.92 (2.54) | 14.36 (2.36) | 13.53 (3.29) |
| Final value | 14.36 (2.04) | 14.45 (2.82) | 13.88 (3.05) | 13.96 (2.73) |
| HLPCQ total | | | | |
| Baseline value | 64.17 (12.54) | 63 (7.53) | 66.76 (8.91) | 60.58 (12.96) |
| Final value | 69.50 (10.34) | 67.27 (8.56) | 68.90 (7.78) | 65.72 (10.18) |

[a]HLPCQ: Healthy Lifestyle and Personal Control Questionnaire.

The Kruskal–Wallis test ($H_3$=2.801; $P$=.42) revealed no statistically significant differences between the groups regarding changes in HLPCQ. However, the control group showed the most significant improvement in terms of a healthy lifestyle.

### Perception of Person-Centered Care: PCPI-SU

At baseline, the highest-rated domain in all 3 intervention groups and the control group was sharing decision-making. The mean scores were 19.57 (SD 4.68) in the first intervention group, 18.00 (SD 4.64) in the second intervention group, 19.39 (SD 4.96) in the third intervention group, and 18.78 (SD 5.08) in the control group. However, engaging authentically was the lowest scoring domain in all groups, with average scores of 11.00 (SD 2.85) in the first intervention group, 10.29 (SD 2.48) in the second intervention group, 11.00 (SD 3.01) in the third intervention group, and 10.31 (SD 2.79) in the control group.

The domains that were highest and lowest rated at the final perception remained unchanged. The average domain scores for sharing decision-making in the first intervention group were 19.77 (SD 4.61), in the second intervention group 20.86 (SD 4.16), in the third intervention group 19.27 (SD 5.80), and in the control group 19.35 (SD 4.91). The lowest-rated domain

XSL•FO
RenderX

was being sympathetically present in all groups. The average scores were 10.96 (SD 2.57) in the first intervention group, 11.55 (SD 2.99) in the second intervention group, 11.42 (SD 3.24) in the third intervention group, and 11.20 (SD 3.16) in the control group.

Missing data were low across variables, with no missing values for several baseline and final measurements. Occasional missing data were observed for working with the person's beliefs and values (n=1), sharing decision-making (n=1), engaging authentically (n=3), being sympathetically present (n=1), and working holistically (n=2). The highest number of missing values occurred in the total PCPI-SU scores, with 3 at baseline and 2 at the final measurement (Table 4).

**Table .** The perception of PCPI-SU[a] and components at the start and end of the study by the groups that were randomly selected.

| | Intervention group 1, mean (SD) | Intervention group 2, mean (SD) | Intervention group 3, mean (SD) | Control group, mean (SD) |
|---|---|---|---|---|
| Working with the person's beliefs and values | | | | |
| Baseline value | 15.43 (3.99) | 14.00 (3.84) | 15.15 (3.83) | 14.44 (4.26) |

[a]PCPI-SU: Person-Centered Practice Inventory—Service User.

This indicates that there are no significant differences between the groups in terms of changes in PCPI-SU. This is consistent with the results of the Kruskal–Wallis test, which showed no statistically significant differences ($H_3$=4.056; *P*=.26). However, it shows that there was a difference in the change in the second intervention group, in which the CGM was worn. Based on this, it can be concluded that the intervention in the second group had an impact on improving the perception of PCC.

## Discussion

### Effectiveness of Risk Visualization and Glucose Monitoring in Reducing CVD Risk

The overall trend for the SCORE2 risk showed a decrease in CVD for all participants over the 6-month period. This suggests that participants showed some improvement in their risk profile regardless of the type of intervention. The group that was exposed to risk visualization through the Petal-X tool as part of the intervention showed the most improvement. When comparing all 3 intervention groups with the control group more explicitly, a clear pattern emerges. The group receiving combined CVD risk visualization and CGM showed the largest numerical reduction in SCORE2, followed by the group receiving visualization only, while the CGM-only group demonstrated a smaller improvement. The control group also exhibited a reduction in SCORE2, but the magnitude of change was consistently lower than in the visualization-based intervention groups. Although these differences did not reach statistical significance, the direction and relative size of the effects suggest that visual risk communication may have stronger motivational value than glucose monitoring alone, and that combining visualization with CGM may provide additional reinforcement. This highlights the potential value of visual feedback in supporting risk awareness and self-regulation. The findings are consistent with previous research indicating that traditional CVD factors, such as elevated BP, high cholesterol levels, and smoking, remain important in predicting future CVD events [56,57]. Despite the use of different methodologies and assessment tools in different studies, the consistency in core risk factors supports the reliability of tools such as SCORE2 for estimating individual risk. In the present study, the use of a

XSL•FO
RenderX

validated prognostic model (SCORE2), combined with robust data collection from the Slovenian population, provided a solid foundation for evaluating risk trends.

Unlike other research designs, such as the focus group methods used by Vivek Dhukaram et al [58] or the large-scale registry analyses conducted in the Taiwanese study using the National Health Insurance Research Database [59], our approach provides clinically relevant insights into how risk evolves in real-world conditions. Furthermore, physician-led evaluations based on European guidelines, as demonstrated in the study by Dudas et al [60], continue to be a fundamental aspect of CVD risk management. Our findings support these approaches by integrating a PCC component through visualization, which may enhance patient engagement and understanding of personal risk. In line with international evidence [57,61], this study confirms that identifying at-risk individuals early on through structured risk assessments enables more precise preventive interventions. Visualizing risk, particularly when paired with ongoing monitoring or tailored counseling, may further encourage behavioral changes and reduce the long-term burden of CVD. The results of the CVD risk assessment allow for early identification of at-risk individuals, which may contribute to more targeted preventive interventions and a reduction of the burden of CVD in the population, and these findings are also consistent with the reviewed literature [56,57,61]. It is important to interpret the results within the context of this feasibility trial. The absence of statistical significance may be related to the modest sample size, baseline variability, and the short duration of exposure to the interventions. These factors limit the ability to detect smaller but potentially meaningful behavioral changes. Therefore, the results should be interpreted as preliminary indicators of trends rather than definitive effect estimates.

### Evaluating and Modifying Lifestyle Behaviors in CVD Risk Patients Through Visualization and Glucose Monitoring

Assessment of lifestyle using the HLPCQ revealed improvements in multiple domains, particularly among participants who received CVD risk visualization and CGM. These tools were most effective in promoting healthy dietary choices and enhancing daily routines, emphasizing the importance of combining risk awareness with real-time feedback [62]. Participants who received only visualization or only CGM also showed progress, though less consistently. Organized physical activity remained the weakest area across all groups, suggesting that general interventions may be insufficient to influence this behavior. Further research confirms the importance of routine, nutrition, and physical activity in improving quality of life and reducing the risk of disease [63-68]. Social and mental balance showed minimal change, which suggests that these aspects may be more resistant to digital or informational interventions and more dependent on the broader psychosocial context. The avoidance of dietary harm also decreased, particularly in groups without combined support. Older participants tended to report better organization of their lifestyle and healthier eating habits. This aligns with findings that age can positively influence adherence to preventive behaviors. Although no statistically significant differences were found, there were meaningful behavioral shifts in groups with combined interventions. The HLPCQ proved to be a useful tool for detecting these changes, particularly given its ability to incorporate self-regulation and health-related behaviors. Its future use in primary care and epidemiological research appears promising. It is important to note that lifestyle change depends not only on information but also on health literacy, motivation, and contextual support [69]. Research from Sweden has emphasized the importance of valid methods for engaging communities in sustainable prevention efforts, particularly among populations with low health literacy or limited access to care [70]. Therefore, enhancing health literacy could be central to national strategies for preventing lifestyle-related conditions [71]. In conclusion, visualization and CGM can support behavioral changes in individuals at risk of CVD, particularly regarding dietary and routine habits. However, more targeted approaches are needed for physical activity and psychosocial domains, which remain less responsive.

### Lifestyle Change Across Intervention and Control Groups

We tested the hypothesis that there would be significant differences in lifestyle change between groups, but this was not confirmed. The Kruskal–Wallis analysis revealed no statistically significant differences in HLPCQ score changes between the 4 study groups (3 intervention groups and the control group). The control group reported the greatest overall change in healthy lifestyle behavior, followed by smaller positive changes in all intervention groups. This suggests that the inclusion of new technologies, such as CVD risk visualization and CGM, did not result in statistically superior lifestyle improvements over 6 months. Nevertheless, the presence of positive trends in all intervention groups indicates a potential motivational effect of the interventions. A sustainable lifestyle change is a long-term process requiring continuity, reinforcement, and individual adaptation to have a lasting impact on quality of life and health-related well-being [17]. Based on other studies with similar intervention durations [17,53], we expected to detect measurable changes after 6 months. However, the short-term use of CGM and limited intervention exposure may have reduced the observable impact within the timeframe of our research.

Additionally, the Petal-X visualization of CVD risk was described as a concrete and motivating element that helped individuals recognize the necessary behavioral changes in their daily lives. These observations indicate that while measurable outcomes were modest, experiential factors may still play an important role in behavior change. Further research should explore longer intervention periods and enhanced support structures to evaluate the full potential of visual and self-monitoring tools in promoting healthy lifestyles. It is important to note that educational level differed significantly between the randomized groups at baseline. This imbalance is a common limitation in small feasibility samples, where randomization may not fully equalize sociodemographic characteristics. Since higher educational attainment is associated with better health literacy, greater engagement in preventive behaviors, and improved ability to interpret risk information, it is possible that educational level influenced participants'

XSL•FO
RenderX

responses to the interventions. Although we cannot determine the extent of this influence, it may have contributed to behavioral differences observed across groups. Future studies should include stratified randomization or larger sample sizes to minimize such baseline imbalances.

### Determining Whether Person-Centered Care Is Associated With Lifestyle Change

A link between PCC and lifestyle change was demonstrated. The results of the correlation analysis revealed a weak, yet statistically significant, positive relationship between perceived PCC and healthy lifestyle behaviors, including self-regulation. The Spearman correlation coefficient showed that higher HLPCQ scores, reflecting healthier lifestyle patterns and greater personal control, were associated with higher perceptions of PCC. Although the correlation was weak, its statistical significance suggests that the association is unlikely to be due to chance. These findings show that improving lifestyle and self-management behaviors could lead to a more positive perception of care quality from the patient's perspective. Therefore, even minor improvements in perceived PCC could be meaningful, particularly when promoting long-term behavioral change and better health outcomes. Researchers emphasize the importance of health care professionals assessing individual risk, designing care plans that are tailored to patients' lifestyles and contexts, and implementing PCC approaches to positively influence health outcomes [72-76]. Furthermore, interventions targeting lifestyle changes have been shown to improve BP and lipid profile control, highlighting the effectiveness of PCC in managing risk factors and encouraging behavioral changes [77]. This evidence highlights the importance of tailoring health care delivery to patients' individual needs and preferences. PCC has the potential to improve patient satisfaction and may reduce CVD risk factors such as hypertension [78-80]. Therefore, integrating lifestyle-oriented PCC strategies into clinical practice should be considered a priority in both prevention and chronic care management.

These findings should be interpreted with caution, as the study may have been underpowered and the intervention period relatively short, both of which could have limited the ability to detect statistically significant effects. It is also important to consider potential clinical significance. Both the HLPCQ and PCPI-SU scores showed improvements across groups, including the control group. Although these changes were not statistically significant, small improvements in lifestyle behaviors or person-centeredness may still be clinically meaningful in a primary care setting. Behavior change is often gradual and incremental, and even minor positive shifts can contribute to long-term cardiovascular risk reduction when sustained over time.

### Limitations

This study has several limitations. The lack of a double-blind design may have introduced bias, and participants may have perceived differences between the intervention groups, which could have influenced the outcomes. The sample included only individuals with an increased risk of CVD based on clinical markers, excluding those with behavioral risk factors. Variability in digital literacy, particularly among older participants, may have affected uptake of the technology-supported interventions. Motivation fluctuated due to personal life events, and some technical issues with CGM devices occurred, but these were resolved. Although the lifestyle questionnaire had not been validated in Slovenia, the necessary cultural adaptations were made in line with WHO guidelines.

Additionally, the study was not sufficiently powered to detect small or moderate effects, as the sample size was limited and no formal power calculation was conducted prior to recruitment. This may have contributed to the absence of statistically significant findings despite observable clinical trends. The 6-month intervention period may have been too short to capture measurable changes in long-term lifestyle behaviors or CVD risk, which typically require sustained support and longer follow-up. This likely reduced the detectable impact of both visualization and CGM-based interventions. Consequently, the trial was not adequately powered to detect small or moderate between-group differences, and the absence of statistically significant findings should therefore be interpreted with caution.

### Key Findings and Recommendations

Although the quantitative results did not confirm statistically significant improvements, participants in the intervention groups reported enhanced awareness, motivation, and engagement in their health management. Digital tools such as Petal-X, CGM, and biological age assessment supported PCC and encouraged meaningful lifestyle adjustments. These findings demonstrate the potential for integrating digital tools into preventive health care to improve understanding of CVD risk and promote behavior change. Future studies should include larger and more diverse samples, extend the follow-up period, and examine effects in specific subgroups. Strengthening digital literacy among health care professionals and patients will be essential for successful implementation. With better training and user-friendly tools, technologies such as Petal-X and CGM could provide substantial support for lifestyle change, ongoing risk monitoring, and more effective PCC.

## Conclusions

This study makes a valuable contribution to the growing field of digital health, demonstrating the potential of combining risk visualization (Petal-X), CGM, and biological age assessment for the lifestyle-based prevention of CVD. While no clinically significant improvements were observed, the findings provide valuable insights into the feasibility, usability, and motivational impact of digital tools in PCC. Integrating such technologies could facilitate the early identification of risk, encourage patient engagement, and promote behavior change. These results emphasize the necessity of further longitudinal research and the development of digital infrastructure to facilitate lifestyle interventions within preventive health care in Slovenia. We also provided a detailed description of the standard care received by the control group to ensure transparency and comparability between intervention arms, in accordance with CONSORT recommendations.

This study highlights the potential of integrating digital tools such as Petal-X visualization, CGM, and biological age

XSL•FO
RenderX

assessment into preventive health care. While statistical significance was limited, participants reported increased awareness, motivation, and involvement in managing their health. These findings support the value of PCC approaches and the need for further research on long-term, technology-supported lifestyle interventions. Expanding digital literacy and developing national guidelines for digital integration will be key to enhancing care quality and reducing CVD risk in the future.

## Acknowledgments

The authors would like to thank all participants who took part in this research.

The authors acknowledge partial support from the Slovenian Research Agency (grant numbers N3-0307 and P2-0057).

The authors declare the use of generative artificial intelligence (GAI) in the research and writing process. According to GAIDeT (Generative AI Delegation Taxonomy; 2025), the following tasks were delegated to GAI tools under full human supervision: translation and reformatting. The GAI tool used was ChatGPT 5.1.

Responsibility for the final manuscript lies entirely with the authors. GAI tools are not listed as authors and do not bear responsibility for the final outcomes.

## Funding

## Abstract

**Background:** Child maltreatment is a major public health issue in the United States, with substantial variation in how states define, report, and respond to abuse and neglect. While prior research has examined individual policy components, less is known about how multiple policies jointly shape broader policy environments and relate to maltreatment outcomes.

**Objective:** This study used natural language processing (NLP) to characterize state child maltreatment policy environments and examine their associations with maltreatment incidence, recurrence, and fatalities across US jurisdictions.

**Methods:** A cross-sectional study was conducted using 2021 data from 50 US states, the District of Columbia, and Puerto Rico (N=52). A total of 411 state maltreatment policy items were derived from the State Child Abuse & Neglect Policies Database. A total of 6 NLP models (bidirectional and auto-regressive transformer [BART], bidirectional encoder representations from transformers [BERT], robustly optimized BERT approach [RoBERTa], decoding-enhanced BERT with disentangled attention [DeBERTa], Copilot, and LLaMA 3.1) were applied using a zero-shot classification framework to quantify policy characteristics. Models were evaluated using intrinsic (category consistency and semantic alignment) and extrinsic (factor analysis and clustering performance) metrics. Exploratory factor analysis was used to identify latent policy domains, and k-means clustering was applied to group jurisdictions with similar policy profiles. Maltreatment outcomes, including incidence, recurrence, and fatalities, were obtained from the National Child Abuse and Neglect Data System. Outcome differences across clusters were assessed using ANOVA with post hoc pairwise comparisons.

**Results:** The study population included 72,838,819 children and 3,774,528 maltreatment reports, of which 751,283 were substantiated or indicated cases. Across 6 NLP models, DeBERTa demonstrated the best overall performance. Exploratory factor analysis identified 3 primary policy domains: maltreatment definition, mandated reporting, and alternative response. A total of 4 policy clusters were identified. Jurisdictions with weaker reporting requirements and fewer penalties (cluster 2) had the highest incidence of maltreatment (mean 17.51, SD 6.13 vs mean 9.65, SD 4.10; mean 10.28, SD 6.47; and mean 11.74, SD 6.47 per 1000 children; $P$=.07) and recurrence (mean 1.74, SD 0.87 vs mean 0.52, SD 0.44; mean 0.66, SD 0.52; and mean 0.68, SD 0.43 per 1000 children; $P$<.001). Jurisdictions with stronger reporting requirements, broader definitions, and greater use of alternative response systems (cluster 1) had the lowest incidence and recurrence. No statistically significant differences in maltreatment fatalities were observed across clusters ($P$=.89). However, in a subanalysis of 18 fatality-related policy items, clusters differed significantly in fatality rates, with jurisdictions characterized by less clearly defined fatality policies exhibiting higher fatality

XSL•FO
RenderX

rates (mean 47.91, SD 8.35 vs mean 22.64, SD 11.82; mean 25.63, SD 18.62; and mean 19.03, SD 11.64 per 1,000,000 children; *P*=.03).

**Conclusions:** State child maltreatment policies form distinct, multidimensional patterns associated with maltreatment outcomes. The findings highlight the importance of evaluating integrated policy frameworks rather than isolated components and demonstrate the use of NLP for large-scale, data-driven policy analysis.

## Introduction

Child maltreatment, which includes both child abuse and neglect, is a critical public health concern in the United States. In fiscal year 2023, the most recent year for which information is available, there were 546,159 reported children who experienced child maltreatment, with an estimated 2000 children dying from maltreatment [1]. Child maltreatment is associated with an increased risk of adverse health outcomes and risk behaviors, including substance use, mental health disorders, chronic physical conditions, and premature mortality [2-5]. The economic burden is substantial, with the total lifetime cost estimated at US $2.94 trillion for investigated cases and US $563 billion for substantiated cases in the federal fiscal year 2018 [6].

Child maltreatment policy refers to states' definitions of child abuse and neglect, along with related regulations that shape child welfare practices. These policies determine how allegations are referred, reported, investigated, and managed [7]. For example, mandated reporting expansion refers to policies that broaden the categories of individuals required to report suspected maltreatment (eg, extending beyond professionals such as teachers and health care providers to include additional occupational groups or, in some states, all adults) [8]. Similarly, policies such as centralized intake systems standardize how reports are received and screened, while differential response systems allow for alternative, noninvestigative pathways for lower-risk cases [9]. Together, these policy components influence both the volume and characteristics of cases that enter and progress through the child welfare system.

At the federal level, the Child Abuse Prevention and Treatment Act (CAPTA), first enacted in 1974 and reauthorized multiple times since, establishes minimum standards for state definitions of abuse and neglect and conditions federal funding on states' compliance with these requirements [10]. However, states retain substantial discretion in translating these federal requirements into policy and practice, resulting in significant cross-state variation [7]. This variation leads to substantial differences in reported maltreatment rates and intervention effectiveness, with substantiation rates ranging from 5% to 45% across states [11].

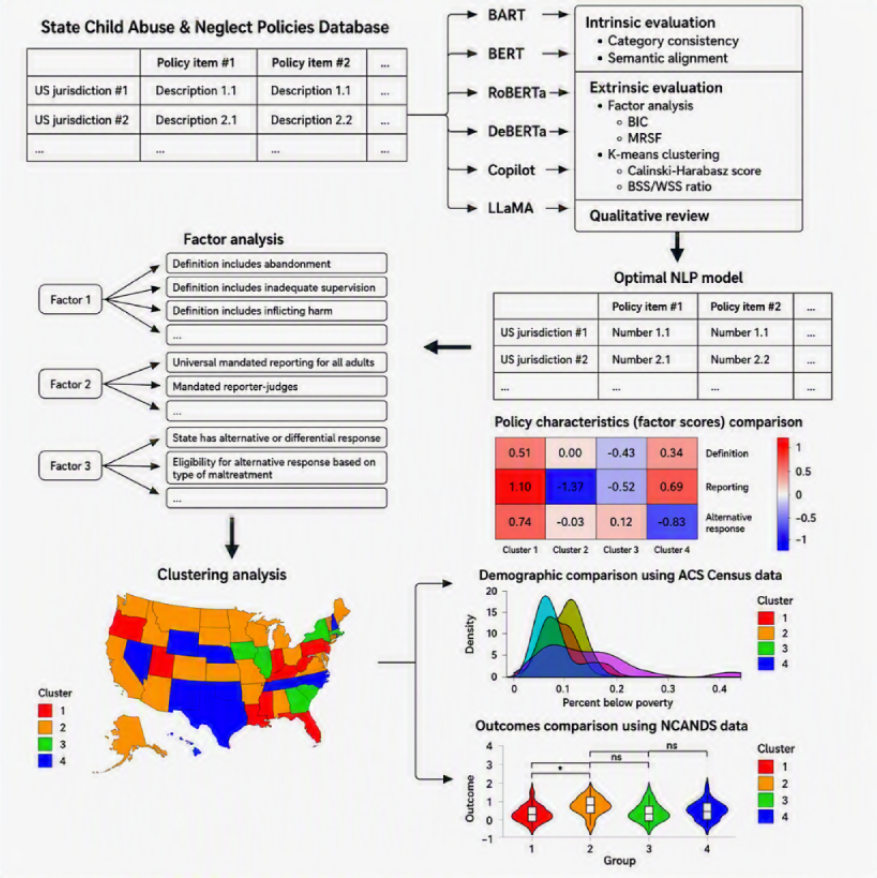
Research suggests that states spending an additional US $1000 per person in poverty on benefits such as cash aid, child care, or Medicaid assistance saw 4.3% fewer maltreatment reports and 4.0% fewer substantiations [12]. Additionally, states that implemented mandated reporting expansion, centralized intake, and increased state staffing saw a 32% increase in maltreatment reports, although substantiated reports declined by 5% to 6% [7]. In contrast, states adopting both differential response and higher standards of proof experienced a 24% decrease in substantiated reports, with differential response accounting for 11% and higher proof standards contributing between 12% and 13% [7]. A separate national quasi-experimental study using data from 2004 to 2017 found that states with differential response programs had approximately 19% fewer substantiated reports and a 17% reduction in foster care use relative to states without differential response [9]. These literatures reflect the complex and sometimes countervailing ways in which policy components interact with one another and with local implementation contexts.

However, existing studies have largely examined individual policies or small sets of policy features in isolation. Less is known about how multiple policy components co-occur within states to form broader policy environments, or how states differ systematically across key policy domains. This limitation is important because child welfare systems operate as integrated structures, where policies governing reporting, screening, investigation, and service response interact with one another. As a result, the relationship between any single policy component and observed outcomes may depend on the broader policy context in which it is embedded.

Recent advancements in natural language processing (NLP), particularly the development of large language models (LLMs), have begun to transform policy research and child welfare research. In policy text mining, zero-shot and few-shot classification have been applied to large corpora of legislative text, demonstrating scalability without extensive hand-labeled training data [13]. Other work has used NLP to construct interpretable, theory-driven measures of legislative quality from statutory text [14] and to track policy status across large sets of climate and environmental documents [15-17]. In child welfare research, NLP and related methods have focused on case-level rather than policy-level data. Predictive risk modeling using structured administrative records has estimated individual maltreatment risk, in some cases outperforming existing screening tools [18,19], while NLP applied to case notes and health records has identified instances of maltreatment [20-23]. These efforts enhanced data-driven decision-making within child welfare agencies by allowing for more nuanced insights into family dynamics and case histories [24]. These approaches demonstrate NLP's value for surfacing information from unstructured text, but case note narratives have also been shown

XSL•FO
RenderX

to embed caseworker bias and uncertainty, raising caution about their use in downstream predictive tasks [25]. However, none of this literature has applied NLP to the formal statutory and regulatory policy documents that define state child welfare systems, as distinct from case-level clinical or casework text.



This study uses NLP to identify key components of state child maltreatment policies, examine how states differ across these components, and assess how these policy configurations are associated with maltreatment outcomes in the United States. By characterizing the multidimensional structure of state policy environments, this study aims to provide a more comprehensive understanding of how policy variation corresponds to differences in observed child welfare outcomes.

## Methods

### Overview

This study was reported in accordance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines. The overall analysis proceeded through 3 stages, as illustrated in Figure 1: comparing and evaluating 6 NLP models and quantifying the 411 state policy items ("Quantification of State Maltreatment Policy Using NLP" section), identifying latent policy dimensions via factor analysis and jurisdiction grouping via k-means clustering ("Exploratory Factor Analysis" and "Clustering Analysis" sections), and comparison of demographic, economic, and maltreatment outcomes across the resulting policy clusters ("Demographic, Economic, and Outcome Comparisons" section).

**Figure 1.** Analytical workflow for evaluating state child maltreatment policy configurations using natural language processing (NLP), exploratory factor analysis, and clustering among 52 US jurisdictions in 2021. ACS: American Community Survey; BART: bidirectional and auto-regressive transformer; BERT: bidirectional encoder representations from transformers; BIC: Bayesian information criterion; BSS/WSS: between-cluster sum of squares to within-cluster sum of squares ratio; DeBERTa: decoding-enhanced BERT with disentangled attention; MRSF: multiple R-squared of scores with factors; NCANDS: National Child Abuse and Neglect Data System; RoBERTa: robustly optimized BERT approach.

### Data Sources

This study used data from 3 sources. State-level child abuse and neglect policy data from 2021 were obtained from the State Child Abuse & Neglect Policies Database (SCAN), which documents state child welfare laws and policies across all 50 US states, the District of Columbia, and Puerto Rico. The database contains 411 standardized policy variables covering state-specific definitions of child abuse and neglect, reporting policies, screening policies, investigation policies, child welfare responses, child welfare system context, and child fatality–related policies in calendar year 2021 [26]. SCAN captures written state laws and policies from publicly available or state-provided sources, including state statutes, regulations, and agency policy documents. Policy variables are coded using a standardized protocol and are verified by state agency contacts when feasible.

Additionally, child welfare agency– and child-level maltreatment data from 2021 were sourced from the National Child Abuse and Neglect Data System (NCANDS), a federally sponsored

XSL•FO
RenderX

program administered by the US Department of Health and Human Services [27,28]. NCANDS collects and analyzes state-reported data on child abuse and neglect known to child protective services, as mandated by the CAPTA [27,28]. Child-level records were used to derive state-level measures of maltreatment incidence and recurrence by aggregating individual cases. Maltreatment fatality rates were obtained from the NCANDS agency-level data because some fatality information is not available in the child-level files for confidentiality and data security reasons.

Finally, demographic and economic data from 2021 were drawn from the American Community Survey, an annual survey conducted by the US Census Bureau that provides detailed estimates of social, economic, housing, and demographic characteristics at the state and local levels [29].

## Study Cohort and Outcomes

The study cohort included all 50 states in the United States, the District of Columbia, and the Commonwealth of Puerto Rico, with 411 state maltreatment policy items assessed in each jurisdiction in calendar year 2021. Each policy item represents a specific child welfare policy provision (eg, a mandated reporting requirement, definition of child maltreatment, screening procedure, or investigation practice) and is organized within the SCAN database into predefined policy domains, including child maltreatment definitions, mandated reporting, screening, investigations, child welfare responses, and child welfare system context (Table S1 in Multimedia Appendix 1). These domains are part of the original SCAN database structure. Policy items vary in measurement format depending on the underlying policy provision and include binary, categorical, ordinal, and descriptive variables. Although the SCAN database organizes policy items into predefined domains, these domains were used only to describe the source variables. The subsequent analyses identified latent policy dimensions empirically using exploratory factor analysis (EFA) rather than relying on the original SCAN categorization.

Maltreatment outcomes were evaluated for individuals aged <18 years. While some states, such as Illinois, allow youth aged 18 years or older to remain in care, others do not. To ensure consistent denominators across jurisdictions, individuals aged 18 years or older were excluded.

The study examined three outcomes: (1) incidence of maltreatment, measured as the number of substantiated or indicated maltreatment cases per 1000 children aged <18 years in each state; (2) maltreatment recurrence, defined as the number of children previously identified as having experienced maltreatment who experienced subsequent incidents per 1000 children in the population; and (3) maltreatment fatalities, defined as the number of deaths resulting from maltreatment per 1,000,000 children. For the first 2 outcomes, only substantiated or indicated maltreatment recorded by state child protective services in NCANDS with report dates in 2021 were included. Although these outcomes represent related dimensions of child maltreatment burden, they capture distinct aspects of child welfare involvement and were analyzed separately rather than modeled as a combined outcome.

## Quantification of State Maltreatment Policy Using NLP

### Overview

The primary study variable was state maltreatment policy. To prepare these data, 411 state maltreatment policy items from 2021 across 52 US jurisdictions were processed using NLP models.

### NLP Approach

This study applied NLP methods to classify and analyze 411 state maltreatment policy items from 2021 across 52 US jurisdictions. A zero-shot classification [30], which uses pretrained models to assign labels without task-specific fine-tuning, was selected because the policy data were not labeled for the specific classification tasks required in this study. Alternative approaches, such as supervised or few-shot classification, typically require curated training examples for each category, which were not available and would require substantial manual annotation. Zero-shot methods provide a scalable and consistent framework for applying predefined policy categories across heterogeneous statutory text while avoiding potential bias introduced through hand-labeled training data.

To evaluate the robustness of this approach, 6 NLP models were compared, representing distinct architectures and training paradigms, including encoder-based, sequence-to-sequence, and generative LLMs. Comparing these models allows assessment of whether classification results are consistent across fundamentally different modeling approaches, and whether more recent generative models provide advantages over traditional transformer-based classifiers in capturing the structure of policy text. The 6 models evaluated were as follows:

1. Bidirectional and auto-regressive transformer (BART) [31], a sequence-to-sequence transformer with a bidirectional encoder and an autoregressive decoder, designed for classification and text generation tasks;
2. Bidirectional encoder representations from transformers (BERT) [32], a bidirectional transformer encoder trained using masked-language modeling for deep contextual text understanding;
3. Robustly optimized BERT approach (RoBERTa) [33], an optimized version of BERT trained longer and on larger corpora to improve robustness and performance;
4. Decoding-enhanced BERT with disentangled attention (DeBERTa) [34], a transformer model that enhances BERT/RoBERTa with disentangled attention and improved position encoding;
5. Microsoft Copilot [35], generative transformer models adapted for instruction-following and classification;
6. Meta LLaMA 3.1 [36], an LLM in the LLaMA family, trained as an autoregressive transformer with strong general-purpose language understanding capabilities.

The models evaluated each policy item independently by assessing whether each jurisdiction's policy text supports or contradicts the policy item's title description. For example, for the policy item titled "How is reporting decentralized?," jurisdiction responses include "Each county has its own

XSL•FO
RenderX

reporting hotline," "Some counties have their own reporting hotlines," and "No county has its own reporting hotline." Each NLP model assigned a likelihood score from 0 to 1 to each response, indicating the degree to which it supported the policy title, where 1 represented the strongest support and 0 the weakest. For instance, the BART model assigned scores of 0.90, 0.81, and 0.59, respectively.

For LLMs, Microsoft Copilot and Meta LLaMA 3.1, the scores were generated by a structured prompt, which was applied separately to each policy item and took the following format:

"Please estimate the likelihood (on a scale from 0 to 1) that the response [A], [B], [C] supports or opposes the statement [Policy Title]. Stronger support should be closer to 1, a neutral or irrelevant stance should be around 0.5, and complete opposition should be close to 0. Provide likelihoods in this format: [A]: score1; [B]: score2; [C]: score3."

### *NLP Evaluation Metrics*

The 6 models were evaluated using intrinsic and extrinsic metrics [37,38]. Intrinsic evaluation measured internal consistency and agreement by testing how well LLM embedding vectors capture the underlying characteristics of the texts, while extrinsic evaluation assessed the performance of key embedding features extracted from the policy documents based on their performance in downstream tasks and analyses [37]. Since later sections of the study applied EFA [39] and k-means clustering [40] to policy data, these techniques were used here as extrinsic evaluation metrics to determine how well different NLP models capture meaningful variation in policy content for the same set of features.

For intrinsic evaluation, 3 metrics were used. First, category consistency was assessed based on the relative ordering of classification scores across response categories. Specifically, items labeled as "Yes" were expected to receive higher scores than those labeled "No," while intermediate responses such as "Not Applicable," "Unknown," or "Missing" were expected to fall between "Yes" and "No." Second, for descriptive responses, semantic alignment was measured using 2 metrics. Because a true gold standard was unavailable for these responses, 2 proxy gold standards were used: (1) cosine similarity scores, where higher values indicate better semantic alignment, and (2) the average score across all methods. The correlation between each model's results and these proxy standards, where a higher correlation indicates better agreement, served as the metric to assess semantic alignment.

Extrinsic evaluation assessed EFA and clustering results derived from each NLP model-specific policy representation. In this stage, each model produced a complete set of scores for the 411 policy items across jurisdictions, which served as inputs for EFA and k-means clustering. Model performance was then assessed by comparing goodness-of-fit and clustering metrics to identify which NLP approaches most effectively capture meaningful structure in the policy data. EFA results were evaluated using the Bayesian information criterion (BIC) [41], where lower values indicate better model fit accounting for complexity, and the multiple R-squared of scores with factors (MRSF) [39], where higher values reflect better explanatory power of the factor scores. To explore different latent structures, EFA models with 2, 3, and 4 factors were examined. Clustering performance was analyzed using the Calinski-Harabasz score (CH) [42], where higher values indicate better cluster separation relative to complexity, and the between-cluster sum of squares to within-cluster sum of squares (BSS/WSS) ratio [43], where higher ratios represent more compact and well-separated clusters. Models with 2, 3, and 4 clusters were examined to evaluate clustering performance.

### *Qualitative Review*

Finally, a qualitative review explored why certain methods perform better on specific metrics by analyzing model outputs, identifying recurring error patterns, and assessing consistency across similar policy items. This review considered factors such as sensitivity to nuanced language, handling of ambiguous or incomplete responses, and stability in scoring across different policy categories. This review aimed to gain an intuitive understanding of model behavior and to verify that the results aligned with expectations.

Overall model performance was determined by considering results across all intrinsic and extrinsic evaluation metrics rather than relying on a single metric or composite score. No weighting scheme was applied. Instead, models were compared based on their relative performance patterns across evaluation dimensions, with qualitative review used to further examine model behavior, identify potential sources of variation, and assess whether quantitative findings were consistent with expected policy interpretation.

## Covariates

Demographic and economic characteristics were included as covariates to contextualize jurisdiction-level differences. Demographic covariates included age distribution, racial and ethnic composition, and gender. Economic conditions were measured by the proportion of the population living below 50%, 100%, 125%, and 400% of the federal poverty level, capturing varying levels of economic vulnerability.

## Statistical Analysis

### *Exploratory Factor Analysis*

Although the SCAN database organizes policy items into predefined domains for documentation purposes, these domains do not necessarily represent latent policy constructs. EFA was conducted on the 411 state maltreatment policy items to identify latent dimensions [39]. Consequently, policy items originating from the same SCAN domain were not constrained to load on the same factor; likewise, policy items from different SCAN domains could load on the same factor if they reflected similar underlying policy characteristics. The number of factors was determined using a scree plot, a graphical tool that helps identify the point where the rate of decrease in explained variance slows [44]. While this plot provides a helpful visual cue, identifying the "elbow" can be subjective and challenging [44,45]. In cases where the exact location of the "elbow" is ambiguous and several factor number choices were similarly justifiable, we opted for the smaller number of factors to ensure concise and easier interpretation.

XSL•FO
RenderX

To identify the underlying themes for each factor, policy items with high factor loadings were reviewed. These factors were then labeled based on the substantive patterns they capture. For each factor in each jurisdiction, factor scores were computed to quantify the degree to which each jurisdiction aligns with the identified policy dimensions [46]. The factor scores provided a reduced representation of the original 411 policy items and were used in subsequent analyses to characterize jurisdiction-level policy configurations.

The internal consistency of policy items contributing to each identified factor was assessed using McDonald ω [47]. ω was calculated based on policy items with absolute factor loadings above 0.4.

### *Clustering Analysis*

K-means clustering was applied to the 411 state maltreatment policy items to identify groups of jurisdictions that share similar policy characteristics [40]. The optimal number of clusters was determined using the Silhouette method [48], which evaluated cluster cohesion and separation, along with interpretability considerations, to ensure the resulting groupings were meaningful and practically relevant. After the number of clusters is selected, each jurisdiction is assigned to a cluster based on the similarity of its policy item representations to the identified cluster profiles. To visually illustrate the geographic distribution of policy clusters, a US map is generated, with jurisdictions color-coded according to their assigned cluster. The policy characteristics of each cluster are identified by comparing average factor scores derived from the factor analysis.

Although k-means clustering and factor analysis are distinct techniques, they serve complementary purposes in this study. Factor analysis reduces the dimensionality of the policy items and identifies underlying policy domains, whereas clustering groups jurisdictions based on similarity across the full set of policy features. By conducting clustering on all items and using factor scores for interpretation, this approach preserves the full information available for grouping while enabling a more interpretable, lower-dimensional characterization of cluster differences. Consistency between cluster profiles and factor structures further supports the coherence and robustness of the observed policy patterns.

### *Demographic, Economic, and Outcome Comparisons*

To characterize each cluster, policy factor scores were compared across clusters. Then, demographic, economic, and outcome differences were examined across jurisdiction clusters. Statistical differences across clusters were tested using ANOVA for continuous variables [49] and chi-square tests for categorical variables [50]. When significant differences are detected, post hoc pairwise comparisons are conducted to determine which clusters differ from each other. Given the small sample size of 52 US jurisdictions, a significance level of 0.10 is used to reduce the risk of type II errors and detect potential associations that may warrant further investigation [51,52].

## Sensitivity Analyses

### *Leave-One-State-Out Sensitivity Analysis*

Cluster robustness was assessed using a leave-one-jurisdiction-out sensitivity analysis. K-means clustering was repeated after sequentially removing each jurisdiction, and agreement between the resulting cluster assignments and the original clustering was evaluated using the adjusted Rand index (ARI) [53]. This analysis was conducted to evaluate whether the identified policy configurations were robust to the exclusion of individual jurisdictions and not driven by any single state's policy profile.

### *Sensitivity Analysis Including All NCANDS Maltreatment Records*

To assess whether findings were sensitive to the definition of maltreatment outcomes, a sensitivity analysis was conducted using all screened-in maltreatment records reported in NCANDS in 2021, regardless of substantiation or indication status. The same outcome comparison procedures across policy clusters were applied to assess whether the observed associations between policy configurations and maltreatment outcomes remained consistent under an alternative maltreatment definition.

## Subanalysis

To further examine policies specifically related to maltreatment fatalities, a separate and independent clustering analysis was conducted using only the 18 fatality-related policy items (Table S2 in Multimedia Appendix 1). Unlike the primary analysis, which clustered jurisdictions based on all 411 policy items, this subanalysis clustered jurisdictions solely according to fatality-related policies.

K-means clustering is applied to these 18 policy items to group jurisdictions with similar fatality-related policy characteristics. The maltreatment fatality rates across these clusters are then compared to identify any notable differences related to policy configurations. A violin plot—a visualization that combines a box plot with a density curve—is used to display the distribution of fatality rates by cluster. Statistical tests are conducted to determine whether the observed differences in fatality rates are statistically significant.

## Ethical Considerations

This study was approved by the Northwestern University Institutional Review Board (STU00222024). The study consisted of a secondary analysis of deidentified administrative data obtained from the National Data Archive on Child Abuse and Neglect (NDACAN). Data access was granted by NDACAN under its Data Use Agreement, and all analyses were conducted in accordance with the terms of the Data Use Agreement and applicable institutional policies. Because the study involved retrospective analysis of existing deidentified data with no direct participant contact, the Northwestern University Institutional Review Board waived the requirement for informed consent.

The authors did not have access to information that could directly or indirectly identify individual participants during or after data collection. All datasets provided by NDACAN were deidentified prior to release, and analyses were conducted using

XSL•FO
RenderX

secure data management procedures in compliance with the NDACAN Data Use Agreement, which prohibits attempts to reidentify participants.

No participants were recruited for this secondary data analysis; therefore, no compensation was provided.

## Results

### Study Cohort Characteristics

The study included 52 jurisdictions in the United States: all 50 states, the District of Columbia, and the Commonwealth of Puerto Rico. In calendar year 2021, these jurisdictions had a combined population of 72,838,819 individuals aged <18 years, with 18,416,713 (25.3%) aged <5 years, and 54,422,106 (74.7%) between ages 5 and 17 years. In the same year, there were 3,774,528 maltreatment records, each representing a unique report and child combination, involving 3,134,446 unique children. Of these, 751,283 records were indicated, affecting 692,891 unique children. Although NCANDS contains individual-level child welfare records, the unit of analysis for this study was the jurisdiction. Individual-level records were aggregated to the jurisdiction level to derive maltreatment outcomes.

### NLP Results

Table 1 presents the comparison of the 6 NLP models: BART, BERT, RoBERTa, DeBERTa, Copilot, and LLaMA 3.1. For intrinsic evaluation, category consistency scores indicate that DeBERTa and Copilot achieve the best performance (0.95). Semantic alignment results vary across metrics. Based on the similarity metric, LLaMA 3.1 performs best (0.21), followed by BART (0.19) and DeBERTa (0.14). In contrast, when evaluated using the average score metric, Copilot ranks highest (0.91).

For extrinsic evaluation, RoBERTa demonstrates the best performance in factor analysis across all models, achieving the lowest BIC values and the highest MRSF scores for different numbers of factors (2-factor: BIC=–601336; MRSF=0.98; 3-factor: BIC=–561327; MRSF=0.98; 4-factor: BIC=–535315; MRSF=0.98). DeBERTa follows closely with competitive results (2-factor: BIC=–581536; MRSF=0.98; 3-factor: BIC=–550143; MRSF=0.98; 4-factor: BIC=–526241; MRSF=0.97). For clustering, DeBERTa outperforms other models, achieving the highest CH and BSS/WSS ratios across all cluster solutions (2 clusters: CH=4.45; BSS/WSS=1.07; 3 clusters: CH=3.90; BSS/WSS=1.08; 4 clusters: CH=3.28; BSS/WSS=1.09).

The qualitative review showed key sources of error and model-specific challenges (Table S3 in Multimedia Appendix 1). For category consistency, RoBERTa had the lowest score due to struggles with negations (eg, “does not” or “failure to report”), leading to misclassifications, while LLaMA 3.1 often hallucinated artificial logic. In semantic alignment, LLM performance varied—while these models sometimes fabricated justifications instead of following response structures, they also demonstrated a better understanding of longer descriptive texts. However, evaluating semantic alignment was challenging, as similarity and average scores served as imperfect proxies. When comparing similarity and average score approaches, DeBERTa was neither the best nor the worst, performing well in some contexts but falling short in others. Finally, in extrinsic evaluation, DeBERTa outperformed other models, likely because it better preserves structural relationships and maintains meaningful variance in the data.

Based on intrinsic, extrinsic, and qualitative evaluations, DeBERTa was the best-performing model overall, achieving the highest category consistency, strong semantic alignment, the second-best factor analysis performance, and the best clustering result. Because a gold-standard annotation of policy items did not exist, a formal error rate was not calculated.

[a]BART: bidirectional and auto-regressive transformer.

[b]BERT: bidirectional encoder representations from transformers.

[c]RoBERTa: robustly optimized BERT approach.

[d]DeBERTa: decoding-enhanced BERT with disentangled attention.

[e]Category consistency: evaluates whether categorical descriptions align with expected patterns. Higher values indicate better consistency.

[f]Semantic alignment—similarity: using a similarity score as the proxy gold standard to evaluate semantic alignment. Higher values indicate better semantic alignment.

[g]Semantic alignment—average: using the average score across all methods as the proxy gold standard to evaluate semantic alignment. Higher values indicate better semantic alignment.

[h]BIC: Bayesian information criterion.

[i]Extrinsic evaluation metric row titles follow the format "[Method] [Number], [Metric]," where the number represents either the number of factors in exploratory factor analysis or the number of clusters in k-means clustering. The metrics include BIC, multiple R-squared of scores with factors (MRSF), Calinski-Harabasz score (CH), and the between-cluster sum of squares to within-cluster sum of squares ratio (BSS/WSS). Lower BIC values indicate a better fit, while higher values are preferable for MRSF, CH, and BSS/WSS.

## EFA Results

The scree plot (Figure S1 in Multimedia Appendix 1) showed that although a clear "elbow" did not appear until over 50 factors—an impractically large number for interpretation—the decline in eigenvalues slowed around 3 factors, suggesting a point of diminishing returns. We interpreted this inflection as a minor elbow and selected a 3-factor solution to avoid the complexity of higher-dimensional models while still retaining meaningful structure.

The items with the highest absolute factor loadings for each factor (Table S4 in Multimedia Appendix 1) indicated that Factor 1 represented the definition domain, Factor 2 focused on the reporting domain, and Factor 3 captured the alternative response domain. Factor 1 (Definition) reflected the scope of maltreatment definitions, with higher scores corresponding to broader definitions that explicitly included emotional harm, abandonment, and sexual abuse, as well as more stringent safe haven requirements. Factor 2 (Reporting) covered policies related to mandated reporting, where higher scores were associated with a greater number of mandated reporters, more

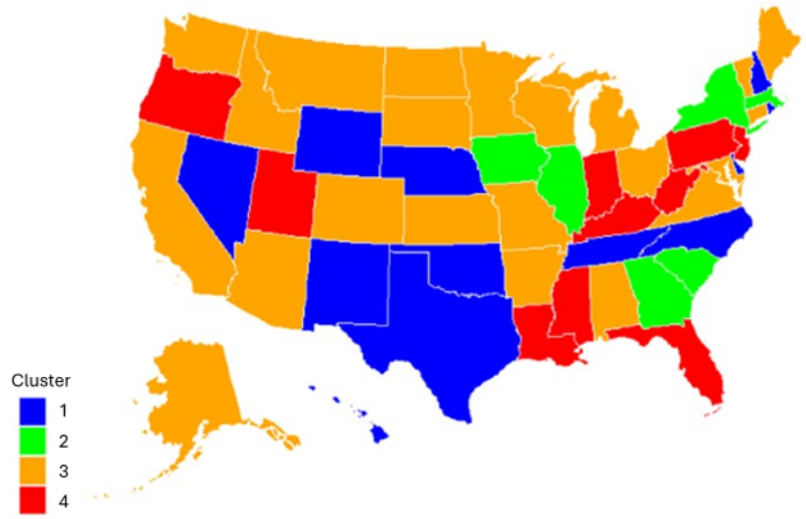
XSL•FO
RenderX

stringent penalties for failure to report, and a reduced emphasis on reporter training. Factor 3 (Alternative Response) captured states' implementation of differential response systems, with higher scores indicating broader eligibility for alternative responses based on case characteristics such as risk level and maltreatment type.

The extracted policy dimensions demonstrated high internal consistency. McDonald ω values were 0.996, 0.959, and 0.938 for the 3 factors, indicating strong coherence among policy items contributing to each latent policy dimension.

## Clustering Results

The k-means clustering analysis was used to identify distinct clusters based on policy characteristics. The optimal number of clusters was determined using the silhouette width, which peaked at 2 and 4 clusters (Figure S2 in Multimedia Appendix 1). To better capture the diversity and variability in the policy characteristics across jurisdictions, 4 clusters were chosen.



A total of 4 distinct policy clusters with varying geographic distributions across US states were identified (Figure 2). Cluster 1 (n=12) was concentrated in the South and parts of the West, including Texas, Oklahoma, and several Rocky Mountain states. Cluster 2 (n=6) was scattered, appearing in parts of the central, Northeast, and Southeast. Cluster 3 (n=23), the largest cluster, covered much of the central and western regions, as well as parts of the northern region, including the Midwest, Great Plains, and Mountain West. Cluster 4 (n=11) was primarily located in the southern and southeastern US, with a few states in the West also assigned to this group.

The policy characteristics of each cluster were assessed using factor scores (Table 2 and Figure S3 in Multimedia Appendix 1). Cluster 1 had the highest scores across all 3 domains (Definition: 0.51, Reporting: 1.05, Alternative Response: 0.74), reflecting broad maltreatment definitions, strict mandated reporting policies with strong penalties, and extensive use of differential response systems. Cluster 2 showed the lowest Reporting score (–1.37), indicating fewer mandated reporting requirements and weaker penalties. Cluster 3 had the lowest Definition score (–0.43), suggesting narrower maltreatment definitions and more lenient safe haven policies. Cluster 4 had the lowest Alternative Response score (–1.05), reflecting the limited implementation of differential response systems and a likely greater reliance on traditional case-handling approaches.

Regarding demographic and economic differences (Table 3), there were no significant differences in child population among clusters (cluster 1: 1.2 million; cluster 2: 2.1 million; cluster 3: 1.3 million; cluster 4: 1.4 million; $P$=.76). Demographically, there were minimal differences in age, gender, and race/ethnicity distributions across clusters. However, poverty status showed significant differences (Figure S4 in Multimedia Appendix 1), with cluster 4 showing a higher proportion of children below poverty levels (cluster 1: 0.17; cluster 2: 0.16; cluster 3: 0.15; cluster 4: 0.21; $P$=.048).

Regarding maltreatment outcomes (Table 4), cluster 2 exhibited the highest incidence of maltreatment, while cluster 1 had the lowest (cluster 1: mean 9.65, SD 4.10; cluster 2: mean 17.51, SD 6.13; cluster 3: mean 10.28, SD 6.47; cluster 4: mean 11.74, SD 6.47; $P$=.07). A similar trend was observed for maltreatment recurrence, with cluster 2 showing the highest rate (cluster 1: mean 0.52, SD 0.44; cluster 2: mean 1.74, SD 0.87; cluster 3: mean 0.66, SD 0.52; cluster 4: mean 0.68, SD 0.43; $P$<.001). In contrast, there were no significant differences in maltreatment fatalities across clusters (cluster 1: mean 21.63, SD 14.83; cluster 2: mean 25.74, SD 14.70; cluster 3: mean 25.80, SD 15.64; cluster 4: mean 23.20, SD 18.80; $P$=.89). Pairwise comparisons (Figure 3) revealed that cluster 2 had a significantly higher incidence of maltreatment than Clusters 1 and 4 and a significantly higher recurrence of maltreatment than Clusters 1, 3, and 4.

**Figure 3.** Pairwise comparisons of maltreatment outcomes across state child maltreatment policy clusters among 52 US jurisdictions in 2021.

## Sensitivity Analyses

The leave-one-jurisdiction-out sensitivity analysis demonstrated high cluster stability (mean ARI 0.984, range 0.726-1.000), suggesting that the identified policy configurations were not driven by individual jurisdictions.

A sensitivity analysis using all screened-in NCANDS maltreatment records in 2021, regardless of substantiation or indication status, showed similar findings. Cluster 2 continued to have the highest maltreatment incidence and recurrence, although only the difference between cluster 2 and cluster 3 remained statistically significant (Figure S5 and Table S5 in Multimedia Appendix 1).

## Subanalysis Results

An independent clustering analysis based solely on the 18 fatality-related policy items (Figure S6 in Multimedia Appendix 1) identified 4 fatality-policy clusters, which are distinct from the 4 policy clusters reported in the primary analysis. Among these fatality-policy clusters, cluster 2 had the least clear definition for child fatalities and near-fatalities, with the lowest scores in "child fatalities definition includes injury," "child fatalities definition includes death of children in foster care," "child fatalities definition includes other," "child near-fatalities definition includes general reference to condition/injury," and "child near-fatalities definition includes specific injury or treatment" (Table S6 in Multimedia Appendix 1).

Regarding outcomes, there were no significant differences among fatality-related policy clusters in terms of incidence of maltreatment or maltreatment recurrence (Table 5). However, a significant difference was found in maltreatment fatalities (cluster 1: mean 22.64, SD 11.82; cluster 2: mean 47.91, SD 8.35; cluster 3: mean 25.63, SD 18.62; cluster 4: mean 19.03, SD 11.64; $P$=.03).

Pairwise comparisons showed that cluster 2 had significantly higher maltreatment fatalities compared to Clusters 1, 3, and 4 (Figure 4). The fatality distribution for cluster 2 was relatively narrow and centered around a higher median, indicating consistently elevated fatality rates. In contrast, cluster 3 showed a wider and more skewed distribution with greater variability, while clusters 1 and 4 showed more moderate and tightly clustered fatality rates with lower medians.

## Discussion

### Summary of Findings

This study analyzed state child maltreatment policies and identified distinct policy clusters associated with maltreatment outcomes. Key findings indicated that states with the fewest mandated reporting requirements and weakest penalties (cluster 2) were associated with the highest substantiated or indicated maltreatment incidence and recurrence rates recorded in NCANDS, whereas states with the strongest reporting requirements, broadest maltreatment definitions, and most extensive use of alternative response (cluster 1) exhibited the lowest rates of substantiated or indicated maltreatment and recurrence. Additionally, states with broad maltreatment definitions and stringent reporting policies (cluster 4) had a high proportion of individuals below the poverty level, although maltreatment outcomes in these states were not significantly different.

### Interpretation of Findings

Previous studies found that mandated reporting policies increased the number of maltreatment reports but did not have a significant impact on substantiated or indicated maltreatment incidence [7,54]. This study expanded upon them by suggesting that mandated reporting policies, when coupled with broad definitions of maltreatment and alternative response systems, were associated with lower rates of substantiated or indicated maltreatment and recurrence. These findings highlight the importance of considering the broader policy context in evaluating the role of mandated reporting.
