While previous studies had linked child poverty to higher maltreatment reports [55,56], this study found that clusters with broader definitions and limited alternative response systems tended to be more economically disadvantaged. Although maltreatment outcomes in these states were slightly higher, differences were not statistically significant. These findings suggest the importance of considering how policy frameworks may intersect with socioeconomic conditions to shape child welfare involvement.

This relationship between child fatality definitions and maltreatment fatality rates has not been explicitly examined in prior research. These findings suggested that a lack of definitional specificity may influence reporting and intervention efforts, potentially contributing to higher fatality rates.

### Policy Implications

The findings suggested several considerations for child maltreatment policy. First, states may benefit from integrating mandated reporting with coordinated prevention and response approaches. Strengthening reporting requirements while also implementing broad maltreatment definitions and alternative response systems was associated with lower rates of

XSL•FO
RenderX

substantiated or indicated maltreatment and recurrence recorded in NCANDS. Developing comprehensive frameworks that balance reporting with both preventive services and supportive response options, such as alternative response systems, could help improve child welfare outcomes [57-59].

Additionally, states with broad maltreatment definitions and stringent reporting policies had higher rates of poverty. While maltreatment outcomes in these states were not significantly different, the overlap between expansive definitions and economic disadvantage raises concerns that reports of maltreatment may, at times, reflect conditions of financial hardship rather than actual harm. This highlights the importance of refining definitions to ensure they do not conflate poverty with neglect [60,61].

Standardizing child fatality definitions across jurisdictions could also enhance the accuracy of reporting and effectiveness of intervention efforts. Establishing clear and consistent criteria for classifying and reporting child fatalities related to maltreatment may improve cross-state comparisons and inform more effective prevention strategies [62,63].

Lastly, the use of NLP and other advanced analytics in policy analysis demonstrated the potential for data-driven approaches in shaping more effective child welfare policies. Leveraging these technologies could provide valuable insights into policy development and evaluation.

### Limitations and Future Directions

This study had several limitations. First, while the NLP models quantified policy characteristics, they may struggle with nuanced interpretations, particularly in complex policy language. Second, the study relied on state-reported NCANDS data, which may contain inconsistencies in reporting practices across jurisdictions. Third, the analysis was limited to policies in 2021, as more recent data were not available at the time of the study, potentially missing subsequent policy changes. Fourth, the cross-sectional design limited the ability to assess causal relationships between policy configurations and maltreatment outcomes. Finally, semantic alignment was challenging to evaluate due to the absence of a true gold standard, and reliance on proxy measures may not fully capture model accuracy.

Beyond these limitations, several sources of structural uncertainty are worth noting, as their exact magnitude remains largely unknown. Cross-state variation in reporting practices means observed outcome differences may partly reflect how jurisdictions define and record cases rather than underlying policy effects alone. Lag times between policy enactment and implementation add further uncertainty, since coded 2021 policies may not yet have been fully operationalized, while outcomes that year may partly reflect earlier policy environments. Tracking inconsistencies across state data systems also introduces measurement noise that is difficult to quantify but may affect the stability of cluster-outcome associations.

Future research should refine NLP approaches to enhance policy interpretation, explore longitudinal analyses to assess policy changes over time, and examine the impact of federal initiatives such as the Family First Prevention Services Act on state policy configurations and child welfare outcomes. With larger longitudinal datasets, future studies could also explore integrated machine learning or hierarchical modeling approaches to jointly model co-occurring policy configurations and multiple child welfare outcomes while accounting for temporal relationships and potential confounding factors. Recent advances in causal machine learning methods for policy evaluation [64] could further help address confounding in future work assessing the causal impact of specific policy configurations on maltreatment outcomes. Finally, parametric approaches integrating multiple co-occurring policies to predict population-level outcomes have also been developed in other domains, such as epidemic modeling of nonpharmacological interventions [65], and may offer a useful direction for future longitudinal extensions of this work.

### Conclusions

This study identified distinct state-level child maltreatment policy configurations and examined their associations with maltreatment outcomes using an NLP-based analytical framework. This study advanced NLP-based analysis of child maltreatment policies across all US states, offering a scalable, reproducible approach to identify policy patterns. By integrating EFA and clustering, this study moved beyond descriptive comparisons and uncovered latent policy structures and their associations with demographic, economic, and child maltreatment outcomes. These findings offered a data-driven basis for comparing policies, identifying gaps, and informing reform.

## Acknowledgments

Generative AI tools were not used in the generation, analysis, or interpretation of this manuscript. Grammarly was used for grammar and language editing assistance.

## Funding

The authors declared no financial support was received for this work.

## Data Availability

The datasets used in this study are available from the National Data Archive on Child Abuse and Neglect (NDACAN) but are not publicly available due to data use restrictions. Both the National Child Abuse and Neglect Data System (NCANDS) and the State Child Abuse & Neglect Policies (SCAN) dataset require submission of a data use agreement and approval by NDACAN.

XSL•FO

## Abstract

**Background:** Frontline workers experience substantial occupational demands that may affect sleep, physical activity, sedentary behavior, recovery, and mental health. Although 24-hour movement behavior (24hrMB) frameworks conceptualize these behaviors as interdependent components of a finite day, it remains unclear how extensively frontline research has adopted integrated approaches, or how evidence is distributed across behaviors, mental health domains, occupations, and measurement methods.

**Objective:** This study aimed to map evidence examining movement behaviors and mental health among adult frontline workers; characterize its distribution and overlap across movement and mental health domains, occupational groups, methods, and contexts; and identify gaps for future research and intervention development.

**Methods:** Following Joanna Briggs Institute methodology and PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidance, 6 databases (PsycINFO, CINAHL, MEDLINE, SPORTDiscus, Scopus, and PubMed) were searched for peer-reviewed studies published from 2000 to 2026. The search was updated on July 30, 2026. Eligible studies included adult civilian frontline workers and examined at least 1 movement behavior in relation to at least 1 mental health domain. One reviewer (AS) screened and charted all studies, while 2 additional reviewers (GH-B and EC) independently screened and charted random subsets to assess reliability. Movement behaviors and mental health domains were coded as non–mutually exclusive. Findings were synthesized using descriptive statistics, narrative synthesis, and evidence mapping.

**Results:** Across the original and updated searches, 613 studies were included. Research was concentrated among health care populations (n=468, 76.3%), with studies predominantly using cross-sectional (n=451, 73.6%), association-focused (n=526, 85.8%), and self-report movement measurement approaches (n=533, 86.9%). Sleep was assessed in 538 (87.8%) studies, physical activity in 177 (28.9%) studies, and sedentary behavior in 24 (3.9%) studies. Most studies assessed 1 movement behavior (n=500, 81.6%), and only 13 (2.1%) assessed all 3 behaviors. Stress was the most frequently assessed mental health domain (n=285, 46.5%), followed by depression (n=243, 39.6%), anxiety (n=224, 36.5%), burnout (n=154, 25.1%), and well-being (n=129, 21.0%). Evidence concentrated on sleep in relation to stress (n=248, 40.5%), depression (n=226, 36.9%), and anxiety (n=208, 33.9%), while comparatively little examined mental health alongside sedentary behavior. Only 9 (1.5%) studies used objective-only movement measurement.

**Conclusions:** Despite a large and rapidly expanding literature, evidence remains dominated by sleep-focused, health care–based, cross-sectional, association-focused, and self-report research. Sedentary behavior, integrated 24hrMB approaches, non–health care frontline occupations, and longitudinal and objective methodologies remain underrepresented. By mapping movement and mental health domains as overlapping rather than mutually exclusive categories, this review identifies both major concentrations and substantive gaps in evidence. Future research should broaden occupational representation, use longitudinal and repeated-measures designs, and examine integrated 24hrMBs using complementary objective and subjective measures. In practice, current evidence can inform priorities for occupational monitoring and intervention development but is insufficient to support specific behavioral prescriptions.

## Introduction

### Background

Frontline occupations are characterized by high workload, trauma exposure, irregular schedules, shift work, emotional labor, and constrained opportunities for recovery, creating occupational conditions associated with elevated psychological burden [1,2]. Across health care, emergency response, policing, firefighting, and related frontline sectors, workers experience high levels of burnout, depression, anxiety, sleep disturbance, emotional exhaustion, and trauma-related symptoms [3-6]. Although the psychological impact of frontline work became increasingly visible during and following the COVID-19 pandemic, growing evidence suggests that these difficulties reflect broader occupational conditions, including sustained operational demands, circadian disruption, staffing pressures, and repeated stress exposure rather than pandemic-related burden alone [2,7,8]. Increasing attention has been directed toward 24-hour movement behaviors (24hrMBs), which conceptualize sleep, sedentary behavior, light physical activity, and moderate to vigorous physical activity as interdependent components of a finite 24-hour day [9,10]. This framework provides a useful perspective for examining health and well-being because occupational demands may influence how time is distributed across movement behaviors and opportunities for recovery [9,11]. Within frontline occupational settings, movement behaviors may be particularly relevant because irregular schedules, shift work, fatigue, and operational demands can constrain opportunities for recovery and create competing demands across the 24-hour day [1,2,8]. Understanding how movement behaviors are distributed and examined in relation to mental health within frontline occupational contexts may therefore provide important insight into the existing evidence base and identify opportunities for more integrated approaches to worker health and recovery [9,11].

### 24hrMBs and Mental Health in Frontline Work

Sleep disruption represents one of the most consistently examined behavioral pathways linking frontline occupational stress with mental health outcomes [2,3]. Many frontline roles involve night shifts, rotating schedules, extended working hours, on-call duties, and irregular operational demands that disrupt circadian rhythms and reduce opportunities for restorative sleep [8,12]. Poor sleep quality and insufficient sleep have been associated with depressive symptoms and perceived stress among frontline workers [13-15]. Physical activity has also received considerable attention in relation to mental health. Evidence from adult populations indicates that higher levels of physical activity are associated with better mental health and well-being [9,10]. Within frontline populations, physical activity may be particularly relevant because workers frequently experience elevated occupational stress and constrained opportunities for recovery [1,7,8,16,17]. However, movement patterns within frontline settings may be shaped by occupational demands, with some roles involving substantial physical exertion and others including prolonged periods of monitoring, driving, documentation, or administrative work [9,18]. Sedentary behavior represents a distinct movement behavior domain with potential relevance to frontline occupational research. Defined as waking behavior characterized by low energy expenditure while sitting or reclining, prolonged sedentary behavior has been associated with depressive symptoms and poorer mental well-being [10,12,19]. The distribution and potential implications of sedentary behavior may also vary according to occupational role structure and work demands [18,20]. Taken together, these behaviors form an interdependent 24-hour movement composition in which time allocated to 1 behavior necessarily affects the time available for others [9,11]. This interdependence highlights the value of examining movement behaviors within an integrated whole-day framework rather than solely as isolated behavioral domains [9,11]. However, the extent to which frontline occupational research has examined multiple movement behaviors concurrently or adopted approaches that account for their interdependence remains unclear. Mapping the representation and overlap of these behavioral domains is therefore necessary to establish how comprehensively the existing literature reflects an integrated 24hrMB perspective.

### Measurement Approaches in Frontline Research

Self-report measures provide practical and scalable methods for assessing behaviors across occupational populations, while objective approaches such as actigraphy, accelerometry, and wearable devices can provide repeated or continuous information on behavioral patterns in real-world environments [21,22]. These approaches may provide complementary information, as subjective and objective measures can capture different dimensions of sleep and movement behavior [21,23-25]. Advances in wearable and ambulatory technologies have expanded opportunities for objective monitoring within frontline occupational research [21,22,26-28]. However, the extent to which self-report, mixed, and objective movement measurement approaches have been adopted across frontline populations and movement behavior domains remains unclear. Mapping these approaches may help identify methodological concentrations and gaps within the current evidence base.

### Rationale for the Current Review

Despite increasing research examining movement behaviors and mental health among frontline workers, the literature spans diverse occupational populations, behavioral domains, mental health outcomes, study designs, measurement approaches, and occupational contexts. Consequently, the overall distribution and characteristics of this evidence base have not been comprehensively mapped. In particular, it remains unclear how research is distributed across sleep, physical activity, and sedentary behavior; which mental health domains are examined alongside these behaviors; how frequently multiple movement behaviors are assessed within the same study; and how evidence is distributed across frontline occupations, study designs, measurement approaches, and contexts. A scoping review is well suited to addressing these questions by systematically mapping the breadth, characteristics, and distribution of a heterogeneous evidence base [29-31]. Such an approach can identify areas of research concentration and relative scarcity across occupational populations, movement behaviors, mental health domains, and measurement approaches. This mapping can clarify the current state of the literature and identify

XSL•FO
RenderX

methodological, occupational, behavioral, and conceptual priorities for future frontline occupational health research.

### Objectives and Review Questions

The primary objective of this scoping review was to systematically map the existing evidence examining movement behaviors and mental health domains among adult frontline workers. The secondary objectives were to (1) characterize the movement behavior and mental health domains examined across frontline populations; (2) describe the occupational groups, study designs, study contexts, and movement measurement approaches represented within the literature; (3) examine the distribution and overlap of movement behavior and mental health domains across the evidence base; and identify methodological, occupational, behavioral, and conceptual evidence gaps relevant to future research and intervention development.

The review sought to address the following questions: (1) What evidence exists examining movement behaviors and mental health domains among adult frontline workers? (2) Which frontline occupational groups, movement behavior domains, mental health domains, study designs, measurement approaches, and study contexts are represented within the literature? (3) How are movement behavior and mental health domains distributed and combined across the evidence base? (4) What methodological, occupational, and conceptual gaps are evident within the current literature?

## Methods

### Protocol and Registration

This scoping review followed Joanna Briggs Institute (JBI) methodology for scoping reviews and was reported in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines [29,30]. A scoping review methodology was selected because the literature examining movement behaviors and mental health in frontline workers is heterogeneous in terms of occupational populations, behavioral operationalization, measurement approaches, study designs, and study contexts. Accordingly, the review aimed to map the breadth and characteristics of the evidence base rather than estimate pooled effect sizes or intervention effectiveness. A protocol outlining the review objectives, eligibility criteria, search strategy, screening procedures, charting framework, and synthesis approach was previously published in *JMIR Research Protocols* [32]. Methodological refinements and deviations from the published protocol are described in the Protocol Deviations subsection. A completed PRISMA-ScR checklist is provided in Checklist 1.

### Eligibility Criteria

Eligibility criteria were developed using the Population-Concept-Context framework [29,30]. Criteria relating to each component are described in the following sections.

### Population

Eligible studies included adults (aged ≥18 years) employed in civilian frontline occupations characterized by high occupational stress, trauma exposure, public-facing responsibilities, emergency response, or irregular operational demands. Populations included health care workers, emergency responders, firefighters, police officers, and related frontline occupational groups. Studies focusing exclusively on military populations, pediatric populations, or nonfrontline occupational groups were excluded unless frontline subgroup data could be extracted separately [6,33-35]. Military populations were excluded because deployment contexts and military organizational structures may introduce occupational demands that differ from those encountered in civilian frontline occupations [6]. Mixed-population studies were included only where data relating to eligible civilian frontline workers could be extracted separately; otherwise, they were excluded from the synthesis. During data charting, studies were categorized by occupational groups to facilitate comparison across frontline sectors.

### Concept

Eligible studies examined at least 1 movement behavior in relation to at least 1 mental health outcome. Movement behaviors included sleep, sedentary behavior, physical activity, and integrated 24hrMB frameworks. Mental health outcomes included stress, burnout, depression, anxiety, posttraumatic stress disorder (PTSD), or trauma-related symptoms, well-being, fatigue, suicidality, and other psychological constructs where authors explicitly framed outcomes as indicators of mental health or psychological functioning. To reduce conceptual heterogeneity, studies were included only where movement behaviors represented substantive variables of interest rather than incidental background characteristics.

### Context

Eligible studies were conducted within civilian frontline occupational environments characterized by high workload, shift work, emergency response, trauma exposure, or other operational stress. Studies conducted in clinical or workplace settings, as well as field, laboratory, or simulated occupational settings, were eligible provided they investigated movement behaviors and mental health among frontline worker populations. Comparative studies involving multiple frontline occupations or conducted across different countries were also eligible where they addressed the review objectives.

### Publication Characteristics

Studies published in English between 2000 and 2026 were eligible for inclusion. This time frame was selected to capture increasing adoption of wearable and ambulatory monitoring technologies alongside contemporary research examining movement behaviors and mental health in frontline workers [36,37]. Eligible evidence sources comprised peer-reviewed empirical quantitative, qualitative, and mixed methods studies reporting primary data. Reviews, editorials, commentaries, opinion pieces, and gray literature were excluded.

XSL•FO
RenderX

## Information Sources

Six electronic databases were searched: PsycINFO, CINAHL, MEDLINE, SPORTDiscus, Scopus, and PubMed. Studies published in English between 2000 and 2026 were eligible for inclusion. Gray literature was not systematically searched, and backward citation searching of reference lists and forward citation searching were not performed. Given the substantial volume of eligible literature identified, the review focused on mapping the peer-reviewed evidence base retrieved through the 6 bibliographic databases. The original searches were conducted on November 19, 2025, with updated searches conducted on July 30, 2026.

## Search

### *Search Overview*

Search strategies were developed iteratively through exploratory searching, consultation with an academic librarian, and refinement of keywords and controlled vocabulary following JBI guidance and PRISMA-S (Preferred Reporting Items for Systematic Reviews and Meta-Analyses literature search extension) recommendations [29,38]. Search terms were organized into three principal concept blocks: (1) frontline workers and high-stress occupations, (2) movement behaviors and related measurement and monitoring terminology, and (3) mental health and psychological well-being. An additional exclusion block was used to reduce retrieval of clinical, patient, and military populations. The movement behavior concept incorporated terms relating to 24hrMBs, physical activity, sedentary behavior, sleep, and circadian or rest-activity patterns, alongside objective monitoring modalities and physiological or psychophysiological indicators that may be captured through wearable or sensor-based approaches (eg, heart rate, heart rate variability, electrodermal activity, respiratory measures, actigraphy, and accelerometry). These broader monitoring terms were included to maximize retrieval of potentially eligible studies in which movement behaviors were assessed alongside physiological monitoring, rather than to define physiological indicators as movement behaviors or mental health outcomes. Boolean operators (AND, OR, and NOT), truncation, phrase searching, and database-specific controlled vocabulary (where available) were used to optimize retrieval. Search strategies were adapted for each database to account for differences in indexing and syntax. Complete database-specific search strategies are provided in Multimedia Appendix 1, and the completed PRISMA-S checklist is provided in Checklist 2.

### *Selection of Sources of Evidence*

All retrieved records were exported into EndNote [39] for deduplication before screening. Records were subsequently imported into Rayyan to support independent screening and duplicate verification [40]. Screening occurred across 3 stages: title screening, abstract screening, and full-text screening. One reviewer (AS) screened all records at each stage, while 2 additional reviewers (GH-B and EC) independently screened randomly selected subsets of records to assess screening reliability. Each additional reviewer independently screened a randomly selected subset of approximately 2% - 5% of records at each stage, resulting in up to 10% overlap with the primary reviewer. Percentage agreement was calculated separately at each screening stage across records independently assessed by both the primary reviewer and additional reviewers. During title and abstract screening, an inclusion-favoring approach was adopted whereby records marked as “include” or “unsure” by either reviewer progressed to the next stage. At full-text screening, studies were required to meet all Population-Concept-Context eligibility criteria for inclusion. Prior to the main screening, pilot screening exercises were conducted at each stage to standardize the interpretation and application of the eligibility criteria [41,42]. Initial title-screening agreement was 84%. Following discussion and refinement of the screening guidance, a second title-screening pilot achieved 94% agreement. Subsequent pilot exercises achieved 100% agreement on both abstract and full-text screening. During the main screening, agreement across independently screened subsets was 99% at title screening, 90% at abstract screening, and 91% at full-text screening. Disagreements were resolved through discussion and consensus, with third reviewer adjudication available where required. The updated search was screened using the same eligibility criteria and screening procedures. Agreement across independently screened subsets was 97% at title screening and 100% at both abstract and full-text screening.

### *Data-Charting Process*

A structured charting framework was developed in accordance with JBI guidance and refined through pilot testing. The initial charting framework was developed a priori to capture study characteristics, movement behaviors, mental health domains, measurement approaches, and contextual factors relevant to the review objectives, and was iteratively refined during charting to accommodate relevant characteristics identified within the included literature. The charting form was piloted independently on a subset of studies to assess clarity, completeness, and consistency of the extraction framework. Any discrepancies or ambiguities identified during piloting were discussed and resolved before full data charting commenced. One reviewer (AS) charted data from all included studies. Two additional reviewers (GH-B and EC) independently charted randomly selected subsets of approximately 2% - 5% of included studies each, resulting in up to 10% of studies undergoing independent duplicate charting to assess reliability. Agreement was calculated across studies independently charted by the primary and additional reviewers, with 100% agreement achieved. Discrepancies, if identified, were resolved through discussion and consensus, with consultation from an additional reviewer where required.

## Data Items

Data items charted included publication year, country, frontline occupational group, study design, sample characteristics, movement behavior domains, movement measurement approach, mental health domains, mental health measurement instruments, study focus, study context, and key findings. Study design and study focus were coded as separate dimensions. Study design described the methodological structure of the study (eg, cross-sectional, longitudinal, intervention, experimental, mixed methods, or qualitative), whereas study focus described the

XSL•FO
RenderX

principal analytic purpose of the study (association, intervention, or monitoring). Consequently, counts within these 2 classification schemes were not expected to correspond directly. Movement behaviors and mental health domains were charted as non–mutually exclusive categories. Movement behaviors and mental health domains were coded as present when directly assessed within a study, irrespective of whether they were analyzed as primary exposures, outcomes, covariates, or descriptive variables. Where studies assessed multiple movement behaviors or mental health domains, each relevant category was coded independently. The sleep domain included measures of sleep duration, sleep quality, sleep efficiency, sleep latency, wake after sleep onset, sleep regularity, chronotype, insomnia, and other sleep-related characteristics. Sleep measures were categorized within this common domain for evidence-mapping purposes while retaining their original study-level operationalization. Divergent sleep metrics were not quantitatively pooled or treated as equivalent measures. The physical activity domain included assessments of physical activity or exercise, including frequency, duration, intensity, steps, and energy expenditure, when used as a proxy for activity. The sedentary behavior domain included sitting time, sedentary time, sedentary bouts, screen-based sedentary behavior, and related sedentary measures.

Mental health domains included stress, burnout, depression, anxiety, PTSD or trauma, well-being, fatigue, suicidality, and other mental health outcomes. Where studies reported multiple mental health domains, each relevant domain was coded independently. The well-being domain included measures explicitly assessing psychological or mental well-being, flourishing, or life satisfaction. Generic health-related quality-of-life measures were not classified as well-being unless they specifically assessed psychological well-being. The "Other Mental Health" category captured psychological constructs that did not align with the predefined domains, including fear, affect, resilience, and related constructs. Movement measurement approach was charted separately from the movement behavior assessed. Approaches were classified according to whether movement behaviors were assessed using self-report, objective measurement, or a combination of subjective and objective methods. Objective approaches were further characterized according to the measurement modality reported, including wearable devices, accelerometry, and actigraphy. Psychophysiological indicators were included within the search strategy to maximize retrieval of studies using objective or wearable monitoring. Individual physiological signals and derived psychophysiological metrics were not independently charted as analytic domains and did not contribute to the movement behavior or mental health domain frequency counts or evidence maps. Both subjective and objective movement measurement approaches were eligible because the review aimed to map the full range of measurement practices used across frontline research rather than privilege or restrict inclusion to a single modality. This allowed the distribution of self-report, objective, and mixed approaches to be examined without treating these approaches as methodologically equivalent or pooling their estimates.

## Synthesis of Results

Findings were synthesized descriptively using narrative synthesis, summary tables, and evidence-mapping approaches [29,43]. Studies were grouped according to frontline occupational sector, movement behavior domain, mental health outcome domain, measurement approach, study design, and contextual setting. Descriptive frequencies and percentages were calculated to summarize the distribution of study characteristics, movement behaviors, mental health domains, and measurement approaches across the evidence base. Because movement behavior and mental health domains were coded as non–mutually exclusive, individual studies could contribute to multiple categories. Consequently, frequencies and percentages across these domains were not expected to sum to the total number of included studies or 100%. Evidence mapping was used to examine the distribution and intersection of movement behaviors, mental health domains, occupational groups, and measurement approaches. Evidence gap maps were developed to visually identify areas of research concentration and relative scarcity across these dimensions. The synthesis aimed to identify evidence clusters, methodological trends, underrepresented occupational groups, and conceptual gaps relevant to future research and intervention development. No meta-analysis or pooled effect estimation was undertaken because of substantial heterogeneity in study populations, designs, movement and mental health measures, and analytical approaches. Formal critical appraisal was not conducted because the objective of the review was to map the breadth and characteristics of the evidence base rather than assess study quality or estimate pooled effects. Methodological limitations identified across the evidence base, including patterns in study design, measurement approach, and monitoring methodology, were documented narratively during synthesis.

## Protocol Deviations

Several methodological refinements and deviations were made following publication of the protocol [32]. Movement behavior and mental health outcome categories were revised from the mutually exclusive classification originally specified in the protocol to non–mutually exclusive coding, allowing studies assessing multiple behaviors to contribute to each relevant domain. Mental health outcome categories were also iteratively refined during data charting to reflect the range of psychological constructs identified across the included literature. The planned synthesis approach was refined to incorporate descriptive evidence mapping and evidence gap visualizations alongside narrative synthesis and summary statistics. Formal thematic analysis of qualitative evidence, as proposed in the protocol, was not undertaken because the final review focused on mapping the distribution, measurement, and characteristics of the evidence base rather than synthesizing qualitative experiences as a distinct body of evidence. The screening and data-charting procedures were also refined from those described in the protocol. Rather than all records being independently assessed or charted by multiple reviewers, 1 reviewer (AS) completed screening and data charting for all eligible records, with 2 additional reviewers (GH-B and EC) independently assessing randomly selected subsets to evaluate reliability. Disagreements were resolved through discussion and consensus, with additional

XSL•FO
RenderX

adjudication where required. The literature search was additionally updated on July 30, 2026, to capture studies published since completion of the original search. Correspondingly, the eligible publication period was extended from 2000 to 2025 to include studies published in 2026.

The same eligibility criteria and screening procedures were applied to newly identified records. Although targeted gray literature searching was specified in the published protocol, this was not undertaken in the final review. Given the substantial volume of eligible peer-reviewed literature identified through the database searches, the final review focused on systematically mapping the peer-reviewed evidence base. The final database set also differed from that described in the published protocol. ScienceDirect was not retained as a separate database source in the final search, and the completed review reports on the 6 bibliographic databases ultimately searched: PsycINFO, CINAHL, MEDLINE, SPORTDiscus, Scopus, and PubMed. Collectively, these methodological refinements were implemented to improve the comprehensiveness and accuracy of the final evidence mapping and to ensure that the synthesis appropriately reflected the breadth, overlap, and characteristics of the evidence identified during the review.

### Stakeholder Consultation

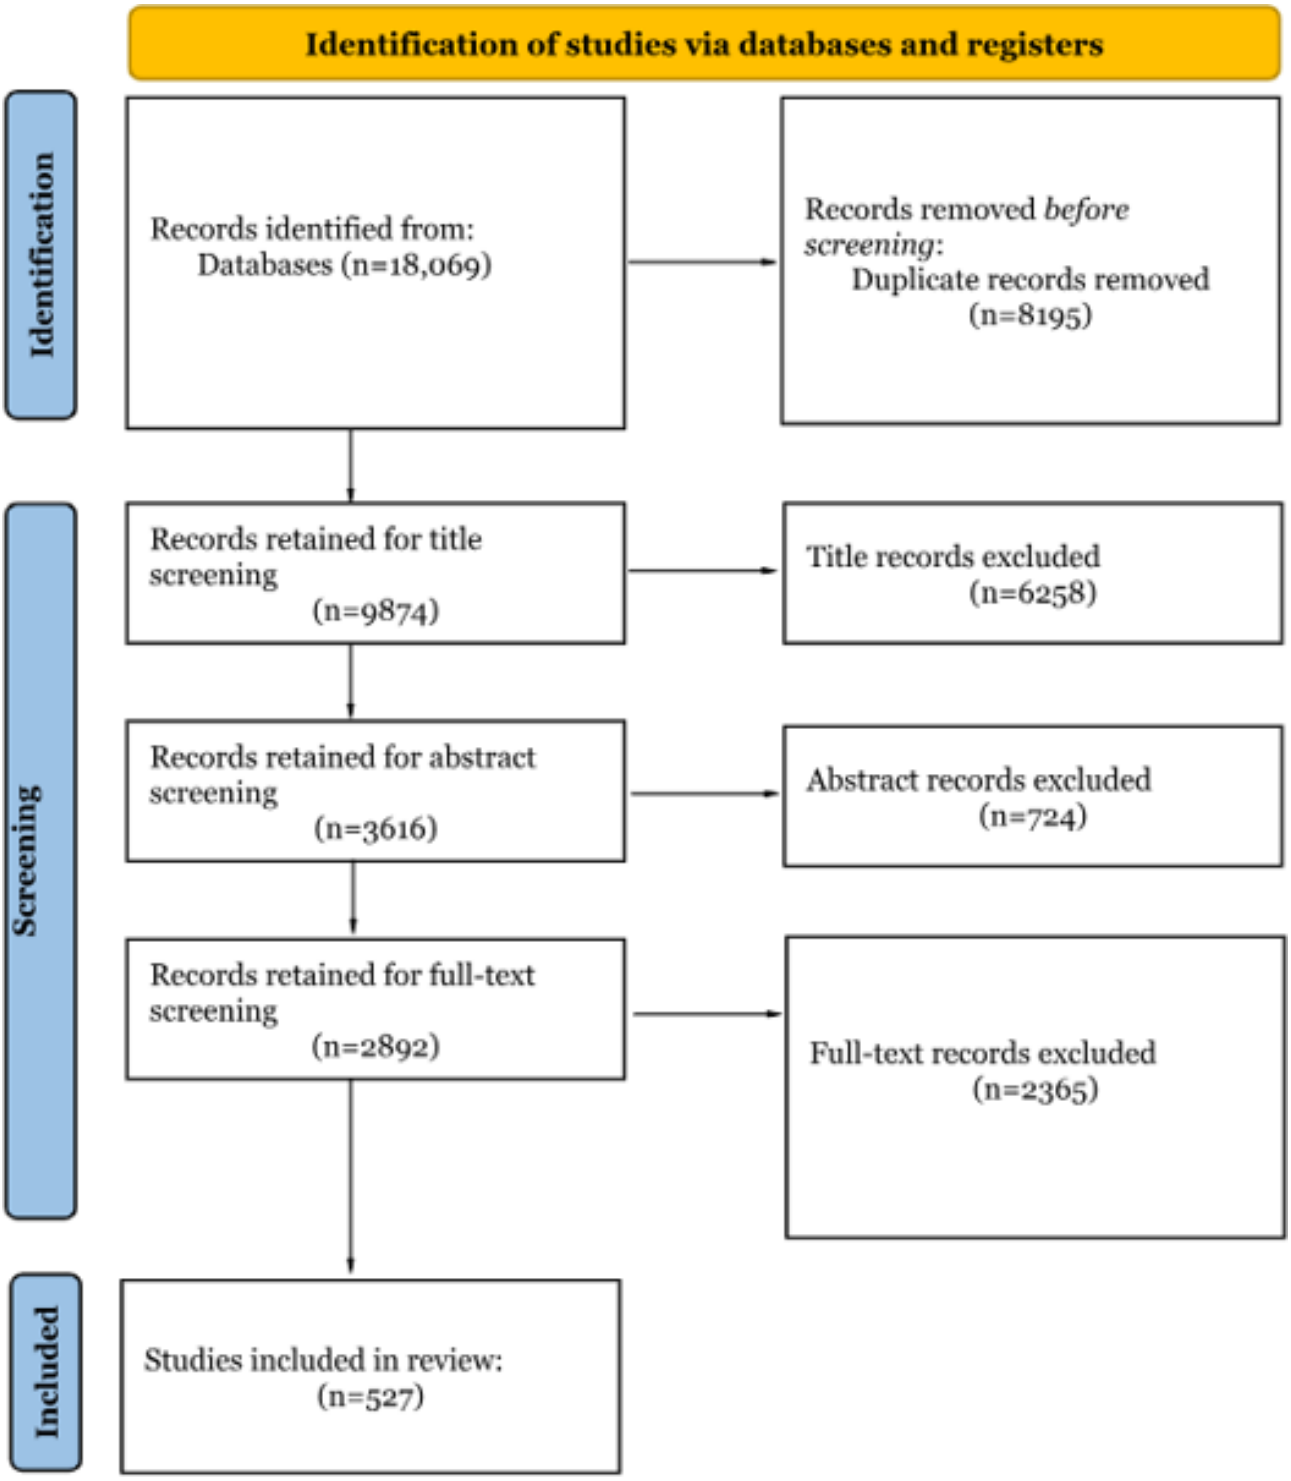
Stakeholder consultation was incorporated throughout the review to support the relevance, applicability, and interpretation of findings within frontline occupational settings. Stakeholders included health care professionals, occupational health researchers, and representatives from organizations supporting frontline worker well-being, and experts in digital mental health and occupational monitoring. Early consultation informed refinement of the review questions, eligibility criteria, and search strategy, including the incorporation of psychophysiological monitoring terminology. Following data charting, stakeholders supported interpretation of emerging patterns, methodological considerations, evidence gaps, and the feasibility of self-report and objective monitoring approaches. Consultation was conducted through meetings, discussions, and email correspondence. Consistent with JBI guidance, this process strengthened the contextual relevance and applicability of the review findings [29].

### Ethical Considerations

Ethical approval was not required because the review synthesized existing publicly available literature and did not involve primary data collection or direct involvement of human participants.

## Results

### Study Selection



The original search identified 18,069 records through database searching. After removal of duplicates, 9874 records were retained for title screening. Following title screening, 3616 records progressed to abstract screening, of which 2892 were retained for full-text assessment. After full-text screening, 527 studies met the inclusion criteria and were included in the review. The study selection process for the original search is summarized in Figure 1.

The literature search was updated on July 30, 2026, to identify studies published since completion of the original search. The updated search identified 2372 records. Following duplicate removal, 1395 records were retained for title screening. Of these, 307 progressed to abstract screening and 281 underwent full-text assessment. Following full-text screening, 86 additional studies met the inclusion criteria. Across the original and updated searches, 613 studies were included in the final scoping review.

XSL•FO
RenderX

**Figure 1.** PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) flow diagram of study identification, screening, eligibility assessment, and inclusion for the original search.

## Characteristics of Included Studies

The 613 included studies were published between 2002 and 2026, despite eligibility extending to studies published from 2000 onward, with a marked increase in publications in recent years (Table 1). Only 10 (1.6%) studies were published between 2000 and 2009 and 104 (17.0%) studies between 2010 and 2019, whereas 499 (81.4%) studies were published from 2020 onward. The largest number of studies was published in 2025 (n=125, 20.4%), followed by 2021 (n=84, 13.7%), 2022 (n=73, 11.9%), 2023 (n=73, 11.9%), and 2024 (n=72, 11.7%). Studies represented a broad international evidence base. Following harmonization of obvious country label variants in the charting data, China contributed the largest number of studies (n=108, 17.6%), followed by the United States (n=104, 17.0%), Turkey (n=34, 5.5%), Brazil (n=26, 4.2%), South Korea (n=22, 3.6%), Taiwan (n=22, 3.6%), and Australia (n=20, 3.3%). Studies were also conducted across Europe, Asia, the Middle East, Africa, North and South America, and multinational settings. Health care workers represented the majority of the evidence base (n=468, 76.3%). Police and law enforcement personnel accounted for 55 (9.0%) studies, firefighters for 42 (6.9%)

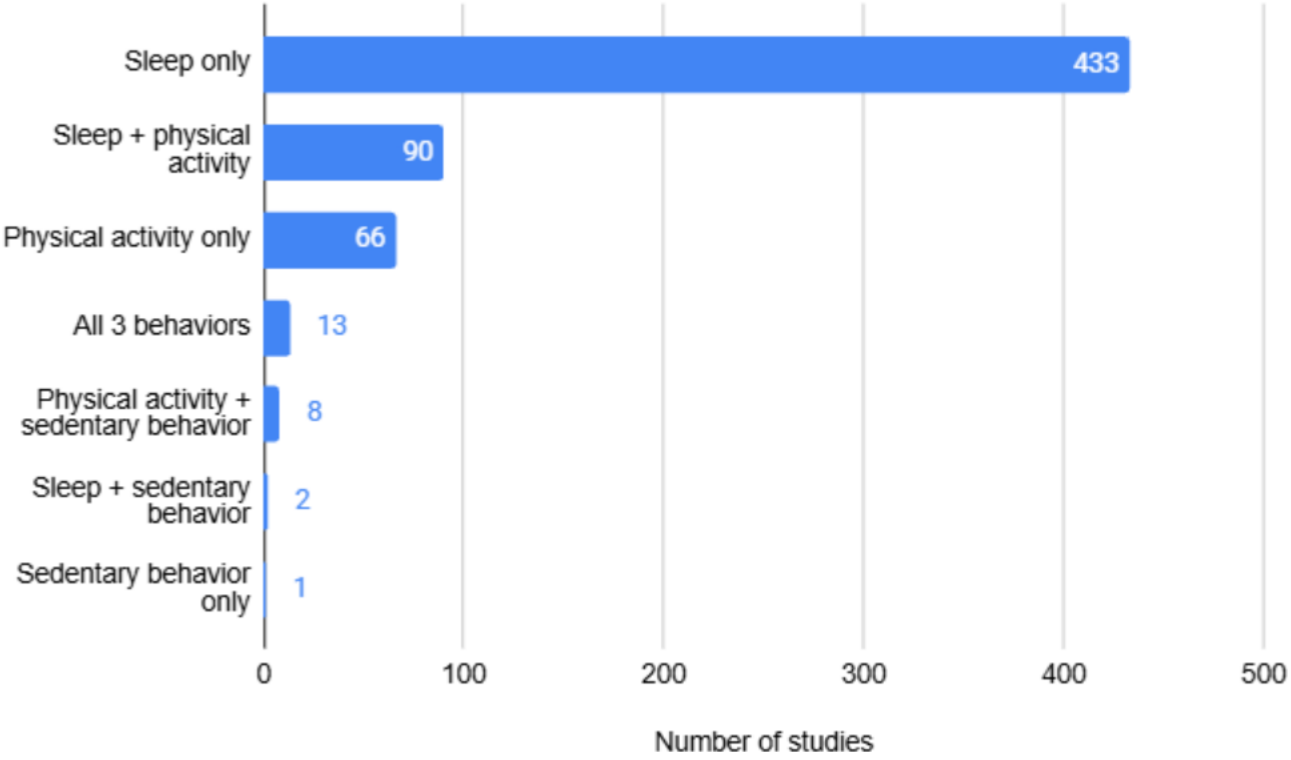
XSL•FO
RenderX

studies, paramedics and emergency medical services personnel for 25 (4.1%) studies, and mixed frontline worker populations for 23 (3.8%) studies. Cross-sectional studies predominated (n=451, 73.6%), followed by longitudinal studies (n=71, 11.6%) and intervention studies (n=54, 8.8%). Mixed methods (n=15, 2.4%), experimental (n=14, 2.3%), and qualitative studies (n=8, 1.3%) were comparatively uncommon. Most studies were classified as association studies (n=526, 85.8%), while 68 (11.1%) were intervention studies and 19 (3.1%) were monitoring studies. Regarding study context, 430 (70.1%) studies were conducted under routine or noncrisis conditions, while 175 (28.5%) studies were conducted in the context of a pandemic. A further 6 (1.0%) studies were conducted in other crisis contexts and 2 (0.3%) studies in the context of natural disasters.

**Table .** Characteristics of included studies across frontline occupational groups, study designs, study focus, and contextual factors (N=613)[a].

| Characteristics | Studies |
|---|---|
| Frontline occupational group, n (%) | |
| Health care workers | 468 (76.3) |
| Police or law enforcement | 55 (9) |
| Firefighters | 42 (6.9) |
| Paramedics or emergency medical services | 25 (4.1) |
| Mixed frontline workers | 23 (3.8) |
| Study design, n (%) | |
| Cross-sectional | 451 (73.6) |
| Longitudinal | 71 (11.6) |
| Intervention | 54 (8.8) |
| Mixed methods | 15 (2.4) |
| Experimental | 14 (2.3) |
| Qualitative | 8 (1.3) |
| Study focus, n (%) | |
| Association study | 526 (85.8) |
| Intervention study | 68 (11.1) |
| Monitoring study | 19 (3.1) |
| Study context, n (%) | |
| Routine | 430 (70.1) |
| Pandemic | 175 (28.5) |
| Other crisis | 6 (1) |
| Natural disaster | 2 (0.3) |

[a]Percentages are based on the total number of included studies (N=613) and may not sum to exactly 100% because of rounding.

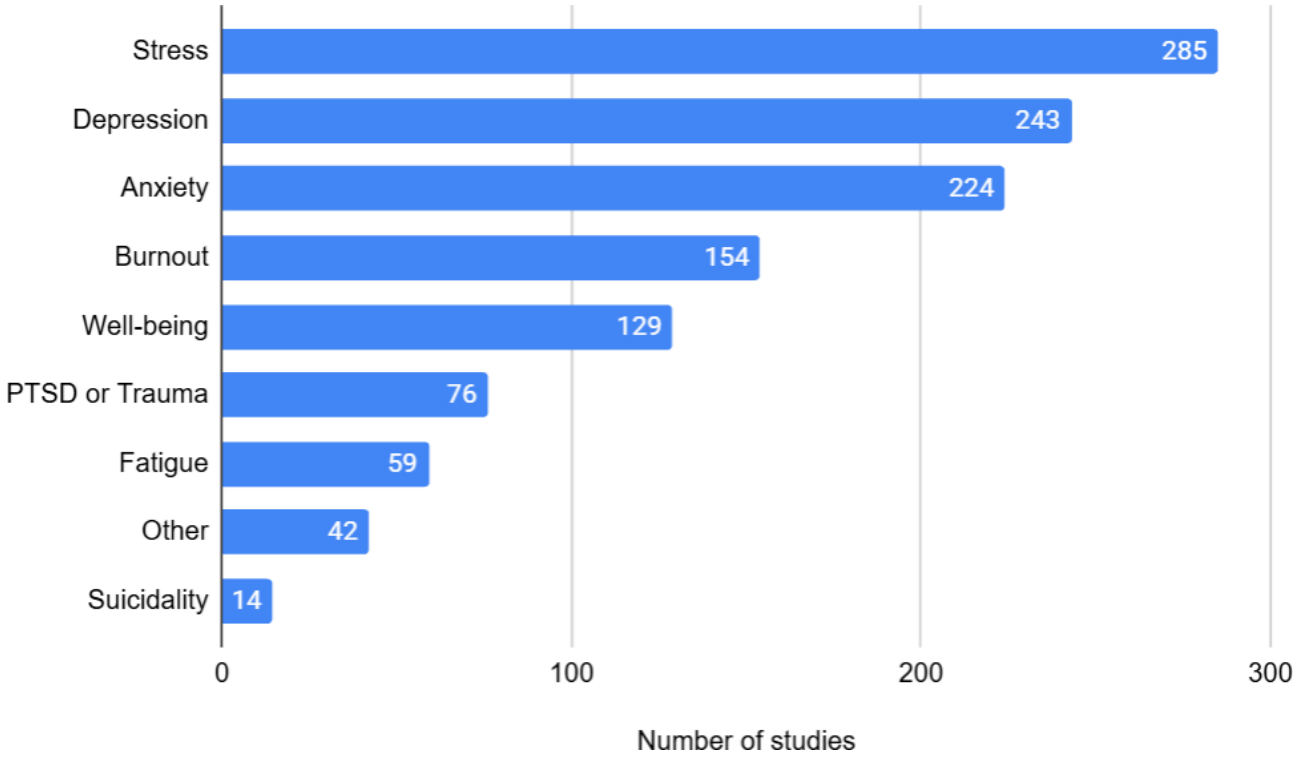


## Movement Behavior Domain

Movement behaviors were coded as non–mutually exclusive domains, allowing studies assessing more than 1 behavior to contribute to each relevant category. Of 613 studies, sleep was the most frequently examined movement behavior assessed in 538 (87.8%) studies. Physical activity was assessed in 177 (28.9%) studies, while sedentary behavior was examined in only 24 (3.9%) studies. As studies could assess more than 1 movement behavior, these percentages do not sum to 100%. Most studies focused on a single behavior. In total, 500 (81.6%) studies assessed only 1 movement behavior, compared with 113 (18.4%) studies that assessed 2 or more. Sleep alone accounted for 433 (70.6%) studies, while physical activity alone was examined in 66 (10.8%) studies and sedentary behavior alone in only 1 (0.2%) study. Among studies examining multiple behaviors, 90 (14.7%) assessed sleep and physical activity, 8 (1.3%) assessed physical activity and sedentary behavior, and 2 (0.3%) assessed sleep and sedentary behavior. Only 13 (2.1%) studies assessed all 3 movement behaviors, sleep, physical activity, and sedentary behavior, within the same study (Figure 2).

XSL•FO
RenderX

**Figure 2.** Distribution and overlap of movement behaviors assessed across included studies (N=613). Movement behavior domains were coded independently and were non–mutually exclusive. The categories displayed in the figure represent mutually exclusive combinations derived from these domains. “All 3 behaviors” refers to studies assessing sleep, physical activity, and sedentary behavior within the same study.

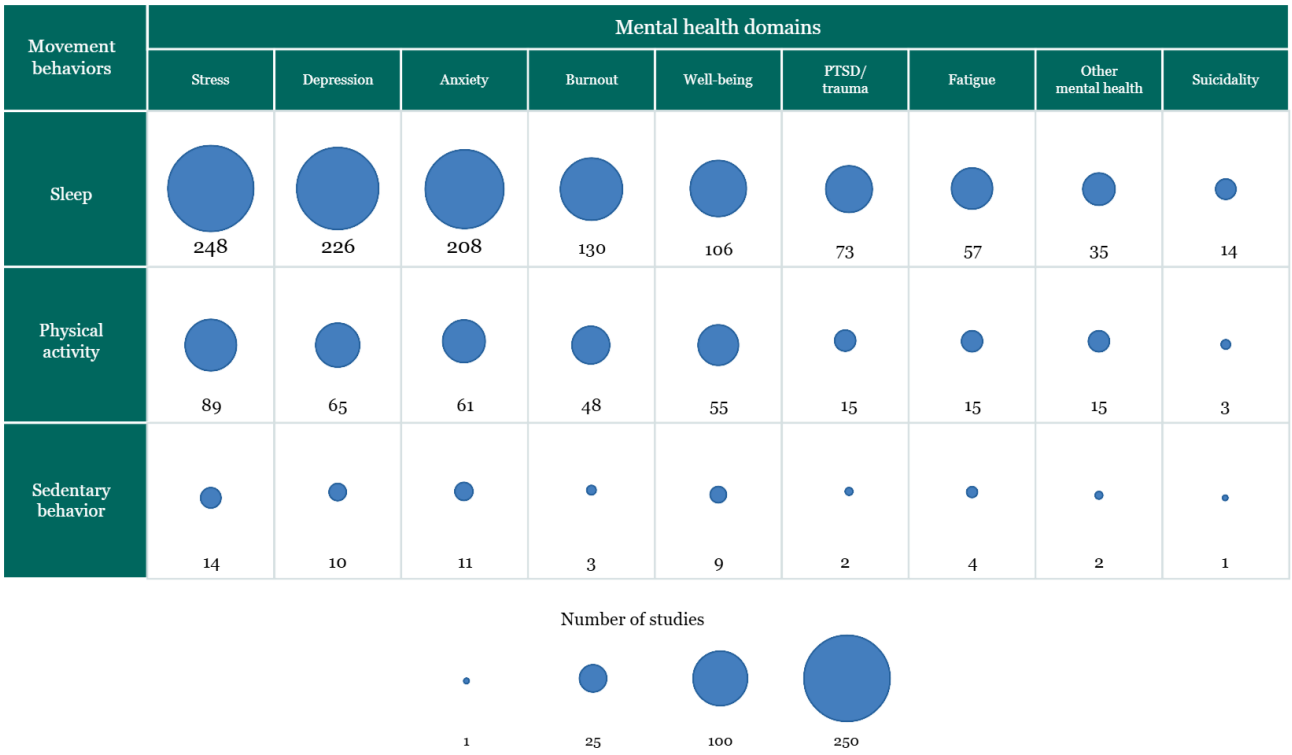


## Mental Health Domains

Mental health outcomes were coded as non–mutually exclusive domains, allowing studies assessing multiple psychological outcomes to contribute to each relevant category (Figure 3). Stress was the most frequently assessed mental health outcome, examined in 46.5% (285/613) of the studies, followed by depression (n=243, 39.6%) and anxiety (n=224, 36.5%). Burnout was assessed in 154 (25.1%) studies, while well-being was examined in 129 (21.0%). PTSD or trauma-related was assessed in 76 (12.4%) studies and fatigue in 59 (9.6%) studies. A further 42 (6.9%) studies assessed other mental health domains, encompassing psychological constructs that did not align with the predefined mental health domains, while suicidality was assessed in 14 (2.3%) studies. As individual studies could assess multiple mental health domains, percentages across domains do not sum to 100%.

XSL•FO
RenderX

**Figure 3.** Distribution of mental health domains assessed across included studies (N=613). Mental health domains were coded independently and were non–mutually exclusive. Individual studies could therefore contribute to more than 1 domain. Accordingly, frequencies and percentages across domains do not sum to the total number of included studies or 100%. PTSD: posttraumatic stress disorder.



## Movement Behaviors and Mental Health Domains

Evidence mapping showed substantial variation in the volume of research across movement behavior and mental health domain combinations (Figure 4). The largest concentrations of evidence involved sleep in relation to stress (n=248), depression (n=226), and anxiety (n=208), followed by sleep in relation to burnout (n=130) and well-being (n=106). Among studies assessing physical activity, stress was the most frequently examined mental health domain (n=89), followed by depression (n=65), anxiety (n=61), and well-being (n=55). Comparatively fewer studies examined sedentary behavior in relation to mental health domains. The most frequently represented combinations were sedentary behavior with stress (n=14), anxiety (n=11), and depression (n=10), while each remaining mental health domain was represented in fewer than 10 studies. Overall, the evidence gap map demonstrated that research was concentrated on sleep in relation to stress, depression, and anxiety, with substantially fewer studies examining physical activity and particularly sedentary behavior across mental health domains.

XSL•FO
RenderX

**Figure 4.** Bubble evidence gap map of movement behaviors and mental health domains across included studies (N=613). Movement behaviors and mental health domains were coded independently and were non–mutually exclusive. Individual studies could therefore contribute to multiple movement behavior and mental health domain combinations. Bubble area represents the number of included studies assessing each combination and reflects the volume of evidence rather than the strength of evidence. "Other mental health" includes fear, affect, resilience, and related constructs. PTSD: posttraumatic stress disorder.

## Measurement Approaches

Self-report measures predominated across the evidence base, representing the movement measurement approach in 86.9% (533/613) of studies. Mixed measurement approaches, incorporating both self-report and objective methods, were used in 71 (11.6%) studies. Objective-only measurement approaches were comparatively uncommon: 7 (1.1%) studies were classified as using wearable devices, 1 (0.2%) used accelerometry, and 1 (0.2%) used actigraphy. Overall, only 9 (1.5%) studies relied exclusively on an objective movement measurement approach, although objective measures were additionally incorporated within the 71 studies classified as using mixed measurement approaches. Measurement approaches also varied across movement behavior domains (Table 2). Among the 538 studies assessing sleep, 476 (88.5%) used self-report measures, while 55 (10.2%) used mixed measurement approaches. Objective-only approaches were uncommon, comprising 6 (1.1%) studies using wearable devices and 1 (0.2%) study using actigraphy. Among the 177 studies assessing physical activity, 133 (75.1%) used self-report measures and 39 (22.0%) used mixed measurement approaches, while 4 (2.3%) used wearable devices and 1 (0.6%) used accelerometry. Of the 24 studies assessing sedentary behavior, 12 (50.0%) used self-report measures, 10 (41.7%) used mixed measurement approaches, and 2 (8.3%) used wearable devices. Self-report remained the predominant measurement approach across all 3 movement behavior domains. However, mixed and objective measurement approaches represented a greater proportion of the comparatively small sedentary behavior literature.

**Table .** Movement measurement approaches according to movement behavior domain[a].

| Movement behavior | Self-report | Mixed | Wearable device | Accelerometer | Actigraphy | Total |
|---|---|---|---|---|---|---|
| Sleep | 476 (88.5%) | 55 (10.2%) | 6 (1.1%) | 0 (0.0%) | 1 (0.2%) | 538 |
| Physical activity | 133 (75.1%) | 39 (22%) | 4 (2.3%) | 1 (0.6%) | 0 (0.0%) | 177 |
| Sedentary behavior | 12 (50%) | 10 (41.7%) | 2 (8.3%) | 0 (0.0%) | 0 (0.0%) | 24 |

[a]Values are n (% within movement behavior domain). Movement behavior domains were coded independently and were non–mutually exclusive. Individual studies could therefore contribute to more than 1 row. Measurement approaches reflect the categories applied during data charting. "Mixed" refers to studies incorporating both self-report and objective movement measurement approaches.

## Evidence Gaps and Research Concentrations

Taken together, the evidence base was concentrated within health care populations, cross-sectional and association-focused designs, sleep research, and self-report measurement. Comparatively limited evidence examined sedentary behavior, integrated movement behavior approaches, objective measurement methods, or frontline occupational groups outside

XSL•FO
RenderX

health care. Evidence was also unevenly distributed across movement behavior and mental health combinations, with the strongest concentrations involving sleep alongside stress, depression, and anxiety. These patterns identify clear behavioral, occupational, and methodological gaps for future research.

## Discussion

### Principal Findings

This scoping review mapped the current evidence examining movement behaviors and mental health among frontline workers and identified a large but unevenly distributed literature. Across 613 studies, evidence was concentrated within health care populations, cross-sectional and association-focused designs, sleep research, and self-report measurement. Physical activity and particularly sedentary behavior received substantially less attention. Although some studies examined multiple movement behaviors, only 13 examined sleep, physical activity, and sedentary behavior together, indicating limited representation of integrated 24hrMB approaches. Mental health research was similarly concentrated around stress, depression, and anxiety, particularly in relation to sleep. Taken together, the findings demonstrate substantial growth in this field while revealing persistent behavioral, occupational, and methodological imbalances.

### Movement Behavior Domains

Sleep was the dominant movement behavior across the evidence base, assessed in 87.8% (538/613) of the studies. This concentration likely reflects the long-standing relevance of sleep to frontline occupational health. Frontline work frequently involves irregular schedules, night shifts, extended working hours, high occupational demands, and restricted opportunities for recovery, all of which can disrupt sleep and circadian functioning [1-3,7,8]. Given the established importance of sleep for recovery, emotional regulation, and occupational functioning, its prominence within the literature is therefore unsurprising [2,13-15]. The prominence of sleep-focused research may also reflect the relevance of circadian disruption within frontline work, as irregular and night shift schedules can alter sleep-wake timing, sleep, and recovery opportunities [2]. Nevertheless, the extent of this concentration indicates that current understanding of movement behaviors and mental health among frontline workers is largely shaped by sleep-focused research. Physical activity was examined considerably less frequently, appearing in 177 (28.9%) studies, while sedentary behavior was assessed in only 24 (3.9%). The particularly limited representation of sedentary behavior constitutes an important gap because sedentary behavior is a distinct component of daily movement rather than simply the absence of physical activity [10]. Greater attention to sedentary behavior may therefore contribute to a more complete understanding of how occupational movement patterns relate to mental health and well-being across different frontline settings.

The limited integration of movement behaviors within individual studies represents a further conceptual gap. Although 113 (18.4%) studies assessed 2 or more movement behaviors, only 13 (2.1%) assessed sleep, physical activity, and sedentary behavior within the same study. Importantly, concurrent assessment of multiple behaviors does not necessarily constitute an integrated 24hrMB approach. Such frameworks conceptualize sleep, sedentary behavior, and physical activity as interdependent components of a finite 24-hour period, whereby time allocated to one behavior necessarily influences the time available for others [11]. Accordingly, future research would benefit not only from assessing a broader range of movement behaviors concurrently but also from considering analytical approaches capable of examining their interdependence and potential behavioral trade-offs [9-11]. Overall, the findings indicate that the frontline movement behavior literature remains substantially weighted toward sleep, with comparatively limited evidence addressing physical activity, sedentary behavior, or the 3 behaviors collectively. Expanding research beyond isolated movement behaviors may provide a more comprehensive account of daily behavioral patterns and their relationship with mental health in frontline occupational contexts.

### Mental Health Domains and Evidence Concentrations

Mental health research was concentrated around stress, depression, anxiety, and burnout. PTSD or trauma, fatigue, suicidality, and other mental health domains were less frequently represented, while well-being was examined less often than the principal distress-related domains. This concentration is consistent with the substantial psychological demands associated with frontline work, including high occupational demands, irregular working patterns, and potential exposure to distressing or traumatic events [1]. However, it also indicates that current understanding of mental health in relation to movement behaviors is shaped predominantly by a relatively small number of commonly examined psychological domains. Evidence was also unevenly distributed across combinations of movement behaviors and mental health domains. The greatest concentrations involved sleep in relation to stress (n=248), depression (n=226), and anxiety (n=208), with sleep also frequently examined alongside burnout (n=130) and well-being (n=106). Comparatively fewer studies examined mental health domains alongside physical activity, while evidence concerning sedentary behavior was particularly limited across all mental health domains. Therefore, despite the substantial overall volume of literature identified, the depth of evidence varies considerably across movement behavior–mental health combinations, with much of the existing research concentrated around sleep and common indicators of psychological distress.

### Occupational and Contextual Imbalances

Health care workers accounted for the substantial majority of the evidence base, representing 76.3% (468/613) of the included studies. In comparison, considerably fewer studies examined police and law enforcement personnel (n=55, 9.0%), firefighters (n=42, 6.9%), paramedics and emergency medical services personnel (n=25, 4.1%), or mixed frontline worker populations (n=23, 3.8%). This occupational concentration is important because frontline roles differ considerably in their operational demands, work schedules, physical requirements, exposure to potentially traumatic events, and opportunities for rest and recovery [1,6,33,44]. For example, police work may combine prolonged sedentary periods during vehicle-based duties, surveillance, or reporting with intermittent periods of high

XSL•FO
RenderX

physical and operational demand, whereas firefighting and emergency medical roles may involve different patterns of acute physical exertion, lifting, equipment carriage, and recovery [45-47]. Such occupational differences may produce distinct movement behavior profiles. Consequently, an evidence base dominated by health care populations may provide a limited understanding of how movement behaviors and mental health are represented across the wider frontline workforce.

The temporal and contextual distribution of the literature may partly explain this occupational concentration. More than four-fifths of included studies were published from 2020 onward, and 175 (28.5%) studies were conducted specifically within a pandemic context. The rapid expansion of research during this period coincided with increased attention to the health and well-being of frontline health care professionals during the COVID-19 pandemic [48,49]. While this substantially expanded the available evidence concerning frontline worker well-being, it may also have contributed to the predominance of health care populations within the literature. Nevertheless, most studies (n=430, 70.1%) were conducted under routine or noncrisis conditions, with comparatively few examining other crisis contexts (n=6, 1.0%) or natural disasters (n=2, 0.3%). Greater occupational diversity within future research would therefore strengthen understanding of movement behaviors and mental health across different frontline settings. Police, firefighters, emergency medical personnel, and other frontline groups may experience distinct combinations of occupational movement, shift work, operational stressors, and recovery opportunities. Expanding research across these populations, and across both routine and crisis contexts, would provide a more comprehensive representation of the frontline workforce and enable greater consideration of occupational and contextual variation [6,45-47].

### Methodological and Measurement Considerations

The evidence base was characterized by a strong predominance of cross-sectional research, with 451 (73.6%) studies using cross-sectional designs, compared with 71 (11.6%) longitudinal and 54 (8.8%) intervention studies. Similarly, most studies were association-focused (n=526, 85.8%), while comparatively few focused on intervention (n=68, 11.1%) or monitoring (n=19, 3.1%). Cross-sectional studies are valuable for characterizing patterns and identifying potential relationships within frontline populations; however, they provide limited insight into temporal relationships or how movement behaviors and mental health may change together over time [43]. The comparatively small longitudinal and intervention literature therefore limits understanding of the temporal dynamics of movement behaviors and mental health and of whether modifying movement behaviors may contribute to changes in mental health domains. Measurement approaches showed a similarly pronounced imbalance. Self-report was the primary movement measurement approach in 533 (86.9%) studies, while 71 (11.6%) combined self-report and objective methods. Only 9 (1.5%) studies relied exclusively on objective movement measurement approaches, including wearable devices, accelerometry, or actigraphy. Although self-report measures provide practical and scalable methods for assessing movement behaviors across large and occupationally diverse samples, comparisons with device-based measures demonstrate that estimates can be affected by reporting, recall, and measurement differences [23-25]. Greater incorporation of objective measurement alongside self-report may therefore provide a more detailed characterization of movement patterns within complex and variable frontline working environments.

Importantly, the use of measurement approaches differed across movement behavior domains. Self-report predominated among studies examining sleep (476/538, 88.5%) and physical activity (133/177, 75.1%), while mixed or objective approaches represented a greater proportion of the comparatively small sedentary behavior literature. These differences demonstrate variation in measurement approaches across movement behavior domains. Objective measurement should not necessarily be regarded as a replacement for self-report, as subjective and objective approaches may capture different aspects of movement and sleep [21,23-25]. Rather, appropriately combining these approaches may provide complementary information, particularly where the research question concerns both perceived experiences and objectively measured behavioral patterns. Where objective monitoring is used, attention should also be given to device validity and reporting standardization. Wearable-derived estimates are not necessarily interchangeable across devices because sensor characteristics, body placement, sampling parameters, wear protocols, and processing algorithms can influence derived movement or sleep metrics [50,51]. External validation approaches, including the framework illustrated by Bačić et al [52] and the broader validation considerations identified by Giurgiu et al [51], demonstrate the value of evaluating wearable-derived estimates against suitable comparator measures under clearly specified conditions and considering how sensor characteristics and processing parameters may influence the resulting metrics. Future studies should therefore report device model, placement, monitoring duration, wear protocol, processing procedures, and relevant validation evidence to support reproducibility and interpretation. These findings also have implications for digital monitoring within frontline occupational settings. Wearable and other objective approaches may enable repeated assessment of movement and recovery patterns across shifts and changing occupational demands; however, their value depends on appropriate validation, transparent reporting, and integration with contextual and self-reported information [21,22,37,50-52]. Future digital monitoring research should therefore prioritize validated devices and metrics, clearly specified monitoring protocols, and worker-centered implementation that considers feasibility, acceptability, privacy, and the interpretation of behavioral or physiological signals within their occupational context.

Future research would therefore benefit from greater methodological diversity, including longitudinal and repeated-measures designs, intervention research, and the considered integration of objective and self-report measurement [21,23-25,43]. Such approaches may be particularly valuable in frontline settings, where movement behaviors, occupational demands, work schedules, and opportunities for recovery can vary considerably within individuals across shifts and overtime [1,2,8]. Together, these methodological developments would

XSL•FO
RenderX

enable the field to move beyond predominantly cross-sectional descriptions of associations toward a more temporally informed understanding of movement behaviors and mental health among frontline workers [43].

### Implications for Future Research and Practice

The findings identify several priorities for advancing research on movement behaviors and mental health among frontline workers. First, greater adoption of integrated 24hrMB approaches is needed. Rather than examining sleep, physical activity, and sedentary behavior predominantly in isolation, future studies should consider these behaviors concurrently and, where appropriate, apply analytical approaches that account for their interdependence within a finite 24-hour period. Compositional data analysis and isotemporal substitution modeling may be particularly valuable in this regard, as they enable examination of how different allocations of time across movement behaviors relate to health domains [9-11]. Such approaches may be especially relevant in frontline settings, where shift patterns, long working hours, staffing pressures, and operational demands can constrain opportunities for sleep, movement, and recovery [1,6,7]. Second, future research should address the substantial behavioral and occupational gaps identified in the evidence base. Greater attention to sedentary behavior is particularly warranted, alongside continued investigation of physical activity and the combined contribution of multiple movement behaviors. Research should also extend beyond the predominantly health care–based literature to include greater representation of police, firefighters, emergency medical personnel, and other frontline occupational groups. Given the differing operational demands and working patterns across these occupations, greater occupational diversity would help establish a more comprehensive understanding of movement behaviors and mental health across frontline contexts.

Methodologically, greater use of longitudinal, repeated measures, and intervention designs would strengthen understanding of how movement behaviors and mental health vary over time and across changing occupational conditions. Combining objective movement measurement with self-report may also provide complementary information by capturing both behavioral patterns and individuals' perceived experiences. These approaches may be particularly useful for examining within-person variation across work shifts, rest days, and periods of differing occupational demand. As longitudinal wearable and repeated-measures datasets develop, future research could also examine appropriately validated predictive modeling and AI approaches for identifying patterns associated with changes in movement behaviors, recovery, or mental health [22,37]. Such applications would require robust validation and careful consideration of privacy, acceptability, and ethical implementation within occupational settings [21,37].

The findings also have implications for occupational practice. The concentration of evidence around sleep reinforces the importance of opportunities for adequate sleep and recovery within frontline work [2,13-15], while the broader evidence gaps suggest that occupational well-being strategies should not necessarily consider movement behaviors in isolation [9-11]. However, the current predominance of cross-sectional and association-focused evidence limits conclusions regarding which changes to movement behaviors would improve mental health domains. Accordingly, the present evidence is better positioned to inform priorities for monitoring and future intervention development than to support specific behavioral prescriptions. Future interventions should also recognize that opportunities to modify sleep, physical activity, and sedentary behavior may be constrained by shift schedules, staffing arrangements, workload, and other organizational factors, highlighting the importance of both individual- and organizational-level approaches [1,2,6-8]. Overall, this review uniquely maps where evidence on movement behaviors and mental health among frontline workers is concentrated and, importantly, highlights the relative absence of research adopting an integrated 24hrMB perspective.

### Strengths and Limitations

This review has several strengths. A comprehensive search strategy was applied across 6 electronic databases and updated on July 30, 2026, to capture recently published evidence, resulting in a large evidence base of 613 studies. Screening procedures incorporated independent assessment of subsets of records by additional reviewers across screening stages, with disagreements resolved through discussion and consensus. Data charting was completed for all included studies by 1 reviewer (AS), with independent charting of random subsets by additional reviewers (GH-B and EC) and 100% agreement within the overlapping sample. The use of non–mutually exclusive coding for movement behaviors and mental health domains enabled studies examining multiple domains to contribute to each relevant category, providing a more detailed representation of the breadth and overlap of the evidence base. Evidence mapping further enabled identification of areas of research concentration and relative scarcity across movement behavior and mental health domains. Stakeholder consultation contributed to refinement of the review questions and eligibility criteria and supported interpretation of the findings and evidence gaps. The review followed JBI guidance for scoping reviews, was reported in accordance with PRISMA-ScR recommendations, and was guided by a previously published protocol, supporting methodological transparency and reproducibility [29,30,32].

Several limitations should also be considered. First, gray literature, citation searching, and other supplementary source searching were not undertaken. The review therefore primarily represents evidence indexed in the 6 searched databases and may not capture relevant unpublished, nonindexed, or otherwise unretrieved studies. Second, formal critical appraisal of individual studies was not undertaken. Critical appraisal is not a mandatory component of scoping review methodology where the objective is to map the extent, characteristics, and distribution of an evidence base rather than to determine intervention effectiveness or estimate the strength or certainty of effects [29]. Accordingly, the findings describe the volume and distribution of research and should not be interpreted as indicating the methodological quality or strength of evidence within individual domains. Third, substantial heterogeneity existed across the included literature in occupational populations, movement behaviors, mental health constructs, study designs, and measurement approaches. Although this

XSL•FO
RenderX

breadth was appropriate to the scoping review objectives, it limits direct comparison across studies and means that studies contributing to the same broad domain may have operationalized constructs differently.

The mental health categories were iteratively refined during charting to accommodate the range of constructs encountered, and some domains grouped within the broader "other mental health" category were necessarily heterogeneous. Similarly, broad measurement categories were used to map movement measurement approaches and do not capture all differences in instruments, devices, protocols, or measurement quality. The predominance of cross-sectional and self-report methodologies within the evidence base limits causal inference and understanding of within-person behavioral variability over time [23-25,43]. The distribution of the underlying evidence base should be considered when interpreting the review findings. Research was disproportionately concentrated within health care populations, sleep-focused studies, cross-sectional designs, and self-report measurement approaches. Consequently, the mapped evidence does not represent all frontline occupations, movement behaviors, or methodological approaches equally. Furthermore, because this review mapped the presence and distribution of movement behavior and mental health domains rather than synthesizing the direction, magnitude, or statistical significance of associations, the findings should not be interpreted as evidence that particular movement behaviors cause, protect against, or worsen specific mental health domains. Finally, because wearable technologies, psychophysiological monitoring approaches, and digital health applications continue to evolve rapidly, the findings should be interpreted as reflecting a developing evidence base rather than a static body of literature [21,22,37].

## Conclusions

This scoping review identified a large but unevenly distributed evidence base examining movement behaviors and mental health among frontline workers. Research was concentrated on health care populations, sleep-focused studies, cross-sectional and association-focused designs, and self-report measurement approaches. Physical activity, sedentary behavior, integrated 24hrMB approaches, non–health care frontline occupations, and longitudinal and objective methodologies remained underrepresented. Evidence was also concentrated around stress, depression, and anxiety, particularly in relation to sleep. By mapping movement behavior and mental health domains as overlapping rather than mutually exclusive categories, this review provides a detailed representation of where evidence is concentrated and where substantive behavioral, occupational, and methodological gaps remain. The present evidence is better suited to informing priorities for occupational monitoring and future intervention development than to supporting specific behavioral prescriptions. Future research should broaden the behavioral and occupational scope of the field and examine the interdependence of movement behaviors within constrained occupational time budgets. Developing this evidence base may support a more comprehensive understanding of how movement behaviors, occupational demands, and mental health intersect across the 24-hour day.

## Acknowledgments

The authors attest that there was no use of generative AI technology in the generation of text, figures, or other informational content of this manuscript.

## Funding

This research forms part of a PhD project funded by the Strathclyde Centres for Doctoral Training (SCDT) award at the University of Strathclyde. The wider PhD project includes an industry collaboration with Sentinel Ltd, including a financial contribution. However, no specific funding was received from Sentinel Ltd or any other external organization for the conduct or preparation of this scoping review.

## Conflicts of Interest

NC serves as chief scientific officer for Sentinel, a digital mental health company that develops tools and resources to support the prevention, management, and recovery of workplace trauma among frontline and high-stress professionals. AK is affiliated with Sentinel, and AS's PhD receives partial support linked to Sentinel-related activities. However, the present review was conducted independently through the University of Strathclyde as part of AS's doctoral research and received no direct funding from Sentinel. Sentinel, as an organization, had no role in the review design, data collection, analysis, interpretation, or preparation of the manuscript. The findings may inform future research and development activities, but the review itself was not conducted for commercial purposes.

## Abstract

**Background:** Healthy lifestyle behaviors are key modifiable factors for the prevention of chronic diseases and premature mortality. Composite lifestyle scores provide a practical framework for capturing the combined impact of multiple health behaviors, but prospective evidence from multiethnic Asian populations remains limited.

**Objective:** This study examined the associations between a composite healthy lifestyle score and the risk of cardiovascular diseases, cancer, and all-cause mortality in a multiethnic Asian population.

**Methods:** We analyzed prospective data from 9920 participants of the Singapore Multi-Ethnic Cohort who were free of major chronic diseases at baseline. A healthy lifestyle score was constructed from 5 components: BMI, smoking, physical activity, diet quality, and screen time. Scores ranged from 0 to 10, with higher scores reflecting healthier lifestyles. An expanded score, including mental well-being, was examined in a subset. Hazard ratios (HRs) and 95% CIs were estimated using the Cox proportional hazards model for acute myocardial infarction (AMI), stroke, cancer, and all-cause mortality, adjusting for sociodemographic factors, energy intake, family history of cancer or heart disease, and menopause status.

**Results:** During a median follow-up of 14 years, 457 AMI cases, 322 stroke cases, 707 cancer incident cases, and 631 deaths were identified. More favorable lifestyle scores were associated with lower risk of cardiovascular outcomes and mortality, consistent with a dose-response relationship. Compared to participants scoring 8 to 10, those with the lowest score (0-3) had more than 2 times the risk of AMI (HR 2.13, 95% CI 1.47-3.07), stroke (HR 3.21, 95% CI 2.12-4.85), and all-cause mortality (HR 2.01, 95% CI 1.46-2.78). In contrast, no significant associations were observed for cancer incidence. Incorporating mental well-being into the lifestyle score yielded similar results.

**Conclusions:** Adherence to a healthy lifestyle was associated with a lower risk of AMI, stroke, and mortality in a multiethnic Asian cohort, highlighting the importance of integrated lifestyle approaches for chronic disease prevention.

## Introduction

Noncommunicable diseases remain the leading cause of death worldwide, accounting for over 70% of mortality, with cardiovascular diseases (CVDs) causing most premature deaths, followed by cancers [1]. Key modifiable lifestyle factors such as smoking, physical inactivity, and unhealthy diets, along with metabolic risks such as overweight and obesity, which largely stem from these behaviors, are major contributors to the development of noncommunicable diseases [1,2].

Composite lifestyle scores that integrate multiple lifestyle factors into a single measure can provide a combined impact and holistic assessment of overall lifestyle [3]. Compared to individual risk factors, these composite scores show stronger associations with major chronic disease outcomes and all-cause mortality. Meta-analyses have reported that individuals with the healthiest composite lifestyle scores had a 55% lower risk of all-cause mortality than those with the worst lifestyle scores [4], while the risk reduction was 33% for physical activity alone [5] and 23% for diet alone [6]. This greater risk reduction likely reflects synergistic or multiplicative interactions among lifestyle

XSL•FO
RenderX

behaviors, which are often not captured when individual factors are examined separately [7,8].

Despite robust evidence from Western populations [8,9], studies in Asian populations are comparatively fewer and largely based on East Asian cohorts in China, Japan, or South Korea [10-12]. This limits the generalizability of existing evidence to more diverse or multiethnic Asian contexts such as Singapore given differences in lifestyle behaviors across ethnic groups [13]. Prior cohort studies have rarely incorporated screen-based behavior or related health indicators such as mental well-being despite their relevance to broader lifestyle patterns. Excessive screen time has been associated with greater sedentary behavior, sleep disruption, and poorer mental well-being [14,15], which may collectively increase the risk of major cardiovascular outcomes and mortality [16-21]. A recent analysis of 13,282 adults aged 65 years and older in the Chinese Longitudinal Healthy Longevity Survey found that better subjective well-being (eg, less anxiety and greater happiness) was independently associated with a 14% lower risk of all-cause mortality and a 30% lower risk when combined with healthy lifestyle behaviors. However, the combined effects of lifestyle factors with mental well-being and screen time on major health outcomes have not been well examined in multiethnic Asian populations.

This study examined the association between a combined lifestyle score incorporating smoking, diet, physical activity, BMI, and screen time and major health outcomes, including all-cause mortality, stroke, acute myocardial infarction (AMI), and cancer, in a multiethnic population. Within individuals with available mental well-being data, the association between major health outcomes and the expanded lifestyle score including mental well-being was studied. In addition, we examined which individual lifestyle component contributed the most to the observed associations, thus providing insights into key targets for prevention and intervention.

## Methods

### Study Population

We used data from the Multi-Ethnic Cohort Phase 1 (MEC1), a population-based study of adult residents aged 21 years and older in Singapore that includes 3 major ethnic groups (Chinese, Indian, and Malay). MEC1 baseline data (T1) were collected between 2004 and 2010. Individuals with a history of cancer, CVD, stroke, renal failure, or serious mental illness at recruitment were excluded from cohort enrollment. The MEC1 baseline dataset was formed by combining 2 existing population-based studies conducted between 2004 and 2007: the Singapore Prospective Study Program and the Singapore Cardiovascular Cohort Study, with additional recruitment of participants from 2007 to 2010 (Singapore Consortium of Cohort Studies–Multi-Ethnic Cohort [SCCS-MEC]) through household visits and community outreach to achieve oversampling of Malay and Indian individuals in Singapore. All participants provided written informed consent, including consent for linkage with national disease registries. Detailed information on the cohort has been published previously [22].

Of the initial 12,988 participants, 12,384 (95.4%) remained after excluding those not from the 3 major ethnic groups (n=33), with missing interview data (n=42), or with preexisting CVD (n=328) or cancer (n=201). After further exclusions of those with missing lifestyle data (n=2376) or covariate data (n=19) and implausible energy intake (≤500 or ≥6000 kcal per day; n=69), 9920 participants were included in the final analysis (Multimedia Appendix 1). The median follow-up duration ranged from 14.1 years for cancer to 14.3 years for all-cause mortality, with 14.2 years for both AMI and stroke. Mental well-being data were available for 4791 participants from a subset of participants (Singapore Prospective Study Program and Singapore Cardiovascular Cohort Study) who completed the 36-item Short Form Health Survey version 2 (SF-36v2) emotional well-being items at baseline; therefore, analyses incorporating mental well-being were restricted to this subset. In the subset with mental well-being data, the median follow-up ranged from 16.1 years (AMI, stroke, and cancer) to 16.2 years (all-cause mortality).

### Construction of a Healthy Lifestyle Score

Six lifestyle factors were assessed at baseline: BMI, cigarette smoking, physical activity, diet quality, and screen time, with mental well-being available in a subset of the participants. BMI was calculated from measured height and weight, while the other factors were self-reported via an interviewer-administered questionnaire [22]. Each factor was categorized into 3 levels and assigned 0 to 2 points, with higher scores representing healthier behaviors. Three levels were chosen to balance the need to capture meaningful variation with the need to maintain sufficient sample size within each category.

BMI was classified using established Asian cutoffs, defined as less than 23.0 kg/m$^2$ (2 points), 23.0 to 24.9 kg/m$^2$ (1 point), and 25.0 kg/m$^2$ or higher (0 points) [23,24]. Smoking status was categorized as “never” (2 points), “former” (1 point), or “current” (0 points). Leisure-time physical activity was assessed using a physical activity questionnaire [25] and expressed in metabolic equivalent of task (MET) hours per week. Participants were categorized into 7.5 or more MET hours per week (2 points), 0 to less than 7.5 MET hours per week (1 point), and none (0 points), consistent with the World Health Organization recommendation of 150 minutes or more of moderate-intensity physical activity per week [26]. Dietary intake was assessed using the validated semiquantitative food frequency questionnaire (FFQ) [27], and diet quality was evaluated using the Alternative Healthy Eating Index (AHEI) 2010 [19], with higher scores indicating better diet quality. Participants were categorized into tertiles: highest (2 points), intermediate (1 point), and lowest (0 points). Screen time was assessed through the amount of time spent watching television or playing computer or handheld video games daily. Participants were categorized into less than 2 hours per day (2 points), 2 to 4 hours per day (1 point), and more than 4 hours per day (0 points). In a subset of the population, mental well-being was assessed using the SF-36v2 emotional well-being subscale derived from 5 items assessing nervousness, low mood (being downhearted or depressed), calmness, and happiness over the previous 4 weeks, with higher scores indicating better mental well-being [28].

XSL•FO
RenderX

Scores were transformed into a norm-based T-score (mean 50, SD 10) following the SF-36v2 scoring manual [28]. Participants were categorized into tertiles: highest (2 points), intermediate (1 point), and lowest (0 points). As mental well-being data were available only for a subset of participants (n=4791), the main analyses were conducted using a 5-factor score in the entire cohort, while mental well-being was incorporated in additional analyses in the smaller subset.

The primary lifestyle score was calculated by summing all 5 factors, with possible scores ranging from 0 to 10. Participants were further grouped into 4 categories: score of 0 to 3 (least favorable lifestyle profile), score of 4 or 5, score of 6 or 7, and score of 8 to 10 (most favorable lifestyle profile; Table 1). In the subset with mental well-being data, an extended 6-factor lifestyle score was calculated by additionally including mental well-being, contributing scores from 0 to 2 to the previous 5-factor lifestyle score. This extended 6-factor score had a wider possible range from 0 to 12 and a different observed distribution. Participants were grouped separately into 4 ordered categories: scores of 1 to 4, 5 and 6, 7 and 8, and 9 to 12.

**Table .** Definition of the healthy lifestyle score.

| Lifestyle factor and points | Description |
|---|---|
| BMI | |
| 0 | Obese (≥25.0 kg/m$^2$) |
| 1 | Overweight (23.0 - 24.9 kg/m$^2$) |
| 2 | Normal (<23.0 kg/m$^2$) |
| Cigarette smoking | |
| 0 | Current smoker |
| 1 | Former smoker |
| 2 | Never smoker |
| Physical activity | |
| 0 | None (0 MET[a] h per wk) |
| 1 | Low (>0 to <7.5 MET h per wk) |
| 2 | Adequate (≥7.5 MET h per wk) |
| Diet quality | |
| 0 | Lowest tertile (poorest diet quality) |
| 1 | Middle tertile |
| 2 | Highest tertile |
| Screen time | |
| 0 | High (>4 h per d) |
| 1 | Moderate (2-4 h per d) |
| 2 | Low (<2 h per d) |
| Mental well-being | |
| 0 | Lowest tertile (poorest mental well-being) |
| 1 | Middle tertile |
| 2 | Highest tertile |

[a]MET: metabolic equivalent of task.

## Outcome Ascertainment

Incident cases of AMI, stroke, all-site cancer, and deaths were ascertained through linkage with national disease registries maintained by the National Registry of Diseases Office, including the Singapore Myocardial Infarction Registry, Singapore Stroke Registry, Singapore Cancer Registry, and Singapore Death Registry.

Follow-up time was calculated from the date of baseline interview to the date of first occurrence of the outcome of interest, death, or end of follow-up (December 31, 2021), whichever came first.

## Covariates

Covariates included age, sex, ethnicity, educational level, income, total energy intake, family history of cancer or heart disease, and menopausal status in women. Age was categorized as 35 years or younger, 36 to 45 years, 46 to 55 years, and 56 years or older. Sex was defined as male or female. Ethnicity was classified as Chinese, Malay, or Indian. Educational

XSL•FO
RenderX

attainment was grouped into 4 categories: primary or lower, secondary, postsecondary, and university or higher. Household income was categorized into predefined levels, with a separate category created for participants who refused to answer, did not know, or had missing information.

Total energy intake (kcal per day) was derived from the FFQ administered at baseline and modeled as a continuous variable. Family history of cancer or heart disease was coded as "yes" or "no" based on self-report. Menopausal status was classified as premenopausal or postmenopausal among women, and male participants were coded as a separate category to retain all participants in the model.

### Ethical Considerations

Ethics approval was obtained from the Institutional Review Board of National University of Singapore (NUS-IRB-2022-27). All participants provided written informed consent, including consent for linkage with national disease registries. Research data used for this secondary analysis were deidentified and key coded, with access restricted to authorized members of the research team.

### Statistical Analysis

Descriptive statistics were presented according to the categories of the lifestyle score. For continuous variables, *P* values were estimated by modeling the median value of each lifestyle score category as a continuous variable in linear regression. For categorical variables, *P* values were calculated using the Cochran-Armitage trend test. To assess potential selection bias related to missing lifestyle data, baseline characteristics were compared between participants included in the final analytic sample and those excluded because of missing lifestyle data.

Cox proportional hazards regression models were used to estimate hazard ratios (HRs) and 95% CIs for associations between the lifestyle score and each outcome, including incident AMI, incident stroke, incident cancer, and all-cause mortality. The proportionality assumption was assessed using Schoenfeld residuals; no violations were detected. Tests for linear trend were performed by modeling lifestyle score categories as a continuous variable in the regression model. All models were adjusted for age, sex, ethnicity, educational level, income, total energy intake, family history of cancer or heart disease, and menopausal status.

Additional analyses were conducted in the subset of participants with available mental well-being data by incorporating mental well-being as a sixth component of the lifestyle score. To facilitate comparison between the primary and extended lifestyle scores, both scores were also modeled as continuous variables, with HRs estimated per 1-point increase. Ethnicity-stratified analyses were performed, and multiplicative interaction terms between the lifestyle score and ethnicity were included in the Cox models to assess potential effect modification by ethnicity. To assess whether the associations were driven by any single component of the lifestyle score, leave-one-out analyses were performed by recalculating the lifestyle score after omitting one component at a time.

## Results

Differences between included participants and those excluded because of missing lifestyle data were observed for age, educational level, household income, total energy intake, and family history of cancer or heart disease, whereas sex, ethnicity, and menopausal status were similar between groups (Multimedia Appendix 2).

Table 2 shows the baseline characteristics of the participants according to the healthy lifestyle score. Of the 9920 participants, 4254 (42.9%) were male, and most (n=4480, 45.2%) were Chinese, followed by Indian (n=2790, 28.1%) and Malay (n=2650, 26.7%). Most participants (2923/9920, 29.5%) were aged 46 to 55 years. Participants with the least favorable lifestyle profile (score of 0 - 3) were younger, more often male, and of non-Chinese ethnicity and had lower income and educational attainment (*P*<.01 in all cases). Compared with participants with the least favorable lifestyle profile, those in the highest category (score of 8 - 10) had lower BMI (median 21.9, IQR 20.1-23.7 vs 27.4, IQR 25.3-30.3 kg/m$^2$); comprised fewer smokers (18/2605, 0.7% vs 479/645, 74.3%); engaged in higher levels of leisure-time physical activity (median 13.6, IQR 8.0-24.5 vs 0.0, IQR 0.0-0.0 MET hours per week); and reported better diet quality (median AHEI score 55.8, IQR 50.5-60.2 vs 41.4, IQR 36.3-45.8), shorter screen time (median 0.0, IQR 0.5-1.5 vs 1.0, IQR 0.0-2.0 hours per day), and better mental well-being (mean T-score 50.9, SD 9.3 vs 48.9, SD 11.2; *P*<.001 in all cases). In contrast, total energy intake, menopausal status, and family history of cancer or heart disease did not differ significantly across categories.

[a]*P* values were estimated by modeling the median value of each lifestyle score category as a continuous variable in linear regression for continuous outcomes and by using the Cochran-Armitage test for categorical outcomes.

[b]Only in women.

[c]MET: metabolic equivalent of task.

[d]AHEI: Alternative Healthy Eating Index.

The associations between the healthy lifestyle score and risk of health outcomes are shown in Table 3. Over a median follow-up of 14 years, 457 AMI cases, 322 stroke cases, 707 cancer cases, and 631 all-cause deaths were documented. In the adjusted model, participants with the least favorable lifestyle profile (score of 0 - 3) had higher risks of AMI (HR 2.13, 95% CI 1.47 - 3.07), stroke (HR 3.21, 95% CI 2.12 - 4.85), and all-cause mortality (HR 2.01, 95% CI 1.46 - 2.78) than those in the most favorable category (score of 8-10). Significant inverse dose-response trends were observed for these outcomes (*P*<.01 in all cases). No significant association was observed for cancer (HR 1.28, 95% CI 0.91 - 1.79). Kaplan-Meier curves showed graded separation for mortality, AMI, and stroke, whereas cancer curves largely overlapped (Multimedia Appendix 3).

**Table .** Hazard ratios (HRs) for the associations between healthy lifestyle score and the risk of all-cause mortality, stroke, acute myocardial infarction (AMI), and cancer adjusting for age, sex, ethnicity, income, educational level, total energy intake, family history of cancer or heart disease, and menopause status.

| Lifestyle scores | All-cause death (n=631; median follow-up 14.3 y) | | AMI (n=457; median follow-up 14.2 y) | | Stroke (n=322; median follow-up 14.2 y) | | Cancer (n=707; median follow-up 14.1 y) | |
|---|---|---|---|---|---|---|---|---|
| | Cases, n | HR (95% CI)[a] | Cases, n | HR (95% CI)[a] | Cases, n | HR (95% CI)[a] | Cases, n | HR (95% CI)[b] |
| 0-3 | 64 | 2.01 (1.46-2.78) | 54 | 2.13 (1.47-3.07) | 45 | 3.21 (2.12-4.85) | 46 | 1.28 (0.91-1.79) |
| 4-5 | 205 | 1.64 (1.28-2.09) | 156 | 1.71 (1.28-2.28) | 97 | 1.54 (1.09-2.18) | 181 | 1.09 (0.87-1.35) |

| 8-10 | 105 | 1.00 | 75 | 1.00 | 55 | 1.00 | 177 | 1.00 |

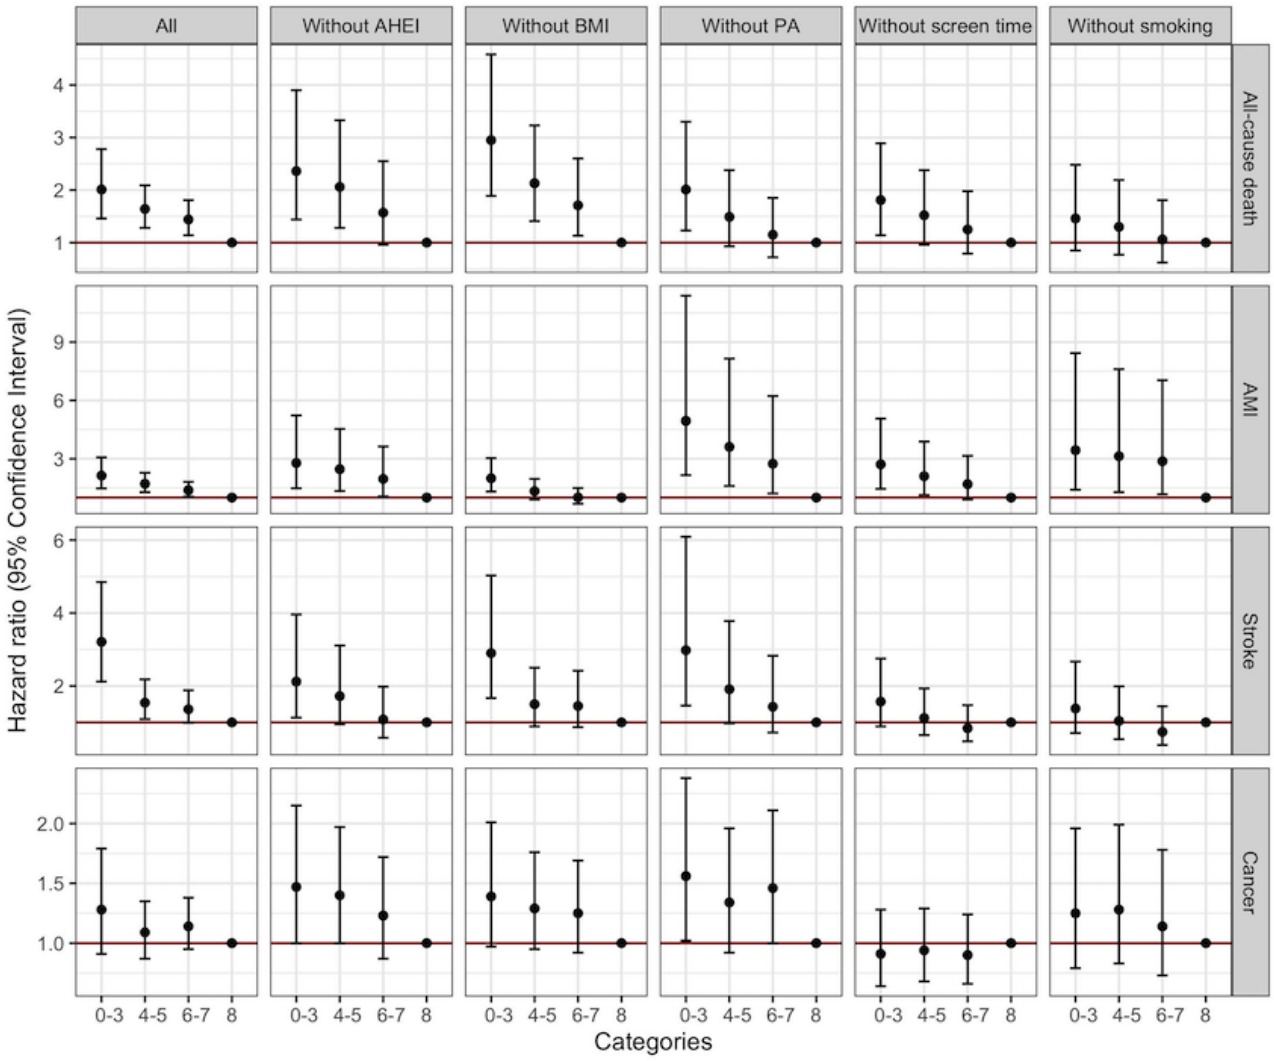
[a]*P*<.001.

[b]*P*=.24.

In analyses incorporating the mental health component into the lifestyle score, results were consistent. Participants with lower healthy lifestyle scores remained at higher risk of all-cause mortality and AMI, with similar estimates for these outcomes, while the association with stroke was slightly attenuated (HR 2.14, 95% CI 1.32 - 3.46). No clear dose-response association was observed for overall cancer incidence (Multimedia Appendix 4).

When modeled as continuous variables, the primary lifestyle score and the score including mental well-being showed similar inverse associations with all-cause mortality, AMI, and stroke. The primary score was not associated with overall cancer incidence, whereas the score including mental well-being showed a modest inverse association with cancer (Multimedia Appendix 5).

Ethnicity-stratified analyses were conducted to assess potential effect modification by ethnicity. No significant interactions were observed for all-cause mortality, AMI, or stroke (*P*=.29, .41, and .43, respectively), whereas an interaction was observed for overall cancer incidence (*P*=.02). However, stratified analyses by ethnicity did not show significant dose-response trends within any ethnic group (Multimedia Appendix 6).



In leave-one-out analyses (Figure 1), exclusion of smoking attenuated the association with all-cause mortality (HR 1.46, 95% CI 0.85 - 2.48), indicating that smoking was a major contributor to this association. For AMI, effect estimates

XSL•FO
RenderX

remained largely significant across all exclusions, suggesting that the association was not driven by any single lifestyle component. For stroke, exclusion of smoking (HR 1.38, 95% CI 0.71 - 2.67) or screen time (HR 1.57, 95% CI 0.89 - 2.75) resulted in attenuation, indicating that these factors may play an important role in the observed associations. For cancer, the lifestyle score excluding physical activity was associated with risk (HR 1.56, 95% CI 1.02 - 2.38), while exclusion of diet quality (AHEI score) showed a borderline significant association (HR 1.47, 95% CI 1.00 - 2.15).

**Figure 1.** Leave-one-out analyses of the healthy lifestyle score in relation to major health outcomes. The healthy lifestyle score ranged from 0 to 10 in the full model and from 0 to 8 when an individual component was excluded. Higher scores indicate healthier lifestyle profiles. The points represent hazard ratios, and the error bars indicate 95% confidence intervals. AHEI: Alternative Healthy Eating Index; AMI: acute myocardial infarction; PA: physical activity.

## Discussion

### Principal Findings

In this multiethnic Asian cohort with over 14 years of follow-up, adherence to a healthy lifestyle as measured using a composite score was associated with substantially lower risks of all-cause mortality, AMI, and stroke. Participants with the least favorable lifestyle profiles had twice the risk of AMI and all-cause mortality and over 3 times the risk of stroke compared with those with the most favorable profiles. Results were consistent when mental well-being was incorporated in the lifestyle score. No significant associations were observed for overall cancer incidence. These findings highlight the importance of healthy lifestyle behaviors for cardiovascular health and longevity in Asian populations.

### Comparison With Previous Studies

Our findings are consistent with those of previous cohort studies reporting that composite healthy lifestyle scores are inversely associated with mortality and CVD outcomes in both Western and Asian populations [29]. Large cohorts from Europe and the United States have demonstrated that combinations of nonsmoking, healthy body weight, regular physical activity, light-to-moderate alcohol consumption, and high-quality diet are associated with reductions in all-cause and cardiovascular mortality [30,31]. Comparable associations have been documented in East Asian cohorts, including China, Taiwan, South Korea, and Japan, where higher lifestyle scores incorporating BMI, smoking, physical activity, diet, and alcohol consumption were observed [32-35]. In our study, participants with the least favorable lifestyle profiles had approximately 2.0

XSL•FO
RenderX

times the risk of all-cause mortality, 2.1 times the risk of AMI, and 3.2 times the risk of stroke, broadly consistent with meta-analyses of prospective cohort studies reporting 2.2 times higher all-cause mortality and 2.2 to 3.4 times higher risk of various cardiovascular outcomes [4]. Our study extends this literature to a multiethnic Southeast Asian population and incorporates screen-based sedentary behavior, assessed as television viewing and computer or handheld video game use, into the composite lifestyle score.

### Interpretation and Implications

A notable contribution of this study is the integration of screen time into the composite lifestyle score. Sedentary behavior, including prolonged screen time, has been increasingly recognized as an independent risk factor for cardiometabolic diseases. Epidemiological evidence across multiple cohorts has shown that increased leisure screen time is associated with greater cardiometabolic risk in both adolescents and adults, as well as with elevated risks of coronary artery disease and mortality [21,36,37]. Consistent with these findings, our leave-one-out analysis showed that removing screen time from the score substantially attenuated the association with stroke, suggesting that screen time may be particularly relevant for cerebrovascular risk. Potential mechanisms include impaired circulation, central adiposity, dysregulated glucose metabolism, elevated blood pressure, and inflammation, all of which are closely linked to ischemic stroke [38-41].

Although there is accumulating evidence suggesting that psychological distress and low mental well-being are associated with higher risks of mortality and CVDs [42-44], mental well-being has rarely been incorporated into lifestyle indexes. While mental well-being is not a lifestyle behavior per se, it is largely shaped by them, and including them in the combined lifestyle score allows for a broader assessment of health. In our study, mental well-being was assessed using the SF-36v2 mental health subscale, which has been used to predict mortality and CVD outcomes in prior prospective cohorts [45]. In the subgroup with available data, adding mental well-being to the score did not substantially change the overall patterns of association. The estimates remained similar for all-cause mortality and slightly attenuated for AMI and stroke but were statistically significant despite the smaller sample size. These findings suggest that mental well-being represents a complementary domain of lifestyle assessment, capturing psychosocial aspects of health that may support overall disease prevention and well-being.

The composite lifestyle score was designed to capture the cumulative influence of multiple lifestyle-related risk factors that commonly co-occur in real-world settings as compared to considering each lifestyle component independently. Smoking, poor diet quality, lower physical activity, and sedentary behaviors may cluster within broader unhealthy lifestyle patterns, and the score provides a practical summary measure of this overall lifestyle risk. In sensitivity analyses excluding smoking, the associations with all-cause mortality and stroke were attenuated and no longer statistically significant, suggesting that smoking was a particularly influential component for these outcomes. This pattern aligns with extensive evidence showing that smoking promotes endothelial dysfunction, systemic inflammation, oxidative stress, and thrombotic pathways that accelerate atherosclerosis and increase risks of ischemic stroke and premature death [46-49]. These findings highlight the importance of smoking prevention and cessation for reducing the risks of premature mortality and stroke.

There was no significant evidence of interaction by ethnicity for the associations with all-cause mortality, AMI, and stroke. Although an interaction was observed for overall cancer incidence, the ethnicity-stratified analyses did not show clear dose-response trends. This finding should be interpreted cautiously. The null association between the lifestyle score and overall cancer incidence should also be interpreted with caution. Cancer encompasses multiple diseases with distinct etiologies and typically long latency periods, and aggregating all cancer types into a single outcome may obscure lifestyle-related associations that differ by cancer site. Furthermore, the relatively young baseline age of our cohort and comparatively short follow-up for cancer outcomes resulted in a limited number of cancer events during follow-up, reducing the power to detect associations.

### Limitations

This study has several limitations. First, the lifestyle score was constructed as an unweighted index summing all lifestyle components equally and assuming each factor had equal importance. Previous studies have examined both weighted and unweighted indexes, showing that both effectively predict CVD risk [50]. The unweighted index is outcome agnostic, which is more practical and can be applied to a broader range of health outcomes. Second, lifestyle behaviors were primarily self-reported, which may introduce recall error or reporting bias. However, such errors are likely nondifferential as outcomes were assessed prospectively. The physical activity questionnaire and FFQ have been validated in independent samples of the local population with similar characteristics [22,27,51]. In addition, differences in several baseline characteristics between included participants and those excluded because of missing lifestyle data may have introduced selection bias. Third, lifestyle behaviors and covariates were measured at baseline only, and changes in these behaviors during follow-up may have introduced nondifferential misclassification that biased the association toward the null. Fourth, alcohol consumption was not included as a separate lifestyle component as it was already incorporated into the AHEI 2010 score to avoid double counting. Fifth, although we adjusted for multiple confounders, our findings could still be influenced by residual confounding and unmeasured factors. While the median follow-up of approximately 14 years allowed for assessment of long-term outcomes, longer follow-up may be needed to further clarify associations, particularly for cancer outcomes with longer latency. Sixth, cancer was analyzed as a single combined end point. Although overall cancer incidence provides a broad assessment of cancer burden alongside other major chronic disease outcomes, cancer comprises a heterogeneous group of diseases with distinct etiologies, and combining all incident cancers may obscure site-specific associations with lifestyle factors. Therefore, findings for overall cancer incidence should be interpreted cautiously. Finally, as this study was conducted

XSL•FO
RenderX

in a multiethnic Asian cohort, the findings may not be generalizable to other populations with different sociodemographic or cultural contexts.

### Conclusions

Our findings highlight the importance of combined lifestyle behaviors, including screen-based sedentary behavior, for cardiovascular and overall health. Incorporating mental well-being yielded similar results, suggesting that a broader conceptualization of lifestyle may be relevant for chronic disease prevention. These results highlight opportunities for comprehensive lifestyle interventions and public health strategies to reduce CVD and premature mortality in Asian populations.

### Acknowledgments

The authors thank all participants, the study team, and the investigators for their research contributions. The Multi-Ethnic Cohort Phase 1 study is supported by individual research and clinical scientist award schemes from the National Medical Research Council and the Biomedical Research Council of Singapore and infrastructure funding from the Singapore Ministry of Health (Population Health Metrics and Analytics), National University of Singapore, and the National University Health System of Singapore. The authors thank the National Registry of Diseases Office for providing the record linkage data.

### Generative AI Use

The authors attest that no generative AI or AI-assisted tools were used in developing and writing this manuscript.

### Funding

This study was funded by the Saw Swee Hock School of Public Health ground-up research seed fund 2021 to support academic or operational insights influencing national policies or programs in the areas of population or public health in Singapore (grant principal investigator: AC).

### Data Availability

The datasets generated or analyzed during this study are available from the Singapore Population Health Studies [52] on reasonable request and with appropriate institutional approvals.

## Abstract

**Background:** Sudden death due to cardiorespiratory arrest has a high mortality rate and often occurs outside hospital settings. Prompt initiation of cardiopulmonary resuscitation (CPR) by bystanders, along with the use of an automated external defibrillator (AED), has been shown to double survival rates. Given the challenges of ensuring timely emergency response in rural areas, implementing basic CPR training programs can help improve survival outcomes.

**Objective:** This study aimed to evaluate the effectiveness of online CPR-AED training delivered to participants from a rural area of Camp de Tarragona.

**Methods:** This quasi-experimental study consisted of 2 phases: phase 1, evaluation of the effectiveness of online training on CPR-AED knowledge (with pretest and posttest assessments), and phase 2, evaluation of the effectiveness of online training on CPR-AED maneuvers through simulation at 1 month and 6 months after online training. The sample of the study comprised residents in a rural area of Tarragona, Spain. A descriptive statistical analysis of the study population was conducted. For quantitative data with a nonnormal distribution, the median and IQR were presented. Categorical data were described as frequencies and percentages. A bivariate analysis was performed to compare the pretraining and posttraining quantitative variables using the Student 2-tailed *t* test.

**Results:** In total, 55 participants were included in the study. Of these, 74.5% (n=55) were women, the mean age was 41.5 (SD 9.1) years, and 94.5% (n=55) were employed. Overall, 52 participants completed the online training. The median time required to complete the course was 261.5 (IQR 935; range 125-327) minutes. In total, 51 participants took part in the first practical simulation, which was conducted 1 month after the theoretical training. The mean score obtained in this first simulation was 7.5 out of 10. Six months after the theoretical training, 46 participants completed a second simulation.

**Conclusions:** Online CPR-AED training is effective in improving CPR-AED knowledge and skills in a rural population in the short and medium term.

## Introduction

Out-of-hospital cardiac arrest (OHCA) remains a major cause of mortality worldwide, with survival critically dependent on early recognition, prompt initiation of cardiopulmonary resuscitation (CPR), and rapid use of an automated external defibrillator (AED). Despite sustained public health initiatives, recent epidemiological data indicate that bystander CPR and AED deployment remain suboptimal in many regions, particularly in rural or geographically dispersed populations [1]. In Europe, OHCA represents a substantial public health burden, with an estimated annual incidence ranging from 53 cases per 100,000 inhabitants in Austria to 166 per 100,000 in Bosnia and Herzegovina [2].

Although advances in prehospital and emergency care have improved outcomes, overall survival remains limited. The EuReCa TWO registry, encompassing resuscitation attempts in 28 European countries, reported survival to hospital discharge in only 8% of patients [2].

In Spain, national registry data from 2022 documented an OHCA incidence of 24.2 cases per 100,000 inhabitants, with marked regional variation, with Catalonia reporting one of the highest incidence rates at 35.2 cases per 100,000. Overall survival to hospital discharge was 11.5%. These outcomes remain strongly associated with the timeliness and quality of bystander intervention, particularly CPR provision and AED accessibility. The “chain of survival”—early recognition, timely bystander CPR, rapid defibrillation, advanced life support, and postresuscitation care—continues to be central to improving OHCA outcomes [3].

Each minute of delay in chest compressions reduces survival by approximately 10%, whereas defibrillation within 3 to 5 minutes for shockable rhythms may increase survival to as much as 30% [4]. However, bystander CPR rates vary widely, from 26% in some regions to approximately 69% in communities with comprehensive public training programs.

Rural populations face distinct barriers to emergency response education, including limited access to certified instructors, long travel distances to training sites, and fewer opportunities for refresher courses [5]. These structural constraints likely contribute to lower CPR training rates and reduced AED awareness compared with urban communities, potentially widening disparities in OHCA outcomes [1]. In such settings, early intervention often depends on lay bystanders before the arrival of emergency medical services (EMS) [6-8].

Hands-only CPR has been demonstrated to be as effective as conventional CPR for most adult cardiac arrests, lowering barriers for lay responders and facilitating dissemination through community-based programs [6]. Nonetheless, substantial inequities persist between urban and rural areas. In rural contexts, EMS response times frequently exceed 10 to 15 minutes, AED availability is limited, and community CPR training coverage is lower. These challenges are often compounded by socioeconomic disadvantage, with underserved populations less likely to receive bystander CPR or early defibrillation [6].

Disparities in early resuscitation are particularly concerning in pediatric OHCA, where rapid intervention is essential. Globally, the annual incidence among children younger than 12 years ranges from 8 to 20 cases per 100,000 [9]. However, most schoolteachers report insufficient CPR training and limited confidence in performing or teaching resuscitation techniques. Although hands-only CPR is generally preferred by educators, overall preparedness remains inadequate [10].

Therefore, training schoolteachers in CPR may have a multiplier effect, enabling them to respond effectively in school environments while simultaneously transmitting life-saving skills to students and fostering a broader culture of preparedness within the community [11]. This approach is especially relevant in rural regions, where access to EMS is constrained and scalable digital solutions—such as online CPR courses—may represent practical and cost-effective alternatives.

Although traditional face-to-face CPR-AED training has proven effective, the COVID-19 pandemic accelerated the adoption of digital health education modalities, including blended and fully online programs. Emerging evidence suggests that online or hybrid CPR instruction combined with simulation-based practice can improve short-term knowledge retention and psychomotor skills, although findings remain heterogeneous and dependent on instructional design, learner characteristics, and assessment strategies [12].

Simulation-based assessment is increasingly used to evaluate CPR competence in standardized environments, enabling objective measurement of procedural accuracy, timing, and checklist-based performance [12,13]. However, improvements observed in simulated contexts should be interpreted cautiously, as such performance may not fully translate to real-world behavior during actual emergencies.

Despite growing interest in remote and community-based CPR education, evidence specifically examining online CPR-AED training for rural lay populations remains limited [1]. Most studies have focused on urban cohorts, health science students, or workplace settings, leaving an important knowledge gap regarding the feasibility and potential impact of digital training strategies in geographically isolated communities [13].

To address this gap, this study evaluates changes in theoretical knowledge and simulated CPR-AED performance among rural community participants before and after completion of an online training program supplemented by in-person simulation practice. Given the quasi-experimental pre-post design and the absence of a concurrent control group, the analysis focuses on observed improvements rather than causal inference.

## Methods

### Study Design, Setting, and Recruitment

This study was designed as a quasi-experimental community intervention without a control group. It was structured in two sequential phases:

- Phase 1: evaluation of the effectiveness of online training on CPR-AED theoretical knowledge

XSL•FO
RenderX

- Phase 2: evaluation of the effectiveness of online training on CPR-AED practical skills through in-person, simulation-based assessment

The study was carried out in 2 primary health care centers located in the municipalities of Borges del Camp and Cornudella de Montsant (province of Tarragona, Catalonia, Spain). The reference population consisted of residents from 3 rural municipalities in Catalonia.

A systematic community-based recruitment strategy was implemented. First, the research team contacted local authorities and institutional representatives to present the objectives and procedures of the study and to request collaboration. The study was subsequently disseminated through municipal associations, schools, and secondary education institutes, as well as through community notice boards and local communication channels. Informational meetings were organized when it was feasible to explain the study and resolve questions from potential participants.

Interested individuals contacted the research team or the primary health care centers directly. After receiving detailed information about the study, those willing to participate provided informed consent and were consecutively enrolled until the target sample size was reached. Recruitment procedures were identical across the participating municipalities to ensure consistency.

## Participant Selection

Participants were selected based on specific eligibility criteria.

The inclusion criteria were as follows:

- Residence and/or employment in the Priorat or Baix Camp regions
- Age ≥18 years
- Access to the internet and compatible devices to complete the online training

The exclusion criteria were as follows:

- Presence of a language barrier (limited or no comprehension of Catalan)
- Presence of any disability preventing participation in the course and/or performance of CPR and AED procedures
- Anticipated inability to attend simulation sessions for evaluation

Prior CPR-AED training was not considered as an exclusion criterion.

## Description of Intervention

The intervention consisted of an online training program based on the European Resuscitation Council (ERC) guidelines, as described in detail in the study protocol [10,14].

The primary objective of the training was to provide both theoretical and practical knowledge regarding emergency situations and the use of an AED.

Participants interested in enrolling were required to register on a Moodle platform, where all training materials were hosted. The course included interactive modules, audiovisual resources, and assessments to ensure the acquisition of both theoretical and practical competencies.

## Evaluation of Intervention

### *Phase 1: Assessment of Knowledge Acquisition Following Online CPR-AED Training*

To evaluate the effectiveness of the online training program, participants completed 2 standardized knowledge assessments: a pretraining test to establish baseline knowledge and a posttraining test to measure knowledge gained after course completion.

The assessment instrument was developed in accordance with the guidelines of the Canadian Council on Resuscitation and the ERC and consisted of 10 multiple-choice questions. Participants were required to achieve a perfect score (10/10) to pass. An unlimited number of attempts was permitted, and results were categorized dichotomously as pass or fail. Only participants who successfully completed the posttraining assessment were eligible to participate in the subsequent phase of the study.

### *Phase 2: Assessment of Practical Skill Retention Over Time*

Participants who consented to continue in the study were invited to perform a simulated CPR-AED scenario at 2 follow-up intervals: 1 month (short term) and 6 months (medium term) after completing the online training.

During these sessions, participants were exposed to a standardized cardiac arrest scenario requiring the application of CPR and AED skills. Each simulation was independently assessed by 2 trained observers using a structured checklist to assess performance and retention of critical skills. The items evaluated in the checklist were (1) safe approach, (2) check response, (3) open the airway, (4) check for spontaneous breathing, (5) request external assistance, (6) ventilation-compressions ratio, (7) quality of chest compressions, (8) patch placement, (9) AED use, and (10) immediate compressions. At the end of the simulation, the participants were informed of the mistakes they made and, when applicable, how they should have proceeded.

## Outcome Measures

### *Effectiveness of Online Training on CPR-AED Knowledge*

The primary outcome measure of effectiveness was the difference in scores between the pretraining assessment and the first attempt of the posttraining assessment at the end of the course. Secondary variables included the number of attempts required to achieve a perfect score and the score obtained on the first posttraining attempt.

### *Effectiveness of Online Training on CPR-AED Performance in a Simulated Environment*

In phase 2, the primary outcome was the performance score obtained during the in-person simulation. Success in the simulation was defined as the correct execution of at least 8 of

XSL•FO
RenderX

10 key actions listed on a standardized evaluation checklist [15,16].

To evaluate the effectiveness of the training in the simulation, the necessary sample size was calculated using the statistical software GRANMO (version 7.11) using the option of averages observed with respect to a reference sample. Accepting an α risk of .05 and a β risk of .2 for a bilateral contrast, 52 participants were needed to detect a difference of ≥0.5 points in the face-to-face evaluation of the online training, assuming a common SD of 1.07. The number of participants was increased by 30% to compensate for potential losses to follow-up [14].

### Statistical Analyses

A descriptive analysis of the study population was conducted. Quantitative variables following a normal distribution are expressed as mean (SD), whereas nonnormally distributed variables are presented as median (IQR). Normality was assessed using the Kolmogorov-Smirnov test. Categorical variables are reported as frequencies and percentages.

Bivariate analyses were performed to compare pretraining and posttraining quantitative variables using the Student 2-tailed *t* test.

### Ethical Considerations

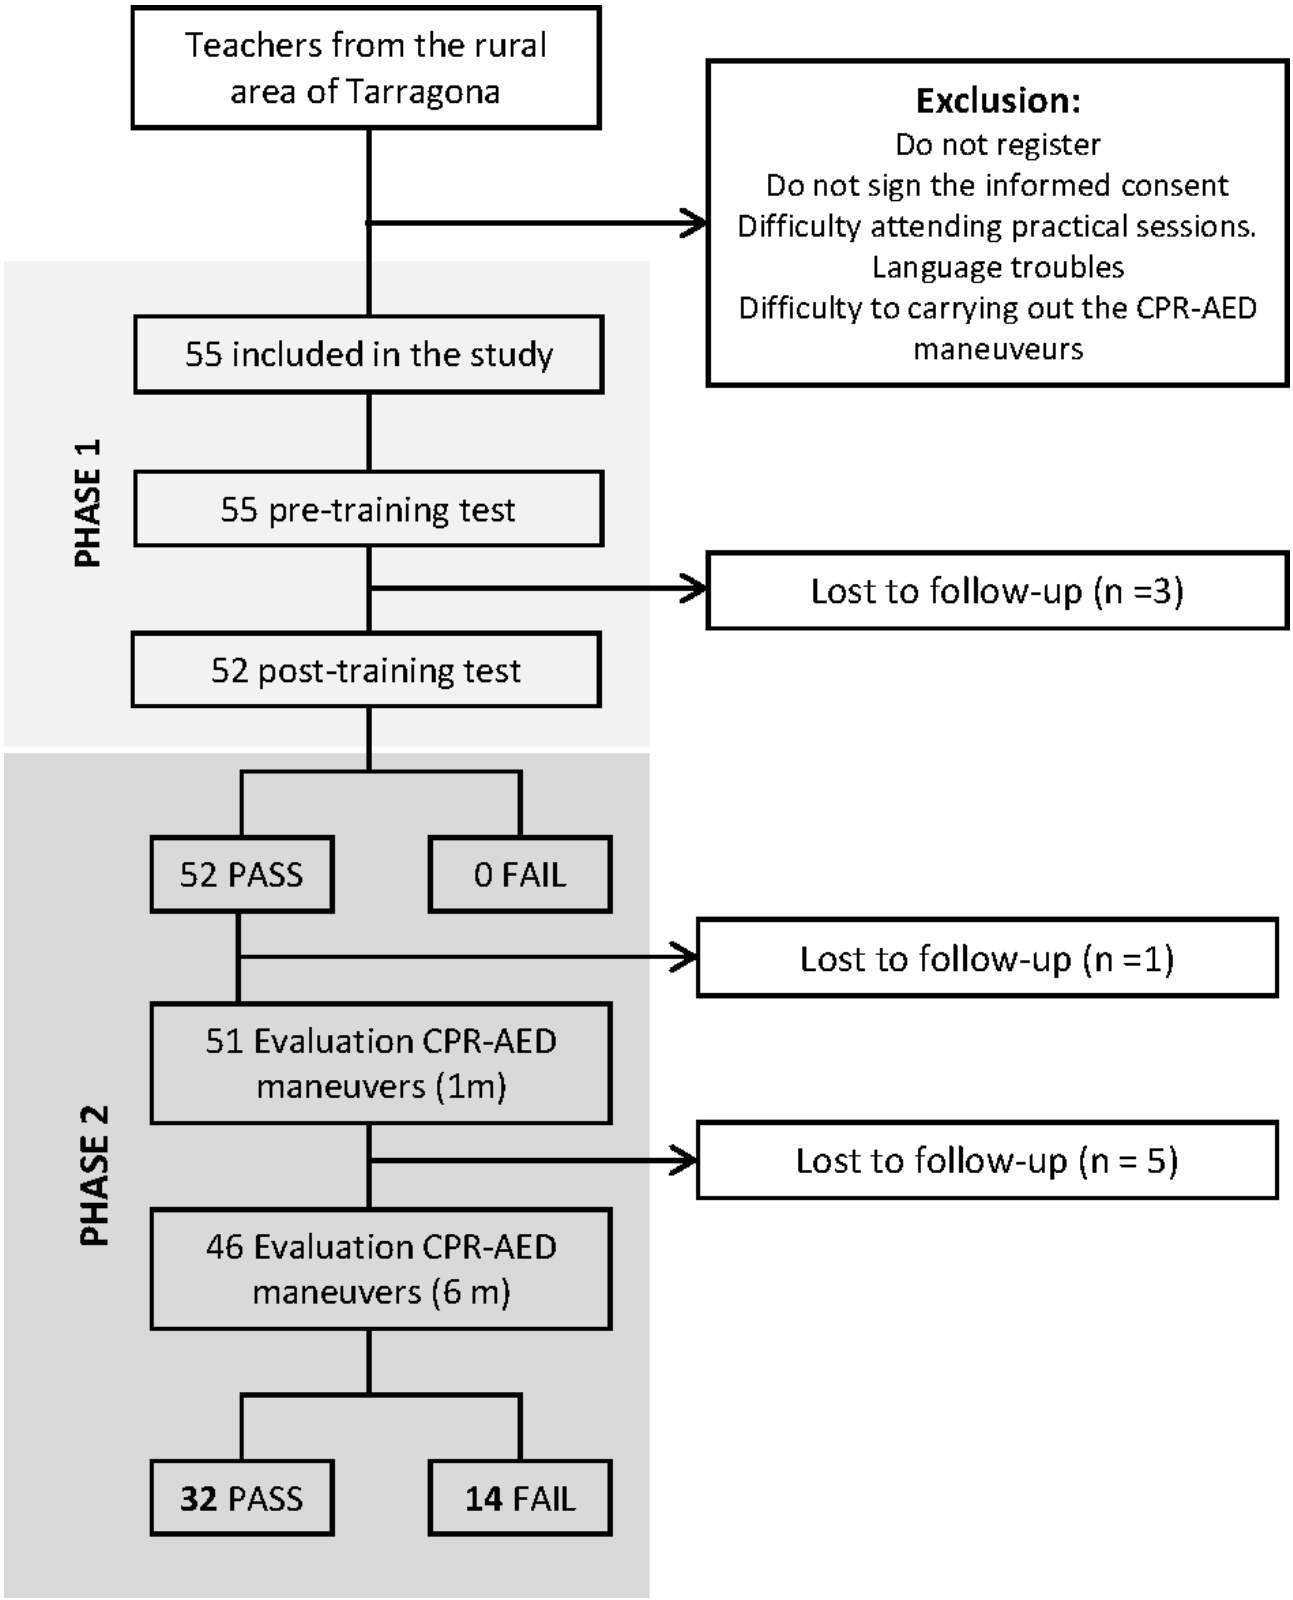
The study was conducted in accordance with the principles of the Declaration of Helsinki and the guidelines of good clinical practice. The protocol was approved by the clinical research ethics committee of the Primary Care Research Institute IDIAP Jordi Gol (23/081-P) on June 15, 2023.

Data confidentiality was ensured in compliance with Spanish legislation on personal data protection (Ley Orgánica 03/2018 of December 5, on the Protection of Personal Data and Guarantee of Digital Rights) [17]. Participants received an information sheet explaining that their participation was voluntary, anonymous, and confidential and that they could withdraw from the study at any time prior to data verification. All participants were given the opportunity to ask questions and receive clarification from the research team before enrollment. Verbal and written informed consent for participation and audio recording were obtained from all participants.

Each participant was assigned a unique identification code upon inclusion. Study data were recorded using a purpose-designed electronic questionnaire and stored on a secure digital platform accessible only through the corporate intranet of the Catalan Health Institute in Tarragona. Access was password-protected and restricted to authorized investigators responsible for data entry. The dataset is not publicly available; however, access may be granted upon reasonable request to the principal investigator and with approval from the IDIAP Jordi Gol Research Ethics Committee.

Participants did not receive any financial compensation for their involvement in the study. Study findings will be disseminated to participating centers and research teams and shared with the scientific community through peer-reviewed publications and conference presentations. Dissemination in nonspecialist settings is also planned.

## Results



### Sociodemographic Characteristics of the Population

In total, 55 participants were included in the study (Figure 1). Of these, 74.5% (n=55) were women, 94.5% (n=55) belonged to the active working population, and 60% (n=33) held a university degree. Slightly more than half (n=32, 58.2%) of the participants had received previous training related to the topic under study. Overall, 7.3% (n=4) had previously witnessed a cardiac arrest; however, none reported knowing how to respond appropriately. Most participants resided in rural areas of the Baix Camp region. The mean age of the participants was 41.5 years. A summary of the main characteristics of the study population is presented in Table 1.

**Table .** Main sociodemographic characteristics of the study population (N=55).

| Variables | Participants, n (%) |
|---|---|
| Sex | |
| Female | 41 (74.5) |
| Male | 13 (23.6) |
| Nonbinary | 1 (1.8) |
| Employment status | |
| Student | 2 (3.6) |
| Unemployed | 1 (1.8) |
| Employed | 52 (94.5) |
| Educational level | |
| University diploma | 33 (60) |
| Bachelor's degree or higher | 17 (30.9) |
| Nonqualified | 1 (1.8) |
| Skilled nonmanual | 3 (5.5) |
| Other | 1 (1.8) |
| Participants with previous training | 32 (58.2) |
| Participants who had witnessed an arrest | 4 (7.3) |
| Participants who did not know how to respond to the arrest | 4 (100) |
| Place of residence: rural | 39 (70.9) |
| Region | |
| Baix Camp | 41 (74.5) |
| Priorat | 6 (10.9) |
| Alt Camp | 2 (3.6) |
| Tarragonès | 5 (9.1) |
| Ribera d'Ebre | 1 (1.8) |

## Phase 1: Evaluation of the Effectiveness of Online Training on CPR-AED Theoretical Knowledge

Of the 55 individuals enrolled in the study, 52 (94.5%) participants completed the online training. The median time required to complete the course was 201.5 minutes, with an IQR of 935 minutes.

The median number of pretest attempts was 1 (IQR 0). The mean pretest score was 6.72 (SD 2.06) points out of 10. The median number of posttest attempts was 2 (IQR 1), with a mean posttest score of 7.77 (SD 1.10) points out of 10.

The mean difference between pretraining and posttraining scores was 1.05 (SD 2.06) points, which was statistically significant ($P$=.01). These data are presented in Table 2.

**Table .** Main variables analyzed from the online training.

| Variables | Values |
|---|---|
| Time taken to complete the course (minutes), median (IQR) | 201.5 (935) |
| Number of pretest attempts, median (IQR) | 1 (0) |
| Pretest score (out of 10), mean (SD) | 6.72 (2.06) |
| Number of posttest attempts, median (IQR) | 2 (1) |
| Posttest score (out of 10), mean (SD) | 7.77 (1.10) |

### Phase 2: Evaluation of the Effectiveness of Online Training on CPR-AED Skills Through Simulation-Based Assessment

Of the 52 participants who completed the online training, 51 (98.1%) took part in the first practical simulation, which was carried out 1 month after the theoretical training. The average score obtained in this first simulation was 7.5 out of 10.

Six months after the theoretical training, 46 participants completed a second simulation. Among them, 42 achieved a passing score—defined as ≥8 points—representing 91.3% of those who participated in this second practical test. The average score was 9.0 out of 10. In contrast, 4 (8.7%) participants did not reach the minimum score to be considered competent, scoring ≤7 points.

A statistically significant improvement was observed between the first and final simulation scores, with a mean difference of 1.31 points (SD 2.05; $P<.001$), indicating a positive evolution in performance over time. Additionally, a paired-samples analysis comparing the scores from both simulations showed a significant increase in the second attempt, with an average difference of 0.89 points ($P=.01$), further supporting the sustained effect of the training over 6 months. The main results obtained in the simulation phases are shown in Table 3.

**Table .** Main results obtained in the simulation phases.

| Simulation phases | First simulation (n=51), n (%) | Second simulation (n=46), n (%) |
|---|---|---|
| Safe approach | 36 (70.6) | 32 (69.6) |
| Check response | 41 (80.4) | 37 (80.4) |
| Open the airway | 19 (37.2) | 17 (37) |
| Check for spontaneous breathing | 42 (82.4) | 38 (82.6) |
| Request external assistance | 31 (60.8) | 33 (71.7) |
| Compressions-breathing relation | 41 (80.4) | 37 (80.4) |
| Quality of chest compressions | 31 (60.8) | 30 (65.2) |
| Patch placement | 41 (80.4) | 37 (80.4) |
| Automated external defibrillator use | 40 (78.4) | 36 (78.3) |
| Immediate compressions | 44 (86.3) | 39 (84.8) |

An analysis of different variables revealed that, in the first simulation, there were no significant differences in scores based on participants' gender, place of residence (rural or urban), prior experience witnessing a cardiac arrest, or having received previous CPR or AED training. These factors did not appear to influence initial practical performance. However, in the second simulation, a significant association was found between having previous training and achieving a passing score ($P=.004$), suggesting that prior exposure to resuscitation concepts may enhance long-term skill retention. No significant differences were observed in the second simulation based on sex, place of residence, or previous experience witnessing a cardiac arrest. The differences in simulation scores according to participant characteristics are presented in Table 4.

**Table .** Differences between the punctuation of the simulation according to different variables.

| Variables | First simulation, n (%) | | | Second simulation, n (%) | | |
|---|---|---|---|---|---|---|
| | Pass | Fail | *P* value | Pass | Fail | *P* value |
| Gender | | | .58 | | | .21 |
| Woman | 17 (51.5) | 16 (48.5) | | 24 (75) | 8 (25) | |
| Man | 6 (50) | 6 (50) | | 8 (61.5) | 5 (38.5) | |
| Nonbinary | 0 (0) | 1 (100) | | 0 (0) | 1 (100) | |
| Participants with previous training | 14 (58.3) | 10 (41.7) | .24 | 22 (8.5) | 5 (18.5) | .04 |
| Participants who had witnessed an arrest | 1 (25) | 3 (75) | .29 | 3 (75) | 1 (25) | .81 |
| Place of residence: rural | 18 (52.9) | 16 (47.1) | .47 | 23 (67.6) | 11 (32.4) | .63 |

## Discussion

This community-based study evaluated changes in theoretical knowledge and simulated CPR-AED performance following completion of an online training program supplemented with in-person simulation among lay participants—primarily primary and secondary schoolteachers—from rural areas in southern Catalonia.

Consistent with the study objectives, participants demonstrated significant improvements in posttraining knowledge scores and simulation performance compared with baseline. These findings suggest that a digitally delivered CPR-AED curriculum, when paired with structured hands-on practice, may enhance preparedness among non–health care professionals in geographically dispersed settings.

Out of the 55 individuals initially recruited, 52 completed the posttraining evaluation. Median knowledge scores increased from 6.72 (IQR 6-8.57) to 7.77 (IQR 7-8.67 out of 10), and participants required fewer attempts to complete the theoretical assessment, suggesting improved mastery of key resuscitation concepts. In addition, the improvement observed between the 2 simulated scenarios indicates retention of procedural skills, which is particularly relevant given that simulation assessments focused on core elements of basic life support and AED use. Although participants could repeat the test, the observed reductions in errors and increased procedural accuracy may reflect learning through feedback and iterative practice.

Unlike many community courses that focus solely on hands-only CPR, this program provided comprehensive basic life support training, including AED deployment. The online format offered logistical advantages and the potential to reach a broad audience, particularly in rural areas where access to face-to-face instruction is often limited.

All simulations were conducted individually at the participants' workplaces using manikins and standardized cardiac arrest scenarios under supervision by certified instructors and observers, following the Catalan Council of Resuscitation guidelines derived from the ERC. The observed gains are consistent with prior studies demonstrating the feasibility and educational value of virtual or blended CPR instruction for lay populations [18-20].

However, the characteristics of the study sample warrant cautious interpretation. Approximately 70% of participants were women, 60% held a university degree, and approximately 30% resided in urban areas while working in rural schools. These demographic features may limit generalizability to the broader rural population and suggest that participants may have been more motivated or educationally advantaged than the general community.

Several limitations should be considered. First, the quasi-experimental pre-post design without a control group precludes causal inference regarding the effectiveness of the intervention. Second, although simulation-based assessments provide standardized and objective measures of performance, they may not fully reflect behavior during real-life cardiac arrest events.

Technical barriers also affected implementation, as internet connectivity was inconsistent in some rural locations, potentially limiting access to the online materials. Additionally, some substitute teachers who participated in the first simulation were unable to complete follow-up assessments because they were no longer employed at the same schools, resulting in attrition between testing phases.

Finally, the demographic composition of the sample and partial inclusion of participants residing in urban settings restrict external validity and should be taken into account when extrapolating these findings to other rural contexts.

This study suggests that online CPR-AED training supplemented by workplace-based simulation may represent a scalable approach to improving resuscitation preparedness among laypeople in rural communities. Beyond immediate educational gains, such programs have the potential to strengthen community emergency response capacity by establishing local networks of trained individuals, particularly in school environments where teachers can serve both as first responders and multipliers of knowledge.

Participants' recommendations to integrate CPR education into primary and secondary school curricula, provide regular refresher training, and improve community awareness of public-access AEDs align with international calls for school-based resuscitation education as a cornerstone of population-wide preparedness. Therefore, future public health strategies should consider incorporating accessible digital training platforms alongside broader AED deployment to reduce disparities in OHCA outcomes, particularly in underserved rural areas.

Further research using controlled designs, longer follow-up periods, and more representative rural samples is needed to determine whether observed improvements in knowledge and simulated performance translate into sustained behavioral change and improved real-world clinical outcomes.

## Abstract

**Background:** Although motorcycle-based food delivery workers face a significant risk of accidents, previous research has primarily focused on traffic accidents, neglecting the multidimensional nature of safety, which includes perceived accident risk, near-miss experiences, and accident-related anxiety.

**Objective:** This study addresses this gap by investigating how occupational fatigue and health behaviors are associated with the Traffic Accident Risk Index (TARI) and its subdomains (near-miss experiences, self-rated accident anxiety, and other-rated accident anxiety).

**Methods:** A cross-sectional study was conducted. Data were collected from South Korean delivery workers via an online survey and analyzed using multiple linear regression.

**Results:** In total, 336 workers were included in the analysis. Occupational fatigue was positively associated with the overall risk index (*B*=0.017, 95% CI 0.012 to 0.021; *P*<.001) and all subdomains, including near-miss experiences (*B*=0.016, 95% CI 0.011 to 0.021; *P*<.001), other-rated accident anxiety (*B*=0.019, 95% CI 0.013 to 0.024; *P*<.001), and self-rated accident anxiety (*B*=0.016, 95% CI 0.011 to 0.021; *P*<.001). Inconsistent helmet use was associated with a higher TARI (*B*=0.413, 95% CI 0.030 to 0.796; *P*=.04), other-rated accident anxiety (*B*=0.495, 95% CI 0.025 to 0.966; *P*=.04), and self-rated accident anxiety (*B*=0.493, 95% CI 0.036 to 0.949; *P*=.04). Insufficient physical activity was associated with a higher TARI (*B*=0.368, 95% CI 0.016 to 0.719; *P*=.04) and self-rated accident anxiety (*B*=0.586, 95% CI 0.168 to 1.005; *P*=.006). Current smoking was associated with near-miss experiences (*B*=0.298, 95% CI 0.041 to 0.555; *P*=.02). Conversely, shorter break times were associated with lower accident risk (30 min to 1 h: *B*=−0.329, 95% CI −0.650 to −0.007; *P*=.045) and near-miss experiences (<30 min: *B*=−0.474, 95% CI −0.936 to −0.011; *P*=.045; 30 min to 1 h: *B*=−0.470, 95% CI −0.846 to −0.095; *P*=.01) than breaks exceeding 2 hours.

**Conclusions:** Occupational fatigue was associated with a higher overall perceived accident risk, more near-miss experiences, and greater accident-related anxiety. Modifiable health behaviors showed additional domain-specific associations. Prevention efforts may benefit from combining fatigue management with strategies to improve helmet use, increase physical activity, and support smoking cessation. Future research should refine the measurement of break time and establish evidence-based rest guidance for motorcycle-based delivery workers.

## Introduction

In recent years, the number of gig workers, defined as individuals who provide labor through digital platforms, has increased significantly worldwide [1]. The rapid expansion of food delivery applications has markedly increased the number of motorcycle-based food delivery workers (MFDWs) [2]. Because MFDWs deliver orders using motorcycles, they are routinely exposed to road hazards and face a disproportionately high risk of traffic accidents when compared with other occupational groups [3]. Furthermore, algorithmic management and piece-rate payment systems often compel MFDWs to operate under intense time pressure, potentially shaping risky riding behaviors and elevating crash risks [4]. Moreover, the concept of rest in the gig economy is often ambiguous; periods labeled as breaks may conflate restorative rest with unpaid

XSL•FO
RenderX

waiting times for algorithmically assigned tasks, potentially hindering effective recovery [5].

Although traffic accidents involving physical injury remain a primary concern [6], safety outcomes in this workforce encompass more than just accidents. Near-miss experiences and accident-related anxiety are critical yet understudied dimensions of traffic safety. Accident-related anxiety reflects not only a psychological response to danger but also a perceived vulnerability to crashes [7]. Accident-related anxiety, when combined with occupational fatigue, a state of exhaustion known to impair cognitive performance and elevate anxiety, may further compromise safety [8]. Importantly, from a preventative perspective, identifying early indicators before actual crash events is crucial for recognizing individuals at high risk of traffic accidents. Measures such as near-miss experiences and accident-related anxiety may provide valuable insight into preaccident risk and support the development of preventive interventions [9]. Therefore, understanding traffic safety requires a multidimensional approach that considers near-miss experiences and anxiety along with actual accidents among MFDWs.

Previous reviews have consistently reported sociodemographic characteristics and behavioral factors as key risk factors for adverse traffic safety outcomes among motorcycle riders. Sociodemographic factors, such as younger age and lower education level, along with behavioral characteristics, including alcohol consumption, smoking, nonhelmet use, and risky driving behaviors, have been consistently associated with traffic crashes and injuries [10,11]. Additionally, occupational status–related factors, such as long working hours and work schedules, are important correlates of traffic safety outcomes, and rider fatigue has been proposed as a significant risk factor [12]. Occupational fatigue has been identified as an important risk factor among motorcycle riders; however, it has rarely been assessed using validated instruments. Moreover, comprehensive analyses that simultaneously consider occupational fatigue, health-related behaviors, occupational status, and sociodemographic characteristics with adequate control for potential confounders remain limited.

Despite a growing literature on gig delivery workers, key gaps remain. Existing evidence has largely relied on crash- or injury-related outcomes, whereas near-miss or traffic-conflict events, widely discussed as proactive surrogate safety indicators, have been less commonly examined in this population [6,13]. Furthermore, the psychological aspects of safety, particularly traffic accident anxiety, have seldom been analyzed in relation to occupational fatigue and health behaviors. Additionally, existing studies lack comprehensive analyses that integrate occupational fatigue measured with validated instruments alongside health-related behaviors, occupational status, and sociodemographic characteristics, while adequately controlling for potential confounders. Addressing these gaps is vital to formulate prevention strategies that transcend regulatory enforcement. Therefore, this study aimed to bridge these limitations by investigating the work- and health-related determinants of traffic safety among MFDWs. Using a multidimensional framework, we assessed 3 distinct domains: Traffic Accident Risk Index (TARI), near-miss experiences, and accident-related anxiety. By integrating these experiential and psychological dimensions, this study aimed to provide comprehensive evidence to help occupational health policymakers improve the safety and well-being of platform delivery workers.

This study aimed to (1) assess the levels of traffic accident risk, including near-miss experiences, other-rated accident anxiety, self-rated accident anxiety, and occupational fatigue; (2) describe the demographic characteristics, occupational status, and health behaviors of MFDWs; (3) investigate the relationship between TARI and occupational fatigue; and (4) identify factors associated with TARI and its 3 subdomains among MFDWs.

## Methods

### Study Design

A cross-sectional descriptive study design was used. This study was reported in accordance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines (Checklist 1).

### Participants

The participants were MFDWs nationwide who were registered with platform-based delivery services and were recruited using convenience sampling. Given the fragmented nature of platform labor and the absence of a centralized registry for gig workers, MFDWs are difficult to reach through probability-based recruitment. Consequently, this sampling strategy was adopted to maximize access to actively working riders in real-world settings. Inclusion criteria were (1) being an adult and (2) having worked as an MFDW for more than 3 months. Individuals who could not understand or communicate in Korean were excluded.

### Data Collection

The participants were recruited between August and October 2023 through offline and online channels. For offline recruitment, the researcher contacted multiple delivery agencies in 2 cities (Asan and Cheonan, Chungcheongnam-do, South Korea) and posted study notices at agencies that agreed to participate. MFDWs who expressed interest were directed to the study information sheet and consent form using QR codes. For online recruitment, a professional survey agency was contracted to distribute study invitations to MFDWs registered on major platform-based delivery services in South Korea. Participants began the survey after confirming their consent online. The study information sheet and informed consent form included details such as the right to withdraw from the study at any time during the study period; guarantees of anonymity; benefits, risks, inconveniences associated with participation; and confidentiality of personal information and records. In total, 336 participants voluntarily submitted consent forms and online survey responses.

### Measures

#### *Demographic Characteristics*

Demographic characteristics were assessed using a questionnaire on age, gender, marital status, education, and socioeconomic status. Educational level was assessed based on the participants'

XSL•FO
RenderX

highest degree and categorized into 3 groups: middle school or below, high school, and college or above. Socioeconomic status was classified as high, moderate, or low.

### *Occupational Status*

Occupational status was assessed using items related to career year, weekly working hours, breaks (including mealtimes), and helmet use. Career year was assessed by identifying the total duration that the participants had worked as professional riders. Break times, including mealtimes, were measured by asking the participants to report their daily break duration: 30 minutes or less, 30 minutes to less than 1 hour, 1 to less than 2 hours, or 2 hours or more. Finally, helmet use was assessed by asking the participants whether they always wear, usually wear, usually do not wear, or never wear. The responses were dichotomized into consistent helmet use (always or usually wear it) and inconsistent helmet use (usually do not wear it or never wear it).

### *Health-Related Characteristics*

The following health-related characteristics were assessed: BMI, smoking status, alcohol problems, physical activity level, sleep duration, and the presence of disease. BMI was calculated from participants' self-reported height and weight by dividing weight (kg) by the square of height ($m^2$). The participants were then classified as underweight (<18.5 $kg/m^2$), normal (18.5 to <23.0 $kg/m^2$), overweight (23.0 to <25.0 $kg/m^2$), or obese (≥25.0 $kg/m^2$). Smoking status was assessed by asking whether the participant currently smoked ("yes" or "no"). Alcohol problems were assessed using the Alcohol Use Disorder Identification Test Concise, which consists of 3 items [14]. The participants were classified as having an alcohol problem if their total score was 6 or higher for males and 5 or higher for females [14]. Physical activity level was measured by asking the participants how many times they exercised per week. Sleep duration was classified into 7 to 9 hours and less than 7 or more than 9 hours based on adult recommendations and increased crash risk among drivers [15,16]. The presence of a disease was determined by asking a physician whether the participant had been diagnosed with any medical condition.

### *Occupational Fatigue*

Fatigue was assessed using the Korean version of the Swedish Occupational Fatigue Inventory [17], originally developed by Ahsberg [18]. It consists of 20 items divided into 5 subscales (lack of energy, physical exertion, physical discomfort, lack of motivation, and sleepiness), each of which is scored on a 7-point Likert scale from 0 ("strongly disagree") to 6 ("strongly agree"). The sum of all the items ranged from 0 to 120 points, with a higher score indicating more severe fatigue. Cronbach α was in the range from 0.81 to 0.92 (lack of energy=0.92, physical exertion=0.87, physical discomfort=0.81, lack of motivation=0.92, and sleepiness=0.89) at development and was 0.95 in this study.

### *Traffic Accident Risk Index*

Developed by Lee and Lee [9] and revised by Song and Lee [19], TARI captures perceived and self-reported dimensions of traffic risk, including near-miss experiences and accident-related anxiety, rather than objective accident incidence. The questionnaire was divided into 3 subdomains: 2 items assessed near-miss experiences as either perpetrators or victims, 2 items assessed other-rated accident anxiety (ie, the perceived likelihood of being involved in an accident as judged by people around the participant), and 2 items assessed self-rated accident anxiety. Each item was measured on a 5-point Likert scale ranging from 1 ("not at all") to 5 ("very much"). The overall score was calculated by averaging the scores of all items (range 1 - 5), with higher scores indicating a higher likelihood of traffic accidents. The score was treated as a continuous variable, and multiple linear regression was applied, as this approach is commonly used and appropriate for composite measures derived from Likert-type items. Cronbach α was 0.87 at development and 0.88 in this study. For the subdomains, Cronbach α values were 0.75 for near-miss experiences, 0.84 for other-rated accident anxiety, and 0.87 for self-rated accident anxiety.

### Data Analysis

Data were analyzed using Stata software (version 18.0; StataCorp LP). The TARI and occupational fatigue levels, along with the participants' demographic characteristics, occupational status, and health-related characteristics, were analyzed using frequencies, percentages, means, and SDs. Correlations between occupational fatigue, TARI, and its domains were analyzed using Pearson correlation coefficient. Multiple regression analyses were conducted separately for TARI and each of its 3 domains to identify associated risk factors. To assess the potential for common method bias, Harman single-factor test was conducted using 26 items from the 2 primary psychological constructs (occupational fatigue and TARI).

### Ethical Considerations

This study was approved by the Institutional Review Board of Soonchunhyang University (202305-SB-065) in accordance with the Declaration of Helsinki. Informed consent was obtained from all participants prior to their participation in the survey. All collected data were anonymized and deidentified to protect participants' privacy and confidentiality. Participants received a coupon worth KRW 10,000 (≈US $7) as a token of appreciation.

## Results

### General Characteristics

General characteristics of the participants are shown in Table 1. Approximately 90.5% (304/336) of the participants were male, with a mean age of 30.78 (SD 6.30) years. Among them, 77.7% (261/336) were single, 16.4% (55/336) had graduated from middle school, and 5.4% (18/336) reported a high socioeconomic status. Regarding occupational status, 9.8% (33/336) had less than 1 year of career experience; 29.2% (98/336) worked less than 40 hours per week; 25.3% (85/336) had breaks of less than 30 minutes, including mealtimes; and 93.2% (313/336) reported consistent helmet use (always or usually wearing a helmet). In terms of health-related characteristics, 47.0% (158/336) had a normal BMI, 36.9% (124/336) were smokers, 26.5% (89/336) reported alcohol problems, 10.4% (35/336) engaged in physical activity almost

every day, the mean sleep duration was 7.79 (SD 1.77) hours, 37.2% (125/336) reported short or long sleep duration, and 14.6% (49/336) reported the presence of disease.

## Traffic Accident Risk and Occupational Fatigue Levels

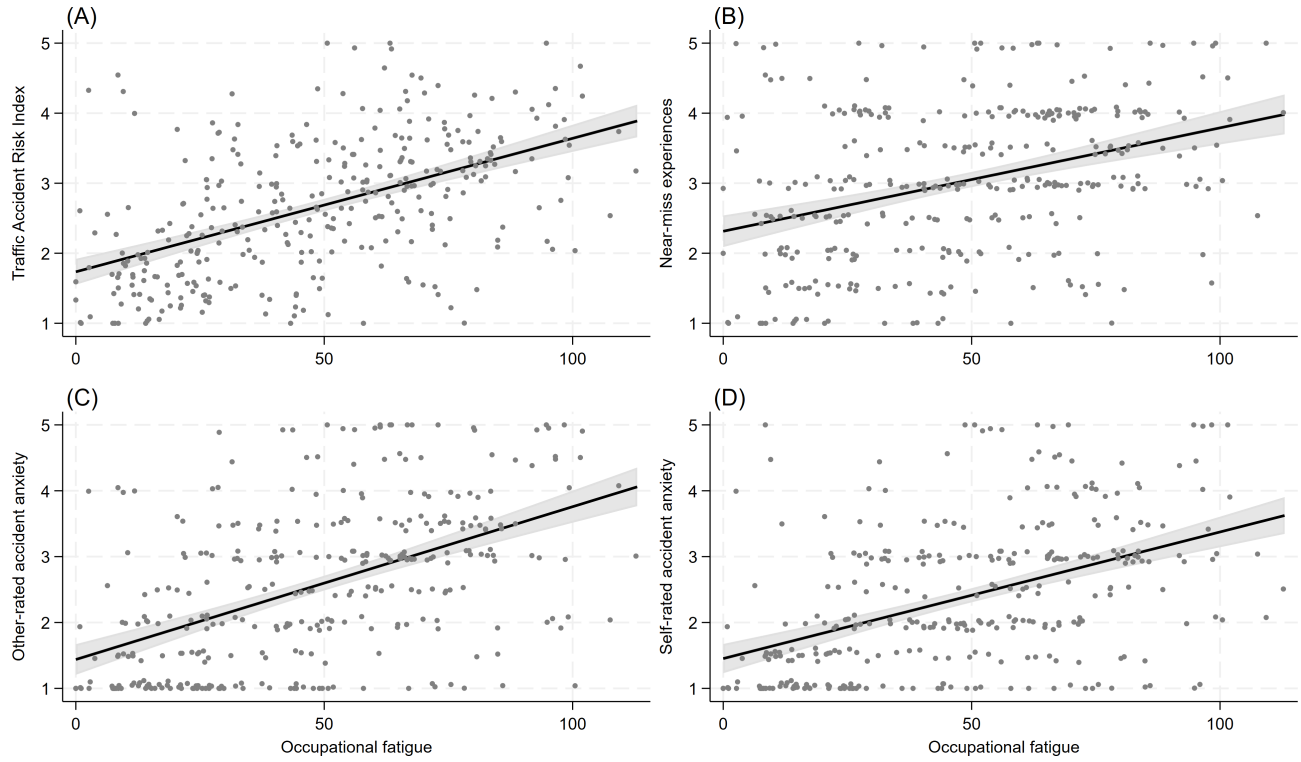
The average TARI score was 2.65 (SD 0.97), with scores ranging from 1 to 5. The means and SDs of the 3 domains of TARI (near-miss experiences, other-rated accident anxiety, and self-rated accident anxiety) were 3.03 (SD 1.08), 2.56 (SD 1.21), and 2.38 (SD 1.11), respectively. The mean total score for occupational fatigue was 48.46 (SD 26.58), with scores ranging from 0 to 113. Table 2 also presents the mean scores for the 5 occupational fatigue subscales.

**Table .** Characteristics of the occupational fatigue and the Traffic Accident Risk Index among motorcycle-based food delivery workers (N=336).

| Variables | Mean (SD; range[a]) |
|---|---|
| Occupational fatigue | 48.46 (26.58; 0-113) |
| Lack of energy | 10.91 (5.93; 0-24) |
| Physical exertion | 7.91 (5.87; 0-20) |
| Physical discomfort | 9.74 (6.15; 0-24) |
| Lack of motivation | 9.01 (5.59; 0-24) |
| Sleepiness | 10.89 (5.85; 0-24) |
| Traffic Accident Risk Index | 2.65 (0.97; 1-5) |
| Near-miss experiences | 3.03 (1.08;1-5) |
| Other-rated accident anxiety | 2.56 (1.21; 1-5) |
| Self-rated accident anxiety | 2.38 (1.11;1-5) |

[a]Minimum-maximum.

Exploratory univariate comparisons suggested that TARI and subdomain scores varied across several demographic,



XSL•FO
RenderX

occupational, and health-related characteristics (Multimedia Appendix 1). These results were used to contextualize and inform the multivariable models.

## Correlation Between Traffic Accident Risk Outcomes and Occupational Fatigue

Occupational fatigue was positively correlated with the overall TARI and its subdomains, including near-miss experiences and accident-related anxiety ($r$=0.36-0.52, all $P$<.001; Figure 1). These unadjusted patterns were consistent with the multivariable models (Table 3). The full correlation matrix is provided in Multimedia Appendix 2.

**Figure 1.** Unadjusted associations between occupational fatigue and traffic accident risk outcomes. Scatterplots show bivariate relationships between occupational fatigue and (A) Traffic Accident Risk Index, (B) near-miss experiences, (C) other-rated accident anxiety, and (D) self-rated accident anxiety. Solid lines indicate fitted values from linear regression, and shaded bands represent 95% CIs. Multivariable-adjusted estimates are reported in Table 3.

## Factors Associated With TARI and the 3 Subdomains Among MFDWs

The results of the multiple linear regression analyses for TARI and its 3 subdomains, including near-miss experiences, other-rated accident anxiety, and self-rated accident anxiety, are presented in Table 3. All 4 regression models were statistically significant, with adjusted $R^2$ values of 29.9%, 21.6%, 29.2%, and 23.5% for the TARI, near-miss experiences, other-rated accident anxiety, and self-rated accident anxiety models, respectively. Multicollinearity was assessed across all regression models, and all variance inflation factors were less than 10, indicating no significant multicollinearity. When TARI was the dependent variable, the statistically significant factors included break time, helmet use, physical activity, and occupational fatigue. Compared with participants with break times of 2 hours or more, those with break times of 30 minutes to 1 hour had lower perceived traffic accident risk (*B*=−0.329, 95% CI −0.650 to −0.007; *P*=.045). Additionally, inconsistent helmet use (*B*=0.413, 95% CI 0.030 to 0.796; *P*=.04), lack of physical activity (*B*=0.368, 95% CI 0.016 to 0.719; *P*=.04), and higher levels of occupational fatigue (*B*=0.017, 95% CI 0.012 to 0.021; *P*<.001) were associated with higher TARI scores.

In the model with near-miss experiences as the dependent variable, the statistically significant factors included break times, smoking, and occupational fatigue. Compared with participants with break times of 2 hours or more, those with break times of less than 30 minutes (*B*=−0.474, 95% CI −0.936 to −0.011; *P*=.045) or between 30 minutes and 1 hour (*B*=−0.470, 95% CI −0.846 to −0.095; *P*=.01) were associated with lower levels of near-miss experiences. Additionally, smoking (*B*=0.298, 95% CI 0.041 to 0.555; *P*=.02) and higher levels of occupational fatigue (*B*=0.016, 95% CI 0.011 to 0.021; *P*<.001) were associated with increased near-miss experiences.

In the model with other-rated accident anxiety as the dependent variable, statistically significant factors included educational level, helmet use, and occupational fatigue. Participants with an educational level of middle school or lower (*B*=0.525, 95% CI 0.036 to 1.014; *P*=.04), compared with those with a college education or higher, those with inconsistent helmet use (*B*=0.495, 95% CI 0.025 to 0.966; *P*=.04), and those with higher

XSL•FO
RenderX

occupational fatigue (*B*=0.019, 95% CI 0.013 to 0.024; *P*<.001) were associated with greater other-rated anxiety about accidents.

Finally, in the model with self-rated accident anxiety as the dependent variable, statistically significant factors included helmet use, physical activity, and occupational fatigue. Participants with inconsistent helmet use (*B*=0.493, 95% CI 0.036 to 0.949; *P*=.04), those who did not engage in physical activity (B=0.586, 95% CI 0.168 to 1.005; *P*=.006) compared with those who exercised almost daily, and those with higher levels of occupational fatigue (*B*=0.016, 95% CI 0.011 to 0.021; *P*<.001) were associated with higher self-rated accident anxiety.

## Discussion

This study contributes to the growing body of literature on MFDWs by adopting a multidimensional view of traffic safety beyond crash-based outcomes. We examined TARI, near-miss experiences, and 2 forms of accident-related anxiety (self-rated and other-rated anxiety). This distinction is meaningful because behavioral precursors to accidents (near-miss experiences) and the psychological dimensions of safety (accident anxiety) may not share identical correlates. By modeling these outcomes separately, our findings offer a more granular understanding of how occupational fatigue and health behaviors are related to safety precursors and perceived vulnerability in platform-based delivery work.

Across all the models, occupational fatigue emerged as the most consistent correlate of adverse safety outcomes. Higher fatigue was associated with a higher overall traffic accident risk, more near-miss experiences, and greater accident-related anxiety. This pattern is broadly consistent with prior evidence indicating that fatigue is linked to degraded cognitive performance and safety-critical decision-making [20,21]. Additionally, fatigue has been associated with reduced situational awareness and slower reaction times, which have been linked to near-miss events and judgment errors in complex traffic environments [22,23]. The consistency of the association across multiple safety domains suggests that fatigue is a salient marker of increased safety risks and psychological strain in MFDWs. Although causal inference was not warranted in this cross-sectional study, the consistency of fatigue associations across all safety domains suggests that fatigue management warrants prioritization in this workforce. At the platform level, immediate steps could include in-app advisory alerts recommending rest after extended delivery periods, as well as the integration of fatigue-related considerations into the delivery system design, followed by rider-facing educational interventions that raise awareness of fatigue-inducing factors and promote monitoring. Looking further ahead, the development of cumulative fatigue monitoring systems integrated into delivery platforms, as well as policy-level requirements for platforms to disclose algorithmic workload indicators to occupational health authorities, should be pursued.

Several modifiable health behaviors were independently associated with specific safety domains, even after adjusting for fatigue and other covariates. The inconsistent use of helmets was associated with a higher overall accident risk and greater levels of self-rated and other-rated accident anxiety, consistent with the evidence that helmet use remains a key protective factor for motorcyclists [10,24]. Insufficient physical activity was associated with higher overall risk and self-rated accident anxiety. This finding aligns with broader evidence linking physical activity to lower anxiety symptoms and improved mental well-being [25] and may plausibly relate to self-regulation or coping capacity relevant to safety, although the underlying mechanisms in this occupational context remain unclear and warrant further investigation. Smoking was specifically associated with higher near-miss experiences, which may reflect distraction-related or broader risk-prone patterns [11,26-28]. Together, these findings provide preliminary evidence supporting a multicomponent view of safety promotion, suggesting that fatigue management may be most effective when considered alongside targeted health-behavior strategies.

The multivariable models explained a significant proportion of the variance in the outcomes (adjusted $R^2$=29.9% for TARI, 21.6% for near-miss experiences, 29.2% for other-rated accident anxiety, and 23.5% for self-rated accident anxiety), suggesting that fatigue and the included behavioral and occupational covariates capture important correlates of multidimensional safety. At the same time, the remaining unexplained variance indicates that additional work- and context-related determinants may also contribute to safety outcomes and should be incorporated in future studies.

We also observed a counterintuitive inverse association between longer self-reported break duration and safety outcomes, with riders reporting breaks of 2 hours or more showing higher accident risk and near-miss experiences. This counterintuitive finding should not be interpreted as evidence that shorter breaks are protective or that reducing rest improves safety among MFDWs. This finding should be regarded as exploratory and hypothesis generating, as alternative explanations cannot be excluded, including reverse causation and potential sensitivity to how break duration was categorized. One plausible hypothesis raised by this study is that the observed pattern may reflect a structural measurement limitation inherent in algorithmically managed delivery. In platform-based food delivery, periods that MFDWs label as “breaks” may frequently coincide with unpaid on-duty waiting time, during which riders remain logged into the app and available for dispatch [5]. If so, those reporting the longest “breaks” may not represent a well-rested MFDW, but rather one with prolonged on-duty availability that sustains cognitive load rather than enabling genuine recovery. Recovery research suggests that the restorative value of rest depends not only on its duration but also on psychological detachment from work demands [29], and such detachment may be structurally difficult to achieve within algorithmically managed gig work. Previous studies further suggested that prolonged idle periods can induce compensatory time pressure once orders resume, which may be associated with riskier riding behavior [4,30]. However, these explanations remain speculative, and this hypothesis requires direct empirical testing in future studies. Future studies should employ more precise measures that distinguish restorative rest from on-duty waiting, ideally complemented by objective indicators such as platform activity logs or ecological momentary assessments.

XSL•FO
RenderX

This study had some limitations. First, its cross-sectional design precluded causal inferences. However, given that MFDWs represent a particularly vulnerable occupational group in which traffic incidents frequently result in serious injuries [3], identifying strong correlates such as occupational fatigue provides critical and immediate evidence for prioritizing interventions, even in the absence of longitudinal confirmation. Second, self-reported measures may have introduced recall or reporting bias. In particular, break times may not clearly distinguish actual rest from idle waiting times. Nevertheless, it is important to note that psychological constructs, such as "accident anxiety" and "near-miss experiences," are inherently subjective. These internal vulnerability states cannot be captured through objective accident records alone, making self-reporting an appropriate and valid assessment method. As the 2 primary psychological constructs, occupational fatigue and TARI, were assessed using a single self-report survey, the possibility of common method bias cannot be fully excluded. To examine this issue, we conducted Harman single-factor test, which showed that the first factor accounted for 45.78% of the total variance, below the commonly used 50% threshold. Third, several important unmeasured variables may limit the interpretation of our findings. Objective exposure indicators such as riding distance, number of deliveries per shift, shift timing, route type, urban traffic exposure, weather conditions, incentive pressure, and platform algorithm demands were not captured. Given that these factors may vary considerably across MFDWs and could independently influence safety outcomes, the findings regarding TARI and its subdomains should be interpreted with caution. Furthermore, residual confounding cannot be ruled out, as health behaviors such as smoking and physical inactivity may partly reflect unmeasured risk-prone tendencies, and unmeasured work-context factors may have contributed to the observed associations. Finally, because convenience sampling was employed, the findings should be generalized with caution. In particular, South Korea's food delivery market is characterized by a predominance of algorithmic dispatch systems, peak-hour demand concentration, and highly developed road infrastructure, which may differ substantially from delivery contexts in other countries [31,32]. Therefore, findings should be interpreted with caution when applied to other national settings. Consequently, future studies should use longitudinal designs and more precise measurements of rest and workload, along with objective exposure indicators, to validate these findings. Real-time approaches, such as ecological momentary assessments and complementary objective indicators, may help clarify temporal relationships and support more actionable guidance on fatigue management and recovery for MFDWs working under algorithmically managed piece-rate conditions.

This study contributes to the literature on MFDWs by conceptualizing traffic safety as a multidimensional construct encompassing accident risk, near-miss experiences, and accident-related anxiety. Occupational fatigue was consistently associated with all the outcomes, suggesting its utility as an important indicator of elevated safety risks and accident-related anxiety. Modifiable health behaviors, including inconsistent helmet use, insufficient physical activity, and smoking, were also associated with specific safety domains, indicating the potential value of considering fatigue management alongside health-behavior approaches. The inverse association observed between longer self-reported break duration and safety outcomes warrants cautious interpretation, as break time may partly reflect on-duty waiting rather than restorative rest. Future studies using longitudinal designs and more precise measures of rest and exposure are required to clarify temporality and inform context-sensitive strategies for supporting recovery during platform delivery.

## Acknowledgments

We thank all participants for their time and valuable contributions to this study. No generative artificial intelligence tools were used in the preparation of this manuscript.

## Funding

This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korean Government (MSIT; RS-2023-00211574) and the Soonchunhyang University Research Fund. The funder was not involved in the study design, data collection, analysis, interpretation, or writing of the manuscript.

## Abstract

**Background:** Hand, foot, and mouth disease (HFMD), a common childhood illness caused by various enteroviruses, poses a significant public health threat in the Asia-Pacific region, where severe cases associated with enterovirus A71 (EV71) are a major concern. The EV71 vaccination program was introduced in China in late 2016. Although randomized controlled trials have established the robust efficacy and safety of these vaccines, assessing their real-world performance remains crucial. Subsequent studies have evaluated its real-world effectiveness in several provinces, including Zhejiang and Guangdong. However, evidence on its real-world impact in reducing EV71-associated HFMD in Jiangsu Province remains limited.

**Objective:** This study aimed to describe HFMD epidemiological characteristics and to evaluate the population-level effectiveness of the EV71 vaccination program in Jiangsu Province.

**Methods:** We characterized the temporal distribution of EV71-related HFMD cases based on longitudinal surveillance data collected through the National Notifiable Diseases Surveillance System in Jiangsu Province from 2012 to 2019 and assessed the impact of vaccination using a Bayesian structural time series model under a counterfactual framework. The intervention effect of the EV71 vaccine was estimated by comparing the observed data with predictions from a counterfactual model scenario without vaccination.

**Results:** A total of 932,274 HFMD cases were reported in Jiangsu from 2012 to 2019, including 5190 (0.56%) severe cases. An estimated 140,876 (15.11%) cases were attributed to EV71. EV71-associated HFMD cases showed a marked decline, with estimated numbers of 22,303, 9796, and 3900 in 2017, 2018, and 2019, respectively. We estimated that 30,117 EV71 cases (95% credible interval −1777 to 93,601) were prevented by the vaccination program from 2017 to 2019, corresponding to a reduction of 45.55% (95% credible interval −5.19% to 72.22%). The effectiveness of vaccination increased annually, with reductions of −1.03% (95% credible interval −94.85% to 48.29%) in 2017, 55.54% (95% credible interval 13.94%-77.56%) in 2018, and 82.28% (95% credible interval 65.77%-90.89%) in 2019. Furthermore, we observed that children younger than 4 years obtained greater benefits compared with those older than 4 years, with the greatest reduction of 57.68% (95% credible interval 13.04%-79.65%) in the 3- to 4-year age group, followed by a 48.09% (95% credible interval 28.00%-62.98%) reduction in the 0- to 2-year age group. In contrast, the reduction was markedly lower, at 16.75 % (95% credible interval −96.53% to 65.47%) in children older than 4 years during the 2017 to 2019 period.

**Conclusions:** EV71 vaccination is an effective measure to prevent HFMD. The sharp decline in EV71-associated HFMD cases following the implementation of the EV71 vaccination program suggests a potential causal relationship. Therefore, strengthening vaccine coverage remains a public health priority.

## Introduction

Hand, foot, and mouth disease (HFMD) is a highly contagious viral illness that is endemic to China and poses a significant public health burden, particularly among children younger than 5 years [1]. Surveillance data from the Chinese Center for Disease Control and Prevention identified 7,200,092 HFMD cases from 2008 to 2012, resulting in 2457 deaths [2]. HFMD can be caused by various enteroviruses, such as enterovirus A71 (EV71) and coxsackieviruses, including serotypes A16, A6, A10, B1, B2, and others. Among the various enteroviruses responsible for HFMD, EV71 has been identified as a major pathogen associated with severe and fatal cases [3]. Its neurotropic nature allows it to cross the blood-brain barrier, potentially causing serious neurological complications, such as poliomyelitis-like paralysis, encephalitis, and fatal cardiopulmonary failure in young children [4,5]. Moreover, EV71 is highly contagious and can be transmitted directly via respiratory droplets, saliva, or the fecal-oral route [6], as well as indirectly through fomites on various surfaces such as metal, plastic, and paper [7].

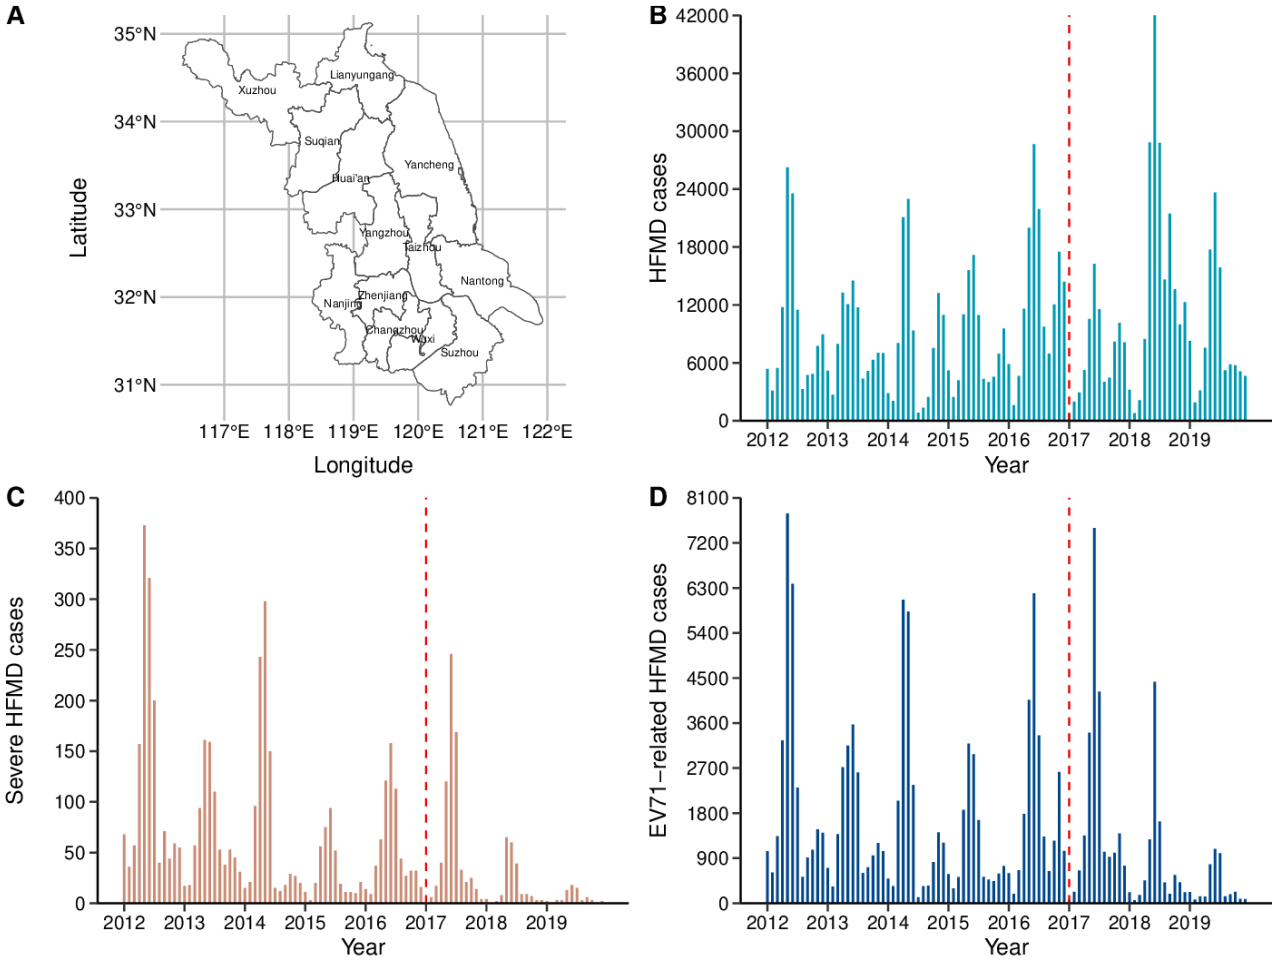
Epidemiological surveillance data have highlighted the substantial disease burden caused by EV71. In 2016, EV71 was estimated to be responsible for approximately 70% of severe HFMD cases and more than 90% of HFMD-associated deaths in China [8,9]. In response to this threat, several inactivated EV71 vaccines were developed by Chinese pharmaceutical companies and were granted regulatory approval in 2015 for use in preventing EV71-related HFMD [10-13]. The national EV71 vaccination program was subsequently launched in 2016, with large-scale promotion and mobilization efforts taking place from 2017 onward [14].

While randomized controlled trials [11-13] have demonstrated the high efficacy and safety of these vaccines in controlled clinical settings [15], it is essential to evaluate their performance under real-world conditions. Postmarketing surveillance and population-level evaluations provide critical evidence to guide public health policy and vaccination strategies. A few recent studies have provided encouraging real-world data. For instance, Xiao et al [16] reported a 41.4% (95% credible interval 37.1%-43.7%) reduction in EV71-associated HFMD cases in Guangdong Province between 2017 and 2019 following the introduction of the vaccine. Similarly, Zheng et al [17] observed a 29% (95% credible interval 24%-34%) decline in EV71-related HFMD cases in Zhejiang Province. Additionally, research by Head et al [18] reported a 60% (95% credible interval 41%-72%) reduction in Chengdu City of Sichuan Province between 2017 and 2018. Recently, a nationwide study further estimated that EV71 vaccination was associated with a reduction of approximately 297,946 EV71-related cases during 2017 to 2018, corresponding to an overall decline of nearly 17% [19]. However, the effectiveness of the EV71 vaccination program varies across regions in China, exhibiting considerable spatial heterogeneity that warrants further investigation.

Despite these findings, there remains a paucity of evidence from other key regions in China. Jiangsu Province, located in eastern China, is one of the most densely populated and economically developed provinces in the country, with high mobility and urbanization that could influence disease transmission dynamics [20]. However, the population-level effectiveness of the EV71 vaccination program in Jiangsu has not been thoroughly investigated.

In this study, we aimed to generate population-level evidence on the real-world effectiveness of the EV71 vaccination program in Jiangsu Province. By leveraging high-quality, longitudinal surveillance data and using an advanced Bayesian structural time series (BSTS) model, we sought to quantify the vaccine's impact on EV71-associated HFMD and provide insights to inform future vaccination strategies and public health decision-making in other endemic regions.

## Methods



### Study Population

We conducted this longitudinal observational study in Jiangsu, located in eastern China, which comprises 13 cities, such as Nanjing, Suzhou, and Changzhou (Figure 1A). This study followed the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) checklist (Checklist 1). The study population consisted of children aged 0 to 14 years, totaling approximately 11 million in 2017 [21].

**Figure 1.** The red dotted line denotes the initiation of large-scale promotion and mobilization for vaccination. (A) Study area comprising 13 cities in Jiangsu Province, China; (B) temporal trends in total hand, foot, and mouth disease (HFMD) cases; (C) severe HFMD cases; and (D) enterovirus A71 (EV71)–related HFMD cases.

## Data Collection of HFMD Surveillance Data

We included reported cases of HFMD among children aged 0 to 14 years reported between 2012 and 2019. HFMD is a notifiable infectious disease in China. Clinically diagnosed cases are required to be reported through the National Notifiable Diseases Surveillance System, a nationwide direct network reporting platform. Demographic and diagnostic information for each HFMD case is included in the report. Physicians must complete and submit a case report card within 24 hours of diagnosis. The information on the report card is subsequently reviewed by the Centers for Disease Control and Prevention at the county, municipal, and provincial levels.

Etiological data on HFMD cases from 2012 to 2019 were obtained from the HFMD etiological surveillance system in Jiangsu Province. According to the surveillance protocol, each county-level hospital was required to collect specimens from at least 5 first-time medical visits for HFMD each month; if fewer than 5 cases were reported, specimens from all available cases were collected whenever possible. In the event of an HFMD outbreak, a minimum of 5 specimens were required for pathogen testing. Additionally, all severe and fatal cases were mandatorily sampled.

Specimens were tested for EV71, coxsackievirus A16, and other enteroviruses using polymerase chain reaction for nucleic acid detection. Because not all reported HFMD cases underwent etiological testing, we used a statistical method to estimate the monthly number of EV71-related HFMD cases:

EV71 cases = (number of general HFMD cases × EV71-positive rate among general cases) + number of EV71-positive cases among severe HFMD cases.

General cases were defined as fever accompanied by rashes on the hands, feet, mouth, or buttocks (with some cases presenting without fever), while severe cases were defined as those with neurological involvement or respiratory or circulatory dysfunction.

## Statistical Analysis

Within a counterfactual framework, we used a BSTS model to evaluate the intervention effects of the EV71 vaccination. The BSTS model is a sophisticated state-space model that integrates Bayesian inference to analyze time-series data [22,23]. It decomposes a time series into interpretable components, such as trend, seasonality, and external covariates, while also providing not only point predictions but also credible intervals, making it a versatile tool in epidemiology.

First, we developed BSTS models based on training sets including EV71-induced cases from 2012 to 2016. Under the counterfactual scenario assuming the absence of the EV71

XSL•FO
RenderX

vaccination program, the model was developed to simulate the monthly number of EV71-related cases. The BSTS model was defined as follows:

$$(1)\log(y_t)=Z_t^T\alpha_t+\varepsilon_t$$

$$(2)\alpha_{t+1}=T_t\alpha_t+R_t\eta_t$$

The equation (1) was the observation equation, which related the logarithmically transformed EV71-induced monthly incidence $y_t$ to a vector of latent "state" variables *at*. In our study, the at contained long-term trend (year) and seasonality (12 months each year). The transition equation (2) specifies the dynamics of latent variables as they change over time. Moreover, $\eta_t$ and $\varepsilon_t$ were independently and normally distributed error terms, and Zt, Tt, and Rt were model matrices mixed with known values (0 or 1) and other unknown parameters [24].

The spike-and-slab prior was applied for the optimal variable selection, and the Kalman filter was used for time-series prediction [24]. We used the Markov chain Monte Carlo algorithm with 10,000 iterations to simulate the posterior distribution of predictions, and then, Bayesian model averaging was used to smooth over a large number of potential results. The model fitting goodness was evaluated by root mean square error, mean absolute percentage error, and $R^2$ [25].

Subsequently, we used the fitted model to predict the EV71-associated HFMD cases from 2017 to 2019. The relative difference (RD) between predicted and observed cases in the BSTS model was used to estimate the EV71 vaccination effectiveness. The RD was calculated by subtracting the observed cases from the predicted cases and then dividing by the predicted cases. Additionally, we performed age-stratified analyses to evaluate the effectiveness of EV71 vaccination program among children aged 0 to 2, 3 to 4, and 5 to 14 years.

### Ethical Considerations

The study received ethical exemption approval from the Ethics Committee of Jiangsu Provincial Center for Disease Control and Prevention (SL2025-B031-01), and the requirement for informed consent was waived by the ethics committee. The HFMD surveillance data used in this study were collected as part of legally mandated infectious disease prevention and control activities. These data were obtained from compliant sources and stored securely, and their secondary use fully adhered to ethical standards. All analyses were performed on deidentified datasets, ensuring that no harm or infringement of rights occurred to data providers. Given that the study is beneficial to HFMD prevention and control and presents minimal risk, it meets the criteria for exemption from ethical review.

## Results

### HFMD Cases

This analysis included 932,274 cases of HFMD in Jiangsu during the period from 2012 to 2019, which exhibited seasonal and biannual patterns (Figure 1B). Among the reported cases, 5190 (0.56%) were classified as severe (Figure 1C), and an estimated 140,876 (15.11%) cases were attributed to EV71.

Notably, we observed that the proportion of EV71 cases declined sharply after the vaccine implementation, with estimated case counts of 22,303 in 2017, 9796 in 2018, and 3900 in 2019. For instance, the number of EV71 cases peaked at nearly 8000 in May of 2012, whereas in 2019, it was almost below 1100 (Figure 1D).

### The Fitting Goodness of BSTS Models

On the basis of the training sets, we constructed the BSTS model and fitted the monthly cases from 2012 to 2016 (Multimedia Appendix 1). In summary, we observed that the performance of the model was accurate and robust, with a root mean square error of 0.33, a mean absolute percentage error of 3.46%, and an $R^2$ of 78.76%.

### The Effectiveness of the EV71 Vaccination Program During 2017 to 2019

Overall, during the EV71 vaccination period (2017 to 2019), the observed number of EV71 cases was significantly lower than the number forecasted by the model (Figure 2 and Table 1). We estimated that 30,117 (95% credible interval −1777 to 93,601) EV71 cases were prevented by EV71 vaccination, corresponding to a relative reduction of 45.55% (95% credible interval −5.19% to 72.22%).

**Figure 2.** Monthly trends of predicted counterfactual enterovirus A71 (EV71)–related cases (blue) and observed cases (red) in Jiangsu Province during 2017 to 2019. HFMD: hand, foot, and mouth disease.

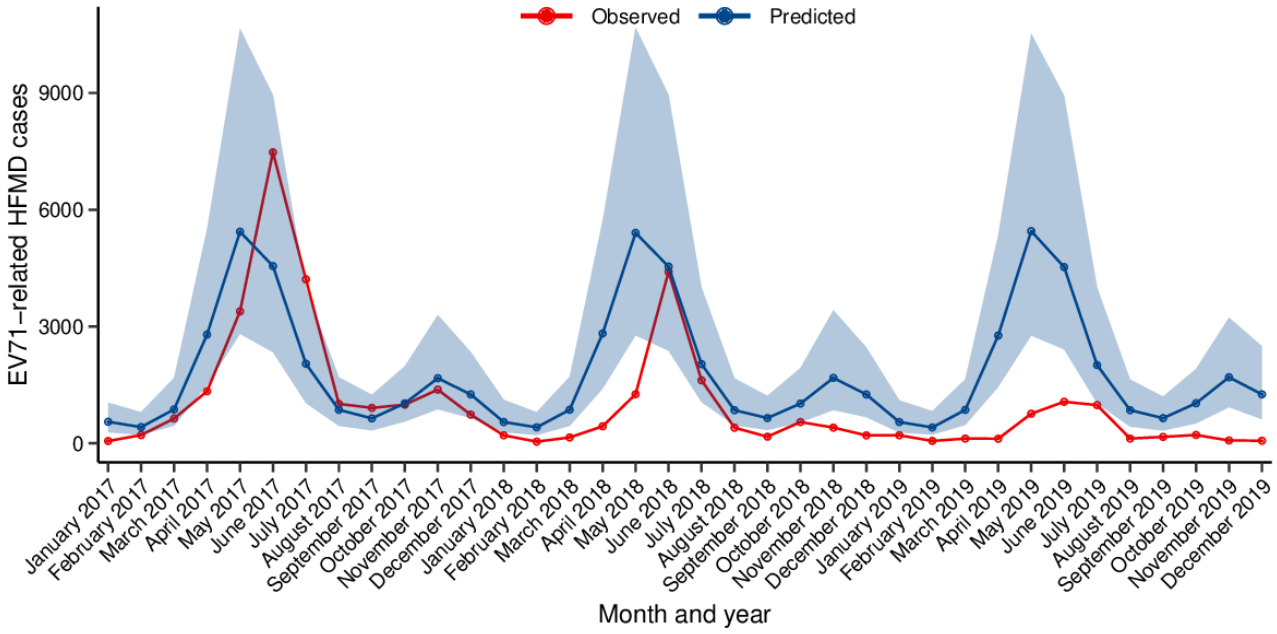

**Table .** The observed, predicted, and prevented enterovirus A71–induced hand, foot, and mouth disease cases and relative reductions among children in Jiangsu Province, 2017 to 2019.

| Year | Observed cases, n | Predicted cases, n (95% credible interval) | Prevented cases[a], n (95% credible interval) | Relative reduction[b] (%; 95% credible interval) |
|---|---|---|---|---|
| 2017 - 2019 | 35,999 | 66,116 (34,222 to 129,600) | 30,117 (−1777 to 93,601) | 45.55 (−5.19 to 72.22) |
| 2017 | 22,303 | 22,077 (11,446 to 43,131) | −226 (−10,857 to 20,828) | −1.03 (−94.85 to 48.29) |
| 2018 | 9796 | 22,032 (11,382 to 43,651) | 12,236 (1586 to 33,855) | 55.54 (13.94 to 77.56) |
| 2019 | 3900 | 22,008 (11,394 to 42,818) | 18,108 (7494 to 38,918) | 82.28 (65.77 to 90.89) |

[a]Prevented cases were calculated as predicted cases under the counterfactual scenario without vaccination minus observed cases.

[b]Relative reduction values were calculated by dividing the number of prevented cases by the number of predicted cases.

Furthermore, the magnitude of the decline exhibited a progressive increase over years. We observed that −226 (95% credible interval −10,857 to 20,828) EV71-infected cases were prevented in 2017, whereas the number of prevented cases increased to 12,236 (95% credible interval 1586-33,855) in 2018 and further to 18,108 (95% credible interval 7494-38,918) in 2019, with the relative reduction of −1.03% (95% credible interval −94.85% to 48.29%), 55.54% (95% credible interval 13.94%-77.56%), and 82.28% (95% credible interval 65.77%-90.89%) for the respective years.

## The Effectiveness of the EV71 Vaccination Program by Age Group

The relative reductions of EV71-related HFMD cases by age group from 2017 to 2019 are shown in Figure 3 and Table 2. Among age subgroups, the RD exhibited an increasing trend over the years, with the highest RD observed in the children aged 3 to 4 years. The relative reduction during 2017 to 2019 was 48.09% (95% credible interval 28.00%-62.98%) for children aged 0 to 2 years, 57.68% (95% credible interval 13.04%-79.65%) for children aged 3 to 4 years, and 16.75% (95% credible interval −96.53% to 65.47%) for children older than 4 years.

**Figure 3.** Monthly trends of predicted counterfactual enterovirus A71 (EV71)–related cases (blue) and observed cases (red) among different age groups in Jiangsu Province during 2017 to 2019. HFMD: hand, foot, and mouth disease. (A) Children aged 0-2 years; (B) children aged 3-4 years; (C) children older than 4 years.

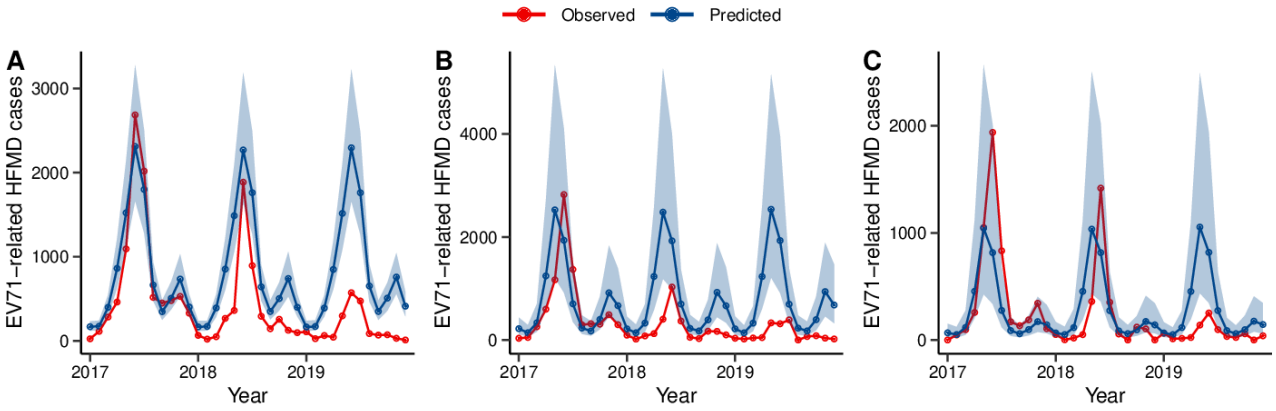

**Table .** Age-stratified relative reduction of enterovirus A71–induced hand, foot, and mouth disease cases among children in Jiangsu Province, 2017 to 2019.

| Age group (years) | Relative reduction in 2017 - 2019, (%; 95% credible interval) | Relative reduction in 2017, (%; 95% credible interval) | Relative reduction in 2018, (%; 95% credible interval) | Relative reduction in 2019 (%; 95% credible interval) |
|---|---|---|---|---|
| 0-2 | 48.09 (28.00 to 62.98) | 9.16 (−25.83 to 35.23) | 54.20 (36.43 to 67.48) | 81.20 (73.91 to 86.53) |
| 3-4 | 57.68 (13.04 to 79.65) | 15.70% (−72.40 to 59.97) | 72.03 (42.94 to 86.55) | 85.44 (69.72 to 92.91) |
| >4 | 16.75 (−96.53 to 65.47) | −52.51 (−260.67 to 7.33) | 24.82 (−76.16 to 69.09) | 77.80 (47.28 to 90.62) |

# Discussion

## Principal Findings

In this study, we used an advanced BSTS model to conduct the first population-based assessment of EV71 vaccine effectiveness using real-world surveillance data from Jiangsu Province, China. Our analysis revealed a stable and consistent seasonal fluctuation in EV71 cases from 2012 to 2016. However, a progressive decline in case numbers over subsequent years was observed from 2017 to 2019. On the basis of a counterfactual analysis framework, we estimated that the EV71 vaccination program led to a 45.55% reduction in EV71-associated HFMD cases. Furthermore, we identified age-related differences in EV71 vaccine effectiveness, with varying levels of protection observed across different age groups. These findings provide robust empirical evidence supporting the real-world effectiveness of the EV71 vaccination program in Jiangsu Province and offer valuable data to inform future public health strategies targeting EV71-related HFMD.

Although EV71 cases declined after vaccine introduction in 2017, the overall HFMD cases showed a temporary increase in 2018. This may be explained by intensified surveillance and reporting efforts following vaccine rollout, as well as the circulation of non-EV71 enterovirus serotypes during that year. Similar postvaccination increases in total HFMD notifications have also been reported in other provinces [16,17,26,27]. Given the geographical proximity and demographic similarities between Jiangsu and Zhejiang Provinces, our findings demonstrate remarkable consistency with the results reported by Zheng et al [17] in Zhejiang, further supporting the robustness of our findings.

However, the protective efficacy observed in our study was lower than that reported in Guangdong Province and particularly in Chengdu City of Sichuan Province, where vaccine effectiveness was estimated to be as high as 60% during 2017 to 2018 [18]. These regional differences may be attributable to variations in age distribution and, more importantly, vaccination coverage rates [17]. For instance, Guangdong Province achieved a median coverage rate of 35.8% in 2019 [16], whereas a study conducted in Chengdu City among children aged 6 to 59 months reported a coverage rate of 54.3% in 2018 [18]. In contrast, Jiangsu Province reported markedly lower vaccination coverage rates. In 2019, vaccination coverage was only 10.6% in Nanjing, the provincial capital, and an estimated 12.7% in Lianyungang [28,29], underscoring the suboptimal vaccination uptake across Jiangsu Province.

Our longitudinal analysis also demonstrated a progressive increase in the relative reduction rate of EV71 cases, which may reflect the incremental improvements in vaccine coverage in Jiangsu Province. For example, in Nanjing, the coverage rate rose from 5.7% in 2017 to 12.6% in 2018, before slightly declining to 10.6% in 2019. Additionally, we found that the vaccine effectiveness was highest among children aged 3 to 4 years, compared with those younger than 3 years or older than 4 years, during the 2017 to 2019 period. This age-specific trend aligns with findings from previous studies, yet it failed to attain statistical significance [17,30]. The superior benefit observed in children aged 3 to 4 years is likely attributable to their more mature immune systems compared with younger children, enabling a stronger and more durable vaccine-induced immune response [31]. In contrast, among children older than 4 years, a substantial proportion may have already acquired natural

XSL•FO
RenderX

immunity through prior EV71 infection, thereby reducing the incremental benefit of vaccination. Additionally, differences in vaccination coverage across age groups may also have contributed to the observed pattern.

Several limitations of this study should be acknowledged. First, our findings may be susceptible to unmeasured confounding factors, such as socioeconomic conditions, differences in vaccination coverage across age groups, or concurrent changes in health care policy. However, the consistency of our results with prior studies, suggesting no substantial unmeasured confounding, strengthens confidence in the robustness of these estimates of EV71 vaccination effectiveness. Second, as an ecological study, we evaluated vaccine effectiveness at the population level and lacked access to individual-level data, which would be necessary to account for potential confounding variables and assess individual-level determinants of vaccine response. Third, although estimates based on EV71-positive rates may involve uncertainty due to incomplete testing, the routine surveillance sampling approach supports their validity. Finally, as with other similar evaluations, our study was limited by the relatively short postvaccination observation period. The wide credible intervals indicate substantial uncertainty in the estimated number of cases prevented. Ongoing long-term surveillance will be essential to fully understand the durability and long-term effectiveness of the EV71 vaccination program.

## Conclusions

Our study provides a robust population-level evaluation of the effect of the EV71 vaccination program in Jiangsu Province during the period of 2017 to 2019. We observed a substantial reduction in EV71-associated HFMD cases following the implementation of the vaccination policy, with the magnitude of the decline increasing progressively in line with improvements in vaccine coverage. Additionally, vaccine effectiveness was notably higher among children aged 3 to 4 years compared with other age groups. These findings provide strong real-world evidence supporting the utility of the EV71 vaccination program in reducing disease burden and offer a scientific basis for optimizing population-level intervention strategies to control EV71-related HFMD.

## Acknowledgments

The authors are grateful to all staff involved in the enterovirus surveillance and monitoring program for their valuable contributions and dedicated work.

## Funding

This work was supported by the National Key Research and Development Program of China (2024YFC2311302 and 2024YFC2310403).

## Abstract

**Background:** In 2023, Esco Bars was the second most commonly reported e-cigarette brand used among US middle and high school student e-cigarette users. These products have not been authorized for sale in the United States by the US Food and Drug Administration (FDA). On May 12, 2025, and May 25, 2023, the FDA issued an import alert and a warning letter, respectively, to the manufacturer requiring them to immediately remove these unauthorized products from the market. On June 22, 2023, and July 27, 2023, the FDA also issued warning letters to US retailers and distributors, respectively, regarding the illicit sale of these unauthorized products. This study evaluated the impact of these advisory and enforcement actions on retail sales of Esco Bars in the United States.

**Objective:** We evaluated the impact of these 2023 FDA advisory and enforcement actions on illicit sales of unauthorized Esco Bars to better inform future regulatory decision-making.

**Methods:** This study used a synthetic control method to evaluate the impact of 2023 FDA advisory and enforcement actions on Esco Bars sales based on weekly sales data from the NielsenIQ Retail Measurement Service between January 1, 2023, and December 30, 2023. Data came from the 48 contiguous states and were not available for internet and vape shop sales. First, we standardized the data by transforming the weekly sales into *z* scores. Second, we created a synthetic comparison for Esco Bars sales based on sales of other e-cigarettes for which the FDA did not take action during the analytical period. Finally, we calculated the difference in sales between Esco Bars and the comparison group before and after the FDA actions. To assess the robustness of the findings, we used other standardization methods for sensitivity analyses.

**Results:** By the last week of 2023, actual Esco Bars' weekly sales were 68.5% lower than the estimated sales in the comparison group ($P$=.02). Over the 5-month period following FDA advisory and enforcement actions, Esco Bars product sales were reduced by approximately 1.7 million equivalized units ($P$=.06). These findings were robust across sensitivity analyses.

**Conclusions:** The FDA's advisory and enforcement actions substantially reduced sales of Esco Bars products in the United States, with a sustained impact noted over a 5-month period. These findings underscore the importance and impact of FDA actions against unauthorized tobacco products as part of a comprehensive regulatory approach.

## Introduction

E-cigarettes have been the most commonly used tobacco product among youth in the United States since 2014, surpassing conventional cigarettes [1]. E-cigarettes can generally have a lower risk than conventional cigarettes and have the potential to benefit adult smokers who transition completely [2]. However, youth uptake and use of these products is problematic, including because e-cigarettes contain nicotine, which is a highly addictive chemical compound. Nicotine exposure can be associated with multiple adverse health consequences, including harming adolescent brain development and priming the brain for addiction to other drugs [3-5].

Youth e-cigarette use prevalence increased rapidly in the early 2010s and peaked in 2019 at nearly 28%, largely driven by flavored cartridge-based systems [6]. Since then, the market landscape has continued to evolve, and flavored disposable

XSL•FO
RenderX

products have become the most popular type of e-cigarettes among youth [7]. According to the 2023 National Youth Tobacco Survey, approximately 60.7% of youth reporting current e-cigarette use used disposable e-cigarettes, and Esco Bars was the second most commonly reported brand used among youth who currently use e-cigarettes [7].

In the United States, tobacco products not on the market prior to 2007, including e-cigarettes, are required to submit a premarket tobacco product application (PMTA) and receive authorization by the US Food and Drug Administration (FDA) before the product can be marketed. The manufacturer of Esco Bars submitted a PMTA. However, in 2022, the FDA issued a refuse to accept (RTA) letter to the manufacturer of Esco Bars, finding that its submitted premarket tobacco product application did not provide sufficient information to permit substantive review per regulatory requirements. Receipt of an RTA letter indicates that a manufacturer does not have authorization to legally market its products in the United States. Nevertheless, the manufacturer continued to produce and sell these products.

As a result of common youth use of Esco Bars, and following the manufacturer's lack of compliance with regulatory review decisions, the FDA took targeted advisory and enforcement actions as a part of a comprehensive approach to reduce youth use of tobacco products [8]. The FDA can issue untitled letters and warning letters as advisory actions to encourage voluntary compliance when responding to illicit tobacco product marketing. Warning letters provide instructions to a company (ie, manufacturer, distributor, or retailer) in violation of FDA regulations, including directions for prompt action to address the violations and a timeline for a response [9]. FDA may also pursue enforcement measures including import alerts, civil money penalties, seizures, and injunctions [10,11]. Import alerts signal that violative products may be detained upon entry into the country [12].

To underscore the FDA's commitment to protecting youth against unauthorized e-cigarettes, the FDA issued an import alert for Esco Bars products on May 12, 2023 [13]. Additionally, the FDA issued a warning letter to the manufacturer of Esco Bars products on May 25, 2023, as the firm had been manufacturing, distributing, and/or importing these unauthorized tobacco products in the United States despite prohibitions stated in the RTA letter [14]. Following these actions, FDA further issued warning letters to retailers and distributors of e-cigarette products on June 22, 2023, and July 27, 2023, respectively [15,16], for selling and/or distributing unauthorized Esco Bars products.

Existing studies have analyzed FDA warning letters on e-cigarettes issued to retailers and manufacturers between 2018 and 2021 by violation type and company characteristic [17,18], including one study that also assessed compliance among online retailers [17]. However, none of these studies have examined the impact of these advisory actions on e-cigarette sales. To our knowledge, this is the first study evaluating the impact of FDA advisory and enforcement actions on illicit tobacco product sales following noncompliance with regulatory review decisions. To address this gap in the scientific literature, this study explores the association between the FDA's targeted advisory and enforcement actions in 2023 and subsequent changes in Esco Bars product sales by the end of 2023.

## Methods

### Overview

#### Data

The FDA's Center for Tobacco Products licenses NielsenIQ Retail Measurement Service (RMS) data, which includes weekly tobacco product sales from 48 contiguous states (not including Hawaii and Alaska). NielsenIQ RMS data come from several sources, including electronic point-of-sale data from stores through product bar code checkout scanners at retailer registers, coding of retail circulars (eg, in-store flyers and advertisements promoting products), and in-store audits (ie, field auditors who capture in-store display information promoting products). NielsenIQ uses proprietary statistical methods to project nationally representative sales of nicotine and tobacco products by universal product code.

#### Unit Sales

The FDA's Center for Tobacco Products receives NielsenIQ tobacco product sales data in both raw and equivalized units. The equivalized unit was created by NielsenIQ to provide a standardized volume measure for products with varying package sizes. Equivalized unit can vary by tobacco product type. For e-cigarettes, 1 equivalized unit is equal to 1 disposable device, prefilled pod, starter kit, or e-liquid bottle. For this study, we used weekly e-cigarette equivalized unit sales from January 1, 2023, to December 30, 2023.

#### Retail Channel

Weekly e-cigarette equivalized sales were assessed by combining two primary NielsenIQ retail channels: (1) convenience stores, which encompass smaller stores with a limited selection of grocery products, including chain, franchise, and independent convenience stores; and (2) Extended All Outlets Combined, which is a combination of food and drug stores plus select mass merchandiser (eg, Target), club store (eg, Sam's Club), military commissary (eg, Army & Air Force Exchange Service), and dollar store (eg, Dollar General) accounts [19].

#### Sample

NielsenIQ reports e-cigarette brands as listed on external product packages. We identified 4 Esco Bars-related sub-brands in NielsenIQ RMS data in 2023, including Esco Bars, Esco Bars Carsonator, Esco Bars Fruitia, and Esco Bars Ripe Collection. According to the data, these 4 sub-brands are produced by the same manufacturer and share the major brand, Esco Bars, in their names. Therefore, we reported all 4 sub-brands as Esco Bars products for the purposes of this study. Following the same approach, we combined other sub-brands that are produced by the same manufacturers and share similar major brand names. Details about these sub- and major brands are available upon request. We included only brands that provided full sales data for the entire study period. In addition, we excluded e-cigarette products that do not contain nicotine, that is, accessories (eg, e-cigarette battery, coils, and carrying cases), as they are not

XSL•FO
RenderX

applicable comparisons for Esco Bars for this study. These excluded products represented very few e-cigarette equivalized unit sales (<0.1%) during the analytical timeframe.

### Study Design

We used the synthetic control method (SCM) to draw inferences about the likelihood that the intervention had a causal effect on Esco Bars' sales. This is similar to a conventional difference-in-difference (DiD) approach, as both methods compare changes over time between a group exposed to the intervention and an unexposed comparison group [20]. Although DiD models have been widely used to assess potential effects of policy interventions, their validity critically relies on the parallel trends assumption (ie, that the treatment and control groups would have changed in the same way over time if the intervention had not occurred, and thus changes during the postintervention period are due to the treatment itself) [21]. DiD was not suitable for this study because all potential comparison e-cigarette brands failed parallel trends tests. Therefore, we used the SCM, which provides a systematic way of creating an appropriate comparison when the parallel trends assumption cannot be met [22].

In this study, the intervention group was Esco Bars, which was subject to FDA advisory and enforcement actions in 2023. The intervention period was between May 14, 2023, and July 29, 2023. Although the FDA first issued an import alert for Esco Bars products on May 12, 2023, we used May 14, 2023, as the first date of intervention because NielsenIQ weekly sales are tracked from Sunday through Saturday. May 12, 2023, was a Friday falling in the week ending May 13, 2023. For the same reason, we chose July 29, 2023, as the last day of the intervention because July 27, 2023, (the date when the FDA took the last advisory action, issuing warning letters to distributors, against Esco Bars product sales in 2023) was a Thursday falling in the week ending on July 29, 2023. We assumed that adjusting the intervention period by one or two days based on NielsenIQ weekly sales would not meaningfully affect our findings.

To be conservative and fully evaluate the combined impact of multiple FDA advisory and enforcement actions together, we defined the postintervention period as 5 months between July 30 and December 30, 2023, and reported our major findings accordingly. In Figure S1 in Multimedia Appendix 1, we present additional estimates, which include the impact of advisory and enforcement actions during the intervention period, starting from May 14, 2023.

The synthetic comparison of Esco Bars was generated from a set of e-cigarettes that did not encounter any FDA advisory and enforcement actions, including import alerts, warning letters, refuse to file letters, RTAs, or marketing denial orders during the analytical period.

Following these criteria, we identified a total of 51 e-cigarette brands for the "donor pool," that is, all brands that were eligible to be part of the comparison, from the 2023 NielsenIQ RMS data. Among these 51 brands, weights for the synthetic comparison were optimized based on their closeness of fit to the actual Esco Bars' sales during the preintervention period, that is, from January 1, 2023, to May 13, 2023. In the main model, the synthetic comparison consisted of a weighted average of 10 selected brands. Details about these brands and their weights are reported in Table S1 in Multimedia Appendix 1.

A proper execution of the SCM requires that variables in the data are rescaled to correct for differences in size between units [23]. Weekly unit sales varied substantially by brand in the final sample, ranging from less than 1000 equivalized units to a little more than 5 million equivalized units each week. To address the issue, following existing studies [24,25], we rescaled weekly equivalized unit sales using a *z* score standardization method. For a given week, we subtracted each brand's preintervention averages from its weekly sales and divided the result by its pre-intervention standard deviation. In this case, a 1-unit change in standardized sales for a given brand is equivalent to a change of 1 preintervention standard deviation. To assess the sensitivity of our findings to the choice of standardization methods, we conducted sensitivity analyses using two alternatives: (1) min-max normalization—subtracting the preintervention minimum and dividing by the preintervention range, and (2) robust rescaling—subtracting the preintervention median and dividing by the preintervention interquartile range. A more detailed methodological approach for each standardization method is provided in Multimedia Appendix 1.

### Statistical Analyses

The application of conventional statistical approaches to assess significance is not available for the SCM approach [22,26]. Therefore, we estimated the *P* value using the concept of the Fisher exact test [27]. First, we calculated differences in sales between Esco Bars and its synthetic comparison during the postintervention period. This difference was calculated as the postintervention mean squared error (MSE). Then we calculated the ratio of the postintervention MSE to the preintervention MSE to determine the relative magnitude of the intervention effect. Second, we constructed synthetic estimates for every comparison brand and calculated intervention effects for each brand. These differences for the comparison brands are false intervention effects because these brands should not have been affected by the intervention (ie, FDA advisory and enforcement actions against illicit sales of Esco Bars). Then, we compared the intervention effect for Esco Bars to the false intervention effects of all 51 brands. Finally, we obtained a *P* value as the share of false intervention effects greater than or equal to the actual intervention effect [28]. If the ratio is sufficiently small, we can reasonably conclude that the intervention effect is unlikely to be a chance result. Technical details of the SCM and Fisher exact test are presented in Multimedia Appendix 1.

All data analyses were independently conducted using Stata version 16.1 (StataCorp LLC), R version 4.3.1 (R Foundation for Statistical Computing), and Python version 3.11.5 (Python Software Foundation) together with Anaconda version 23.10.0 (Anaconda, Inc).

### Ethical Considerations

We used deidentified aggregated retail sales data licensed from NielsenIQ for this study. All sales data were fully anonymized. Therefore, this study did not involve human participants, human

XSL•FO
RenderX

tissue, or identifiable personal data, and ethical approval was not required in accordance with institutional and national guidelines.

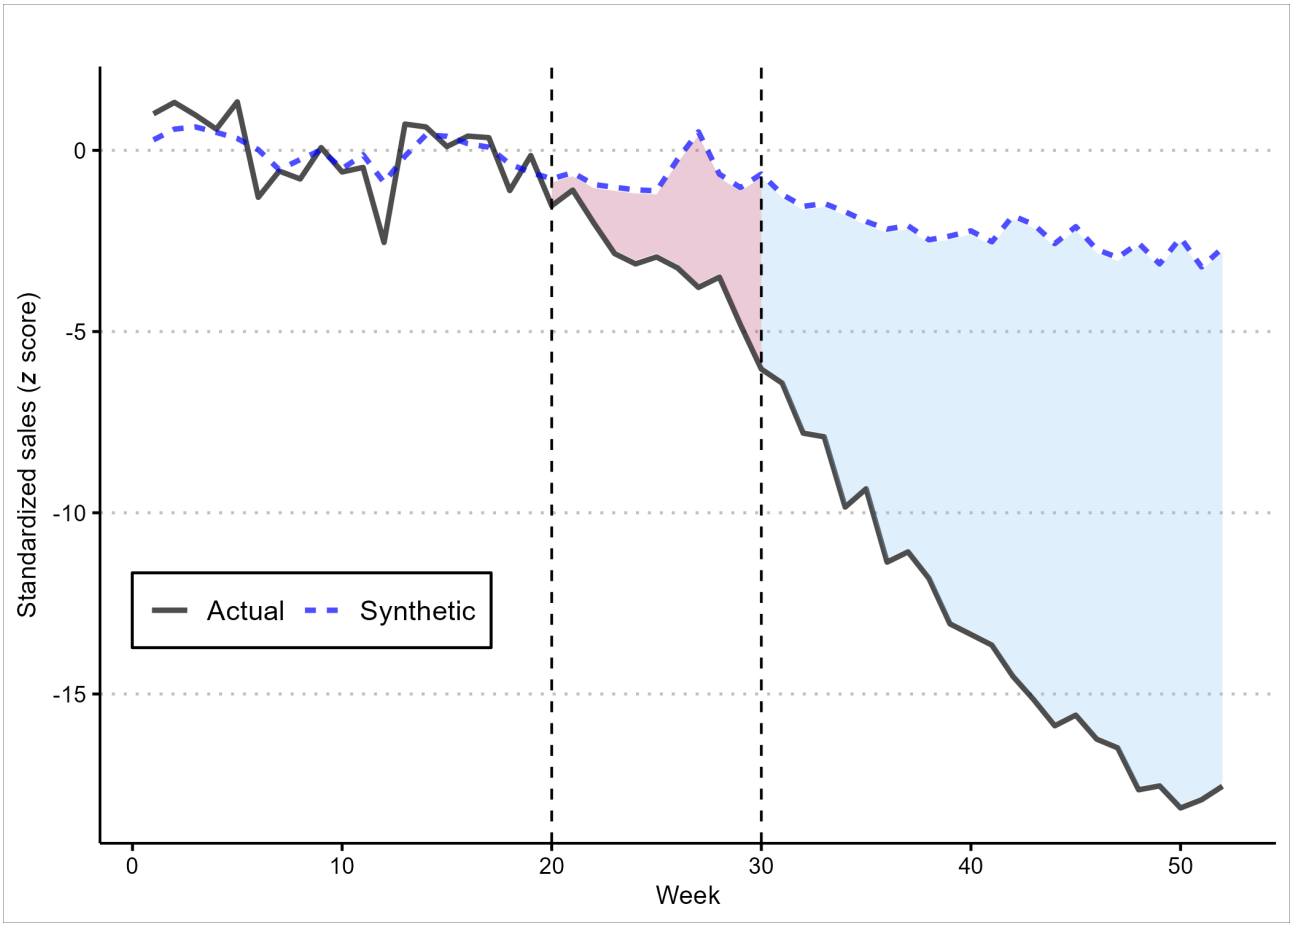
## Results

### Findings

Of the 52 brands in our final sample, including Esco Bars, 67.3% (35/52) of brands represented only disposable e-cigarettes, 1.9% (1/52) represented only prefilled cartridges, and 30.8% (16/52) represented multiple types of e-cigarette products. The average weekly sales were estimated at approximately 114,000 equivalized units per brand (SD 662,000), with the median at 1400 units per week (IQR 10,000). The large difference between the mean and median reflects the disproportionate share of sales captured by the most popular brands in our sample, providing additional supporting evidence for using standardized sales prior to implementing the SCM.

Figure 1 presents weekly standardized unit sales of Esco Bars and the synthetic comparison in 2023. Unit sales of Esco Bars were very close to that of the comparison, 0.03% lower on average, during the preintervention period. The high similarity provides strong evidence for the parallel trends assumption to support the validity of the SCM model. Our findings also show that Esco Bars sales started to decline the week ending May 21, 2023, immediately after the FDA advisory and enforcement actions, while estimated sales of the synthetic comparison remained largely steady compared to the preintervention period, following a similar moderate downward trend throughout 2023. As a result, during the 5-month postintervention period, between the week ending on July 29, 2023, and the week ending on December 30, 2023, total Esco Bars unit sales were 1.7 million units lower than the synthetic comparison, which represented estimated sales in the absence of FDA intervention. Weekly sales of Esco Bars were 68.5% lower than that of the synthetic comparison by the week ending December 30, 2023.

**Figure 1.** Weekly *z* score standardized unit sales of Esco Bars and the synthetic comparison before and after the US Food and Drug Administration (FDA)'s advisory and enforcement actions. Comparison of weekly observed (actual) versus modeled (synthetic) Esco Bars sales in 2023 in *z* score standardized units [2,3]. The red area represents the difference between the standardized actual and synthetic Esco Bars sales during the intervention period, while the blue area represents the same difference for the postintervention period. Week 1 and week 52 correspond to the week ending January 7, 2023, and the week ending December 30, 2023, respectively. Dashed vertical lines denote the first and last weeks during which the specified FDA advisory and enforcement actions occurred: Week 20 corresponds to the week ending on May 20, 2023, denoting the first week after the FDA's import alert for Esco Bars was issued on May 12, 2023. Week 30 corresponds to the week ending on July 29, 2023, denoting the week of the FDA's last advisory action against unauthorized Esco Bars in 2023, warning letters issued to distributors on July 27, 2023.



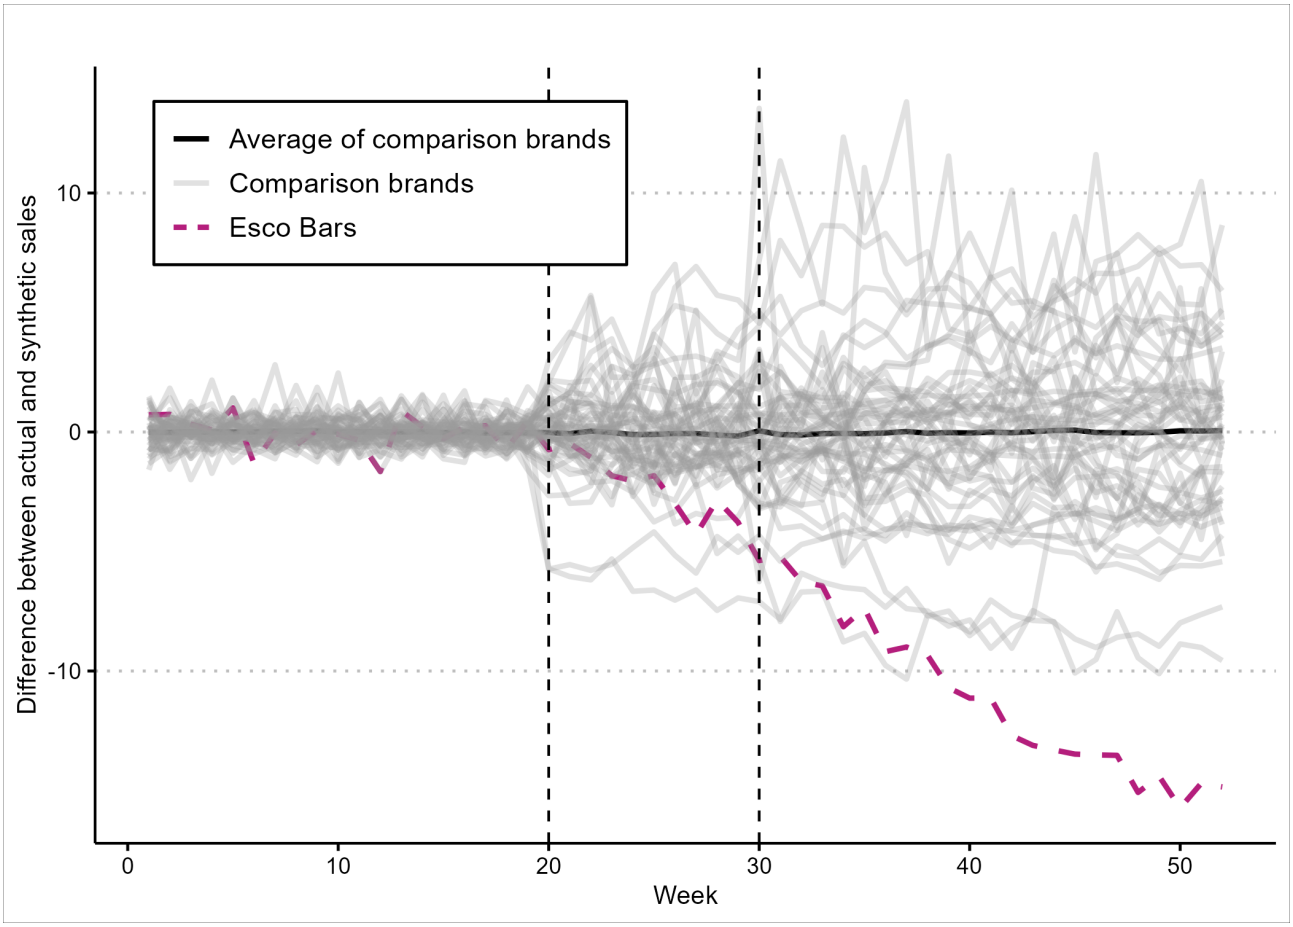


Figure 2 presents the intervention effect of Esco Bars and false intervention effects of all 51 e-cigarette brands in the "donor pool." In all cases, the effects illustrate the difference between weekly sales of a brand and estimated sales from that brand's synthetic comparison. Figures 1 and 2 show that Esco Bars sales started to decline immediately following FDA's first enforcement action, when the import alert for Esco Bars was issued on May 12, 2023. In addition, it also suggests that,

XSL•FO
RenderX

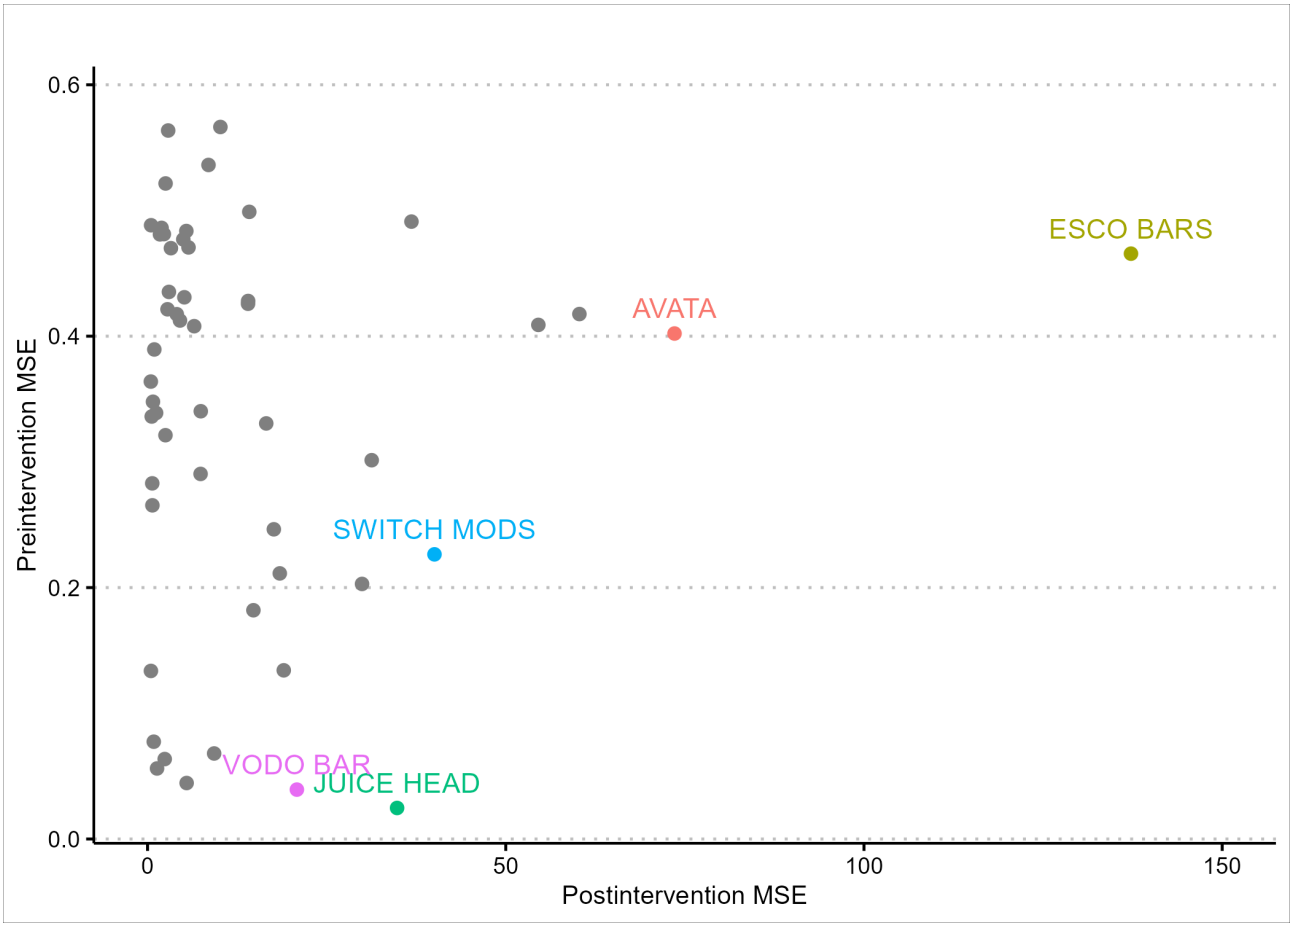
compared to all other brands included in the analysis, Esco Bars had the largest sales reduction during the postintervention period (a decline of 14.8 SDs vs 9.5 SDs from Avata, the brand having the second largest sales decline). The findings in Figure 2 further reinforce the causal connection between FDA advisory and enforcement actions subsequent to noncompliance with regulatory review decisions and Esco Bars sales reductions.

**Figure 2.** Estimated intervention effect: differences between actual weekly sales for an e-cigarette brand and corresponding synthetic sales. Gray and purple lines represent differences between weekly observed sales for a brand and modeled sales estimated using a corresponding synthetic comparison. Week 1 and week 52 correspond to the week ending January 7, 2023, and the week ending December 30, 2023, respectively. Dashed vertical lines denote the first and last weeks during which the specified US Food and Drug Administration (FDA) advisory and enforcement actions occurred. Week 20 corresponds to the week ending on May 20, 2023, denoting the first week after FDA's import alert for Esco Bars was issued on May 12, 2023. Week 30 corresponds to the week ending on July 29, 2023, denoting the week of FDA's last advisory action against unauthorized Esco Bars in 2023, warning letters were issued to distributors on July 27, 2023.

We estimated *P* values based on the concept of the Fisher exact test, which depends on the ranking of the ratio of sales changes between the post- and preintervention periods. Esco Bars were ranked third out of the 52 brands in the analysis and thus had a *P* value of .06 (3/52, 5.8%). Two other brands, Juice Head and Vodo Bar, were ranked higher than Esco Bars based on the Fisher exact tests. We further investigated these 2 brands with higher significance (Figure 3). Among all brands included in this analysis, Esco Bars had the largest postintervention MSE by a substantive margin, indicating that in the postintervention period, Esco Bars sales diverged from its synthetic comparison more than any other e-cigarette brand. However, the MSE ratios for Juice Head and Vodo Bar were ranked higher because they had the lowest MSEs in the preintervention period, indicating their sales diverged from their synthetic comparisons less than any other brand in the period. This context suggests that the higher MSE ratios of Juice Head and Vodo Bar do not preclude our finding that the FDA advisory and enforcement actions had significant impacts on Esco Bars sales during the postintervention period.

XSL•FO
RenderX

**Figure 3.** Investigation of esco bars ranking among all e-cigarette brands. Postintervention mean-squared error (MSE) and preintervention MSE were presented for each e-cigarette brand included in this study. MSE measures how close each brand's actual sales were to modeled sales of the corresponding synthetic comparison. Labels reflect the 5 e-cigarette brands from our sample with the highest ratios of postintervention MSE to preintervention MSE.



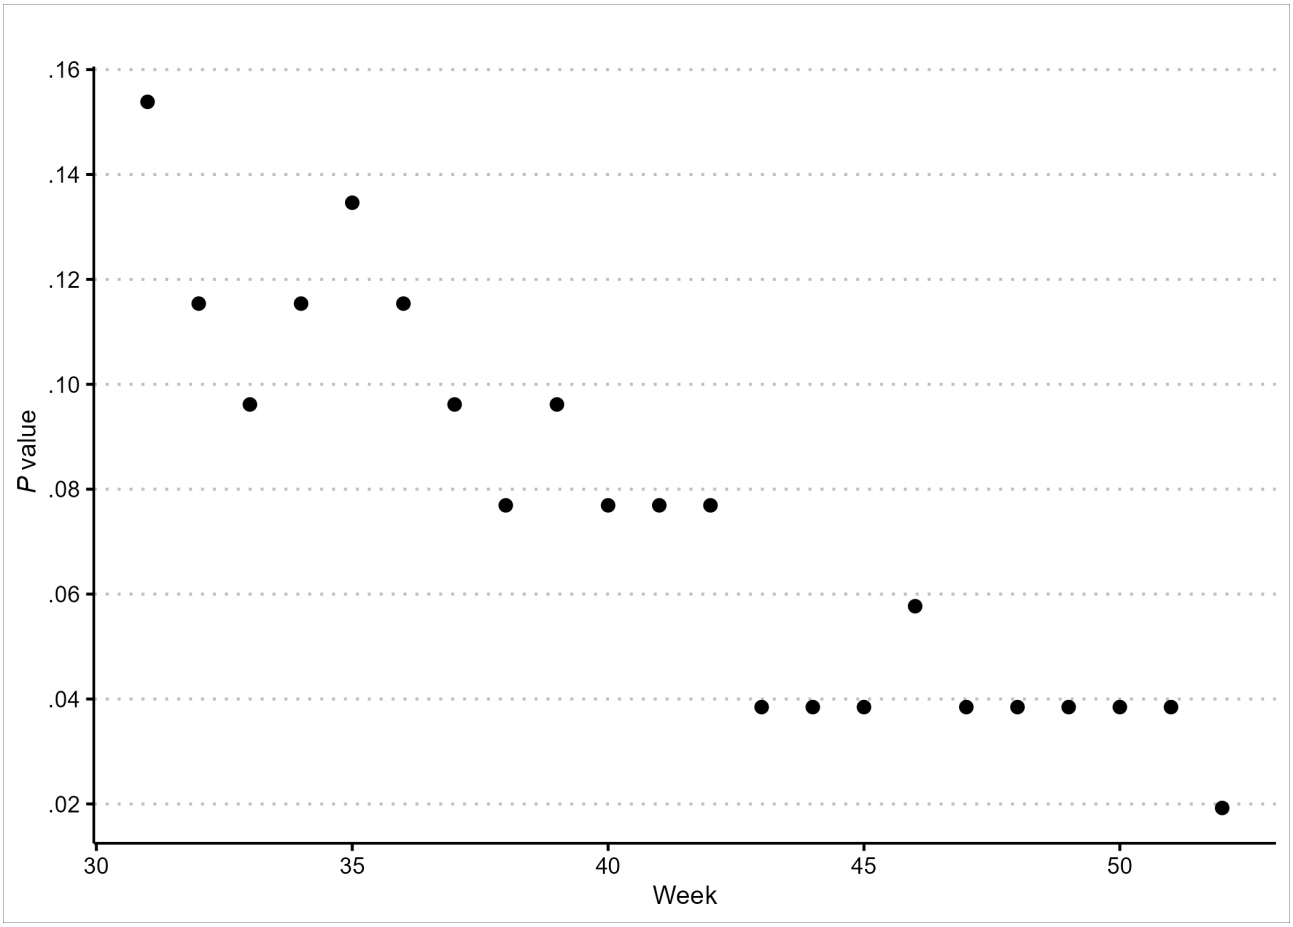


Figure 4 presents *P* values of weekly intervention effects of Esco Bars sales during the postintervention period. In addition to the overall *P* value (.06), week-specific *P* values provide additional evidence on the variations of intervention effects over time. Our findings show that week-specific *P* values decreased rapidly during the postintervention period. The *P* values of the intervention effect immediately after FDA advisory and enforcement actions were .15 (8/52, 15.3%) on the week ending on May 21, 2023, and .02 (1/52, 2%) on the week ending on December 30, 2023. By the 17th week after FDA advisory and enforcement actions, the intervention effect for Esco Bars was statistically significant based on the conventional threshold ($P<.05$). This indicates that these FDA actions were associated with a reduction in Esco Bars sales.

XSL•FO
RenderX

**Figure 4.** Week-specific *P* values for intervention effect on Esco Bars during the postintervention period. This figure depicts week-specific *P* values for the intervention effect on sales of Esco Bars in the postintervention period in 2023. Week 30 corresponds to the week ending on July 29, 2023, denoting the week of FDA's last advisory action against unauthorized Esco Bars in 2023, and warning letters were issued to the distributors on July 27, 2023. Week 52 corresponds to the week ending on December 30, 2023, the end of our postintervention period. Following the Fisher exact test, the *P* value for a given week represents the total share of intervention effects (placebo plus actual) that is greater than or equal to the actual intervention effect in a given week. By the final week in the study, the actual intervention effect was the highest out of 52 total intervention effects (1/52, 2%; *P*=.02).

## Sensitivity Analysis

Table 1 presents the results based on alternative data standardization methods. These sensitivity analyses confirmed that our findings are independent of standardization methods for weekly sales. Our major findings remained consistent across all 3 methods, suggesting that the total Esco Bars sales fell by 1.7 million EQ units during the 5 months after the FDA's advisory and enforcement actions. By the last week of 2023, weekly sales of Esco Bars were reduced by almost 70%, and *P* values of week-specific intervention effects ranged from .02 to .04, reflecting the significant sales changes during the postintervention period.

**Table .** Sensitivity analysis results by the standardization method. Three standardization methods were used in this sensitivity analysis: (1) a *z* score method in the main model, which subtracts each brand's preintervention average from its weekly sales and divides the result by its preintervention SD; (2) a min-max normalization method, which subtracts the preintervention minimum and divides by the preintervention range; and (3) a robust rescaling method, which subtracts the preintervention median and divides by the preintervention IQR. The min-max normalization and robust rescaling methods are used for sensitivity analyses.

| | *z* score (main model) | Min-max normalization | Robust rescaling |
|---|---|---|---|
| Esco Bars rank among 52 brands | 3rd | 6th | 4th |
| Overall *P* value | .06 | .12 | .08 |
| *P* value at the final week in 2023 | .02 | .04 | .04 |
| Total reductions in Esco Bars sales within 5 months (equivalized units) | 1.7 million | 1.7 million | 1.7 million |
| Weekly Esco Bars sales reduction by the final week of 2023 (%) | 68.50 | 68.50 | 68.70 |

XSL•FO
RenderX

## Discussion

### Principal Findings

Our findings demonstrate that the FDA's advisory and enforcement actions against illicit sales of unauthorized Esco Bars, including the import alert and warning letters that occurred from May to July 2023, resulted in a substantial reduction in product sales within 5 months. These actions not only reduced Esco Bars weekly sales by nearly 70% but also had sustained effects through the end of 2023 in the United States. As a result, total Esco Bars sales were reduced by approximately 1.7 million EQ units over the 5-month period. Notably, our conclusions were consistent and robust across sensitivity analyses.

Our findings confirmed that the FDA's import alerts and warning letters against Esco Bars products, which were illegally marketed following FDA's regulatory review decisions, were successful deterrents and had sustained impacts on illicit sales and distribution of these products across the supply chain. It is possible that the manufacturer, distributors, and retailers of these unauthorized products also took voluntary actions to restrain sales and availability of this product after receiving warning letters and/or being placed on import alert. These actions, although voluntary, were under the influence of FDA advisory and enforcement actions, and thus, should be considered as part of the impacts of these actions. These findings reinforce that the FDA's targeted advisory and enforcement actions are effective against sales and availability of other unauthorized commercial tobacco and nicotine products in the US market.

Our findings also generally align with concurrent patterns of youth cigarette use [7,29]. For example, data from the 2023 and 2024 National Youth Tobacco Survey found substantial declines in youth use of Esco Bars products, dropping from an estimated 440,000 students in 2023 to 160,000 in 2024, with the brand falling out of the top 5 most popular among youth by 2024 [7,29]. Although the focus of these studies was not specifically on FDA advisory and enforcement actions against illicit sales of unauthorized Esco Bars products in 2023, the findings on youth behaviors provide indirect supporting evidence for the effectiveness of these actions.

However, it is also important to note that, although Esco Bars' sales fell significantly after FDA regulatory review decisions and advisory and enforcement actions, these unauthorized products continued to be available illegally in the United States throughout 2023. This shows that there are actors in the marketplace who are intent on marketing unauthorized products, and thus regulatory vigilance needs to be an active and continual effort.

Accordingly, the FDA has continued to issue additional warning letters and updated import alerts and has pursued enforcement actions against firms to address the continued marketing, distribution, and sales of unauthorized products, including youth-appealing e-cigarettes, beyond 2023. As of October 2024, the FDA had issued more than 700 warning letters to firms for manufacturing, selling, and/or distributing unauthorized new tobacco products including e-cigarettes; issued more than 690 warning letters to retailers, including brick-and-mortar and online retailers, for the sales of unauthorized tobacco products; and filed civil money penalty complaints against more than 75 manufacturers and more than 150 retailers for distribution and/or sales of unauthorized tobacco products [30]. In addition, the Department of Justice (DOJ), in collaboration with the FDA, has filed a total of 8 injunctions against firms that continued to market unauthorized e-cigarette products [31]. Our findings in this analysis suggest that such actions are likely to have similarly successful impacts on regulating the marketplace and enforcing FDA decisions requiring the removal of illegal products from the market.

The complexity of the ever-evolving US e-cigarette marketplace has been exacerbated by the flow of unauthorized e-cigarettes entering the country. The availability and illicit sales of these unauthorized e-cigarette products, many of which are popular among young people, pose serious threats to the health and development of US youth and young adults [3-5,29,32,33]. To address these unauthorized products, the FDA has developed and implemented a comprehensive strategy across the supply chain including with other federal enforcement partners, such as the US Customs and Border Protection and the DOJ.

For example, in collaboration with US Customs and Border Protection, the FDA has made multiple seizures of unauthorized e-cigarettes, including (1) the seizure announced on December 14, 2023, of approximately 1.4 million units of unauthorized e-cigarettes with an estimated retail value of more than US $18 million;[34,35] (2) the seizure announced on April 30, 2024, of more than 45,000 units of unauthorized e-cigarette products with an estimated retail value of US $0.7 million;[36] (3) the seizure announced on May 22, 2025, of nearly 2 million units of unauthorized e-cigarette products with an estimated retail value of US $33.8 million [37]; and (4) the seizure announced on September 10, 2025, of approximately 4.7 million units of unauthorized e-cigarette products with an estimated retail value of US $86.5 million to accelerate further enforcement actions [38]. More recently, as announced on September 25, 2025, the FDA, DOJ, the Bureau of Alcohol, Tobacco, Firearms and Explosives, and the US Marshals Service seized more than 2.1 million unauthorized e-cigarettes taken from 5 distributors and 6 retailers across 7 different states [39].

These enforcement actions are part of the FDA's comprehensive enforcement strategy across the entire supply chain to increasingly address illicit sales of unauthorized e-cigarette products, particularly for products popular among youth. In addition to these enforcement strategies, the agency continues to educate the public about the risks of these products and to increase voluntary compliance by educating those in the supply chain (eg, retailers) about which products are legal to sell.

Continued surveillance of commercial tobacco and nicotine products available in the United States can provide data on unauthorized product sales and better support FDA efforts to protect the public health, while additional evaluation studies of application review decisions, warning letters, and import alerts can provide further evidence of the effectiveness of the FDA's regulatory authorities, including product review and advisory and enforcement actions. In addition, given the extent of illicit

XSL•FO
RenderX

tobacco product sales globally, including e-cigarette sales, continued surveillance could also help inform regulatory actions across the world, as appropriate.

### Limitations

This study has some limitations. First, the NielsenIQ RMS data did not include e-cigarette sales from Alaska or Hawaii. The data also did not include e-cigarette sales from certain retail outlets, including tobacco specialty stores such as vape shops, liquor stores, and online stores. However, studies based on nationally representative data have shown that less than 25% of current youth e-cigarette users obtained their products from vape shops or online stores [40,41]. Second, this analysis did not account for state or local advisory and enforcement actions against unauthorized e-cigarettes during the analytical time period. However, it is reasonable to assume that these actions would have broadly applied to all unauthorized e-cigarettes and thus were unlikely to differentially affect the estimated impact of this analysis, which was focused on Esco Bars. While this study was not designed to assess the impact of FDA advisory and enforcement actions against unauthorized Esco Bars products on disposable e-cigarette sales, other data have shown that disposable e-cigarette sales have also declined from June 18, 2023, throughout the rest of the year [42]. Third, our findings may underestimate the overall impact of FDA advisory and enforcement actions against Esco Bars, as our analytical period stops at the end of 2023, and the FDA took additional actions in 2024. In addition, since the study was based on retail sales data, we were unable to assess potential behavioral changes among Esco Bars users. However, economic studies have shown that sales and consumption tend to be highly correlated [43-45], and recent studies have shown that Esco Bars has become less popular among youth between 2023 and 2024 [7,29]. Additional research using population-based survey data could present direct behavioral changes associated with the FDA's tobacco and nicotine product advisory and enforcement actions.

### Conclusions

In response to the illicit sale of Esco Bars e-cigarette products, FDA issued multiple advisory and enforcement actions against firms that marketed, sold, and/or distributed unauthorized tobacco products. Our findings demonstrate that these actions (ie, warning letters and an import alert) substantially reduced sales of Esco Bars products in the United States, with a sustained impact noted over a 5-month period. Specifically, these actions reduced sales by approximately 1.7 million EQ units within 5 months. These findings underscore the importance and impact of FDA actions against unauthorized tobacco products as part of a comprehensive regulatory approach.

## Acknowledgments

The authors would like to thank Esther Salazar and Deborah Neveleff from the US Food and Drug Administration for their insightful feedback. BAK's work on the study was undertaken while he was employed at the US Food and Drug Administration's Center for Tobacco Products. The authors confirm that no generative artificial intelligence tools (such as ChatGPT or other large language models) were used in the writing, editing, data analysis, or creation of content for this manuscript. All work presented is the original creation of the authors.

The findings and conclusions in this study are those of the authors and do not necessarily represent the official position of the US Food and Drug Administration. The author's own analyses, calculations, and conclusions were informed in part by NielsenIQ's Retail Measurement Service data for the e-cigarettes category from January 1, 2023, to December 30, 2023, for Total US Extended All Outlets Combined and convenience stores and are those of the US Food and Drug Administration and do not reflect the views of NielsenIQ. NielsenIQ is not responsible for, had no role in, and was not involved in analyzing and preparing the results reported herein, or in developing, reviewing, or confirming the research approaches used in connection with this report. NielsenIQ Retail Measurement Service data consist of weekly purchase and pricing data generated from participating retail store point-of-sale systems in all US markets. See the NielsenIQ website for more information [46].

# Uncovering the Reasons Behind Maternal Care Dropout in Bangladesh: Cross-Sectional Study

Syeda Saima Alam[1], MSc; Plabon Sarkar[2], MSc; M A Rifat[3], MSc, MPH; Sumaiya Jahan[2], MSc; Rokibul Islam[2], MSc; Israt Jahan[1], MSc; Sanjib Saha[4], PhD

## Abstract

**Background:** Utilization of the maternal continuum of care (CoC)—comprising adequate antenatal care (ANC), skilled birth attendance, and postnatal care (PNC)—is critical for improving maternal and child health outcomes. However, dropout from the CoC remains substantial in Bangladesh, with women discontinuing services at different stages of pregnancy, delivery, and postpartum care.

**Objective:** This study aimed to quantify maternal dropout at each stage of the CoC and identify socioeconomic and demographic factors associated with discontinuity, comparing two nationally representative survey rounds.

**Methods:** Data were drawn from the Bangladesh Demographic and Health Surveys (BDHS) 2017‐2018 and 2022. Women aged 15 to 49 years with a live birth in the preceding 2 to 3 years were included. Completion of full CoC was defined as receiving at least 4 ANC visits, delivering with a skilled birth attendant, and obtaining at least 1 PNC contact within 48 hours of delivery. Predisposing (age, education, parity, religion, and division), enabling (wealth index, media exposure, health care access, and residence), and need factors (terminated pregnancy and desired pregnancy status) were identified using the Andersen Behavioral Model. Survey-weighted multivariable logistic regression models were fitted for each CoC component and overall CoC completion, with interaction terms to assess whether associations differed between survey rounds.

**Results:** Among 8424 mothers, 27.9% (n=2350) failed to complete all components of the maternal CoC. Dropout was highest at the ANC stage (n=4962, 55.7%), followed by PNC (n=3976, 47.2%) and skilled birth attendant–assisted delivery (n=3378, 40.1%). Between survey rounds, overall CoC dropout decreased significantly from 31.9% (BDHS 2017‐2018) to 22.4% (BDHS 2022), reflecting modest improvements in service continuity. Factors significantly associated with higher odds of CoC dropout included lower maternal education (adjusted odds ratio [AOR] 2.70, 95% CI 1.94‐3.77; *P*<.001), higher parity (AOR 2.73, 95% CI 2.12‐3.50; *P*<.001), lower wealth quintiles (AOR 4.04, 95% CI 3.02‐5.41; *P*<.001), and rural residence (AOR 1.40, 95% CI 1.18‐1.67; *P*<.001). Protective factors included older maternal age at delivery (AOR 0.56, 95% CI 0.42‐0.74; *P*<.001) and history of ever-terminated pregnancy (AOR 0.74, 95% CI 0.63‐0.86; *P*<.001). Significant temporal interactions (all *P*<.05) indicated that the strength of associations for education, parity, religion, wealth, media exposure, health care access barriers, residence, and pregnancy desire differed between survey rounds, reflecting changing determinants of CoC engagement amid policy reforms and pandemic disruptions.

**Conclusions:** Maternal, socioeconomic, and geographic factors are strongly associated with discontinuity along the maternal health care continuum in Bangladesh. Statistically significant temporal variations underscore the impact of evolving health policies and system disruptions on maternal service utilization patterns. Targeted, area-specific interventions addressing these determinants across all CoC components are essential to improve maternal health care retention and achieve better maternal and child health outcomes.

## Introduction

The maternal continuum of care (CoC) consists of 4 or more antenatal care (ANC) visits, childbirth by a skilled birth attendant (SBA), and a postnatal care (PNC) visit by skilled health care providers within 48 hours of delivery [1]. When a woman and child pair fulfills all 3 criteria, they are considered to have attained a complete CoC [1]. The CoC encompasses integrated service delivery for mothers and children, ensuring that women have access to quality care throughout pregnancy, childbirth, and the postpartum period [2]. It is critical for improved health outcomes, efficient and effective delivery of nutritional interventions, increased service utilization, and addressing underlying factors [3], with recent multicountry evidence underscoring that completion of the CoC remains suboptimal, particularly in the low- and middle-income countries [4].

The completion of CoC demonstrates a marked reduction in undernutrition indicators, for example, stunting, wasting, and underweight among children alongside a decline in maternal and child mortality rates [3,5]. Empirical research indicates that adequate continuity of care can avert half a million maternal fatalities, 4 million neonatal fatalities, and 6 million pediatric fatalities worldwide [6-8]. Consequently, withdrawal from the CoC signifies noncompliance with prescribed maternal care measures [9], and emerging findings from Bangladesh indicate that the use of the full maternal CoC is positively associated with optimal complementary feeding practices among children aged 6 to 23 months [10].

In Bangladesh, around 53% of pregnant women drop out from receiving 4 or more ANC visits, 47% of the childbirths are not supported by SBAs, and 48% of women do not receive PNC visits within 2 days after the delivery [11,12]. The dropouts of women and children from the CoC can severely impact maternal and child nutrition. For instance, lower ANC and PNC visits result in poor infant and young child feeding practices that increase the risk of malnutrition and impaired cognitive development, which may result in long-term adverse educational and economic outcomes for children [13]. In addition, insufficient ANC visits and nutrition counseling can lead to maternal malnutrition, such as anemia and pregnancy complications, while a lack of SBA during delivery and PNC visits might pose a risk to maternal mortality and poor reproductive health [13]. Considering the significance of the CoC components, they are being evaluated for consistency to safeguard the survival and welfare of both mother and newborn. This, in turn, may serve as a crucial strategy for achieving the Sustainable Development Goals' target of a maternal mortality ratio under 70 per 100,000 live births and a neonatal mortality rate under 12 per 1000 live births by 2030 [6,13].

The CoC is essential for enhancing maternal and child nutrition outcomes, as interruptions in one service frequently cause disruptions in others. For example, data from Bangladesh indicate that women who cease ANC are more inclined to also abandon skilled birth attendance and PNC [13,14]. It is important to understand the many factors that lead to dropout in both individual and combined parts of the CoC to create complete and effective interventions. Key factors—such as maternal age, socioeconomic status, education level, place of residence, religion, parity, and occupation—significantly influence adherence to and gaps within the continuum, affecting the success of maternal and child nutrition initiatives [13,15]. To create targeted and comprehensive services that can remove barriers, make sure services continue, and ultimately improve the health and nutrition of mothers and children in Bangladesh, it is important to identify and analyze these factors in a strong way.

This study aims to comprehensively quantify and compare maternal dropouts at each stage of the CoC (ANC, delivery, and PNC) and from the overall CoC between Bangladesh Demographic and Health Surveys (BDHS) 2017-2018 and BDHS 2022, and to identify and contrast the socioeconomic and demographic factors associated with these discontinuities. It is hypothesized that the magnitude and pattern of maternal dropouts differ significantly between BDHS 2017 - 2018 and BDHS 2022 across the stages of the CoC and for the overall CoC, and that the socioeconomic and demographic determinants of discontinuity at different stages of the CoC differ in strength and direction between the 2 survey rounds.

By exploring where and why women disengage from critical services and by comparing 2 distinct survey rounds, the research provides crucial insights into gaps that undermine maternal and child health outcomes. The findings from this study will help inform targeted strategies and policy interventions to reduce dropouts, improve service uptake, and ultimately contribute to achieving maternal and child health goals nationwide.

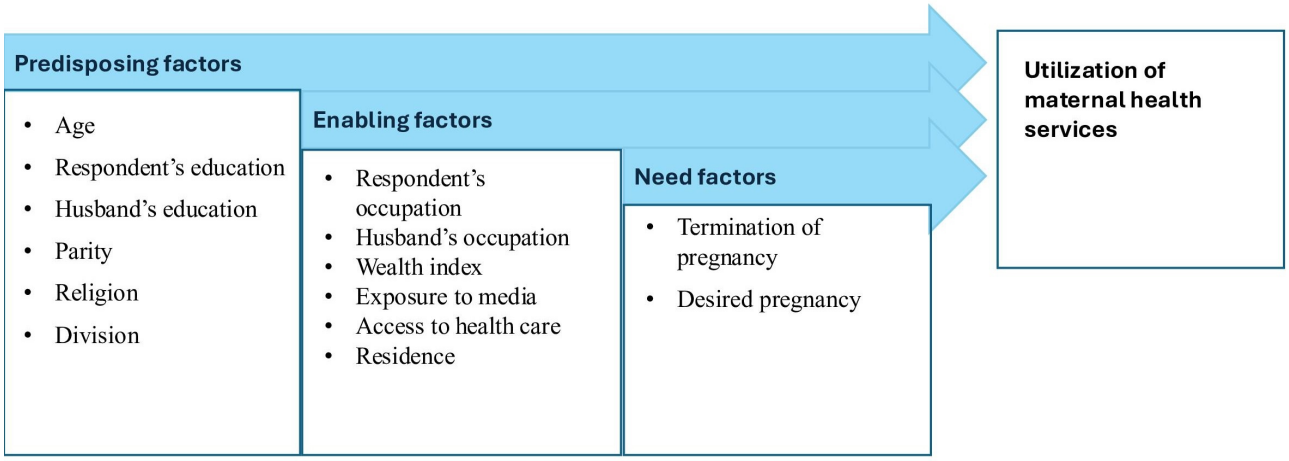
## Methods

### Study Design, Data Sources, and Sampling

This study used data from BDHS 2017 - 2018 and BDHS 2022 to determine how CoC utilization and its covariates have changed over time. Both surveys are nationally representative, are cross-sectional in design, and employed 2-stage stratified random sampling. The overall response rate for both surveys was 98%. The detailed methods are outlined elsewhere [11,16].

A total of 8424 ever-married women aged 15 to 49 years who had a live birth within the last 3 and 2 years prior to the surveys, respectively, for BDHS 2017 - 2018 and BDHS 2022, were retrieved. However, the study only analyzed samples with complete information regarding maternal utilization of CoC and coupled with respective covariates.

### Conceptual Model



This study utilized the Andersen Behavioral Model of Health Care Services to systematically identify factors affecting the utilization of CoC services. The Andersen model is a widely used conceptual framework for understanding health care utilization, positing that service use is shaped by 3 key domains: predisposing, enabling, and need factors [17,18]. Predisposing factors encompass demographic and social attributes, including age, gender, education, and health beliefs, that affect an individual's propensity to pursue care. This study identified maternal age, respondent's education, husband's education, parity, religion, and division as predisposing factors. Maternal

XSL•FO
RenderX

age and parity are recognized factors influencing obstetric risk and health-seeking behavior, whereas maternal education affects health literacy, awareness of maternal health risks, and autonomy in decision-making. The husband's education is a significant predisposing factor, as it indicates social status, influences household health beliefs, and affects decision-making authority concerning maternal health care utilization [19]. Enabling factors include the means and resources that make it easier or harder to get services, such as community resources, household wealth, and health care availability [20]. This study identified the respondent's occupation, the husband's occupation, wealth index, media exposure, health care access, and residence as enabling factors. The household wealth index indicates the economic ability to access services, while exposure to mass media functions as a crucial enabling factor by disseminating maternal health information, shaping health-seeking behaviors, and addressing knowledge deficiencies, especially in resource-constrained environments. Access to health care and residence encompasses geographic and structural impediments to service utilization. Need factors encompass both perceived and assessed health status, indicating the actual or subjective requirement for medical attention [21]. Termination of pregnancy and desired pregnancy were chosen as need factors because termination of pregnancy indicates obstetric history that heightens the risks of future pregnancy complications, whereas pregnancy intention affects the motivation to pursue and complete the continuum of maternal care. In this study, the classification and definitions of analytical variables adhered closely to the established schema, ensuring conceptual coherence. Figure 1 shows how these areas interact with each other, as described in the Andersen Behavioral Model. It shows how combinations of predisposing, enabling, and need factors affect the use of CoC services and, in the end, maternal and child health outcomes.

**Figure 1.** Theoretical framework based on the Andersen Health Care Utilization Model.

## Outcome Variable

The outcome variable is maternal dropout from CoC, which consists of dropping out from three integral components, which are (1) at least 4 ANC visits by skilled care providers during pregnancy, (2) delivery assisted by SBAs, and (3) at least 1 PNC visit by skilled care providers within 48 hours of delivery [14]. The skilled care providers in this aspect are designated as doctors, nurses, midwives, paramedics, community SBAs, and subassistant community medical officers. A mother was considered to have dropped out from the full CoC if she had not received any of these components. The mothers were assigned code 1 if they received all 3 components of the CoC; otherwise, code 0. Similarly, mothers who utilized any specific component of the CoC were assigned a code 1, otherwise 0, and analyzed separately.

## Covariates

We considered covariates, including age at delivery (<19 y, 19-30 y, and 31 - 49 y); education level (no education, primary, secondary, and higher); husband's education level (no education, primary, secondary, and higher); occupation (not working and working); husband's occupation (not working and working); parity (1, 2 - 3, and >3); ever-terminated pregnancy (never/no and ever/yes); desired pregnancy (yes and no); wealth index (poorest, poorer, middle, richer, and richest); any exposure to television, radio, or news (yes and no); facing problems such as getting permission and money and long distance to access health care (big problem and not a big problem); religion (Muslim and other); place of residence (rural and urban); division of residence (Barisal, Chittagong, Dhaka, Khulna, Mymensingh, Rajshahi, Rangpur, and Sylhet); and survey round (BDHS 2017 - 2018 and BDHS 2022). These covariates were categorized based on how they align with the Andersen Behavioral Model (Figure 1).

## Statistical Analysis

The distribution of covariates by maternal dropouts from CoC was examined using cross-tabulations in a frequency distribution table, and the differences among 4 individual components were observed using the $\chi^2$ test.

The association between prevalence of dropout from maternal CoC and covariates was analyzed using logistic regression models. Four models were utilized based on the outcome variables, including dropout from (1) 4 ANC, (2) delivery assisted by SBAs, (3) PNC within 48 hours of delivery, and (4) all CoC components. Given that the selection of variables was guided by a theoretical framework, the Andersen Behavioral Model of Health Services, no covariate was excluded in the

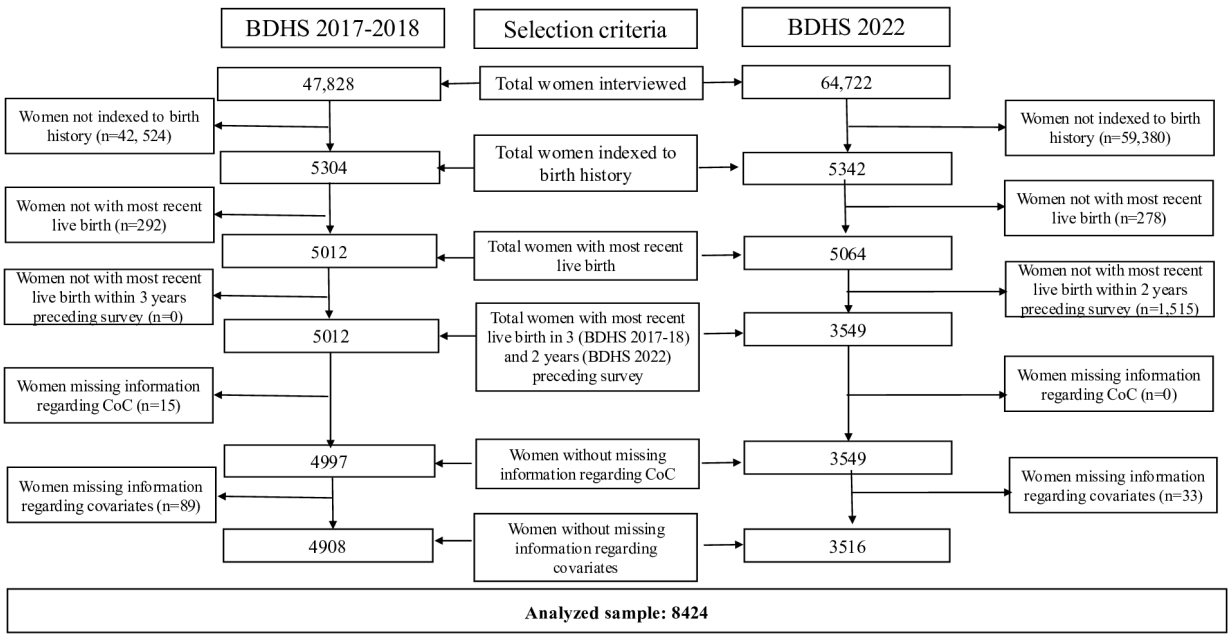
XSL•FO
RenderX

multivariable models, irrespective of the level of significance of the association in the univariable models.

Data from BDHS 2017 - 2018 and BDHS 2022 were pooled, and a binary indicator for survey round was included in all models. We fitted survey-weighted logistic regression models for each stage of the CoC (completion of adequate ANC, institutional delivery, and PNC contact) as well as overall CoC completion, with socioeconomic and demographic characteristics as predictors. To assess whether the patterns of dropout and the associations between maternal characteristics and CoC engagement differed between survey rounds, we included interaction terms between survey round and each key predictor (eg, wealth quintile, education level, and place of residence). Equality of the survey-specific effects across socioeconomic and demographic factors was evaluated using joint Wald tests of the interaction coefficients; statistical significance indicated that the log odds ratios (ie, the strength and direction of associations) differed between BDHS 2017 - 2018 and BDHS 2022 [22].

To ensure the accuracy of the estimates, the analyses were adjusted for sampling weight, strata, and primary sampling units. SEs of the odds ratio and variance inflation factors were observed to examine the multicollinearity. An SE of the odds ratio >2 was considered to indicate multicollinearity among the covariates [23]. All the statistical tests were conducted considering $P<.05$ as the significance level. The software STATA 17 (StataCorp, College Station) was used for data analysis. The study is reported in accordance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines for observational studies (Checklist 1).

### Ethical Considerations



The Demographic and Health Survey received approval from the ICF Macro Institutional Review Board, United States, which complies with all the criteria of 45 CFR 46 “Protection of Human Subjects.” As the data were collected in Bangladesh, the BDHS received ethical approval from the National Research Ethics Committee of the Bangladesh Medical Research Council, Dhaka, Bangladesh. Before being enrolled in the study, verbal informed agreement was obtained from each participant and their intimate partners (all ever-married women aged 15 - 49 y). If the respondents were incapable of reading, verbal consent was considered the most appropriate method to confirm participation.

All survey data were anonymized before being made available for analysis, and no financial or other incentives were offered to participants for their participation or for the use of their data in this study. The manuscript and its supplementary materials do not include any information or images that could lead to the identification of individual respondents. Comprehensive descriptions of the ethical procedures and informed consent process are provided in the BDHS documentation and official reports.

## Results

The sample selection process for this study is illustrated in Figure 2. In this study, 8424 mothers with complete information about outcome and covariates were analyzed. In the analyzed sample, maternal dropouts from having ≥4 ANC, delivery assisted by SBAs, PNC within 48 hours of delivery, and full CoC were 55.7% (n=4962), 40.1% (n=3378), 47.2% (n=3976), and 27.9% (n=2350), respectively (Figure 3).

**Figure 2.** The sample selection process. BDHS: Bangladesh Demographic and Health Surveys; CoC: continuum of care.

XSL•FO
RenderX

**Figure 3.** Maternal dropout from the continuum of care (CoC) and its component. ANC: antenatal care; BDHS: Bangladesh Demographic and Health Surveys; PNC: postnatal care; SBA: skilled birth attendant.

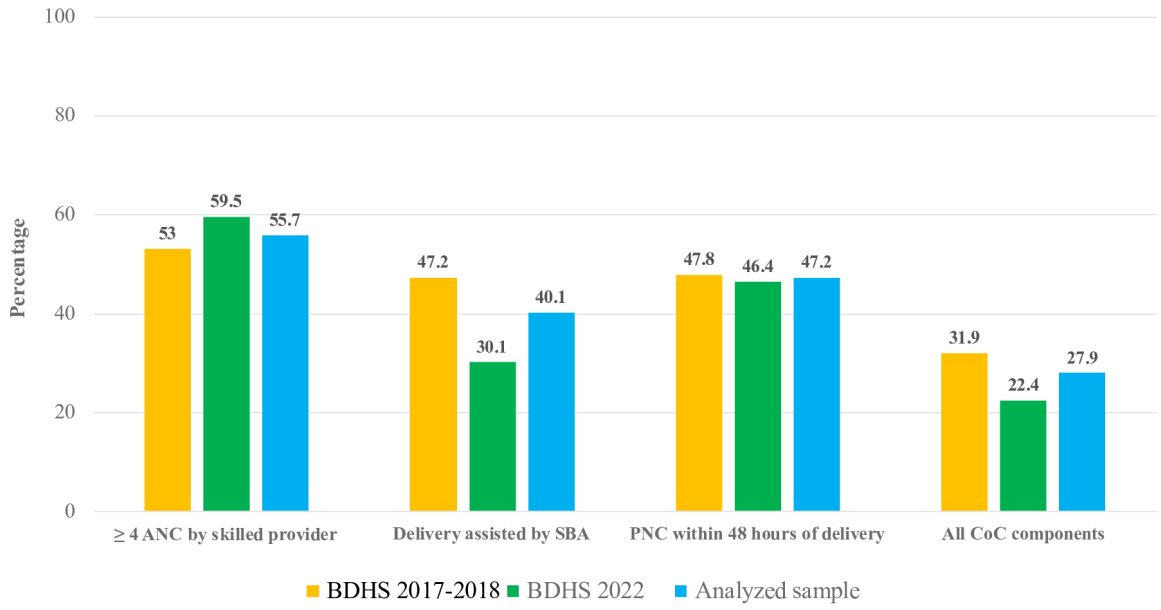


Table 1 demonstrates the difference in dropouts from individual and all CoC components across BDHS 2017 - 2018 and 2022 and shows clear changes over time. Across both BDHS rounds, dropouts from the maternal CoC remained high, with particularly large attrition among socioeconomically disadvantaged and rural women. The dropout at each stage (≥4 ANC visits, SBA-assisted delivery, and ≥4 PNC contacts) was consistently higher among women with little or no education, from poorer households, without media exposure, reporting major problems in accessing care, and residing in rural or underserved divisions. Educational and wealth gradients were steep: women with no schooling or in the poorest quintile had roughly doubled the dropout from full CoC compared with highly educated or richest women in both surveys. Although some absolute levels improved between 2017 - 2018 and 2022, the pattern of persistent socioeconomic and geographic inequities in CoC coverage remained the dominant feature of the data.

[a]BDHS: Bangladesh Demographic and Health Surveys.

[b]AOR: adjusted odds ratio.

[c]*P* value obtained from joint Wald tests of the interaction coefficients between survey years and covariates.

[d]Not applicable.

[e]Media exposure: newspaper, television, or radio.

[f]Problem to access health care: permission to go, monetary constraints, or distance to health facilities.

The impacts of age at delivery, maternal education, husband's education, parity, religion, division, wealth index, media exposure, health care access, residence, terminated pregnancy, and desired pregnancy exhibited significant variations between survey rounds. Conversely, the associations with maternal occupation (*P*=.40) and husband's occupation (*P*=.95) exhibited no significant differences between BDHS 2017 - 2018 and

XSL•FO
RenderX

BDHS 2022, indicating consistent patterns for these variables over time.

Some important patterns that were specific to the survey are as follows: the protective effect of older age at delivery was stronger in 2017 - 2018 (AOR 0.49, 95% CI 0.34-0.69 for 31–49 years) than in 2022 (AOR 0.68, 95% CI 0.41-1.14); the aOR for Muslim religion went up from 1.50 (95% CI 1.08-2.07) in 2017 - 2018 to 2.42 (95% CI 1.39-4.23) in 2022; and women with no education were at a greater disadvantage in 2017 - 2018 (AOR 3.20, 95% CI 2.12-4.82) than in 2022 (AOR 2.16, 95% CI 1.22-3.81), which suggests that the education gradient is getting smaller. The survey round main effect shows that the odds of dropping out are much lower in BDHS 2022 than in 2017 - 2018 (AOR 0.59, 95% CI 0.51 - 0.69, $P$<.001). This means that the completion of the CoC has improved over time.

In the supplementary materials, we presented the factors associated with dropouts from ANC, SBA, and PNC, separately (see Tables 1, 2, and 3 in Multimedia Appendix 1). In all the regression models, SEs of the odds ratio for all covariates were <2, indicating an acceptable level of multicollinearity among the independent variables. Furthermore, the variance inflation factor of the covariates was less than 3 for both the adjusted and unadjusted models (see Table 4 in Multimedia Appendix 2).

## Discussion

### Principal Findings

This study investigated the trends in the CoC over the past 5 years and analyzed the factors contributing to dropouts from CoC in Bangladesh, which include ANC, skilled birth attendance, and PNC. Using the Andersen Healthcare Utilization Model, we discovered that predisposing factors (age, education level of the respondent and her husband, parity, desired pregnancy, religion, and survey round), enabling factors (occupation of the respondent and her husband, wealth index, and media exposure), and need factors (desired pregnancy and terminated pregnancy) increased the likelihood of maternal dropout from CoC. From BDHS 2017 - 2018 (31.9%) to BDHS 2022 (22.4%), there was a significant drop in the overall dropout from CoC. This suggests that maternal health service utilization has gotten a little better.

The statistically significant differences noted in the associations between covariates and maternal CoC dropouts across the 2 survey rounds ($P$<.05 in the interaction test) illustrate Bangladesh's evolving maternal health landscape from 2017 to 2022, characterized by policy reforms and unprecedented disruptions in the health system. During this time between surveys, Bangladesh put the National Strategy for Maternal Health 2019 - 2030 into action. This plan focused on making it easier for everyone to get maternal health services and improving community-based care delivery [24]. The COVID-19 pandemic (2020 - 2022) significantly disrupted maternal health service provision and utilization, with studies indicating approximately 30% reductions in ANC, institutional deliveries, and postnatal care in 2020, followed by an incomplete recovery by 2021 [25]. This disruption had a bigger impact on vulnerable groups, such as women from lower wealth quintiles, people who live in rural areas, and people with little education. This could make existing inequalities worse. The substantial interaction effects for enabling factors, including wealth index ($P$<.001), media exposure ($P$<.001), health care access barriers ($P$=.02), and residence ($P$<.001), indicate that the protective or risk-enhancing roles of these determinants fluctuated between survey rounds. This likely reflects the health system's varying capacity to serve different population subgroups during the pandemic and the inconsistent pace of postpandemic recovery across socioeconomic strata [26-28].

These changes in CoC dropout patterns over time can be explained by a number of interconnected barriers. Lower maternal education is frequently correlated with diminished financial independence and decision-making abilities, which subsequently adversely impacts the continuity of health care services for both the mother and her children [29]. The COVID-19 pandemic made financial problems worse. Studies showed that household income dropped by 19% to 20%, and access to maternal health care was disrupted [25,30]. As the cost of living went up, there were more demands on limited household resources. For example, maintaining continuity through the CoC requires multiple visits to health care facilities. This requirement competes with time for household duties and leads to high indirect medical costs, such as transportation and medications [26]. Women from lower socioeconomic backgrounds in Bangladesh bear a disproportionate share of health care financing [31]. This makes the burden of out-of-pocket costs even heavier for them.

To address dropout from maternal health services, Bangladesh has implemented social health protection schemes, such as Shasthyo Surokhsha Karmasuchi and Maternal Health Voucher Scheme, targeting disadvantaged populations [32]. However, evidence suggests that these programs typically fail to monitor the complete maternal CoC, resulting in women discontinuing service uptake after initial contact with 1 component of the continuum [33]. This programmatic limitation highlights the critical gap between initiating maternal health care and maintaining continuity across all phases of pregnancy, delivery, and postpartum care.

Moreover, the notable temporal fluctuations in need factors, especially desired pregnancy status ($P$=.07) and history of terminated pregnancies ($P$<.001), may indicate evolving reproductive health behaviors and family planning dynamics amid this era of economic instability and service interruption [34]. The temporal fluctuations in the strength of associations concerning predisposing factors, such as age at delivery, parity, religion, and division, signify the changing socioeconomic and geographic determinants of maternal health care utilization. The significant interaction for division ($P$<.001) highlights enduring geographic disparities in maternal health care access, with regions such as Khulna and Rangpur exhibiting improved outcomes, whereas others encountered heightened obstacles during the intersurvey period. These ongoing geographic disparities, along with the ongoing difficulty of keeping CoC continuity across all parts, show that Bangladesh needs customized, area-specific interventions to make the full maternal health care pathway stronger [35].

XSL•FO
RenderX

Moreover, the high rate of unintended pregnancies, which are frequently identified late, along with related effects, such as anxiety and depression, discourages women from obtaining CoC in Bangladesh. In addition, late detection inhibits mothers from commencing ANC punctually, resulting in inadequate access to the prescribed number of ANC visits. Our finding that women with unwanted pregnancies had higher odds of dropping out of the CoC is consistent with previous literature linking unintended pregnancy to lower utilization of ANC, skilled delivery, and postnatal services in Bangladesh and other low- and middle-income countries [36,37]. This pattern does not merely indicate a lack of motivation; it likely signifies the presence of multiple intersecting disadvantages. Women with unintended pregnancies are more prone to encounter financial constraints, restricted decision-making authority, stigma or fear of judgment from health care providers, and symptoms of depression or stress, all of which can hinder timely and sustained engagement with services [36].

The study utilized the latest 2 consecutive nationally representative surveys, with high response rates. Therefore, these datasets allow for reliable conclusions about maternal health care utilization patterns across the country within the defined time. In addition, the selection of factors is guided by the Andersen Behavioral Model of Health Care Services, providing a more precise estimate. The evaluation of outcomes and factors followed validated measurements, minimizing the risk of assessment bias. In contrast to the strengths of the study, there remain some challenges to interpreting the findings. First, the cross-sectional design of the study limits establishing a causal nature of the association found between identified factors and CoC components. Second, the possibility of recall bias may affect the accuracy of findings, as the recall period spanned up to 3 years in the datasets. Third, the analyses were restricted to women with complete information on CoC utilization and all covariates, which introduces the possibility of selection bias if women with missing data differ systematically from those included in the analytic sample. Finally, the study did not explore health care system–related factors, such as health care providers' attitudes, patient-provider relationships, availability of workforce, quality of care, and factors underlying the decision-making dynamics of women to uptake CoC services. These contextual elements are critical to fully understanding health care utilization.

This study offers crucial insights into the utilization of CoC in maternal health care, emphasizing the importance of policy support to improve the maternal utilization of CoC, the development of relevant interventions, and the provision of services.

## Conclusion

In this study of 8424 mothers, more than 1 in 4 failed to complete the continuum of maternal care, with dropout most pronounced at the ANC stage. Dropout was strongly associated with lower education, higher parity, lower wealth, rural residence, and younger maternal age and was also influenced by media exposure, pregnancy intention, and religious affiliation, underscoring the complex interplay of sociodemographic and experiential factors in maternal health service utilization.

## Abstract

**Background:** It is important to understand the motives behind why people want to reduce their alcohol consumption to inform messaging for public health campaigns.

**Objective:** This study aimed to identify the motives for reducing alcohol consumption among users of the Drink Less app in the United Kingdom.

**Methods:** Content analysis of Drink Less app users' responses to the prompt "I want to drink less because..." Users were aged 18 years or older, lived in the United Kingdom, and had downloaded the app between May 20, 2016, and June 24, 2024 (n=2520). Inductive content analysis was conducted to analyze users' motives to drink less, and the frequencies were stratified by age, sex, and Alcohol Use Disorders Identification Test (AUDIT) score categories.

**Results:** The most common motives to drink less were wanting to improve their physical health (1329/2520, 52.7%), feel better in their body (823/2520, 32.7%), improve their mental well-being (567/2520, 22.5%), regain agency (483/2520, 19.2%), live a different life (321/2520, 12.7%), and have better relationships (309/2520, 12.3%). The motives for drinking less,"improve physical health" and "feel better in their body," had a lower prevalence among users in higher AUDIT risk zones compared with low-risk, while wanting to "improve their mental well-being," "regain agency," "live a different life," and "have better relationships" had a higher prevalence among users in higher AUDIT risk zones.

**Conclusions:** Users of an alcohol reduction app in the United Kingdom most commonly reported wanting to improve their physical health, feel better in their bodies, and improve their mental well-being as their motives for drinking less alcohol. The pattern of prevalence of different motives varied by AUDIT risk zones, highlighting the importance of tailoring interventions based on what is most likely to be motivating for individuals.

## Introduction

Alcohol consumption is a leading risk factor for early mortality, ill health, and disability in the United Kingdom [1], as well as contributing to health inequalities [2]. There is a dose-response relationship between the volume of alcohol consumed and the risk of alcohol-related harm (eg, stroke) [3], meaning anyone who drinks alcohol can benefit from reducing their consumption. It is important to understand the motives behind why people want to reduce their alcohol consumption to inform messaging for public health campaigns and create targeted guidance based on high-risk groups.

As of December 2025, around a third of risky drinkers had made an attempt in the past year to cut down or stop drinking, and a third believed they should or wanted to cut down [4]. Motivation is an important part of behavior change [5], and there is evidence that high motivation levels predict whether someone makes an attempt to reduce their consumption [6]. Motivation is commonly addressed in guidance documents and treatment manuals for brief alcohol interventions, and in the Cochrane Review of brief alcohol interventions in the form of identifying reasons for wanting to reduce alcohol consumption [7]. Having personally relevant motives may help to increase the level of motivation and lead more people to make a reduction attempt. Therefore, it is important to understand, among those who are motivated to make a reduction attempt, what the motive behind this was. This could be used to inform public health campaigns,

XSL•FO
RenderX

with common motives highlighted to encourage others to make a reduction attempt as well.

Previous research has looked at understanding people's motives for reducing their alcohol consumption. Adults in England reported motives to improve fitness, weight loss, future health concerns, social factors, cost, advice from a health care professional, and fewer social occasions [8-10]. Adults in Australia reported that health, lifestyle, and social motives were most common [11], alongside fear of the negative consequences among younger age groups [12,13]. People drinking at heavier levels reported motives such as major life changes, weighing up pros and cons of drinking and not drinking, health and financial concerns, and being affected by seeing someone drunk or high [14,15].

However, there are some gaps in the previous research. Some studies only included risky drinkers, so no one who had reduced their drinking to low-risk levels was asked about their motives [8,9]. In the cases of population surveys [8-11], very heavy drinkers tend to be underrepresented [16] despite being at greater risk of alcohol-related harm. In most previous research, participants were asked to select their motives for drinking less from a list of response options [8-12,14], and the process of selecting or deriving the response options was unclear. And finally, the timing of the data collection in these studies was either retrospective, introducing scope for recall bias [8-11], or participants were asked to report why they were considering changing their drinking behavior [15].

The Drink Less app is a theory-based intervention to support users in reducing their alcohol consumption in the United Kingdom that has been developed and refined in a systematic way involving user feedback [17,18] with evidence for its effectiveness [19]. It is widely used [20] and popular among its users, with a 4.6-star rating on the UK Apple App Store as of February 2026 [21]. Drink Less is one of the top apps for alcohol-related searches and has over 90,000 unique users [21]. The app collects anonymous data on users' motives for drinking less in the form of an open-text response to the prompt "I want to drink less because..." These data can provide insight on motives to reduce alcohol consumption among UK drinkers at the moment at which they are making such an attempt. The aim of this study was to identify the Drink Less users' motives for reducing their alcohol consumption.

# Methods

## Study Design

Qualitative analysis of previously collected short-text responses to the prompt "I want to drink less because..." among users of the Drink Less app. The study protocol was preregistered on the Open Science Framework (osf.io/gnb8p) prior to data analysis starting.

## Participants

The Drink Less app is freely available on the UK Apple App Store [21]. App users had to agree to the app's "Privacy Policy" and "Terms and Conditions" for their anonymous data to be used for scientific research purposes. In addition to this, for this study, users had to be aged 18 years or older, live in the United Kingdom, and have downloaded the Drink Less app between May 18, 2016, and July 20, 2024 (there was no minimum engagement required) to be included in this study. In cases of duplicate device IDs, only the first download was included.

## The Drink Less App

The Drink Less app consists of 8 evidence-based modules to help users change their drinking behavior: Goal Setting, Self-Monitoring and Feedback, Action Planning, Normative Feedback, Cognitive Bias Re-Training, Insights, Behavioral Substitution, and Information About Antecedents [17,18]. The app was designed to help people reduce their alcohol consumption though there was no explicit user motive for reducing alcohol consumption that it was designed for or targeted on. Users could access all parts of the app at all times. The onboarding process (when first downloading the app) involves users agreeing to the app's "Privacy Policy" and "Terms and Conditions" (they can opt out at any time, and if they do not agree, they can still use the app but not have their data used for scientific research purposes). During the time period of this study, research studies were conducted within the app (eg, [19,22]) though none of these affected the functionality or visibility of the "I want to drink less because..." prompt.

## Measures

### *Motive to Drink Less*

All users received the prompt "I want to drink less because..." on the app dashboard and when setting goals though did not have to complete it. There was an open-text box for users to respond. If users changed their original response, the most recent version was used. There was no time limit on when the response had to be made by.

### *Demographic Characteristics*

During app onboarding, users input their sex (male/female) and their year of birth (which was used to calculate their age). There were no other additional sociodemographic characteristics measured consistently across the time period to minimize participant burden and increase engagement with the app.

### *Alcohol Use Disorders Identification Test (AUDIT) Score*

Users completed the AUDIT, a 10-item questionnaire with total scores ranging from 0 to 40 categorized into 4 risk zones [23]: zone I (score 0 - 7, low-risk); zone II (score 8 - 15, increasing risk); zone III (score 16 - 19, higher risk); and zone IV (score 20 - 40, at risk of alcohol dependence). This was completed during onboarding (ie, at the time of app download).

## Data Analysis

An inductive content analysis was conducted to analyze the users' motives to drink less, allowing for large amounts of textual data to be explored qualitatively, identifying categories which can be quantified in terms of frequency [24]. This allows for patterns and meanings to be reported in a simpler manner with the aim of representing new insights and knowledge practically, guiding future action [25].

Researcher LPS familiarized themselves with the data and coded it inductively in Microsoft Excel using an iterative process that led to the development of *subthemes*, which came together to

XSL•FO
RenderX

form *themes* and ultimately into *categories*. The criteria for selection were broad in that everything mentioned was considered as a motivation and not discounted for not fitting the previous literature, considering that our aim was to inductively explore motivations to drink less. Furthermore, the analysis was limited to a descriptive level so as to not become too abstract or look for underlying meaning due to both the volume of data and the short-form text (which cannot provide context or insight into potential underlying meanings in the way long-form text or interviews can) [26]. Each user response could be coded multiple times. Once an initial codebook came together, LPS met with CG and OMM to discuss it, for example, whether anything had been overlooked or something may have more than one meaning, after which LPS returned to the coding individually, shaped by the discussion. As all available data on motives to drink less were coded, inductive thematic saturation (when new codes or themes are rarely or never generated) [27] was not considered as a marker at which to stop coding, though it was reached before the end of the coding process. Each response was coded by its content, up until the last response. The prevalence of users reporting each subtheme, theme, and category was quantified.

The frequency of categories and themes was also stratified by age group, sex, and AUDIT risk zones. There was a change to the preregistered protocol in that subthemes were not stratified by age group, sex, and AUDIT risk zones due to very small cell sizes.

### Ethical Considerations

Ethics approval for the use of the Drink Less data for research purposes has been granted by University College London (CEHP/2020/579) and the University of Bristol (#23313) ethics committees. This particular study was approved by the School of Psychological Science Research Ethics Committee at the University of Bristol (#22068). The app has a privacy notice, and users provided consent for their anonymized data to be used for academic research purposes after downloading the app. Users can opt out from their data being used for academic research purposes within the app at any point. Participants were not compensated for taking part in this study.

## Results

### Overview

There were 93,640 unique users of the Drink Less app between May 20, 2016, and June 24, 2024, and 2550 (2.7%) of these users had responded to the prompt “I want to drink less because...” Of these, 30 responses were excluded due to being uninterpretable (eg, incoherent, not in English) (n=26), the user being under 18 years (n=3), or having missing demographic data (n=1).

The final sample consisted of 2520 unique user responses. The majority of users were between the ages of 35 and 54 years (n=1488, 59.1%) and identified as female (n=1594, 63.3%). Fewer than 5% (n=123) of users were categorized as a low-risk drinker, 57.2% (n=1441) as an increasing or higher risk drinker, and 37.9% (n=956) as at risk of alcohol dependence (see Table 1). The sample (ie, users completing the prompt) had a higher proportion of users who were younger (less than 54 years old), a higher proportion of female users, and a higher proportion of users at higher risk or risk of alcohol dependence compared with those not completing the prompt (see Table 1).

**Table .** Characteristics of users of the Drink Less app (2016-2024), including all users (n=93,640) and sample users (n=2520).

| Characteristics | All users (n=93,640) | Users not completing the prompt (n=91,120) | Sample users (n=2520) | Chi-square (*df*) | *P* value |
|---|---|---|---|---|---|
| Age (years), n (%) | | | | 51.1 (5) | <.001 |
| 18 - 24 | 4124 (4.4) | 4038 (4.4) | 86 (3.4) | | |
| 25 - 34 | 15,045 (16.1) | 14,614 (16.0) | 431 (17.1) | | |
| 35 - 44 | 24,143 (25.8) | 23,405 (25.7) | 738 (29.3) | | |
| 45 - 54 | 27,295 (29.1) | 26,545 (29.1) | 750 (29.8) | | |
| 55 - 64 | 17,170 (18.3) | 16,748 (18.4) | 422 (16.7) | | |
| 65+ | 5863 (6.3) | 5770 (6.3) | 93 (3.7) | | |
| Sex, n (%) | | | | 202.6 (1) | <.001 |
| Male | 47,522 (50.7) | 46,596 (51.1) | 926 (36.7) | | |
| Female | 46,118 (49.3) | 44,524 (48.9) | 1594 (63.3) | | |
| AUDIT[a] risk zone, n (%) | | | | 290.4 (3) | <.001 |
| I (score 0-7; low risk) | 10,679 (11.4) | 10,556 (11.6) | 123 (4.9) | | |
| II (score 8-15; increasing risk) | 41,614 (44.4) | 40,701 (44.7) | 913 (36.2) | | |
| III (score 16-19; higher risk) | 17,062 (18.2) | 16,534 (18.1) | 528 (21.0) | | |
| IV (score 20-40; at risk of alcohol dependence) | 24,285 (25.9) | 23,329 (25.6) | 956 (37.9) | | |

[a]AUDIT: Alcohol Use Disorders Identification Test.

Of the sample users, the time difference between downloading the app and the date of the last update to users' drink less motive had a median value of 0.9 (IQR 0.6 - 6.6), indicating that over half of users reported their drink less motive within a day and three-quarters had reported their motive within 7 (mean 16.3, SD 57.8) days.

There were 19 categories, 29 themes, and 96 subthemes. On average, each response was coded 2.1 times, resulting in 5362 codes. The frequency of each category and theme is reported in Table 2, and the frequency of each category stratified by age, sex, and AUDIT risk zone is reported in Table 3. The frequency of users reporting each category and theme, and stratified by age, sex, and AUDIT risk zone, is reported in Multimedia Appendix 1. The frequency of subthemes is reported in Multimedia Appendix 2.

XSL•FO

**Table .** Frequency of categories and themes of motives to drink less reported by users of the Drink Less app (2016-2024; sample users: n=2520).

| Categories and themes[a] | Sample users (n=2520), n (%) |
|---|---|
| I want to improve my physical health | 1329 (52.7) |
| I want to live a healthier lifestyle | 1129 (85.0) |
| I am worried about future health problems | 180 (13.6) |
| I have other health problems | 72 (5.4) |
| I want to feel better in my body | 823 (32.7) |
| Help with weight loss | 718 (87.2) |
| Improve my fitness | 113 (13.7) |
| I want to improve how I look | 48 (5.8) |
| I want to improve the features on my body | 32 (3.9) |
| I want to feel more attractive/sexy | 3 (0.4) |
| I want to improve my mental well-being | 567 (22.5) |
| I want to improve my overall well-being | 346 (61.0) |
| Improve mental health | 198 (34.9) |
| I want to feel clearer-headed, more alert, focused/be present | 87 (15.3) |
| I want to regain agency | 483 (19.2) |
| I want to be in control of my drinking | 330 (68.3) |
| I want to be in control (of my actions, life...) | 114 (23.6) |
| I do not want drinking to define me | 93 (19.3) |
| I want to live a different life | 321 (12.7) |
| I want to make space in my life for other things | 136 (42.4) |
| I want to live (longer) | 91 (28.3) |
| I want to be more... | 83 (25.9) |
| I want to improve my quality of life | 46 (14.3) |
| To have better relationships with the people in my life | 309 (12.3) |
| I am doing it for someone | 261 (84.5) |
| Drinking affects my relationships/social life | 48 (15.5) |
| My drinking affects the way I treat and impact people | 21 (6.8) |
| I want to improve my sex life | 4 (1.3) |
| A decision that drinking was too expensive | 228 (9.1) |
| Restore my energy | 212 (8.4) |
| I do not want to (re)experience the side effects/consequences | 162 (6.4) |
| Drinking hurts me | 94 (3.7) |
| I want to have a better relationship with alcohol | 64 (2.5) |
| I want to moderate my drinking, not abstain | 61 (95.3) |
| Temporary abstinence (eg, Dry January) | 4 (6.3) |
| I have changed my attitude about drinking | 43 (1.7) |
| To support or encourage people in my life to drink less/have a better relationship with alcohol | 43 (1.7) |
| Improve work life | 40 (1.6) |
| I am planning for my future (eg, starting a family/finding a partner/planning for retirement) | 36 (1.4) |
| Future family planning | 19 (52.8) |

XSL•FO
RenderX

| Categories and themes[a] | Sample users (n=2520), n (%) |
|---|---|
| Planning for retirement/old age | 17 (47.2) |
| Other | 30 (1.2) |
| Someone or something inspired me to | 28 (1.1) |
| Advice or concern | 26 (92.3) |
| Media | 2 (7.1) |
| I have seen the effects drinking has had on other people | 17 (0.7) |
| I do not want to end up like someone I know | 17 (100.0) |
| A significant holiday or event (eg, birthday or upcoming trip) | 17 (0.7) |

[a]The percentage of users for all categories and for themes within each category may be greater than 100% because each response could be coded multiple times.

[a]AUDIT: Alcohol Use Disorders Identification Test.

[b]The percentage of users for all categories may be greater than 100% because each response could be coded multiple times.

[c]Zone I (score 0-7), zone II (score 8-15), zone III (score 16-19), and zone IV (score 20-40).

### Category 1: I Want to Improve My Physical Health

Over half of users reported wanting to improve physical health (1329/2520, 52.7%), and most responses were under the theme "wanting to live a healthier lifestyle" (n=1129, 85%; such as unspecified goals to take care of one's general health or specific goals like lowering one's cholesterol), in contrast with being "worried about future health problems" (n=180, 13.6%; specific concerns such as future liver failure or cancer). The least common theme was having other health problems, which directly inspired a reduction attempt, including motives to stop the exacerbation of health problems caused through or impacted on by alcohol. This theme also described motives where alcohol reduction was not the primary goal, such as reducing consumption to aid recovery from something else.

The "improving physical health" category was reported by users across all age groups, increasing in prevalence from 34.9% (30/86) among 18 - 24 year olds to 63.4% (59/93) among those over 65 years old. This category had similar prevalence among male and female users. The prevalence of users reporting wanting to improve physical health was higher among those in AUDIT risk zone I (76/123, 61.8%), with prevalence at a lower level (457/956, 47.8%) among those in risk zone IV.

### Category 2: I Want to Feel Better in My Body

Nearly a third of users (823/2520, 32.7%) reported wanting to feel better in their body. The most common theme was "Help with weight loss" (718/823, 87.2%), followed by "Improve my fitness" (113/823, 13.7%), consisting of either a general motive to do so or wanting to improve in a specific sport or exercise. The other themes were "I want to improve how I look" (48/823, 5.8%), "I want to improve the features on my body" (32/823, 3.9%), mainly referring to the skin, and "I want to feel more attractive/sexy" (3/823, 0.4%).

All age groups reported wanting to feel better in their body (20.4% to 36.1%), with prevalence highest across age groups 35 - 64 years old. More female users reported wanting to feel better in their body (572/1594, 35.9%) compared with male users (251/926, 27.1%). The prevalence of reporting wanting to feel better in their body was highest among AUDIT risk zone I (48/123, 39%) and lowest in prevalence among risk zone IV (271/956, 28.3%).

### Category 3: I Want to Improve My Mental Well-Being

Around a quarter of users reported wanting to improve their mental well-being (567/2520, 22.5%), with the most common theme being to improve their overall well-being (346/567, 61%), mainly wanting to feel better or not wanting drinking to impact on their mood. Some also specified wanting a better relationship with themselves as well as to feel less irritable, stressed, or frustrated. The other common theme was improving mental health (198/567, 34.9%), which specified motives to reduce the symptoms of mental health conditions such as anxiety and depression, and a general desire to improve mental health.

It was more common to report wanting to improve mental well-being as a motive to drink less among users in the age groups of 18 - 54 years (over 23.6%). The prevalence of reporting wanting to improve mental well-being was slightly higher among female users (396/1594, 24.8%) compared with male users (171/926, 18.5%). Reporting wanting to improve mental well-being was highest among users in AUDIT risk zone IV (243/956, 25.4%) and lowest in prevalence among risk zone I (13/123, 10.6%).

### Category 4: I Want to Regain Agency

Wanting to regain agency was reported by 19.2% (483/2520) of users, with the most common theme being "I want to be in control of my drinking" (330/483, 68.3%), which mainly consisted of a fear of becoming or being dependent as well as feeling guilty or ashamed about one's drinking or expressing concern about usually drinking more than intended. A small percentage of users wanted to make themselves or others proud or prove that they could reduce their consumption, whereas others felt that they "have to" or "need to" reduce for unspecified reasons.

Within this category, a quarter of users (114/483, 23.6%) expressed wanting to be in control over more than just their drinking, such as their actions or life. This consisted of users reporting wanting to be more responsible/reliable and the feeling that alcohol prevents them from making "good" choices. Lastly,

XSL•FO
RenderX

some users mentioned that they did not want drinking to define them (93/483, 19.3%), which mainly referred to issues of identity (ie, feeling more like oneself without drink), but also not wanting their drinking to embarrass them or others, and not wanting others to worry about them.

Over a quarter of users aged 18 - 24 years reported this category of wanting to regain agency (24/86, 27.9%) compared with slightly lower prevalence (17.6% to 21.6%) among other age groups. More female users (337/1594, 21.1%) reported wanting to regain agency as a motive to drink less compared with 15.8% (146/926) of male users. Reporting wanting to regain agency was highest among users in AUDIT risk zone IV (232/956, 24.3%) and lowest in risk zone I (11/123, 8.9%).

### Category 5: I Want to Live a Different Life

Wanting to live a different life was reported by 12.7% (321/2520) of users. The most common theme was "I want to make space in my life for other things" (136/321, 42.4%), then "I want to live (longer)" (91/321, 28.3%) and "I want to be more" (83/321, 25.9%) of a certain quality, such as productive, successful, or resilient.

This category was more prevalent among users aged 25 - 44 years (~15%) compared with other age groups and was similarly prevalent between male (119/926, 12.9%) and female users (202/1594, 12.7%). The prevalence of wanting to live a different life was highest among users in the AUDIT risk zone IV (152/956, 15.9%) and lowest among those users in risk zone I (6/123, 4.9%).

### Category 6: To Have Better Relationships With the People in My Life

Wanting to have better relationships with the people in their life as a motive to drink less was reported by 12.3% (309/2520) of users. The main theme of this category was "I am doing it for someone" (261/309, 84.5%), such as family, partners, friends, or someone unspecified. Other themes included "Drinking affects my relationships/social life" (48/309, 15.5%) and "My drinking affects the way I treat and impact people" (21/309, 6.8%).

The prevalence of wanting to have better relationships with the people in their life was higher among the 25 - 34 and 35 - 44 years age groups (60/431 [13.9%] and 133/738 [18%], respectively) and lower among other age groups. A higher proportion of male users reported this motive to drink less (136/926, 14.7%) compared with female users (173/1594, 10.9%). The prevalence of wanting to have better relationships with the people in their life was highest among users in AUDIT risk zone IV (179/956, 18.7%) and lowest among users in risk zone I (6/123, 4.9%).

### Other Categories

All other categories for motives to drink less were mentioned by fewer than 10% of users: deciding that drinking was too expensive (228/2520, 9.1%), restoring energy (212/2520, 8.4%), not wanting to experience the side effects/consequences (162/2520, 6.4%), drinking hurts me (94/2520, 3.7%), wanting to have a better relationship with alcohol (64/2520, 2.5%), changed attitude about drinking (43/2520, 1.7%), supporting others to drink less (43/2520, 1.7%), improve work life (40/2520, 1.6%), planning for future (36/2520, 1.4%), other (30/2520, 1.2%), being inspired to (28/2520, 1.1%), seen the effects drinking has on others (17/2520, 0.7%), and a significant event (17/2520, 0.7%).

## Discussion

### Main Findings

The most common motives to reduce drinking among users of the Drink Less app in the United Kingdom were wanting to improve their physical health, feel better in their body, improve their mental well-being, and regain agency. These participants, by the nature of the sample, had all taken some action to download and start using an evidence-based digital intervention with evidence for its effectiveness [19], suggesting that these individuals were in either the "action" stage of change or perhaps in "preparation" [28], having downloaded the app but may not have planned on using it immediately. Wanting to improve their physical health was reported as a motive to drink less by over half of users, and this was present across all age groups though increased with age. Nearly a third of users reported wanting to feel better in their body (eg, weight loss and improved fitness), and this was more common among female users. Interestingly, there were clear patterns for the prevalence of motives across users' AUDIT risk zones. "Improving physical health" and "wanting to feel better in their body" were highest among users drinking at low-risk levels and decreased in prevalence with higher AUDIT risk zones (though in absolute terms, these motives were still higher than for other motives for drinking less).

In contrast, motives to "improve their mental well-being," "regain agency," "live a different life," and "have better relationships" all had the highest prevalence among users at risk of alcohol dependence and the lowest among those drinking at low risk. About a quarter of users reported wanting to improve their mental well-being, and this motive was reported more among users aged between 18 and 54 years and was slightly more common among female users. Around a fifth of users reported wanting to regain agency, mainly reporting wanting to be in control of their drinking and being worried about dependency. About a tenth reported wanting to live a different life and to have better relationships with the people in their life.

### Comparison With Other Studies

The findings of this study that physical health and wanting to feel better in their body were common motives for drinking less is consistent with previous research [8-11,14,15,29], including that these motives were more commonly reported by older age groups. This study found that improving mental health was a relatively common motive to drink less though this motive is not typically seen across previous research, where there tends to be a focus on physical health, or health more generally. There were also some motives that came up in previous research, such as fewer social occasions [10] and treatment or therapy [15], that were not common in this study. This could be due to differences in the samples with participants in the current study being users of an alcohol reduction app and therefore consciously trying to reduce their alcohol consumption. The

XSL•FO
RenderX

motive to drink less due to worries around dependency tended not to be included as a response option in previous research but came up in this study and another study where participants could give free responses [15]. The samples in these two studies both included heavier drinkers, highlighting the importance of sampling heavier drinkers when assessing motives for drinking less as an important group to consider for tailoring public health interventions.

This study found motives to drink less that were about seeking a positive outcome (eg, wanting to feel happier and have better relationships with themselves) and not just avoiding a negative outcome (eg, not wanting to experience the consequences and worries about dependency). Another study asking participants about their motives to drink less without using preset response options found similarly positive reasons for reducing alcohol consumption [15].

A previous study found differences in motives based on the level of severity of alcohol use with "consequence-related" reasons (such as health problems and financial concerns) more common among those with more severe alcohol use, and "drifting out" reasons (changes in circumstances such as having children) more common among those with less severe alcohol use [30]. While the current study saw different patterns in motives to drink less based on AUDIT risk zone, it did not follow the same pattern as the previous study with physical health and feeling better in their body (both "consequence-related" reasons) being more common among app users with low-risk AUDIT zones.

### Strengths and Limitations

A major strength of this study was that data collection was remote and in a naturalistic setting, meaning these findings are likely to have high external validity. Participants were also those that were currently trying to reduce their alcohol consumption and prompted to enter their motive (as free text) for drinking less when they downloaded the app, avoiding issues around recall bias. The app is also a stand-alone intervention, so no researcher was present, avoiding potential fear of judgment or social conformity [31]. Data were also collected from users with a range of ages and AUDIT scores, therefore, capturing data from heavier drinkers and people at risk of alcohol dependence, which is sometimes underrepresented in household surveys [16].

This study collected data from 2016 to 2024, though we did not adjust for time periods such as the COVID-19 pandemic, which are known to have affected the prevalence of attempts to reduce alcohol consumption in the United Kingdom [32]. Previous research has looked at time trends in motives for attempts to reduce alcohol consumption from a nationally representative cross-sectional survey and saw increases in attempts motivated by health concerns and those motivated by cost and social factors [9]. Future research could look to identify any trends in the prevalence of different alcohol reduction motives among this user group over time to see if this reflects what was seen across the general population.

The app users included in this study, who reported their motive for drinking less in the app, were only a small proportion of total app users (fewer than 3%) and differed by their age, sex, and AUDIT risk zone. Therefore, this sample is self-selected and not generalizable to all users of the Drink Less app. However, not completing the prompt is unlikely to have a bearing on users' readiness to change given the level of motivation already likely present; participants had downloaded and completed the onboarding process for an app named "Drink Less," which has a description in the UK App Store of "Are you looking to cut down how much you drink? If so, we can help." Also, there is previous evidence that the extent of behavioral engagement (eg, time spent on the app) with Drink Less does not have a mediating effect on its effectiveness, suggesting that these users who have greater behavioral engagement with the app and report their motive for drinking less are not more or less likely to be successful in reducing their alcohol consumption [33]. Therefore, we believe these findings provide useful information on what actually motivates an attempt to reduce alcohol consumption even though they are from a self-selected sample of users, and these may generalize to other people motivated to reduce their alcohol consumption but not using the app. Further to this, we only analyzed data on motives to drink less alcohol from one app. While the Drink Less app is a widely used, popular [21] and evidence-based app [19], future research could explore whether similar motives to drink less are reported in other alcohol reduction apps.

The vast majority of motives to drink less were reported within 1 week of downloading the app suggesting that these motives related to why they had made an attempt to reduce their drinking (by downloading the Drink Less app). While we do not know if users sustained their motive throughout their attempt, they were able to update it at any point. A quarter of users last updated their motive to drink less over a week after downloading the app, meaning that their AUDIT score (recorded on the day of app download) may have changed since onboarding. However, while the AUDIT-C (the first 3 items) is responsive to change [34], the full 10-item AUDIT is likely to be less responsive to change given the nature of the remaining 7 items. Further to this, in this study, we categorized users by their AUDIT risk zone (ie, scores ranging from 0 to 40 grouped into 4 categories), meaning a greater change in AUDIT score would be required for the user to change AUDIT risk zone.

Another limitation of this study was that the content analysis was conducted manually by one researcher, with no interrater reliability calculated.

### Future Research

Understanding people's motivations to reduce their alcohol consumption has important implications for how to motivate risky drinkers to make reduction attempts given that identifying these motives is commonly addressed across guidance documents and treatment manuals for brief alcohol interventions [7]. We found different patterns in motives to drink less for people at either end of the AUDIT risk zone, which could be further explored in other populations and potentially used to inform tailoring of public health campaigns and interventions. This study's findings can be used to inform materials or public health campaigns encouraging risky drinkers to use the Drink Less app with examples of other users' motives, rather than to

XSL•FO
RenderX

only consume less alcohol given the skepticism and denial of national alcohol guidelines that some people have (eg, [35]).

By the nature of the sample, all the study participants were using an evidence-based digital intervention with evidence for its effectiveness for helping users reduce 2 UK units a week over a 6-month period [19], and therefore, their motives to drink less had all resulted in action to do something. However, we do not know whether there were certain types of motives which are more successful in reducing alcohol consumption than others, and this is something that we will look to investigate in the future.

The findings of this study also informed the response options for the question on motives for cutting down on alcohol consumption included in the Alcohol Toolkit Study [36] (with 2 new response options "Improve my mental health or well-being" and "To avoid bad experiences when drinking (aggressive behavior, hangovers, risk of injury, etc)" included).

## Conclusions

Users of an alcohol reduction app, Drink Less, in the United Kingdom most commonly reported improving their physical health, feeling better in their body, improving their mental well-being, regaining agency, living a different life, and having better relationships with the people in their life as their motives for reducing their alcohol consumption. Wanting to improve mental well-being, regain agency, live a different life, and to have better relationships were all motives that had the highest prevalence among people at risk of alcohol dependence and the lowest among those drinking at low-risk levels. Understanding the motives behind why people are attempting to reduce their alcohol consumption, particularly among heavier drinkers, could inform how to encourage more people to make an attempt to reduce their drinking.

## Funding

The development, refinement, and evaluation of Drink Less has been funded by the National Institute for Health and Care Research (NIHR), NIHR School for Public Health Research (NIHR SPHR), UK Centre for Tobacco and Alcohol Studies (UKCTAS), Society for the Study of Addiction (SSA), and Cancer Research UK (CRUK). This study is part of and contributing to a larger programme of research funded by NIHR (NIHR302923). The views expressed are those of the author(s) and not necessarily those of the NIHR or the Department of Health and Social Care.

## Data Availability

The data used in this study cannot be shared openly as the app users were not asked to consent for their data to be made open access.

## Authors' Contributions

Conceptualization: CG
Data curation: CG
Formal analysis: LPS
Funding acquisition: CG
Supervision: CG
Supervision: OMM
Writing – original draft: LPS, CG
Writing – review & editing: LPS, OMM, DK, JAC, CG

## Conflicts of Interest

LPS, OMM, DK, and JAC have no conflicts of interest to declare. CG worked on a project funded by Alcohol Change UK (ACUK) that ran from September 2021 to March 2023, with a no cost extension running until March 2025. The authors have since become aware that ACUK received <0.6% of its funds in 2024 - 25 from Lucky Saint, an organization that produces and sells nonalcoholic drinks, and owns a pub that sells standard alcoholic drinks. In March 2025, Lucky Saint became an associate member of The Portman Group, a self-regulatory organization that is fully funded and controlled by the alcohol industry.

## Abstract

**Background:** In France, reluctance toward hepatitis B vaccination remains high, despite the availability of a safe and effective vaccine to prevent this infection. To boost vaccination coverage, it is therefore essential to identify the factors that are likely to encourage a more favorable opinion of this vaccine. Health literacy (HL) is one such factor. It refers to the individual ability to access, understand, critically appraise, and apply health information to make informed decisions about health issues for oneself and for others.

**Objective:** This study explored the mechanisms through which HL might affect opinions about hepatitis B vaccination, both directly and indirectly, by relevant factors, including opinions about vaccination in general, trust in government health agencies, and trust in medical doctors.

**Methods:** The analysis used data from the SLAVACO-Wave 3 (Suivi Longitudinal des Attitudes à l'Égard d'un Vaccin Contre la COVID-19) survey, conducted in December 2021 among a representative sample of French adults (N=1932). Favorable and unfavorable opinions of hepatitis B vaccination were measured using a 5-point Likert scale, while HL was assessed using the $HLS_{19}$-Q12 questionnaire (12-item general health literacy questionnaire used in Health Literacy Survey 2019-2021). A structural equation model examined the relationship between HL and hepatitis B vaccination opinions, taking into account the potential mediating role of trust in the health care system (ie, government health agencies and medical doctors).

**Results:** Findings showed that individuals with a favorable opinion of hepatitis B vaccination (1437/1932, 74.4%) had a higher HL level than those with a negative or neutral opinion (62.6 vs 57.0, $P$<.001). The association between HL and hepatitis B vaccination opinions was fully mediated by trust in the health care system. The indirect effect of HL was estimated at 0.068 (95% CI 0.042-0.093), accounting for 52.4% (0.068/0.1297) of the total effect. This effect was particularly pronounced in people over 50 years (0.084, 95% CI 0.042-0.126, accounting for 0.084/0.1306, 64.3% of the total effect). Goodness-of-fit indicators were satisfactory.

**Conclusions:** Enhancing HL might positively influence hepatitis B vaccination opinions and uptake through greater trust in the health care system. From a public health perspective, strategies should go beyond providing clear information and access to vaccines and actively work to strengthen trust in health care institutions and professionals. National campaigns correcting misconceptions about hepatitis B vaccination could be complemented by targeted interventions for groups most likely to hold negative opinions. Repeating this survey in the post–COVID-19 context could also reveal different trends, given evolving public perceptions of vaccines and health authorities.

## Introduction

Hepatitis B is a communicable infectious disease associated with an increased risk of cirrhosis and liver cancer [1]. In 2022, the World Health Organization (WHO) estimated that 254 million people were living with chronic hepatitis B infection and that approximately 1.1 million died as a result of the disease, mainly from cirrhosis or hepatocellular carcinoma [2]. Although safe and effective vaccines have been developed, 1.5 million new hepatitis B virus (HBV) infections occur annually worldwide [3,4]. The WHO aims to reduce the incidence of chronic hepatitis infection by 90% and the annual number of deaths due to chronic hepatitis by 65% before 2030 [5]. To achieve these targets, the organization's guidelines [6] include systematic treatment for people with chronic HBV infection, the prevention of perinatal and infant infection through vaccination, and catch-up vaccinations for both high-risk populations (eg, injection drug users, men who have sex with men, and sex workers) and health care professionals. As of 2023, hepatitis B vaccination for infants was mandatory in 190 countries, and global coverage was estimated at 83% [7].

Hepatitis B is slightly endemic in France; in 2016, the estimated prevalence in the general population in metropolitan France was 0.3% [8]. Although this prevalence may seem low in the European context—it is higher than in Germany (0.2%) but lower than in Southern and Eastern European countries, where it varies between 0.5% and 1.5% [9]—hepatitis B remains a major public health problem due to its chronic progression and severe complications. Moreover, the burden is marked by unequal distribution, with significant socioeconomic disparities disproportionately affecting the most vulnerable populations [10]. Its impact is also reflected in mortality; from 2005 to 2020, a total of 2133 deaths occurred in patients hospitalized for related complications (cirrhosis or hepatocellular carcinoma) in metropolitan France, representing a lethality rate of 6% [11]. Beyond morbidity and mortality, hepatitis B also generates substantial direct and indirect health care costs, particularly in the stages of cirrhosis or hepatocellular carcinoma [12]. To combat this infection, starting in the late 1980s, the French National Authority for Health recommended vaccination for individuals at high risk of exposure and for all newborns. Moreover, a catch-up program for children and adolescents younger than 15 years was implemented in 1995 [13]. In the context of the WHO's goal to eliminate viral hepatitis by 2030, primary vaccination became mandatory for all infants born on or after January 1, 2018 [14]. The French primary childhood immunization schedule recommends 3 doses: the first at 2 months of age, the second at 4 months, and a booster at 11 months [15]. Full immunization is considered complete once the 3-dose series has been administered. As the majority of HBV infections in France in adults occur through sexual transmission [16], vaccination is strongly encouraged for persons older than 18 years of age. The immunization schedule consists of 3 doses, administered at 0, 1, and 6 months [15]. According to the 2021 LaboHEP survey, which was conducted among all public and private bioanalytical testing laboratories to estimate hepatitis screening activity, the rate of positive HBV diagnosis in metropolitan France was 54/100,000, representing a 10% increase compared to 2016 [17]. In addition, although hepatitis B vaccination coverage among infants has gradually increased over time, reaching over 90% for children aged 21 months since 2018 [18], it was below 50% among adolescents and adults in 2015 [19,20]; this reflects a clear generational gap in hepatitis B immunization.

Health Barometer surveys conducted between 2010 and 2023 show that in terms of vaccine hesitancy rankings in metropolitan France, the hepatitis B vaccine placed third after COVID-19 and influenza vaccines [21]. Despite this, no recent study has investigated the determinants of hesitancy over this vaccine. In the present analysis, we formulate the hypothesis that health literacy (HL), defined by Sørensen et al [22] as a concept "linked to literacy and that entails people's knowledge, motivation and competences to access, understand, appraise, and apply health information to make judgments and take decisions in everyday life concerning healthcare, disease prevention and health promotion to maintain or improve quality of life during the life course," might explain hepatitis B vaccine hesitancy in France. In general, higher HL is associated with greater vaccine acceptance and lower hesitancy [23]. This relationship may be influenced by the type of vaccine and the population studied. In the case of hepatitis B vaccination, controversies surrounding a potential link to demyelinating diseases [24] may contribute to differences or similarities compared to other vaccines. These specificities highlight that vaccine hesitancy is not uniform but rather a complex and multifactorial challenge to public health [25-27], frequently rooted as much in a lack of trust as in limited access to, and limited understanding of, vaccine-related information. Trust in the health care system—understood here as health agencies and medical doctors—is well-documented as a central determinant of vaccine acceptance [28,29]. However, it is often difficult to create strategies to build this trust. This gap highlights the relevance of exploring HL as a sustainable mediating lever to support trust [30]. Additionally, given that vaccine hesitancy does not necessarily regard specific vaccines but vaccination more broadly [31], any examination of opinions on a particular vaccine should also cover opinions on vaccination in general.

In this context, to enhance our understanding of hepatitis B vaccine opinions in France, this study explored the mechanisms by which HL influences the general public's opinion on hepatitis B vaccination. We used a structural equation model [32] to investigate the direct and indirect effects of HL on these opinions. A model with 5 hypotheses was analyzed as follows: (1) a higher HL is associated with a more favorable opinion of hepatitis B vaccination (direct effect represented by the coefficient "A"); (2) a higher HL contributes positively to trust

XSL•FO
RenderX

in the health care system and this trust is associated with a more favorable opinion of hepatitis B vaccination (indirect effect via "D" and "C"); (3) a higher HL has a positive influence on opinions about vaccination in general, which in turn are associated with a more favorable opinion of hepatitis B vaccination (indirect effect via "E" and "B"); (4) together, trust in the health care system and positive opinions of vaccination in general are mediators in the relationship between HL and opinions on hepatitis B vaccination (indirect effect via "D, F, and B"); and (5) the expected effect of HL on opinions of hepatitis B vaccination, in hypotheses 1 to 4, might vary according to gender, age, and financial deprivation.

## Methods

### Recruitment Procedure and Study Sample

For the present analysis, we used data from SLAVACO-Wave 3 (Suivi Longitudinal des Attitudes à l'Égard d'un Vaccin Contre la COVID-19), which was conducted between December 2 and 17, 2021. The SLAVACO project was a multiwave longitudinal survey conducted across metropolitan France. Its primary objective was to study the evolution of public attitudes toward different aspects of COVID-19 vaccination and attitudes toward vaccines more generally. Data were collected by the French Provence-Alpes-Côte d'Azur Regional Health Observatory using online self-administered questionnaires, lasting approximately 15 minutes, sent to 25,800 French adults selected by random sampling in an online panel of over 750,000 French households (Bilendi panel). The quota sampling method was then used to obtain a final sample of 2022 respondents corresponding to the adult French population in terms of gender (male and female), age (18-24, 25-34, 35-49 50-64, and 75+ years), type of employment (farmers, craftsmen, executives, intermediate professions, employees, workers, retirees, and other inactives), and population density (<2000, 2000-20,000, 20,000-100,000, and >100,000 inhabitants) in respondents' region of residence (Alsace, Aquitaine, Auvergne, Burgundy, Brittany, Center, Île-de-France, Languedoc, Nord-Pas-de-Calais, Normandy, Pays de la Loire, and Provence-Alpes-Côte d'Azur) [33]. Final adjustments were applied by weighting the data with the raking ratio and the macro Calmar program of Statistical Analysis System. The latter was designed using census data from the French INSEE (National Institute for Statistics and Economic Studies) [34].

### Data Collected

After the participants' consent was obtained, we assessed their opinions about vaccination in general using a question taken from the national Health Barometer survey; this survey has been conducted regularly in France over the past 2 decades [35]. The question was as follows: "Are you strongly, moderately, not really or not at all in favour of vaccination in general?" with the following 5 answer options: "yes, strongly," "yes, moderately," "I don't have an opinion," "no, not really," and "no, not at all." Opinions specifically on hepatitis B vaccination were also assessed in SLAVACO using a similar question as follows: "Are you strongly, moderately, not really or not at all in favour of hepatitis B vaccination?" with the same 5-option response scale. Respondents who did not answer both of these 2 questions were excluded from the present analysis.

SLAVACO also assessed HL using the European Health Literacy Survey 2019-2021 Questionnaire, $HLS_{19}$-Q12 (12-item general health literacy questionnaire used in Health Literacy Survey 2019-2021). This questionnaire has been translated, applied, and validated in 17 countries [36,37], including France. Based on Sorensen's matrix, the $HLS_{19}$-Q12 comprises 12 items that measure HL in 4 cognitive dimensions (accessing, understanding, evaluating, and applying health information) and in 3 health contexts (health care, disease prevention, and health promotion) [22]. The answers to each question are selected on a 4-point scale from 0 (very difficult) to 3 (very easy). After summing the scores for all 12 items, we standardized the total score, ranging from 0 to 100, where a higher score reflected a higher level of HL. Internal consistency was excellent with a Cronbach $\alpha$ coefficient of 0.91.

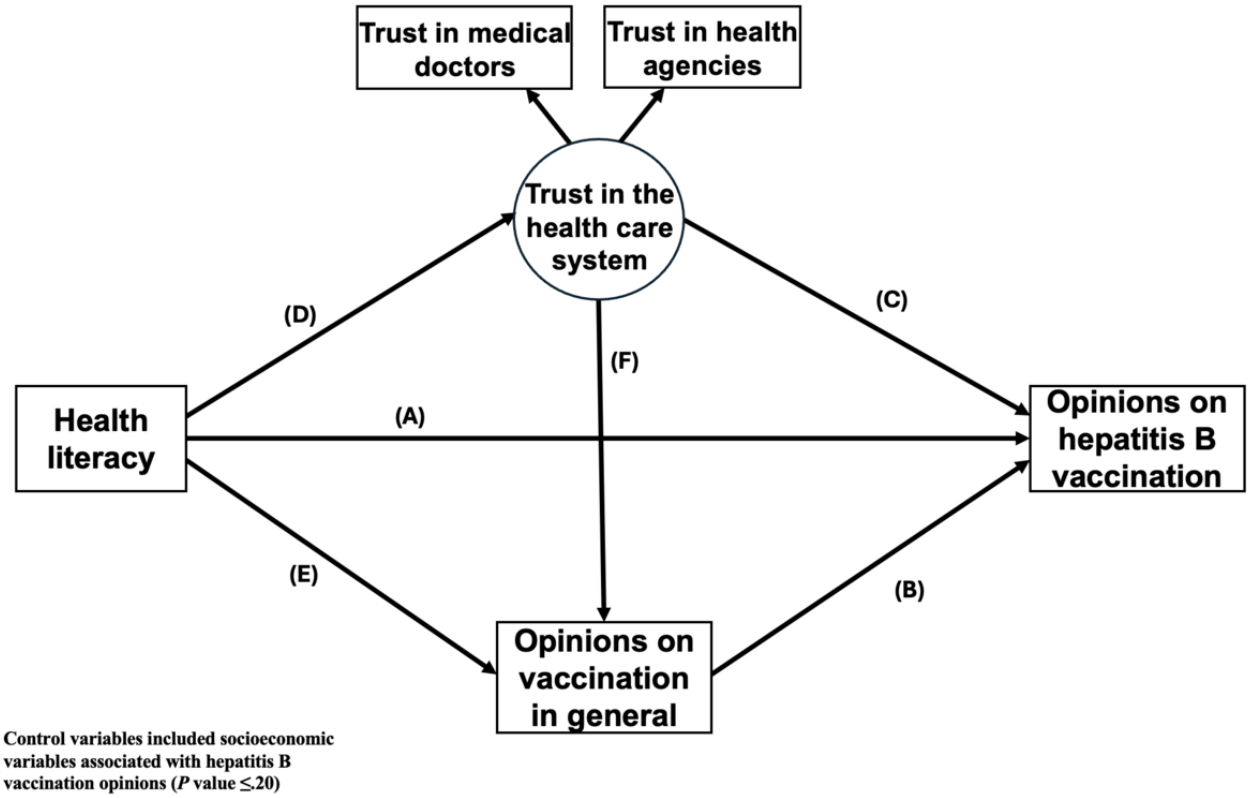
To measure trust in the health care system, we used the methodology used in the 2021 Political Confidence Barometer, the main French longitudinal study on public trust in politics [38]. We measured 2 dimensions: trust in government health agencies and trust in medical doctors. A 5-point scale ranging from 0 (no trust at all) to 4 (complete trust) was used for each measure.

Our analysis also included self-reported socioeconomic variables. Specifically, gender was reported using 3 categories (man, woman, and other), and age was categorized into the following groups: 18-24, 25-34, 35-49, 50-64, 65-74, and 75+ years, in line with the INSEE's age categories [39]. Educational attainment was measured using 6 categories: no educational qualification, lower secondary school certificate, upper secondary school certificate, bachelor's degree, master's degree, and doctorate, while employment status was recorded as currently employed, not employed, or retired. Financial deprivation was determined using the question "How easy or difficult is it for you to pay all your bills at the end of the month?" Respondents who answered "difficult" or "very difficult" were classified as having financial difficulties. Finally, the presence of one or more chronic diseases was assessed using a "yes" or "no" question.

### Statistical Analyses

Continuous variables were reported in terms of the mean and SD, while categorical variables were reported in terms of frequency and percentages. We performed descriptive analyses to explore covariables associated with opinions on hepatitis B vaccination. To do this, we treated these opinions and opinions on vaccination in general as binary variables: a favorable opinion was defined as an answer of "yes, strongly" or "yes, moderately." An unfavorable opinion was defined as responding "I don't have an opinion," "no, not really," or "no, not at all." For the bivariate and mediation analyses, a 0 to 4 scale was used ("no, not at all"=0; "no, not really"=1; "I don't have an opinion"=2; "yes, moderately"=3; and "yes, strongly"=4).

We conducted a Pearson correlation analysis to investigate the bivariate association between the 5 variables of interest (ie, opinions on vaccination in general, opinions on hepatitis B



XSL•FO
RenderX

vaccination, HL level, trust in government health agencies, and trust in medical doctors).

We performed a mediation analysis to explore whether favorable opinions toward vaccination in general and trust in the health care system mediated the association between HL and favorable opinions toward hepatitis B vaccination (Figure 1). Trust in the health care system was modelled using a latent variable based on 2 observed indicators: trust in government health agencies and trust in medical doctors. Possible mediation was then examined after stratification by gender (man vs woman), age (<50 years vs ≥50 years), and financial deprivation (yes vs no). The control variables included socioeconomic variables associated with hepatitis B vaccination opinions (*P* value ≤.20). The 95% CI for the direct, indirect, and total effects of the mediation models were estimated using 5000 bootstrap samples. The effects of HL were estimated per 10-point increase in the HL score. We used a series of indicators to assess the goodness-of-fit of the model: Tucker-Lewis Index (considered excellent above 0.95); comparative fit index (considered excellent above 0.95); and root-mean-square error of approximation (RMSEA, considered excellent if below 0.05).

**Figure 1.** Hypothesized mediation model for health literacy's effect on hepatitis B vaccination opinions (A-F are the coefficients from the Introduction).

All analyses were performed on the weighted database. Analyses were carried out with statistical R software (version 4.4.1; R Foundation), and the significance level was set to 5% for all 2-sided tests.

### Ethical Considerations

This study was approved in France by the Ethics Evaluation Committee of the National Institute of Health and Medical Research (IRB00003888) on February 9, 2021 (21-770). After receiving information about SLAVACO-Wave 3, informed consent was obtained from all the participants before they started the survey. In accordance with standards practice for web-based surveys, we did not have access to any data that could identify respondents. Participants received no compensation.

## Results

### Sample Characteristics

Among the 2022 individuals who participated in SLAVACO-Wave 3, we excluded 90 (4.4%) because of missing answers to the questions on opinions on hepatitis B vaccination and/or vaccination in general. Of the 1932 adults comprising this study's sample, 52.6% (n=1016) were women and 34.1% (n=658) were retirees (Table 1). Most of the participants (n=1184, 61.4%) had at least an upper secondary school certificate, and most (n=1210, 62.6%) did not report financial difficulties. Half of the participants (n=952, 49.3%) reported one or more chronic diseases. A quarter (n=495, 25.6%) expressed an unfavorable opinion about hepatitis B vaccination, and a fifth (n=375, 19.4%) towards vaccination in general. Among those hesitant toward hepatitis B vaccination, 58.6% (290/495) were nevertheless favorable to vaccination in general, while 18.6% (290/1557) of those favorable to vaccination in general expressed hesitancy toward hepatitis B vaccination.

| Variables | Overall (N=1932) | Opinions on hepatitis B vaccination | | *P* value |
|---|---|---|---|---|
| | | Favorable (n=1437, 74.4%) | Unfavorable (n=495, 25.6%) | |
| Moderately (3) | 1232 (63.8) | 901 (73.1) | 331 (26.9) | |
| Completely (4) | 462 (23.9) | 393 (85.2) | 69 (14.8) | |

Approximately half the sample (n=923, 47.8%) reported trusting government health agencies, while 87.7% (n=1694) reported trusting medical doctors. The mean HL score in the sample was 61.1 (SD 17.0). Individuals with a favorable opinion of hepatitis B vaccination had a higher HL score than those with an unfavorable opinion (62.6 vs 57.0, *P*<.001).

## Correlation Analyses

The correlation matrix for all variables in the mediation model is reported in Table 2. A favorable opinion on hepatitis B vaccination was associated with a higher HL level (*r*=0.18, *P*<.001), a favorable opinion on vaccination in general (*r*=0.44, *P*<.001), a higher level of trust in government health agencies (*r*=0.27, *P*<.001), and a higher level of trust in medical doctors (*r*=0.22, *P*<.001). A higher HL level was positively and significantly correlated with a positive opinion on vaccination in general (*r*=0.20, *P*<.001), with a higher level of trust in government health agencies (*r*=0.27, *P*<.001), and with a higher level of trust in medical doctors (*r*=0.27, *P*<.001). A favorable opinion on vaccination in general was positively associated with a higher level of trust in government health agencies (*r*=0.27, *P*<.001), and with a higher level of trust in medical doctors (*r*=0.27, *P*<.001).

**Table 2.** Correlation matrix of mediation model variables.

| Variables | Health literacy (A) | Opinion on hepatitis B vaccination (B) | Opinion on vaccination in general (C) | Trust in government health agencies (D) | Trust in medical doctors (E) |

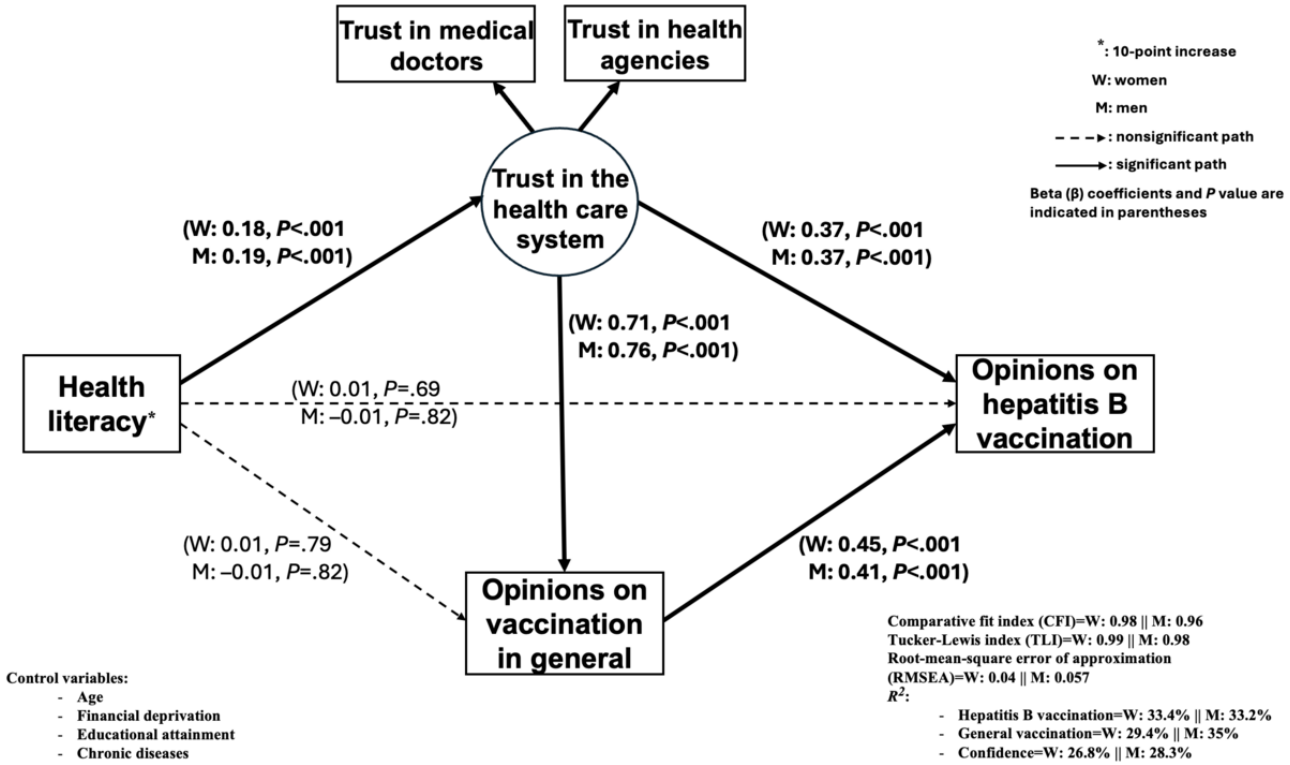
## Mediation Analyses

The mediation model for all participants, with 2 mediators and a direct path, is presented in Figure 2. A significant and positive relationship was observed between trust in the health care system and a favorable hepatitis B vaccination opinion (β=0.37; *P*<.001). There was also a significant positive relationship between a favorable opinion on vaccination in general and a favorable opinion on hepatitis B vaccination (β=0.44; *P*<.001). A higher level of trust in the health care system had a significant and strong positive association with a favorable opinion on vaccination in general (β=0.74; *P*<.001). A higher HL level was positively and significantly associated with a higher level of trust in the health care system (β=0.18; *P*<.001), but not associated with a favorable opinion on vaccination in general and with a favorable opinion on hepatitis B vaccination (β=0.00; *P*=.89 and β=–0.00; *P*=.98, respectively). All estimations were adjusted for educational attainment and the presence of chronic diseases.

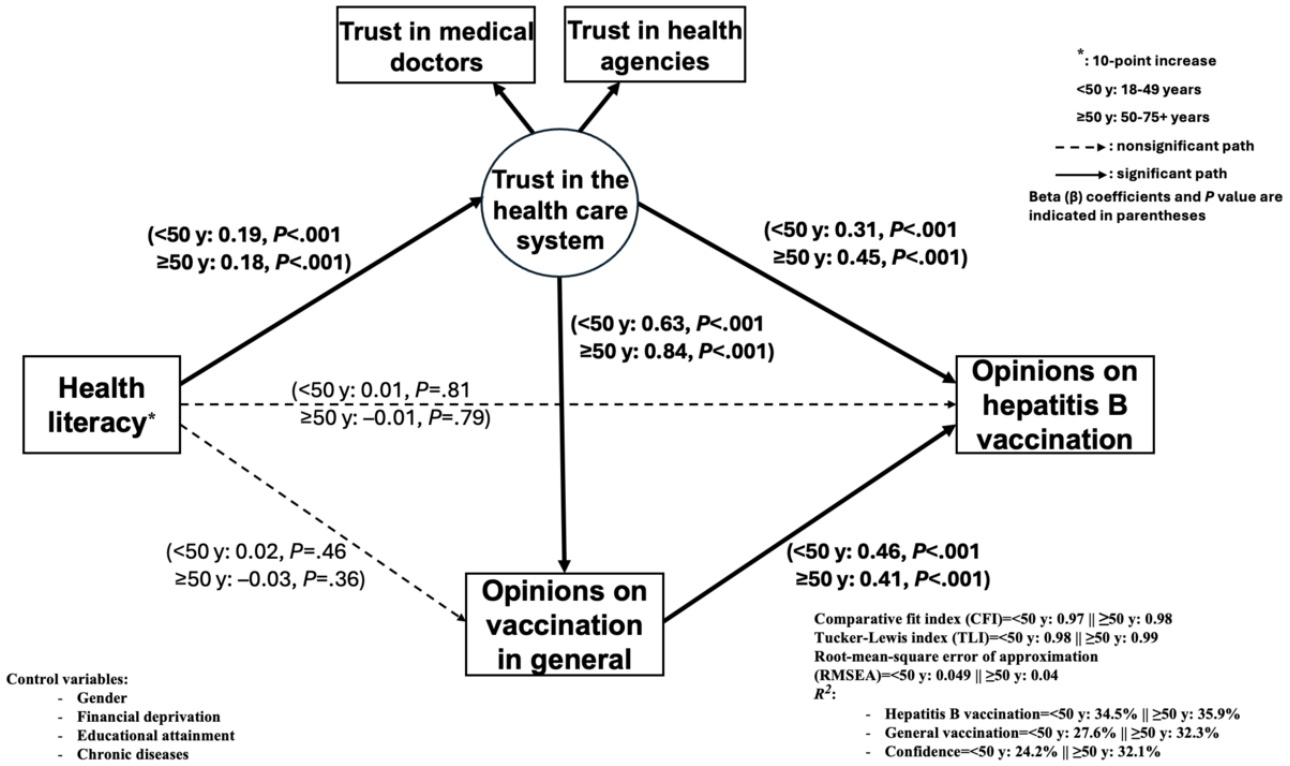


XSL•FO
RenderX

**Figure 2.** Mediation model of health literacy on opinions about hepatitis B vaccination (N=1932).

After stratifying by gender (Figure 3), we found that a higher level of trust in the health care system was positively associated with a favorable opinion on hepatitis B vaccination in women and men (β=0.37; *P*<.001 for both). A higher level of trust in the health care system was also significantly associated with a favorable opinion about vaccination in general for both genders (women: β=0.71; *P*<.001 and men: β=0.76; *P*<.001). A higher HL level was positively associated with a higher level of trust in the health care system for both genders (women: β=0.18; *P*<.001 and men: β=0.19; *P*<.001) but had no direct effect on a favorable opinion about vaccination in general or about hepatitis B vaccination.

**Figure 3.** Mediation model of health literacy on opinions about hepatitis B vaccination according to gender (number of women=1016; number of men=916).



XSL•FO
RenderX

In terms of age (Figure 4), similar associations were observed in the <50 years and ≥50 years age groups. A higher level of trust was positively associated with a favorable opinion on hepatitis B vaccination, with a stronger association observed in adults ≥50 years (β=0.45; *P*<.001) than in younger adults (β=0.31; *P*<.001). The association between trust in the health care system and a favorable opinion on vaccination in general was strong for both age groups (<50 years: β=0.63; ≥50 years: β=0.84; *P*<.001). A higher HL level had a positive influence on trust in the health care system in both age groups (<50 years: β=0.19; ≥50 years: β=0.18; *P*<.001) but had no significant direct effect on a favorable opinion about vaccination (general or hepatitis B).

**Figure 4.** Mediation model of health literacy on opinions about hepatitis B vaccination according to age (number of participants aged <50 years=943; number of participants aged ≥50 years=989).

Lastly, after stratifying by financial deprivation (Figure 5), the association between trust in the health care system and a favorable hepatitis B vaccination opinion was stronger among individuals who did not have financial deprivation (β=0.41; *P*<.001) than among those who did (β=0.29; *P*=.006). In contrast, the association between trust in the health care system and a favorable opinion on vaccination in general was more pronounced among individuals who had financial difficulties (β=0.82; *P*<.001) than among those who did not (β=0.69; *P*<.001). A higher HL level remained positively associated with trust in the health care system in both subgroups (no financial deprivation: β=0.19; financial deprivation: β=0.16; *P*<.001), although there was no direct effect on favorable vaccination opinions (in general or hepatitis B).

XSL•FO
RenderX

**Figure 5.** Mediation model of health literacy on opinions about hepatitis B vaccination according to financial deprivation (number of participants with no financial deprivation=1210; number of participants with financial deprivation=722).

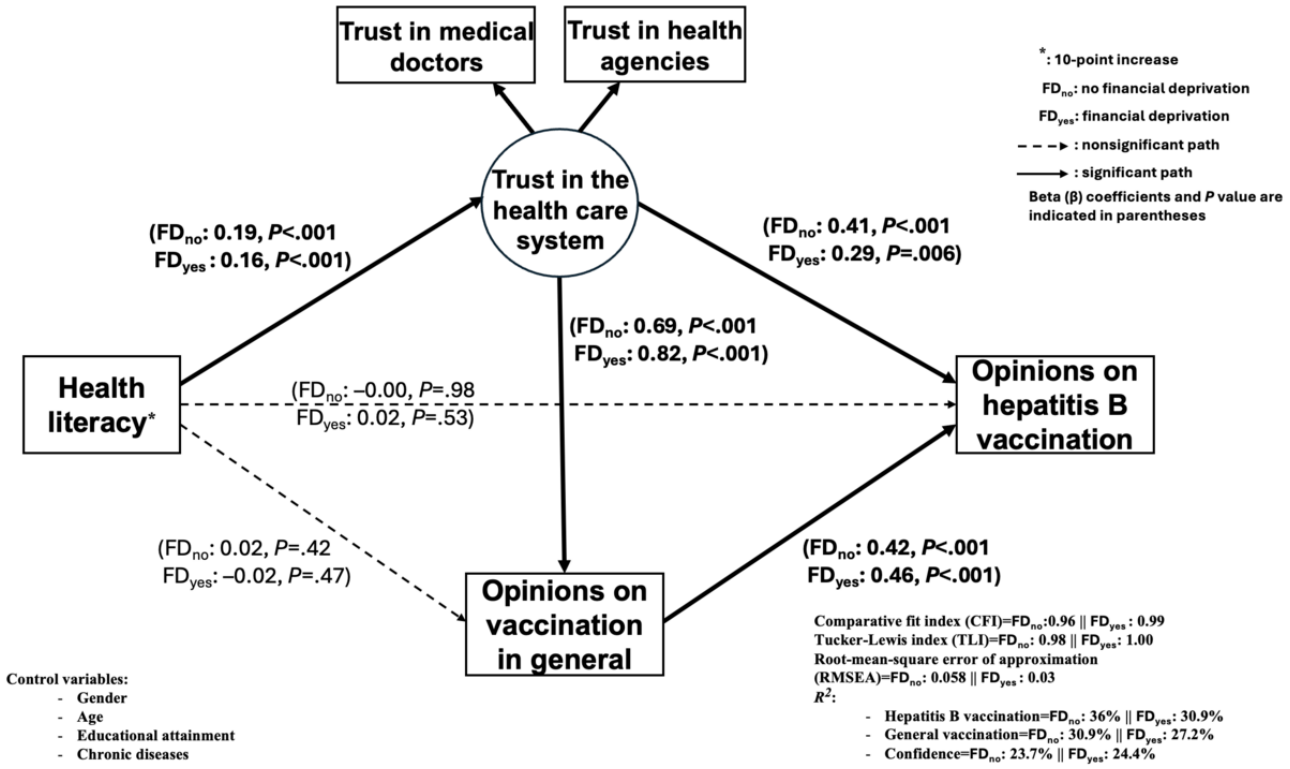


Table 3 shows that the effect of HL on hepatitis B vaccination opinions among all participants was fully mediated by trust in the health care system, after adjusting for educational attainment and the presence of chronic diseases. When trust was the only mediator, the indirect effect of HL was estimated at 0.068 (95% CI 0.042-0.093), accounting for 52.4% (0.068/0.1297) of the total effect. When trust and opinion on vaccination in general were combined as parallel mediators, the indirect effect attributable to HL was 0.059 (95% CI 0.048-0.07), representing 45.5% (0.059/0.1297) of the total effect. Mediation analyses stratified by gender, age, and financial deprivation status also confirmed the complete mediation of the relationship between HL and hepatitis B vaccination opinion through trust in the health care system, even after adjustment for different sets of control variables depending on the stratum (gender, age, educational attainment, financial deprivation, and chronic diseases). The total effect of HL on hepatitis B vaccination opinion was more pronounced among women and those without financial deprivation.

[a]10-point increase.

[b]Estimated effects are controlled for gender, age, educational attainment, financial deprivation, and chronic diseases.

[c]Estimated effects are controlled for age, educational attainment, financial deprivation, and chronic diseases.

[d]Estimated effects are controlled for gender, educational attainment, financial deprivation, and chronic diseases.

[e]Estimated effects are controlled for gender, age, educational attainment, and chronic diseases.

For the control variables (Multimedia Appendix 1), the presence of chronic diseases was significantly associated with a higher level of trust in the health care system (β=0.11; *P*=.004), particularly among women (β=0.15; *P*=.004) and individuals without financial deprivation (β=0.14; *P*=.006). About educational attainment, having only a lower or upper secondary school certificate was negatively associated with the level of trust in the health care system among women (lower secondary school certificate β=–0.29; *P*=.004; upper secondary school certificate β=–0.23; *P*=.03) and among financially deprived individuals (β=–0.27; *P*=.01 and β=–0.26; *P*=.03, respectively).

All models showed an excellent goodness-of-fit (Tucker-Lewis Index >0.95, comparative fit index >0.95, and RMSEA <0.05), except for the men stratum (RMSEA=0.057) and for individuals without financial deprivation (RMSEA=0.058).

## Discussion

### Principal Findings

France has one of the highest rates of vaccine hesitancy in the world. According to an international study conducted in 2015, a total of 41% of French people considered that vaccines might be dangerous, which was the highest rate among the 67 countries studied [40]. The significant proportion of individuals expressing an unfavorable opinion on hepatitis B vaccination (495/1932, 25.6%) in our present study highlights the persisting skepticism concerning vaccines in the French population. Our findings highlight that this skepticism was more pronounced than for vaccination in general. The moderate correlation between opinions on vaccination in general and those on hepatitis B vaccination (*r*=0.44) indicates that these 2 dimensions only partially overlap; this justifies the detailed focus on this specific vaccine.

The particularly high level of skepticism toward hepatitis B vaccination, which we identified, could be the result of a historical context marked by health controversies, particularly in the 1990s, when cases of central nervous system demyelination after hepatitis B vaccination raised fears in the general public of a potential link [41]. Although subsequent investigations did not establish a causal link [24,42] and even though French authorities officially declared that there was no risk of developing a demyelinating disease from hepatitis B vaccination [43], the impact of these events on the general perception of hepatitis B vaccination persists today.

Our study results showed that women, people with a lower level of educational attainment, and individuals with no chronic disease were all significantly more likely to have an unfavorable opinion about hepatitis B vaccination. This greater vaccine hesitancy in women might reflect their greater engagement with health information than men. This engagement may, in turn, leave them more exposed to negative discourses, especially if they echo personal or shared experiences linked to past health controversies [44]. Although men in our study were more likely to have a favorable opinion of hepatitis B vaccination, some studies have suggested that women are more invested in health care and child-rearing than men, and so are more likely to get this vaccine [45,46].

The significant association that we found between the presence of chronic diseases and a higher level of trust in the health care system might partly explain the more favorable opinions toward hepatitis B vaccination, which we observed among people with chronic diseases. In addition to a lack of trust in the health care system, the greater reluctance to hepatitis B vaccination we observed in individuals with no chronic disease could be explained by greater complacency, identified as one of the key determinants of vaccine hesitancy. Complacency occurs when the perception of risk from vaccine-preventable diseases is low and when vaccination is not perceived as necessary [47]. Without a perceived risk to their health and without regular contact with health care services, these individuals might develop a less favorable opinion about vaccination.

The association we observed between intermediate educational attainment (ie, having only a lower or upper secondary school certificate) and less trust in the health care system among women and people in financial difficulty suggests that this level of education may sometimes be associated with a more skeptical attitude toward medical recommendations. This association is also reflected in the relatively high proportion of individuals in our study who expressed an unfavorable opinion about hepatitis B vaccination within these 2 subgroups. About the influence of educational attainment on vaccination opinions, findings in the literature are mixed; some studies emphasize its central role in shaping provaccination opinions [40,48], while others show that individuals with higher educational attainment might also

XSL•FO
RenderX

be more likely to adopt skeptical attitudes [49]. These contrasting views highlight the need to develop other, more actionable and multidimensional measures, such as HL.

In our study, a favorable hepatitis B vaccination opinion was significantly positively associated with a higher HL level before mediation was taken into account. In the mediation model, this association was fully mediated by trust in the health care system, even after stratifying by gender, age group, and financial difficulties. There was no significant direct relationship between HL and opinions on vaccination (ie, general or hepatitis B) when trust was considered in all strata. Although no study to date has directly investigated the mediating role of trust in the health care system on the relationship between HL and hepatitis B vaccination opinion, many studies have highlighted the positive influence of HL and trust in the health care system on hepatitis B prevention behaviors. For example, a group study of sociocultural barriers to hepatitis B prevention among Korean Americans suggested that there were specific HL barriers that governed individuals' behavior in terms of hepatitis B prevention and care access [50]. Similarly, in a study in the Democratic Republic of Congo [51], trust in the health care staff increased the public's acceptance and the effectiveness of community initiatives to prevent mother-to-child transmission of the disease, especially initiatives focusing on adherence to vaccination and antiviral uptake. HL could become an essential tool to overcome the challenge of improving trust in the health care system to reduce vaccine hesitancy [52]. By strengthening individuals' ability to understand how the health care system functions, to evaluate the reliability of health information, and to communicate effectively with professionals in order to both avoid negative interactions and engage proactively in their own care [53], HL could contribute to creating sustainable trust in the health care system.

Our key finding—the absence of a direct relationship between HL and a favorable opinion on hepatitis B vaccination—might be specific to this vaccination. This is because, in order to have a favorable opinion, a degree of trust in the expected long-term benefits (which are not visible) is needed, especially given the controversy surrounding this vaccine in France. This finding may also reflect the specific nature of vaccination as a public health issue; vaccination is particularly exposed to conflicting information at the heart of political and social debate, and is increasingly shaped by dynamics of trust or the lack thereof, which in turn are often associated with collective reasoning. Accordingly, the absence of a direct relationship between HL and opinions on vaccination in general, which we observed in the mediation model, might indicate the limitations of using an approach based solely on increasing general HL to combat vaccine hesitancy. This is a very important point, because over the last decade, the vaccine debate has become a way for the French public to express social tensions and political mistrust [54]. As our results suggest, interventions to improve the level of HL, such as cross-cutting strategies, might contribute to strengthening trust in the health care system.

## Limitations

This study has limitations. First, its cross-sectional design prevented us from establishing causal relationships between the variables analyzed. Second, the quota sampling method we used does not guarantee the geographical and socioeconomic representativeness of the whole population of French adults. Our findings must therefore be interpreted with caution. Third, the SLAVACO survey was conducted during the COVID-19 pandemic, when vaccination was the subject of intense media attention, frequently affected by misinformation and disinformation. This may have strongly influenced participants' opinions on vaccination and amplified the mediating effect of trust in the health care system, which we observed. Lastly, following the framework by Parker [55], HL is influenced by both internal (cognitive, educational, and socioeconomic) and external (social, health care, and macroeconomic) factors. Our study did not systematically assess these determinants, highlighting the need for tools that capture the full spectrum of HL in future research.

## Conclusions

Enhancing the level of HL may lead to greater trust in government health agencies and medical doctors, which are 2 essential dimensions for positively influencing hepatitis B vaccination opinions. To achieve the WHO's goal of hepatitis elimination by 2030, future public health strategies in France should take HL and these 2 dimensions into account to effectively reduce the country's currently high rate of hepatitis B vaccine hesitancy. From a public health perspective, these findings suggest that strategies should not only focus on providing clear information about vaccines and ensuring access, but also on actively strengthening trust in health care institutions and professionals. National communication campaigns aimed at correcting misconceptions about hepatitis B vaccination could be complemented by targeted interventions for groups most likely to hold negative opinions, such as women, individuals with intermediate education levels, those without chronic diseases, and higher-income populations. In parallel, incorporating HL modules into school curricula and community programs could provide a sustainable means of fostering trust and supporting informed decision-making.

For future research, it will be important to develop and apply vaccine-specific HL tools, to longitudinally assess the causal relationships between HL and the key determinants of vaccine hesitancy (7C-model), and to compare these dynamics across different vaccines. A broader assessment of trust encompassing all 6 components of the health care system—governance, financing, service delivery, human resources, health products and interventions, and health information—as defined by the WHO [56], would also provide a more comprehensive understanding. Conducting a similar survey in the post–COVID-19 context could also reveal different trends, reflecting the evolving public perceptions of vaccines and health authorities.

## Acknowledgments

We would like to thank all the persons who contributed to the SLAVACO (Suivi Longitudinal des Attitudes à l'Égard d'un Vaccin Contre la COVID-19) project. Our thanks to Jude Sweeney, MSc, for the English revision and copyediting of this paper.

## Funding

This research was supported by grants from the Agence Nationale de la Recherche (ANR-20-COVI-0035-01, ANR-20-COVI-0102, and ANR-22-CE36-0015-01) and the Agence Nationale de la Recherche Scientifique - Maladie Infectieuses Emergentes (ICOVAC). However, the funding sources had no part in the design of this study, the data analysis, or the writing of this paper. Additionally, BC is personally supported by the Aix-Marseille University PhD Programme.

## Data Availability

The datasets used and/or analyzed during this study are available from the corresponding author on reasonable request. Information and agreement to use $HLS_{19}$-Q12 (12-item general health literacy scale) can be found on the M-POHL (Action Network on Measuring Population and Organizational Health Literacy) web page.

## Authors' Contributions

BC, JM, and SB conceptualized this study. BC formally analyzed the data. BC wrote the original draft in preparation. BC, JM, and JKW wrote, reviewed, and edited this paper. All authors have read and agreed to the published version of this paper.

## Conflicts of Interest

None declared.

## Abstract

**Background:** Hypertensive disorders of pregnancy (HDP) may cause lasting vascular, cardiac, and renal damage, potentially increasing the risk of postpartum cardiovascular disease.

**Objective:** This study aimed to examine the association between gestational blood pressure (BP) trajectories in HDP and the risk of unrecovered BP at 6 weeks post partum.

**Methods:** A total of 3162 women with HDP were obtained from the antenatal care and the postpartum follow-up information system, between January 1, 2018, and December 31, 2024. Of the 3162 women included, 1674 had gestational hypertension, 607 had preeclampsia, 246 had chronic hypertension with superimposed preeclampsia, and 635 had chronic hypertension. Group-based trajectory modeling was used to fit systolic BP (SBP), diastolic BP (DBP), and mean arterial pressure (MAP) trajectories during pregnancy. Modified Poisson regression was used to assess the association between gestational BP trajectories and the risk of unrecovered BP at 6 weeks post partum.

**Results:** Trajectories of SBP, DBP, and MAP during pregnancy were significantly associated with unrecovered BP at 6 weeks post partum. For gestational hypertension, those with the high-consistent rise (adjusted relative risk [aRR] 2.493, 95% CI 1.093-5.689) and high-late surge SBP trajectories (aRR 4.535, 95% CI 1.884-10.917) were associated with a significantly increased risk of BP nonrecovery at 6 weeks post partum. Similar associations were observed for DBP and MAP. For chronic hypertension with superimposed preeclampsia, women with high-late surge in SBP (aRR 2.792, 95% CI 1.081-7.214), DBP (aRR 4.043, 95% CI 1.327-12.324), or MAP (aRR 4.018, 95% CI 1.462-11.045) had a significantly increased risk of BP nonrecovery at 6 weeks post partum. Among women with chronic hypertension, those with the high-consistent rise trajectories of SBP (aRR 2.557, 95% CI 1.256-5.207), DBP (aRR 3.862, 95% CI 1.673-8.913), and MAP (aRR 3.714, 95% CI 1.682-8.201) had a significantly increased risk of BP nonrecovery at 6 weeks post partum. Among women with preeclampsia, only high-consistent rise SBP trajectory remained significantly associated with unrecovered BP post partum (aRR 3.355, 95% CI 1.140-9.873). The high-consistent rise and high-late surge trajectories of SBP, DBP, and MAP in gestational hypertension started at similar initial levels and crossed at approximately 22 weeks of gestation.

**Conclusions:** The gestational BP trajectories in women with HDP are positively associated with the risk of unrecovered BP at 6 weeks post partum. Early identification of women at high risk for poor postpartum BP recovery through BP trajectory analysis may have important clinical implications for improving long-term cardiovascular outcomes in this population.

blood pressure trajectory; group-based trajectory modeling; hypertensive disorders of pregnancy; postpartum BP recovery status

## Introduction

Hypertensive disorders of pregnancy (HDP) encompass a spectrum of conditions characterized by elevated blood pressure (BP) during gestation, affecting approximately 5%-12% of pregnancies. Based on the type of disease, HDP include gestational hypertension (GH), preeclampsia-eclampsia, chronic hypertension (CHTN) with superimposed preeclampsia, and CHTN [1,2]. HDP pose a serious threat to maternal health and are among the leading causes of maternal morbidity and mortality worldwide [3]. Women with a history of HDP are at increased risk of developing cardiovascular disease (CVD), the leading cause of death among women [4,5].

Although BP in most patients with HDP gradually normalizes after delivery, the exact time to recovery remains inconsistent across studies [6-8]. The vascular, cardiac, and renal damage caused by HDP may persist beyond pregnancy [9], potentially resulting in persistent postpartum hypertension [10] and an increased long-term risk of adverse cardiovascular events [9]. Postpartum hypertension after preeclampsia may take up to 2 years to resolve [11]. A study found that 39% of women still had hypertension three months after delivery, while this figure dropped to 18% after 2 years [11]. Therefore, when studying remaining hypertension after pregnancies complicated by hypertensive disorders, it is important to take this time frame into consideration [12].

Evidence suggests that the first 6 weeks post partum represent a critical window for cardiovascular risk intervention [8,13]. This aligns with Chinese clinical guidelines, which recommend a postpartum follow-up visit at 6 weeks for women with HDP [14,15]. The Hypertension Canada guidelines recommend continued hypertension management and monitoring until at least 6 weeks post partum in women with cardiovascular risk factors [16]. From 2014 to 2017, HDP, including preeclampsia, accounted for 6.8% of pregnancy-related deaths in the United States, with 65% occurring within 6 weeks post partum [17]. Thus, assessment of BP recovery at this time point is of significant clinical relevance.

While clinical risk factors for impaired postpartum BP recovery are generally considered to include HDP subtype, BP at onset, and maximum antepartum systolic BP (SBP) [18-20], these single-time measurements are susceptible to variability. In contrast, BP trajectories derived from repeated measurements better capture cardiovascular adaptation during pregnancy and are stronger predictors of adverse outcome. For instance, first-trimester BP trajectories correlate strongly with later hypertension [21]. Thus, analyzing BP trajectories rather than isolated readings may offer superior insight into postpartum BP recovery in HDP.

In this study, we classified patients with HDP into 4 subtypes: GH, preeclampsia, CHTN with superimposed preeclampsia, and CHTN [14]. We modeled trajectories of SBP, diastolic BP (DBP), and mean arterial pressure (MAP) across multiple time points during pregnancy within each subtype to evaluate the association between BP trajectories during pregnancy and the risk of unrecovered BP at 6 weeks post partum. By elucidating the heterogeneity of BP changes across HDP subtypes, we aim to improve risk stratification and management of HDP. Furthermore, identifying high-risk trajectory may enable early detection of women at increased risk of poor BP recovery, thereby providing a scientific basis for individualized postpartum follow-up and early intervention of future CVD.

## Methods

### Study Participants

This study was mainly conducted in the western region of Guangdong Province, China, including Zhanjiang, Maoming, and Yangjiang. Data were obtained from the antenatal care and the postpartum follow-up information system. Routine clinical data from local maternity care, generated through standard practice, were used in this study without active recruitment. Diagnostic criteria for HDP were based on the Chinese Society of Obstetrics and Gynecology guidelines [14], consistent with international standards [2,22]. GH was defined as new-onset hypertension (SBP ≥140 mm Hg and/or DBP ≥90 mm Hg) after 20 weeks of gestation without proteinuria or other features of preeclampsia. Preeclampsia was diagnosed as new-onset hypertension after 20 weeks with either significant proteinuria or, in its absence, new-onset maternal organ dysfunction or placental-fetal compromise (eg, fetal growth restriction). CHTN referred to hypertension present before 20 weeks of gestation. CHTN with superimposed preeclampsia was diagnosed in women with CHTN who developed new features of preeclampsia after 20 weeks. Baseline information was collected for pregnant women who initiated antenatal records between January 1, 2018, and December 31, 2024. Inclusion criteria were (1) diagnosis of 1 of the 4 HDP subtypes (GH, preeclampsia, CHTN with superimposed preeclampsia, or CHTN), (2) at least 1 BP measurement in each trimester, with a total of ≥3 measurements during pregnancy, and (3) available BP data at 6-week postpartum follow-up. Exclusion criteria were (1) age <18 years, (2) history of smoking or alcohol consumption, (3) multifetal pregnancy, (4) women with severe CVDs (such as valvular heart disease, myocarditis sequelae and arrhythmias requiring medication), hematologic disorders (including anemia, thrombophilia, or coagulation dysfunction),

XSL•FO
RenderX

endocrine diseases (such as medication-requiring diabetes mellitus, thyroid diseases, and prolactinoma), or immune system diseases requiring hormone therapy, and (5) women with missing or incomplete BP data from antenatal or follow-up visits (only SBP or DBP available). After applying the inclusion and exclusion criteria, 3162 women were included in the final analysis. Specifically, 1674, 607, 246, and 635 pregnant women were classified as having GH, preeclampsia, CHTN with superimposed preeclampsia, and CHTN, respectively. A flowchart for the selection process of the study is provided in Figure S1 in Multimedia Appendix 1.

### BP Measurement During Pregnancy

According to the Chinese Guideline of Preconception and Prenatal Care [23], pregnant women are recommended to have regular checkups, including BP measurement, at 7 specific gestational windows. BP is measured at every antenatal visit. However, as this is a retrospective study relying on routine health information systems, not all measured BP values were consistently recorded or available in the databases. Therefore, to ensure data completeness and consistency across all included women, we applied the criterion of at least 1 recorded BP measurement per trimester (first, second, and third). The description of BP measurement frequency during pregnancy is provided in Tables S10 and S11 in Multimedia Appendix 1. SBP and DBP measurements during pregnancy were obtained from the electronic medical record system. MAP was calculated as (SBP + 2 × DBP)/3. According to the Guidelines for the Management of Hypertensive Disorders of Pregnancy (2015), participants were required to rest for at least 5 minutes prior to each BP measurement. HDP are defined as SBP ≥140 mm Hg or DBP ≥90 mm Hg on at least 2 measurements in the same arm. In women with newly detected elevated BP, a repeat measurement after ≥4 hours is required, and hypertension is diagnosed if the initial and repeat measurements both show SBP ≥140 mm Hg or DBP ≥90 mm Hg. In cases of severe hypertension, defined as SBP ≥160 mm Hg or DBP ≥110 mm Hg, the diagnosis can be confirmed by a repeat measurement after several minutes.

### Assessment of Covariates

Maternal baseline information during the study period was extracted from the electronic medical record system. Data included demographic characteristics (maternal age and education level), obstetric history (parity status, vaginal deliveries, cesarean deliveries, gravidity, abortion history, and gynecological surgery history), delivery-related factors (mode of delivery, delivery gestational age, and intrapartum BMI), and neonatal characteristics (sex, birth weight, and Apgar scores at 1, 5, and 10 minutes). Intrapartum BMI was calculated as weight at delivery (kg)/height ($m^2$). Missing covariates were imputed using a random forest–based method to ensure the reliability of the analyses. Covariates adjusted in modified Poisson regression models were determined based on previous literature [21,24] and results from univariate analyses, including maternal age, education level, gravidity, delivery gestational age, parity status, mode of delivery, neonatal birth weight, and sex. As data on medication use during pregnancy and the postpartum period were not available, this variable could not be adjusted for in this analysis.

### Exposure and Outcome

In this study, the exposure was defined as BP trajectory during pregnancy. Group-based trajectory modeling (GBTM) was conducted using the TRAJ procedure (the Stata command for group-based trajectory modeling); in Stata (version 18.0; Stata Corp) to identify SBP, DBP, and MAP trajectories. GBTM classifies individuals with similar developmental patterns within a heterogeneous population, allowing for better subgroup characterization [25,26]. As BP measurements are continuous and normally distributed, trajectory fitting used a censored normal model [27]. Since no universally accepted criteria exist for optimal model selection [28], objective indices, trajectory plot simplicity, clinical interpretability, and practical use were considered to select the final model in this study [29]. Starting from the third-order polynomial, models with various polynomial orders were repeatedly constructed and compared. Model fitting parameters for GBTM are presented in Tables S1-S8 in Multimedia Appendix 1. The objective criteria for selecting the optimal GBTM model included (1) lower absolute values of Bayesian information criterion and Akaike information criterion indicating better model fit, (2) average posterior probability of assignment >0.7 for each trajectory group, (3) odds of correct classification >5.0 for each trajectory group, (4) each trajectory group accounting for at least 5% of the sample, (5) good concordance between the posterior probability of group membership (Pj) and the actual proportion of group membership (πj), (6) minimum proportion of each trajectory group [30], and (7) statistical significance of the highest-order polynomial term in each trajectory.

The outcome was the BP recovery status at 6 weeks post partum, defined as a binary variable. BP recovery to normotension at 6 weeks post partum was defined as SBP <140 mm Hg and DBP <90 mm Hg, while BP nonrecovery to normotension was defined as SBP ≥140 mm Hg or DBP ≥90 mm Hg (1 mm Hg=0.133 kPa). BP measurements at 6 weeks post partum were measured in patients with resting HDP using an electronic sphygmomanometer. BP measured at 6 weeks post partum was obtained by a qualified physician. If the reading was abnormal (≥140/90 mm Hg), the measurement was repeated.

### Statistical Analysis

Statistical analyses were conducted using R software (version 4.4.2; R Foundation for Statistical Computing) and Stata 18.0. Statistical tests were 2-sided, and $P \leq .05$ was considered statistically significant. The normality of continuous variables was assessed by the Shapiro-Wilk test, and homogeneity of variance by the Bartlett test. Variables that met normality and homogeneity of variance assumptions were presented as mean (SD), and for multiple group comparisons, one-way analysis of variance (ANOVA) was performed. Variables not meeting normality assumptions were presented as median (IQR), and the Kruskal-Wallis test was used for multiple group comparisons. Categorical variables were expressed as n (%), with group comparisons performed using the chi-square test or Fisher exact test. Postpartum BP recovery status at 6 weeks (nonrecovery=1 and recovery=0) was used as the dependent

XSL•FO
RenderX

variable, and SBP, DBP, and MAP trajectory groups as independent variables. Modified Poisson regression was used to estimate risk ratios and 95% CIs for the association between gestational BP trajectories and postpartum BP nonrecovery. Sensitivity analysis was conducted among individuals with at least 4 BP measurements during pregnancy, including at least 1 per trimester, by repeating the trajectory fitting and regression analyses to assess the robustness of the main findings (Figure S2 and Table S9 in Multimedia Appendix 1).

### Ethical Considerations

This study complied with the Declaration of Helsinki and was approved by the ethics committee of Guangdong Women and Children Hospital (number 20251125). Informed consent was waived due to the retrospective study design. All data were anonymized to protect participant confidentiality. No compensation was provided to participants.

## Results

### Baseline Characteristics of Study Participants

A total of 3162 pregnant women were included in the study. Of these, 1674 were diagnosed with GH, 607 with preeclampsia, 246 with CHTN with superimposed preeclampsia, and 635 with CHTN. The proportions of women with gravidity ≥3 were 38.11% (638/1674), 42.17% (256/607), 41.87% (103/246), and 50.08% (318/635), respectively. The proportions of multiparous women were 53.11% (889/1674), 60.13% (365/607), 55.69% (137/246), and 68.35% (434/635), respectively. The median maternal age was 31.00 (27.00–35.00), 30.00 (27.00–34.00), 32.00 (28.00–36.00), and 33.00 (30.00–37.00) years, respectively. The median gestational age at delivery was 38.71 (37.57–39.71), 38.71 (37.43–39.57), 38.00 (36.71–39.11), and 38.29 (37.29–39.29) weeks, respectively (Table 1).

### Trajectories of BP During Pregnancy

A total of 4 trajectories of SBP, DBP, and MAP were identified for GH, and 3 for preeclampsia, CHTN with superimposed preeclampsia, and CHTN. Trajectories were named according to overall relative position and slope and were consistent across SBP, DBP, and MAP within each subtype. For GH, the identified trajectories were (1) low-late gradual rise trajectory, (2) low-late rapid rise trajectory, (3) high-consistent rise trajectory, and (4) high-late surge trajectory (Figure 1). For preeclampsia, trajectories were (1) low-stable trajectory, (2) mid-mid stable trajectory, and (3) high-consistent rise trajectory (Figure 1). For CHTN with superimposed preeclampsia, trajectories were (1) low-stable trajectory, (2) mid-stable trajectory, and (3) high-late surge trajectory (Figure 1). For CHTN, the trajectories were (1) low-stable trajectory, (2) mid-stable trajectory, and (3) high-consistent rise trajectory (Figure 1).

**Figure 1.** Trajectories of systolic blood pressure (SBP), diastolic blood pressure (DBP), and mean arterial pressure (MAP) during pregnancy in different types of hypertensive disorders of pregnancy in Western Guangdong, China, 2018-2024. ### Incidence of Unrecovered BP at 6 Weeks Post Partum by BP Trajectories During Pregnancy

For GH, the high-late surge SBP trajectory was associated with the highest rate of BP nonrecovery at 6 weeks post partum (29/204, 14.2%) compared to the other 3 SBP trajectories. For DBP, there was no statistically significant difference in nonrecovery rates between the high-late surge and high-consistent rise trajectories, while significant differences were observed among the remaining DBP trajectories. For MAP, significant differences were observed among all trajectories, with the high-late surge trajectory showing the highest nonrecovery rate (22/164, 13.4%; Figure 2). For preeclampsia, only the high-consistent rise SBP trajectory had a higher rate of BP nonrecovery at 6 weeks post partum (16/155, 10.3%) than the mid-mid stable (8/293, 2.7%) and low-stable (4/159, 2.5%) SBP trajectories (Figure 2). For CHTN with superimposed preeclampsia, the high-late surge DBP trajectory had a higher rate of BP nonrecovery (6/22, 27.3%), compared to the low-stable (7/130, 5.4%) trajectory. MAP trajectories showed a similar distribution (Figure 2). For CHTN, the high-consistent rise SBP trajectory was associated with a higher rate of BP nonrecovery at 6 weeks post partum (12/60, 20%) than the low-stable trajectory (16/235, 6.8%). DBP and MAP trajectories showed a similar distribution of nonrecovery rates as the corresponding SBP trajectories (Figure 2).

**Figure 2.** Incidence of unrecovered blood pressure (BP) at 6 weeks postpartum by BP trajectories during pregnancy in different types of hypertensive disorders of pregnancy in Western Guangdong, China, 2018-2024. CHTN: chronic hypertension; DBP: diastolic blood pressure; GH: gestational hypertension; MAP: mean arterial pressure; PE: preeclampsia; SBP: systolic blood pressure.

### Association Between BP Trajectories During Pregnancy and the Risk of Nonrecovery to Normotension at 6 Weeks Post Partum

In the adjusted model for GH, compared to pregnant women with the low-late gradual rise SBP trajectory, those with the high-consistent rise (adjusted relative risk [aRR] 2.493, 95% CI 1.093-5.689) and high-late surge SBP trajectories (aRR 4.535, 95% CI 1.884-10.917) were associated with a significantly increased risk of BP nonrecovery at 6 weeks post partum. Similar associations were observed for MAP, with the high-consistent rise (aRR 4.838, 95% CI 1.890-12.382) and high-late surge (aRR 6.717, 95% CI 2.414-18.691) trajectories showing increased risks. For DBP trajectories, the low-late rapid rise (aRR 3.064, 95% CI 1.075-8.736), high-late surge (aRR 6.452, 95% CI 2.103-19.798), and high-consistent rise (aRR 5.603, 95% CI 1.941-16.177) trajectories were all significantly associated with increased risk of BP nonrecovery at 6 weeks post partum, compared to the low-late gradual rise trajectory (Table 2).

In the adjusted model for preeclampsia, only high-consistent rise SBP trajectory remained significantly associated with BP nonrecovery (aRR 3.355, 95% CI 1.140-9.873; Table 2).

In the adjusted model for CHTN with superimposed preeclampsia, compared to the low-stable trajectory, women with high-late surge in SBP (aRR 2.792, 95% CI 1.081-7.214), DBP (aRR 4.043, 95% CI 1.327-12.324), or MAP (aRR 4.018, 95% CI 1.462-11.045) had a significantly increased risk of BP nonrecovery at 6 weeks post partum. Additionally, women with mid-stable DBP trajectory (aRR 3.412, 95% CI 1.467-7.937) and MAP trajectory (aRR 2.280, 95% CI 1.030-5.049) were also associated with higher risk (Table 2).

[e]MAP: mean arterial pressure.

[f]CHTN: chronic hypertension.

In the adjusted model for CHTN, compared to pregnant women with the low-stable trajectory, those with the high-consistent rise trajectories of SBP (aRR 2.557, 95% CI 1.256-5.207), DBP (aRR 3.862, 95% CI 1.673-8.913), and MAP (aRR 3.714, 95% CI 1.682-8.201), as well as mid-stable trajectories of DBP (aRR 2.536, 95% CI 1.224-5.256) and MAP (aRR 2.095, 95% CI 1.071-4.098) had a significantly increased risk of BP nonrecovery at 6 weeks post partum (Table 2).

### Sensitivity Analysis

In the sensitivity analysis, 1656 individuals were diagnosed with GH, 603 with preeclampsia, 245 with CHTN with superimposed preeclampsia, and 631 with CHTN. For GH, 4 trajectories were identified for each BP type, while 3 trajectories were identified for each of the other subtypes. The changing trends of each BP trajectory were highly similar to those in the main analysis: most trajectories remained stable in early pregnancy, followed by a marked increase in the third trimester. Sustained-rising and late-acceleration BP patterns were still observed and remained statistically associated with unresolved postpartum BP ($P$<.05). For instance, regarding SBP, pregnant women who exhibited the high-consistent rise trajectories were associated with a significantly increased risk of BP nonrecovery at 6 weeks post partum (GH: aRR 2.529, 95% CI 1.110-5.765; preeclampsia: aRR 3.230, 95% CI 1.101-9.477; CHTN: aRR 2.575, 95% CI 1.262-5.250). For CHTN with superimposed preeclampsia, women with high-late surge in SBP (aRR 2.759, 95% CI 1.068-7.133) had a significantly increased risk of BP nonrecovery at 6 weeks post partum. This is similar to the results of our main analysis (Figure S2 and Table S9 in Multimedia Appendix 1).

## Discussion

### Principal Findings

In this study, GBTM were used to fit BP trajectories in pregnancy for different HDP subtypes of pregnant women. The results revealed variations in the number and shape of trajectories across HDP subtypes, which is consistent with the findings by Sinkey et al [31], who also reported divergent BP trajectories among different HDP categories [31]. Another study investigating dynamic BP changes during pregnancy similarly indicated that BP trajectories reflect, to some extent, the type of HDP, with SBP, DBP, and MAP following generally consistent overall trends within the same subtype, differing mainly in magnitude and timing [32]. In our analysis, we also found that SBP and MAP trajectories within the same subtype were highly comparable. Although SBP and DBP trends were not entirely consistent within subtypes, this finding supports the view that these 2 parameters may follow a distinct trajectory pattern [33]. Furthermore, our results demonstrated that women with HDP who exhibited higher overall BP trajectory levels during pregnancy had a greater risk of being nonrecovery to normotension at 6 weeks post partum. A prospective cohort study examining the association between early-pregnancy BP trajectories and postpartum hypertension also found a graded increase in risk for postpartum hypertension, ranging from moderate-rapid-decline to sustained-high trajectories [21]. Other studies have similarly identified risk gradients from low to high for DBP and MAP trajectories [34,35]. Within the GH subgroup, we observed that both the high-consistent rise trajectory and high-late surge trajectory for SBP, DBP, and MAP started at similar baseline levels but crossed around 22 weeks of gestation. Moreover, women with high-late surge trajectory had a higher risk of unrecovered BP at 6 weeks post partum compared to those with high-consistent rise trajectory. These findings suggest that the period around 22 weeks of gestation may represent a critical window for risk stratification and intervention. This timing aligns with the characteristic hemodynamic shift in pregnancy, during which BP normally reaches its lowest point before commencing a subsequent rise [36-38]. The divergence of pathological trajectories we identified at this juncture indicates that women who progress to GH begin to exhibit distinct deviations from the expected physiological pattern. The crossing of trajectories likely captures differing degrees of maladaptation in vascular function. Consequently, assessing BP trends across this window thus offers a dynamic metric for early risk stratification regarding postpartum BP recovery [39,40]. For women with elevated BP in the first and second trimester, intensified monitoring during the second and third trimester is recommended to facilitate timely detection of accelerating BP trends, accurate trajectory classification, and informed initiation of antihypertensive therapy. However, further research and clinical trials are warranted to validate these observations.

A systematic review showed that in women with HDP, SBP did not change significantly in the first 6 months of pregnancy and began to rise by 31 mm Hg in the third trimester [33]. Our study also identified similar patterns. Specifically, the low-late gradual rise and low-late rapid rise SBP trajectories for GH, the low-stable and mid-mid stable SBP trajectories for preeclampsia,

XSL•FO
RenderX

the low-stable and mid-stable SBP trajectories for CHTN with superimposed preeclampsia, and CHTN were all relatively stable during the first and second trimesters but increased in the third trimester, with the degree of increase varying by subtype. Additionally, across all 4 HDP subtypes, we identified a subset of women with specific SBP trajectories characterized by high baseline levels and SBP values exceeding 140 mm Hg in the third trimester. Although the high-consistent rise trajectory in GH did not exceed this threshold in the third trimester, it had the highest baseline level and showed a linear rising trend. Our results indicate that these women had greater difficulty achieving BP recovery at 6 weeks post partum, consistent with previous studies reporting that more severe and longer duration of HDP are associated with greater vascular, renal, and multisystem injury, leading to poorer postpartum BP recovery [8,18]. In this study, SBP trajectories across all 4 HDP types were significantly associated with the risk of unrecovered BP at 6 weeks post partum. This may be attributable to SBP being a better predictor of CVD [41], providing biological plausibility for our findings.

Regarding DBP trends, our study showed different trends, mainly in the second trimester. Specifically, women with GH, preeclampsia, and CHTN who exhibited high-consistent rise trajectories, as well as those with GH showing high-late surge trajectory, all demonstrated rising DBP during the second trimester. This is similar to previous research reports stating that in women with HDP, DBP shows an upward trend, increasing by approximately 5 mm Hg in the second trimester compared with the first trimester [42,43]. Additionally, some trajectories in our study—such as the low-late gradual rise and low-late rapid rise trajectories in GH, and the low-stable and mid-mid stable trajectories in preeclampsia, as well as the low-stable and mid-stable trajectories in CHTN—did not show significant rising or falling trends during the second trimester but began to increase toward the end of the second trimester. This trend differs from most previous reports. Similar trends were observed in CHTN with superimposed preeclampsia. Notably, previous studies have suggested that women with GH may experience a distinct time point—occurring at various stages of pregnancy—at which DBP rises abruptly. Before this point, DBP typically remains stable and within the normal range, but increases sharply thereafter [44], further supporting the concept of heterogeneous dynamic BP changes during pregnancy. Finally, across all subtypes, DBP trajectories significantly associated with unrecovered BP at 6 weeks post partum ($P<.05$) were characterized by higher overall levels. Specifically, in women with CHTN with superimposed preeclampsia and those with CHTN, the relevant trajectories reached DBP ≥90 mm Hg before 20 weeks of gestation, whereas in women with GH, this threshold was attained after 20 weeks.

In this study, baseline levels and trends of MAP were similar to those of SBP. Similar to the SBP results, pregnant women with GH or CHTN who exhibited high-consistent rise MAP trajectory, as well as those with GH and CHTN with superimposed preeclampsia who exhibited high-late surge MAP trajectory, were all at high risk for unrecovered BP at 6 weeks post partum. Unlike the SBP trajectories, the mid-stable MAP trajectory in the CHTN with superimposed preeclampsia and the CHTN remained statistically associated with the risk of unrecovered BP at 6 weeks post partum. Previous studies have shown that MAP has predictive value for adverse pregnancy outcomes [45] and may be superior to both SBP and DBP in clinical application [46], possibly because elevated MAP induces abnormalities in the nitric oxide (NO) synthesis process, thereby triggering a series of vascular dysfunctions [47]. However, research on the application of MAP in pregnancy is still limited [48], and further studies are needed.

Giorgione et al [49] demonstrated that persistent postpartum hypertension following HDP is predicted by a confluence of demographic factors (age or Afro-Caribbean ethnicity), clinical metrics (early pregnancy MAP and BMI), and, most significantly, peripartum echocardiographic evidence of pathological cardiac remodeling (elevated left ventricular mass index or relative wall thickness) and subclinical myocardial dysfunction (impaired global longitudinal strain and diastolic indices). Their findings posit that persistent hypertension reflects underlying cardiovascular maladaptations unmasked by pregnancy, which can be effectively identified through peripartum screening [49]. Little is known about the potential mechanisms linking dynamic changes in BP during pregnancy to postpartum BP recovery status. A study using a new 3D miniheart model revealed that GH may activate cell death signaling pathways and promote cardiac fibrosis, leading to cardiovascular damage; preeclampsia may cause vascular dysfunction-related inflammation, protein disorders, and endothelial dysfunction, thereby adversely affecting cardiovascular health [50]. A retrospective analysis of patients with preeclampsia and CHTN with superimposed preeclampsia demonstrated that autonomic dysregulation may occur within the first week post partum [51]. An imbalance between sympathetic and parasympathetic regulation can promote elevated BP and peripheral vasoconstriction, thereby increasing cardiac afterload and myocardial oxygen consumption [51]. Moreover, women with CHTN, who typically have hypertension prior to pregnancy, often present with underlying endothelial dysfunction. This dysfunction may be further aggravated by systemic inflammation during pregnancy, contributing to persistent postpartum hypertension [52].

Endothelial dysfunction is an early pathological change in hypertension [53,54]. Soluble fms-like tyrosine kinase-1 (sFlt1) and placental growth factor (PLGF) are important factors affecting maternal endothelial function, and their abnormal expression is closely related to endothelial dysfunction. sFlt1 is an antiangiogenic soluble protein, while PLGF promotes placental angiogenesis and repair [55,56]. Studies have shown that increased circulating sFlt1 and decreased proangiogenic factors such as PLGF contribute to impaired placental angiogenesis [57]. The imbalance of angiogenic factors can lead to maternal systemic endothelial dysfunction and vascular hyperreactivity, and clinical symptoms such as hypertension, proteinuria, and organ dysfunction [58]. One study showed that serum PLGF levels in the HDP group were significantly lower than those in the normal pregnancy group and declined further with increasing disease severity. Specifically, PLGF levels showed a significant stepwise decline from GH to mild preeclampsia and severe preeclampsia [59]. NO is a key endogenous molecule for regulating vascular tone and

XSL•FO
RenderX

maintaining BP stability [60]. Studies indicate that plasma endothelial NO synthase levels are significantly lower in women with GH and preeclampsia compared to normal pregnant women, with the lowest levels in the preeclampsia group. Reduced endothelial NO synthase leads to impaired NO synthesis [61]. Decreased NO bioavailability results in vascular relaxation disorders, increased systemic vascular resistance, elevated BP, and impaired placental and fetal development [62]. In addition, elevated asymmetric dimethylarginine, reduced dimethylarginine dimethylaminohydrolases, and insufficient L-arginine transport in patients with preeclampsia also inhibit NO production [62].

Based on these mechanisms and the trajectory disparities identified in our study, we recommend stratified management for women with HDP. For those with sustained-rise or late-acceleration trajectories, postpartum BP often remains difficult to normalize. These high-risk patients can be classified as key populations for monitoring during pregnancy, with daily BP measurements at fixed times, the plotting of BP trend charts, clarification of the type of hypertension, and early implementation of pharmacological interventions. These patients should also receive prioritized and more frequent postpartum follow-up visits, with prolongation of the follow-up duration, in order to reduce their long-term risk of CVD [63-65]. For pregnant women with low-risk BP trajectories, nonpharmacological interventions should also be emphasized [48]. A meta-analysis demonstrated that moderate walking, upper and lower limb muscles training, and stretching exercises are more effective in reducing gestational SBP and DBP in women with HDP than healthy pregnant women [66]. Deep breathing exercise and progressive muscular relaxation can significantly reduce SBP, DBP, and MAP in pregnant women with mild preeclampsia [67,68]. Therefore, a combination of pharmacological and nonpharmacological approaches tailored to BP trajectory type during pregnancy may help manage BP and reduce the risk of postpartum BP not returning to normal.

Postpartum follow-up guidelines for patients with HDP are lacking or insufficient in most countries [69]. Early diagnosis, risk stratification, standardized postpartum care, and strict BP management can effectively reduce postpartum cardiovascular risk and mortality [64]. Our findings indicate that BP trajectories during pregnancy are valuable for HDP risk stratification and for identifying women at high risk of poor postpartum BP recovery. Incorporating BP trajectories into postpartum follow-up may optimize management and improve both short- and long-term cardiovascular outcomes. Currently, predictive models based on BP trajectories during pregnancy are in the stages of algorithm validation and prospective testing [70]. Trajectories are constructed from BP data collected under routine clinical conditions, demonstrating practicality and feasibility. Emerging evidence suggests that the early postpartum period represents a critical therapeutic window for mitigating the long-term cardiovascular sequelae of HDP. For instance, a self-management intervention optimizing BP control within the first few weeks post partum led to favorable left ventricular and left atrial remodeling that was evident nearly a year later [13].

Developing a trajectory-specific tool to predict postpartum BP nonrecovery could enhance risk assessment and facilitate personalized intervention and follow-up strategies. It should be noted that postpartum BP recovery status is also influenced by multiple factors, such as maternal serum albumin levels, family history of hypertension, and prepregnancy body weight [18]. Further studies should explore the interactions between these risk factors and BP trajectories to better elucidate the relationship between BP dynamics during pregnancy and postpartum BP recovery status.

This study used real-world data from women with HDP, all of whom had at least 3 BP measurements during pregnancy spanning the first, second, and third trimesters. This comprehensive sampling strengthens the reliability of the findings. Sensitivity analyses further supported the robustness of our results: the number, trends, and relative proportion of trajectory groups in each subtype were generally consistent with those in the main analysis, with only minor changes in statistical associations. To enhance internal validity, we excluded multiple pregnancies, as this condition represents an important cardiovascular risk factor that may confound the association between BP trajectories and postpartum outcomes.

Nevertheless, this study has several limitations. First, we lacked data on antihypertensive use, so we could not adjust for potential confounding by treatment. While this may have led to some underestimation of true BP levels, the associations held across HDP subtypes—including in CHTN, where treatment is most likely—and remained consistent in direction and magnitude. Because antihypertensive therapy is part of routine care, the trajectories observed here reflect real-world BP patterns under standard clinical management. Second, owing to follow-up challenges, only BP recovery at 6 weeks post partum was assessed; longer-term BP recovery status remains unexplored. Future large-scale, multicenter cohort studies with extended follow-up are therefore warranted to further validate these findings. This study suggests a strong association between antenatal BP trajectories during pregnancy and failure to achieve normotension by 6 weeks post partum. As an observational study, however, our results indicate correlation rather than causation. These findings contribute to the understanding of postpartum BP changes in women with HDP, but further prospective and mechanistic studies are needed for validation.

## Conclusion

This study identified distinct antepartum BP trajectories across HDP subtypes, with MAP and SBP showing similar trends and DBP showing more variability. Sustained-rising and late-acceleration patterns, particularly in GH, CHTN with superimposed preeclampsia, and CHTN, were associated with a higher risk of nonrecovery to normotension at 6 weeks post partum. In preeclampsia, only the high-consistent rise SBP trajectory predicted nonrecovery of normotension postpartum. Trajectory analysis, therefore, could support early risk identification and individualized postpartum care to improve long-term cardiovascular outcomes in patients with HDP.

## Abstract

**Background:** Mental distress represents a major public health challenge worldwide, affecting work ability, productivity, and social functioning. Public-sector employees face high psychosocial demands, but data on their mental health literacy and supportive behaviors remain scarce. Mental Health First Aid (MHFA) aims to improve knowledge, attitudes, and behaviors (KAB) toward psychological distress among nonspecialists, but evidence among civil servants and on skill retention over time is limited.

**Objective:** This study aimed (1) to determine KAB related to psychological distress among French civil servants, (2) to examine associations between KAB scores and MHFA training exposure, and (3) to explore gradients according to time since training as an indirect indicator of potential retention of MHFA-related competencies.

**Methods:** A nationwide cross-sectional survey was conducted in November 2025 among French civil servants. Participants completed an online questionnaire adapted from a published instrument. The 3 dimension scores were normalized to a 0-40 scale, yielding a total KAB score of 0-120, categorized as inadequate (0-70), marginal (71-88), or adequate (89-120). Multivariable linear regression models identified factors associated with KAB outcomes, adjusting for sociodemographic and professional variables.

**Results:** Among 338,560 eligible civil servants invited by email, 6526 (1.93%) initiated the questionnaire, and 4679 (1.38% of those invited) fully completed it and were included in the analysis. Participants were predominantly women (3022/4679, 64.59%), aged 40-69 years (4317/4679, 92.26%), and belonged to professional category A (2207/4679, 47.17%). The mean total KAB score was 82.88 (SD 19.14; 95% CI 82.33-83.43), corresponding to a marginal level. Mean subscores were 31.31 (SD 5.26; 95% CI 31.16-31.46) for knowledge, 29.72 (SD 11.52; 95% CI 29.39-30.05) for attitudes, and 21.86 (SD 7.96; 95% CI 21.63-22.09) for behaviors. MHFA-trained participants (545/4679, 11.65%) obtained significantly higher total KAB scores than untrained participants (mean 95.56, SD 14.17; 95% CI 94.37-96.75 vs mean 81.21, SD 19.09; 95% CI 80.63-81.79; $P$<.001), with higher scores for knowledge (mean 33.31, SD 5.26 vs mean 31.04, SD 5.35), attitudes (mean 34.35, SD 8.81 vs mean 29.10, SD 11.70), and behaviors (mean 27.87, SD 6.13 vs mean 21.06, SD 7.84; all $P$<.001). Among MHFA-trained participants, scores decreased over time (<6 months, 6-12 months, >12 months; $P$<.001), but remained higher than in untrained individuals even beyond 12 months after training. In adjusted models, MHFA training was strongly associated with higher KAB scores (β=14.63 for <6

XSL•FO
RenderX

months; β=13.61 for 6-12 months; β=10.33 for >12 months; all *P*<.001). Lower scores were observed in professional categories B and C and among men.

**Conclusions:** Mental health literacy and supportive behaviors among French civil servants remain heterogeneous and, on average, marginal. MHFA training is associated with substantially higher KAB scores, even beyond 12 months, supporting its role as a public health literacy intervention in occupational settings. Declining scores over time supports reinforcement strategies to sustain competencies.

## Introduction

Mental health disorders—defined in the *International Classification of Diseases, 11th Revision* as clinically significant disturbances in cognition, emotional regulation, or behavior associated with distress or impairment in personal, social, educational, or occupational functioning—represent one of the leading public health challenges worldwide [1]. Nearly 1 in 7 people globally, more than a billion individuals, are living with a mental disorder, with depressive and anxiety disorders being the most prevalent. Mental disorders are the leading cause of suicide [2], and also the leading cause of years lived with disability globally, accounting for 1 in 6 years lived with disability [3,4]. The COVID-19 pandemic further intensified this burden, leading to an estimated 27.6% increase in major depressive disorders and a 25.6% increase in anxiety disorders worldwide [5].

Against this global background, similar trends have been observed in France, where data from 2017 to 2021 indicate a clear increase in major depressive episodes, by roughly 3 to 4 percentage points, as well as a high prevalence of anxiety disorders, which affects nearly one-fifth of adults depending on the subgroup considered (men or women) [6]. These findings are consistent with international observations [7] and point to a significant deterioration in the mental health of the French population.

Mental health disorders contribute substantially to disability, reduced social participation, and impaired occupational functioning. Psychosocial distress also plays a significant role in long-term sickness absence, with substantial indirect costs (particularly productivity losses linked to difficulties in maintaining employment), which are often more costly than direct health care expenditures [3]. Thus, the burden of mental disorders and their societal impacts has led to the designation of mental health as France's "National Cause" for 2025 and 2026, reflecting its strategic importance for societal sustainability [8].

More specifically, public sector employees are affected. In 2023, 19% of public-sector employees presented a risk of depressive symptoms [9], which is concerning, given their essential societal role and frequent exposure to emotionally demanding or high-responsibility situations [10,11]. Epidemiological studies have shown that workload, low decision latitude, and imbalance between effort and reward significantly contribute to the onset of common mental disorders [12]. Recent international guidelines from the World Health Organization (WHO) and the International Labour Organization emphasize the responsibility of governments, both as public employers and regulators, to prevent work-related mental disorders and support employees experiencing psychological difficulties [13,14]. Explicit consideration of the mental health of public-sector workers is thus essential for service quality, sustainability of public systems, and collective resilience. In this perspective, strengthening the capacity of civil servants to identify, understand, and respond appropriately to psychological distress emerges as a strategic priority.

Mental Health First Aid (MHFA) first emerged in Australia as a relevant resource. It aims to improve mental health literacy and reduce stigma among the general public. It also equips people with the skills to encourage those with mental issues to seek professional help. In France, the MHFA program, named "Premiers Secours en Santé Mentale," has expanded rapidly since 2018, with more than 120,000 trained "first aiders" and over 1400 certified instructors as of May 2024 [15]. This rapid dissemination reflects strong institutional interest in equipping nonclinicians with the skills needed to recognize early signs of psychological distress and provide timely support. In 2022, a ministerial directive requested the establishment of MHFA within public employers [16]. Although several French studies [17,18] have highlighted the promising effects of MHFA training on trainees, these findings emphasize the need for additional analysis to further optimize the program [19]. Indeed, existing evidence is primarily based on student populations and has not specifically examined long-term effects. Consequently, it remains unclear whether similar benefits can be observed beyond the short term and in other populations such as civil servants. This group differs substantially in age and professional constraints, while their predefined socioprofessional classification offers a methodological asset for analyzing socioprofessional gradients.

Within the framework of improving mental health support in the workplace, particularly in the civil service, it is therefore essential to assess whether employees are able to recognize signs of psychological distress in their colleagues and respond appropriately. This requires a structured approach based on the knowledge, attitudes, and behaviors (KAB) model, which captures how individuals perceive, evaluate, and act upon a given situation. This can shed light on levels of mental health literacy. Indeed, KAB allows measurement of (1) knowledge

XSL•FO
RenderX

of symptoms, risk factors, and help-seeking pathways; (2) attitudes regarding stigma and self-efficacy; and (3) supportive behaviors, including intent to help and referral practices. The KAB framework originates from health behavior and public health research and assumes that knowledge influences attitudes, which in turn may shape behaviors. Although these relationships are not necessarily linear, KAB models provide a useful framework for assessing health literacy and informing prevention strategies [20-22]. To date, despite the expansion of MHFA, no study has evaluated mental health KAB among civil servants in France, compared MHFA trained and untrained agents, or examined the persistence of skills over time in this context. Addressing this gap is crucial for informing national strategies aimed at strengthening mental health–related competencies within the civil service.

This study aimed (1) to determine KAB related to psychological distress among French civil servants, (2) to examine associations between KAB scores and MHFA training exposure, and (3) to explore gradients according to time since training as an indirect indicator of potential retention of MHFA-related competencies.

# Methods

## Study Design

This study adopted a descriptive, cross-sectional, quantitative design to examine KAB regarding mental disorders in others. Such a design is well suited to KAB surveys, particularly when data are scarce and baseline information is needed before developing interventions [21,23]. This study was performed in accordance with the CROSS (Checklist for Reporting Of Survey Studies; Multimedia Appendix 1) [24].

## Study Setting

This cross-sectional KAB survey was conducted in France from November 13-27, 2025, among active French civil servants who had a digital personal account on the national health insurance website and had agreed to receive information by email. Within the French civil service, positions are organized into 3 main professional categories: A, B, and C, which represent different corps of professions characterized by varying levels of responsibility, qualification, remuneration, and recruitment criteria. These categories structure the civil service hierarchy, with specific access conditions and baseline remuneration associated with each [9].

## Participants

### *Eligibility Criteria*

To be included, participants had to (1) be at least 18 years of age, (2) be active public service employees, (3) have agreed to receive information at their email address, and (4) consent to complete the online questionnaire.

Retired individuals and nonpermanent civil servants (ie, public sector contract employees not belonging to public service category A, B, or C) were excluded from the study.

### *Recruitment*

The recruitment frame consisted of all French civil servants who had a personal digital account within the Union Régime Obligatoire Prévention Santé system and had previously agreed to receive email communications. A total of 338,560 individuals met these criteria and received the study invitation.

No sampling, stratification, or additional selection procedures were applied because the invitation was sent to the entire eligible recruitment frame. The invitation email and study information letter were distributed to the entire eligible recruitment frame, followed by 1 reminder sent 1 week later to the same distribution list.

Participation was entirely voluntary. Individuals who provided informed consent, met the eligibility criteria, and initiated the online questionnaire were included in the study. Participants who completed all items required for KAB score calculation were included in the final analyses.

## Questionnaire

The French questionnaire developed and used by Llopis et al [17] to assess mental health–related knowledge, attitudes, and practices (KAP) among French university students who received MHFA training was adapted for the study population. The questionnaire was not originally developed as a psychometric instrument, and no formal psychometric validation was performed in this study. Specifically, age and date of MHFA training were collected using predefined categories, job position and education level items were adapted for relevance to French public service classifications, and some items were removed to reduce questionnaire length. In total, 5 questions were adapted for this study population, 1 question was shortened, and the other 32 items were retained in their original form. No new items were created. The wording of the questions was kept as original.

It comprised 38 closed-ended questions and covered the following domains: (1) sociodemographic data (age collected in ranges and job position collected according to French public service categories A, B, and C) and information on MHFA training (including motivations and time since training: <6, 6-12, and >12 months)—7 questions, (2) mental health knowledge—10 questions, (3) attitudes toward people with mental health disorders—4 questions, and (4) behaviors toward individuals experiencing psychological difficulties—17 questions. Among these questions, 5 were specifically reserved for MHFA trainees. The survey required approximately 10 minutes to complete. The original French version and an English translation of the questionnaire are provided in Multimedia Appendices 2 and 3.

## Scoring System

From the collected responses, new variables were created: knowledge score related to mental health: sum of items 8 to 17 (1 point per correct response and 0 points per incorrect response or “do not know”). Attitude score toward people with psychological distress: sum of items 18 to 21 (1 point per correct response and 0 points per incorrect response or “do not know”). Behavior score toward individuals experiencing psychological distress, to assess the level of consistency with the recommendations made during MHFA training: sum of items 22 to 26 and 31 to 38 (1 point per correct response and 0 points per incorrect response or “do not know.” Likert items scored

XSL•FO
RenderX

0-4). This scoring system was developed in accordance with the WHO KAP survey methodology [20], which recommends simplified and direction-oriented coding approaches for population-based assessments of health-related KAB. The normalization and categorization procedures were adopted to facilitate interpretation and comparison of KAB dimensions at the population level. Equal weighting of items was intentionally adopted because the objective of the study was to generate descriptive population-level indicators rather than to develop a diagnostic or psychometric scale. No empirical or theoretical framework was available to justify differential weighting of individual items. Consequently, each item contributed equally to its corresponding KAB dimension, consistent with WHO KAP survey methodology and previous population-based KAP or KAB surveys.

Scores for each KAB dimension were normalized on a scale from 0 to 40, with total KAB score ranging from 0 to 120. Because the 3 KAB dimensions were based on different numbers of items and score ranges, raw scores were transformed to a common 0-40 scale using a linear normalization procedure according to the following formula:

$$\text{Normalized score} = (\text{observed score}/\text{maximum possible score}) \times 40 \quad \textbf{(1)}$$

This transformation allowed direct comparison of the 3 dimensions while preserving the relative position of participants within each dimension. The total KAB score corresponded to the sum of the 3 normalized dimension scores and therefore ranged from 0 to 120. Details of the raw and normalized score ranges are provided in Multimedia Appendix 4.

Categories were set as follows: inadequate (0-70), marginal (71-88), and adequate (89-120) based on previous questionnaires [23]. These categories were intended to facilitate interpretation of population-level KAB results and should not be considered clinically validated thresholds.

## Survey Platform

The questionnaire was hosted online using LimeSurvey (version 6.16.5; LimeSurvey GmbH) on a dedicated server with 2048 bitset Secure Sockets Layer/Transport Layer Security encryption and without collecting IP addresses. Measures were taken to ensure secure, anonymous participation, cookies to block duplicate submissions, and unique tokens for log-in. Respondents could pause and resume the survey as needed.

## Study Outcomes

The primary outcome was to determine KAB of civil servants when addressing psychological distress in others.

The secondary outcomes were to examine associations between KAB scores and MHFA training exposure and to explore gradients according to time since training as an indirect indicator of potential retention of MHFA-related competencies. Accordingly, analyses comparing MHFA-trained and untrained participants, as well as analyses according to time since training (<6, 6-12, and >12 months), were predefined secondary exploratory analyses.

## Statistical Analysis

### Sample Size Calculation

Based on an eligible population of 338,560 civil servants who received the email invitation, corresponding to the entire accessible Union Régime Obligatoire Prévention Santé recruitment frame, a minimum of 1064 completed questionnaires was calculated to ensure a 95% confidence level and a ±3 percentage-point margin of error for proportion estimates (finite population correction applied). This calculation was derived from the standard formula for estimating a proportion, assuming a conservative prevalence of 50% to maximize variance:

$$n = Z^2 \times p(1-p)/e^2 \quad \textbf{(2)}$$

where $Z$=1.96 (95% confidence level), $p$=0.50 (maximum variance assumption), and $e$=0.03 (margin of error). The resulting sample size was then adjusted using the finite population correction:

$$n = n/[1+(n-1)/N] \quad \textbf{(3)}$$

where $N$=338,560. The final minimum sample size was estimated at 1064 completed questionnaires.

### Data Analysis

Data were analyzed using R (R Foundation for Statistical Computing) via RStudio. Descriptive statistics were computed using standard R packages, and forest plots were generated using the *ggplot2* package. Descriptive statistics (counts and percentages) were used for categorical sociodemographic variables and general information related to MHFA training. Means and SDs were reported for continuous KAB score variables.

The sample was divided into 2 groups according to MHFA training status (yes vs no), and KAB scores were compared using 1-way ANOVA. Among participants who received MHFA training, 3 categories were defined based on time since training, and KAB scores were compared across these groups using 1-way ANOVA. Prior to conducting ANOVA analyses, normality was assessed using the Shapiro-Wilk test and visual inspection of quantile-quantile plots. Although the formal Shapiro-Wilk test indicated departures from normality, visual inspection suggested only minor deviations, and parametric analyses were considered appropriate, given the large sample size and the robustness of ANOVA to modest departures from normality. Homogeneity of variances was assessed using the Levene test. When the Levene test indicated heterogeneity of variances, corresponding nonparametric tests (Wilcoxon rank sum test with continuity correction or Kruskal-Wallis rank sum test, as appropriate) were performed as sensitivity analyses and yielded the same conclusions regarding statistical significance. Moreover, because comparisons according to MHFA training status and time since training were predefined secondary analyses addressing specific study objectives rather than exploratory post hoc analyses, no formal adjustment for multiple comparisons was applied. Achieved statistical power was estimated for the predefined subgroup analyses according to time since MHFA training.

All complete questionnaires were included in descriptive and inferential analyses, as complete KAB score calculation required

XSL•FO
RenderX

complete responses for the corresponding items. To evaluate the potential for selection bias related to missing data, respondents with complete questionnaires were compared with participants who did not complete the questionnaire but who had provided at least the sociodemographic information required for comparison analyses (Multimedia Appendix 5). Because KAB scores were directly derived from questionnaire responses, imputation of missing outcome items would have required strong assumptions regarding unobserved responses. Consequently, analyses were restricted to complete questionnaires, and potential selection bias was evaluated through comparison of complete and incomplete respondents. Inverse probability weighting was not performed because comparisons between complete and incomplete respondents showed only negligible-to-small differences across the available baseline characteristics and no difference in MHFA training status, the primary exposure variable. In addition, only a limited set of baseline variables was available for incomplete respondents, preventing construction of a robust response-propensity model. Determinants of KAB scores were examined using multivariable linear regression models. Covariates included job position, level of education, age, gender, MHFA training status, and time since training. All covariates were modeled as categorical variables according to the categories in which they were collected. For each variable, one category was used as the reference category in the regression models. Models were estimated by using generalized linear modeling procedures in R.

Regression coefficients (β) were reported with 95% CIs and associated *P* values. A 2-sided *P* value <.05 was considered statistically significant.

### Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki and approved by the research ethics committee of the Vinatier Hospital, Lyon, France (CEREVI/2025/45; July 7, 2025). Before accessing the questionnaire, all participants received study information electronically and provided informed consent to participate. Participation was entirely voluntary, and participants could discontinue the questionnaire at any time without consequence. To protect privacy and confidentiality, the questionnaire was administered anonymously through a secure online platform. No IP addresses were collected, and all data were analyzed in aggregated form only. Participants did not receive any financial compensation or incentive for participation.

## Results

### Characteristics of the Participants

Figure 1 shows the flowchart of the study. A total of 338,560 civil servants received the study invitation. Among them, 6526 (1.93%) individuals provided consent, were eligible, and initiated the questionnaire. Of these participants, 4679 (1.38% of invited individuals) completed all items required for KAB score calculation and were included in the final analyses. This sample size, well above the calculated minimum, ensured high statistical precision, whereas the voluntary recruitment process may limit full population representativeness.

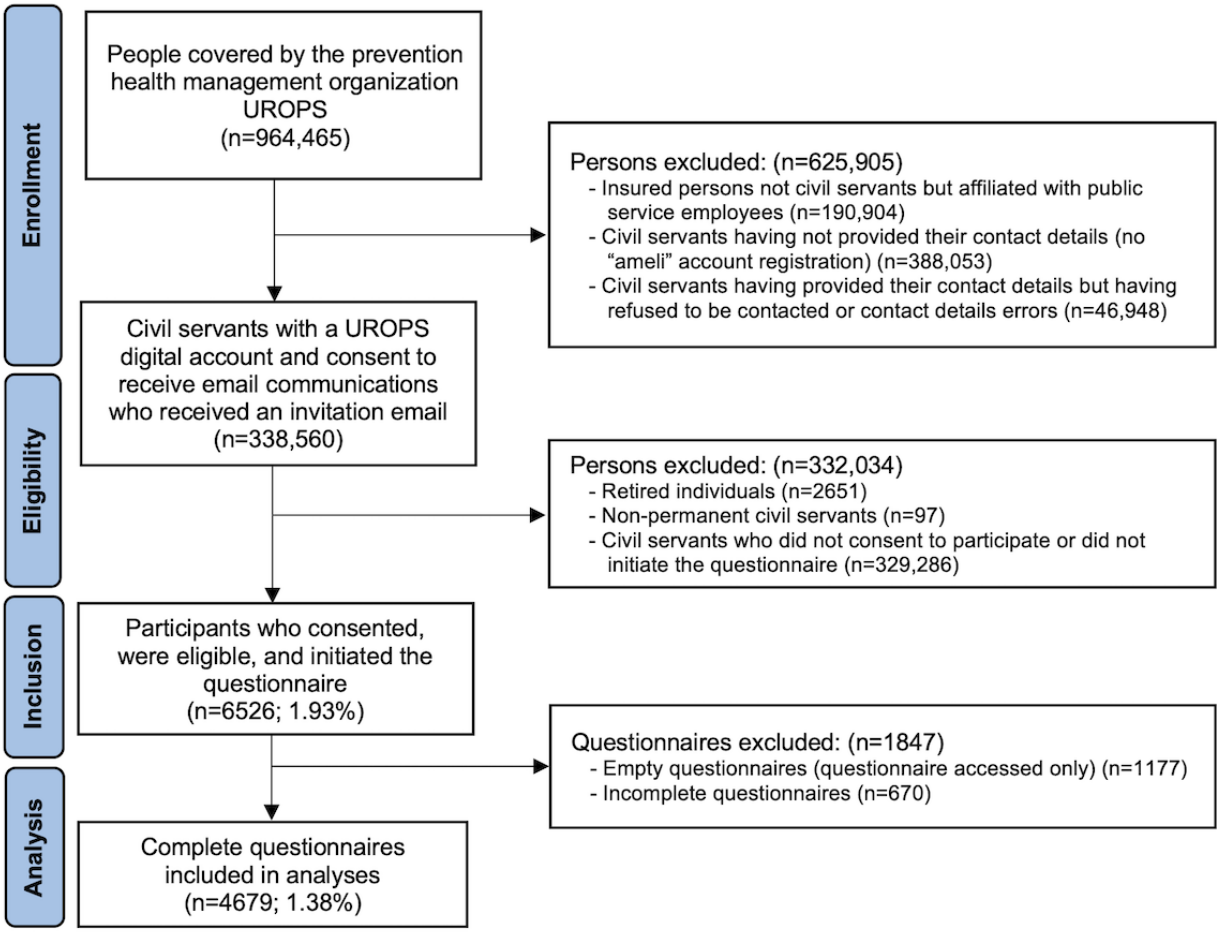

Table 1 shows the sociodemographic characteristics and information related to MHFA training of the participants. Most participants were women (3022/4679, 64.59%), aged between 40 and 69 years (4317/4679, 92.26%), and belonged to the A professional category (2207/4679, 47.17%). Participants with an undergraduate degree (first-cycle university degree and second-cycle university degree) were predominant (2220/4679, 47.45%). Most participants had never received training in mental health (3652/4679, 78.05%) and had not had the opportunity to follow an MHFA training (4134/4679, 88.35%).

The distribution of questionnaire breakoff according to the last completed questionnaire item is presented in Multimedia Appendix 6. Characteristics of complete and incomplete respondents are presented in Multimedia Appendix 5. Compared with respondents who completed the questionnaire, those with incomplete questionnaires differed slightly in age, gender, professional category, and educational level (all *P*<.001). However, effect sizes were negligible to small (Cramer *V*=0.06-0.11), suggesting limited practical differences between groups. No significant differences were observed regarding previous mental health training (*P*=.20) or MHFA training status (*P*=.75).

## KAB Scores in the Civil Servant Population in France

Table 2 presents descriptive statistics of KAB scores. In the overall civil servant population (N=4679), the mean total KAB score was 82.88 (SD 19.14; 95% CI 82.33-83.43), based on a normalized scale theoretically ranging from 0 to 120 points, corresponding to a “marginal” level according to the predefined scoring thresholds.

The mean scores for the 3 subdimensions—knowledge, attitudes, and behaviors—were 31.31 (SD 5.26; 95% CI 31.16-31.46), 29.72 (SD 11.52; 95% CI 29.39-30.05), and 21.86 (SD 7.96; 95% CI 21.63-22.09), respectively, each based on a normalized scale theoretically ranging from 0 to 40 points.

KAB scores differed according to MHFA training status and, among trained participants, by time since training (Table 2). Participants who had received MHFA training had a significantly higher mean KAB score than those without training (mean 95.56, SD 14.17; 95% CI 94.37-96.75 vs mean 81.21, SD 19.09; 95% CI 80.63-81.79; $P$<.001). Similar patterns were observed for each KAB dimension. Trained participants showed higher mean scores for knowledge (mean 33.31, SD 3.96; 95% CI 32.98-33.64 vs mean 31.04, SD 5.35; 95% CI 30.88-31.20;

XSL•FO
RenderX

*P*<.001), attitudes (mean 34.35, SD 8.81; 95% CI 33.61-35.09 vs mean 29.10, SD 11.70; 95% CI 28.74-29.46; *P*<.001), and behaviors (mean 27.87, SD 6.13; 95% CI 27.36-28.38 vs mean 21.06, SD 7.84; 95% CI 20.82-21.30; *P*<.001).

In addition to statistically significant differences, the comparison between MHFA-trained and untrained participants showed small-to-moderate effect sizes for knowledge (Cohen *d*=0.44) and attitudes (*d*=0.46), a large effect size for behaviors (*d*=0.89), and a moderate-to-large effect size for the overall KAB score (*d*=0.77; Multimedia Appendix 7).

Among participants who had completed MHFA training, a decreasing gradient of mean scores was observed with increasing time since training (<6, 6-12, and >12 months) for the total KAB score (*P*<.001) as well as for knowledge, attitudes, and behaviors scores over time (*P*<.001, *P*=.04, and *P*<.001, respectively). Results of the post-hoc power calculations for these subgroup analyses are presented in Multimedia Appendix 8.

**Table 2.** Descriptive statistics and univariable comparisons of knowledge, attitudes, and behaviors (KAB) scores by Mental Health First Aid (MHFA) training status and time since training.

| MHFA training status | All (N=4679), mean (SD; 95% CI) | No (n=4134), mean (SD; 95% CI) | Yes (n=545), mean (SD; 95% CI) | Yes (<6 months; n=216), mean (SD; 95% CI) | Yes (6-12 months; n=117), mean (SD; 95% CI) | Yes (>12 months; n=212), mean (SD; 95% CI) | *P* value (yes or no)[a] | Cohen *d* | *P* value (<6 or 6-12 or >12 months)[b] |

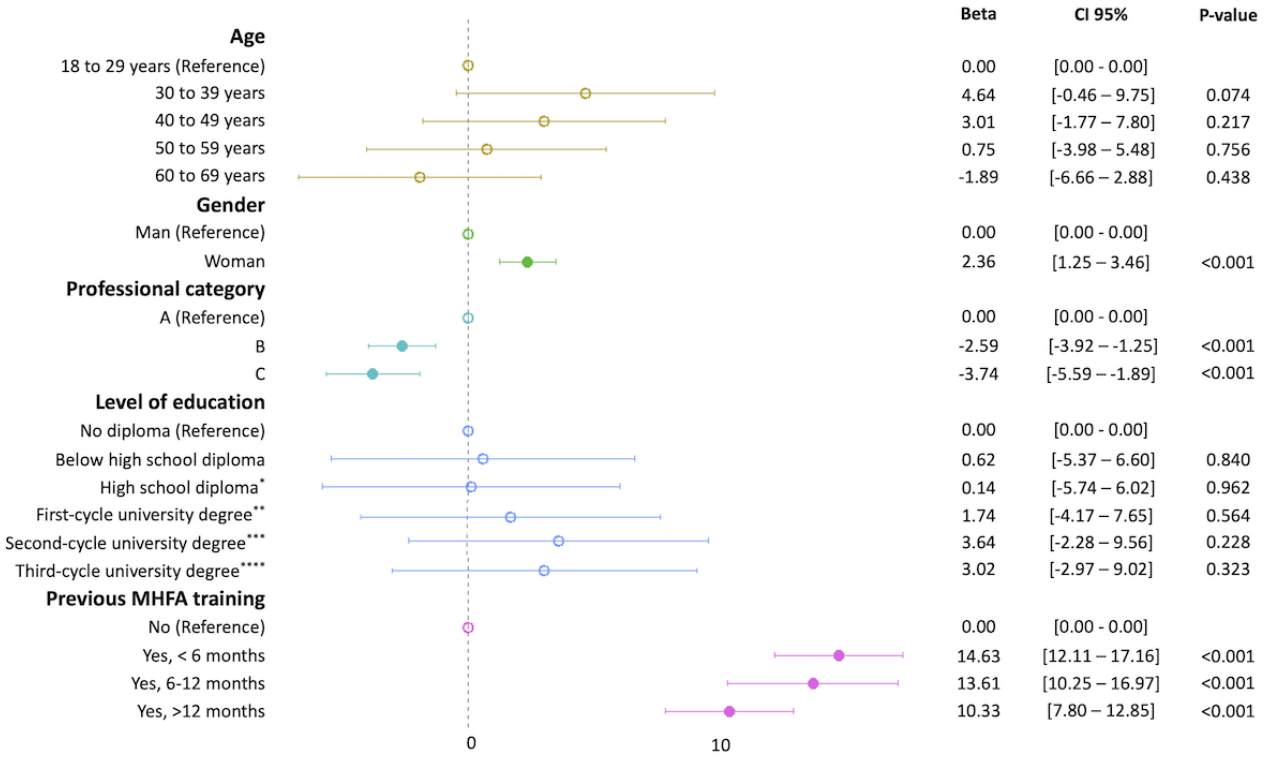
## Identification of Determinants Associated With KAB Scores

To examine factors associated with KAB scores while accounting for potential confounders, multivariable linear regression models were fitted. These analyses aimed to identify variables statistically associated with KAB outcomes, rather than to infer causal effects.

### *Total KAB Score*

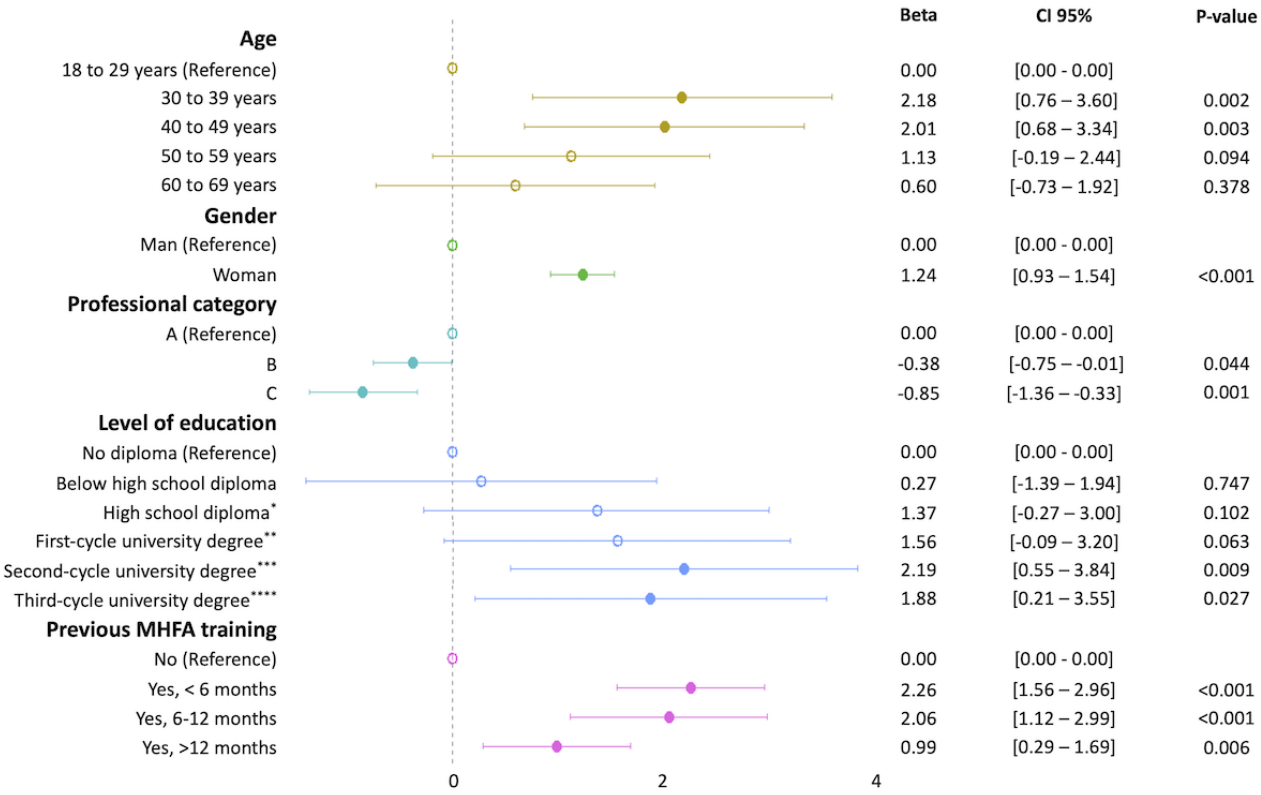


As shown in Figure 2, previous MHFA training was strongly associated with higher total KAB scores. Compared with untrained participants, mean KAB scores were higher among those trained: less than 6 months ago (β=14.63, 95% CI 12.11-17.16; *P*<.001), 6-12 months ago (β=13.61, 95% CI 10.25-16.97; *P*<.001), and more than 12 months ago (β=10.33, 95% CI 7.80-12.85; *P*<.001).

Women had higher total KAB scores than men (β=2.36, 95% CI 1.25-3.46; *P*<.001). In contrast, participants in professional categories B and C had lower KAB scores compared with those in category A, with mean decreases of 2.59 (95% CI –3.92 to –1.25) points and 3.74 (95% CI –5.59 to –1.89) points, respectively (all *P*<.001).

XSL•FO
RenderX

**Figure 2.** Forest plot representing the determinants of the KAB score regarding psychological distress in others. Filled circles indicate statistical significance (P≤.05), while empty circles indicate nonsignificance (*P*>.05). Reference categories are specified in parentheses next to the variable labels. KAB: knowledge, attitudes, and behaviors; MHFA: Mental Health First Aid. *French baccalaureate, **Baccalaureate+2 years, ***Baccalaureate+3 years, ****Baccalaureate+5 years and more.



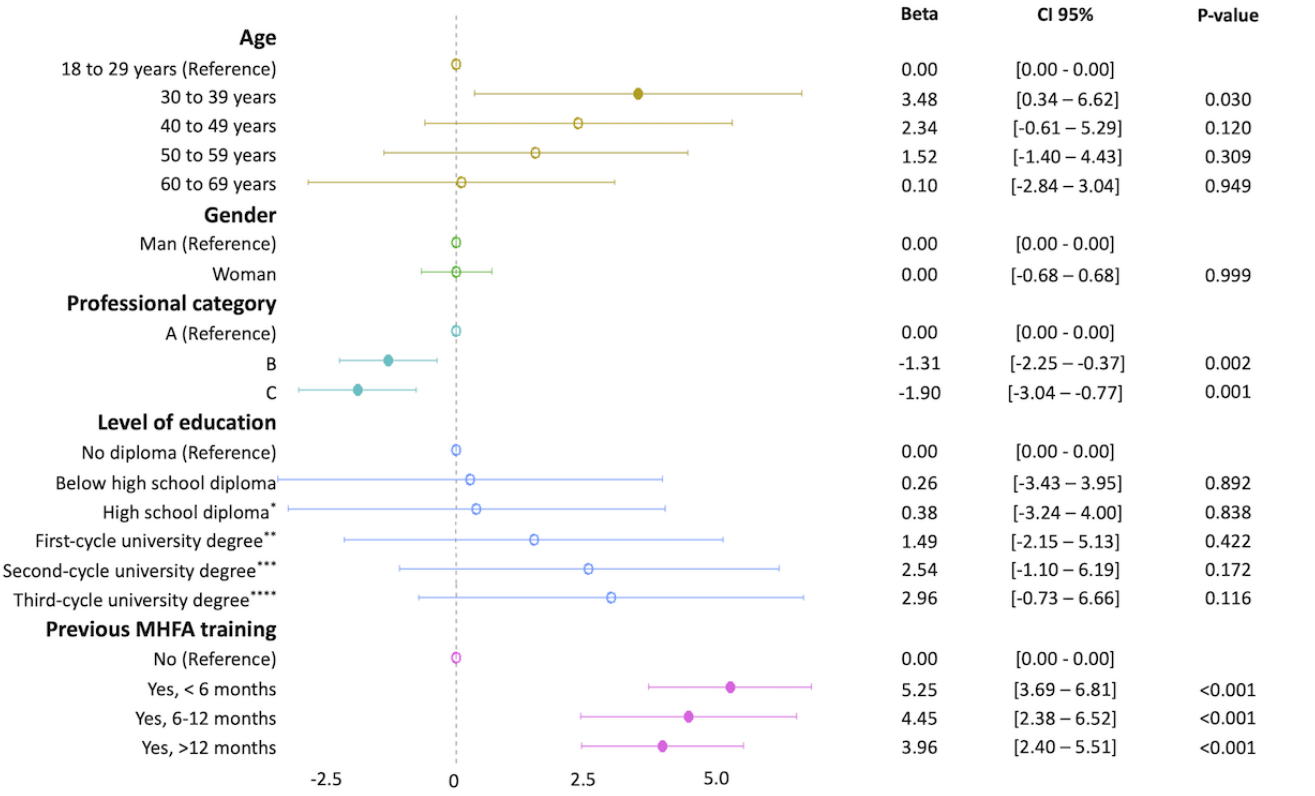
### *Knowledge Score*

As shown in Figure 3, higher knowledge scores were associated with MHFA training status, women gender, and higher professional category. Participants aged 30-39 and 40-49 years had higher knowledge scores than those aged 18-29 years (β=2.18, 95% CI 0.76-3.60; *P*=.002 and β=2.01, 95% CI 0.68-3.34; *P*=.003, respectively). Higher knowledge scores were also observed among participants with an undergraduate degree or a postgraduate or graduate degree compared with those without a diploma (β=2.19, 95% CI 0.55-3.84; *P*=.009 and β=1.88, 95% CI 0.21-3.55; *P*=.03, respectively).

XSL•FO
RenderX

**Figure 3.** Forest plot representing the determinants of the knowledge score regarding psychological distress in others. Filled circles indicate statistical significance (P≤.05), while empty circles indicate nonsignificance (*P*>.05). Reference categories are specified in parentheses next to the variable labels. MHFA: Mental Health First Aid. *French baccalaureate, **Baccalaureate+2 years, ***Baccalaureate+3 years, ****Baccalaureate+5 years and more.

### *Attitude Score*



As shown in Figure 4, attitude scores were positively associated with MHFA training across all time categories. Participants trained less than 6 months ago had the highest adjusted attitude scores, followed by those trained 6-12 months and more than 12 months ago.

Professional categories B and C were negatively associated with attitude scores compared with category A. Age, gender, and education level were not significantly associated with attitude scores in adjusted models, except participants aged 30-39 years who had significantly higher attitude scores than those aged 18-29 years (β=3.48, 95% CI 0.34-6.62; *P*=.03).

XSL•FO

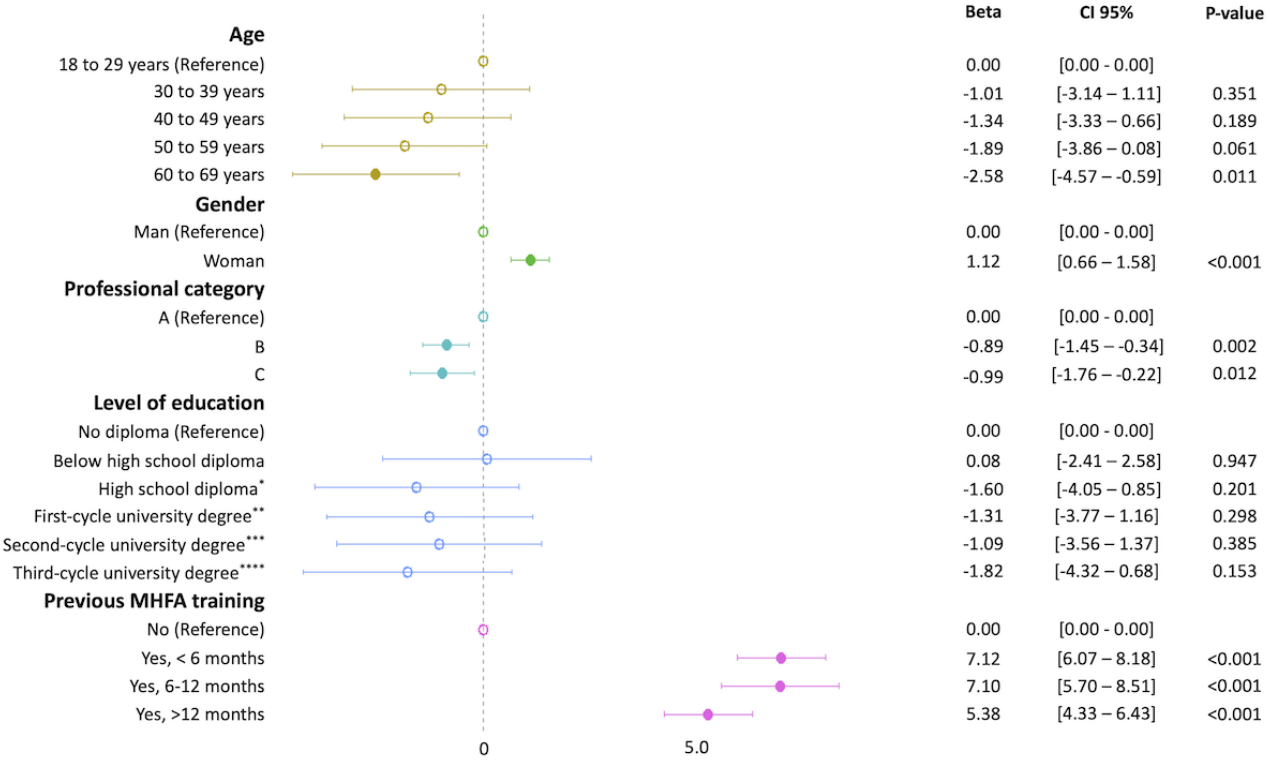
MHFA: Mental Health First Aid. *French baccalaureate, **Baccalaureate+2 years, ***Baccalaureate+3 years, ****Baccalaureate+5 years and more.



### *Behavior Score*

As shown in Figure 5, MHFA training status was strongly associated with higher behavior scores across all time categories. Woman gender was also associated with higher behavior scores, whereas increasing age and lower professional categories were associated with lower scores.

XSL•FO
RenderX

**Figure 5.** Forest plot representing the determinants of the behavior score regarding psychological distress in others. ## Motivations, Knowledge Retention, and Application of MHFA Skills Among Trained Civil Servants

Table 3 describes the motivations for MHFA training, knowledge of ALGEE (Approach, Listen, Give support, Encourage professional help, Encourage other supports), and application in practice. Among the 545 participants who had completed MHFA training, the majority reported enrolling for reasons related to their professional or academic environment (384/545, 70.46%), while over half cited the desire to better support family members or friends (290/545, 53.21%). Additional motivations included a personal interest in mental health (228/545, 41.83%), the wish to better understand their own mental health (188/545, 34.50%), and civic engagement (193/545, 35.41%). Fewer participants indicated motivations related to the COVID-19 crisis (26/545, 4.77%) or the free nature of the training (33/545, 6.06%).

Assessment of core MHFA concepts showed high levels of retention of key components of the ALGEE action plan (a major component of MHFA training), with over 97% correctly identifying the importance of listening without judgment (531/545, 97.43%) and providing comfort and information (528/545, 96.88%). However, some participants still endorsed less appropriate responses, such as “encouraging the person to pull themselves together” (206/545, 37.80%) or “trying to solve their problems” (137/545, 25.14%).

Approximately one-third of trained participants (194/545, 35.60%) reported having used MHFA skills to help someone experiencing psychological distress. Among these, most had supported 1 to 4 individuals (145/545, 26.61%), while a smaller number reported helping 5 or more (49/545, 8.99%). Among those who had used their training, the majority (170/194, 87.63%) perceived it as helpful in supporting the person in distress.

# Discussion

## Principal Findings

This large cross-sectional study provides the first comprehensive assessment of KAB related to psychological distress among French civil servants. The results reveal substantial heterogeneity within this population, with an overall mean KAB score of 82.88 of 120 (SD 19.14), classified as marginal (95% CI 82.33-83.43). From a public health perspective, it highlights that mental health competencies remain insufficiently consolidated in a workforce central to public service delivery and social functioning. While these observations provide valuable insight into mental health literacy within the French civil service, they are based primarily on self-reported measures and should therefore be interpreted with appropriate caution. In particular, reported use of MHFA-related skills and perceived usefulness of training reflect participants’ own perceptions and were not independently validated through recipient-level outcomes.

Mental health disorders are now among the leading causes of disability worldwide, with well-documented consequences for work ability, productivity, and long-term labor participation [3,25,26]. In this context, the marginal level observed highlights a gap between the growing burden of mental health needs and the collective capacity of institutions to recognize and respond to psychological distress. Addressing mental health in the

XSL•FO
RenderX

workplace must thus go beyond clinical care and be integrated into public health strategies.

The strongest finding of this study is that MHFA-trained participants displayed substantially higher KAB scores than nontrained participants across all dimensions: knowledge (+2.3 points), attitudes (+5.3 points), and behaviors (+6.8 points). Trained participants had a total KAB score of 95.56 versus 81.21 for untrained individuals ($P$<.001). This interpretation is further supported by effect size estimates, which were moderate for the overall KAB score (Cohen $d$=0.77) and particularly large for the behavior dimension ($d$=0.89). However, given the cross-sectional design and the voluntary nature of participation in MHFA training, these differences should be interpreted as associations rather than evidence of a causal training effect. Importantly, participants who had completed MHFA training more than 12 months previously continued to display higher KAB scores than untrained individuals. Although lower scores were observed among participants reporting longer intervals since training, this pattern should be interpreted cautiously because time since training represents only an indirect indicator of retention and may also reflect differences in opportunities for skill application, workplace environment, refresher activities, or other unmeasured factors. Beyond these quantitative findings, responses from trained participants also provide insight into the motivations for attending MHFA training and the practical application of acquired skills. Most cited professional or academic reasons for attending MHFA (384/545, 70.46%), followed by the desire to support relatives or friends (290/545, 53.21%). These findings highlight the strategic relevance of MHFA training within the civil service and underscore participants' recognition of the importance of mental health considerations in the workplace.

Core ALGEE principles were well retained—for example, 97.43% (531/545) recalled the importance of nonjudgmental listening—though some suboptimal reflexes persisted (eg, 206/545, 37.80% agreed with "pulling oneself together"). About 35.60% (194/545) had applied MHFA skills to help someone, most often 1 to 4 individuals, and 87.63% (170/194) found the training useful in doing so. These findings suggest that MHFA can be meaningfully translated into supportive behaviors.

Finally, the sample was predominantly women (3022/4679, 64.59%) and aged 50 years and older (3242/4679, 69.29%), aligning with broader public service demographics [9]. This should be considered when tailoring future training strategies to subgroups with differing needs or exposure.

## Comparison With Prior Work

The positive impact of MHFA training found in this study aligns with existing literature [27-31]. A 2018 meta-analysis by Morgan et al [27] showed consistent improvements in mental health knowledge, stigma reduction, and helping behaviors across diverse international contexts. Our findings extend these results to a civil service context—a group not yet well represented in MHFA research. Nevertheless, unlike the intervention studies cited earlier, this study was not designed to evaluate MHFA effectiveness. Participation in MHFA training was voluntary, and self-selection mechanisms may partly explain the higher KAB scores observed among trained participants. Consequently, our findings should be interpreted as evidence of an association between MHFA training exposure and KAB outcomes rather than proof of a causal effect.

French studies conducted among university students [17,18] as well as a randomized controlled trial in Switzerland [32] have shown significant posttraining improvements in knowledge, attitudes, and peer support capacities. Effects were particularly strong for proximal outcomes such as confidence and willingness to help. Our study confirms that these improvements are also observable in older, more professionally diverse cohorts, offering useful insights for public policy and workforce-based mental health strategies.

Beyond perceived improvements, this study documents the self-reported application of MHFA skills. Over one-third of trained participants reported supporting someone in psychological distress, with the vast majority considering their training helpful in doing so. These findings suggest that MHFA-related competencies may be actively mobilized in professional or social contexts. However, as highlighted in a systematic review by Forthal et al [33], the evidence on real-world outcomes remains mixed, and few studies have rigorously assessed whether actions taken by trainees are truly helpful or improve recipient outcomes. Consequently, this study cannot determine whether actions taken by trainees actually improved recipient outcomes, increased professional help-seeking, reduced psychological distress, or improved other recipient-level outcomes. Our findings therefore extend the MHFA literature by documenting self-reported application of MHFA skills, but independent validation of recipient outcomes remains an important gap in the literature. Further research using validated recipient-level outcomes is needed to establish the real-world impact of MHFA training.

Among MHFA-trained civil servants, a high level of retention of key elements of the ALGEE action plan was observed, particularly nonjudgmental listening (531/545, 97.43%) and providing comfort and information (528/545, 96.88%). These rates are in line with previous findings from student populations, where essential MHFA principles remained well retained months after training [17,32]. Nonetheless, some persistent misconceptions were noted—nearly 37.80% (206/545) of trained participants agreed with the idea of "encouraging the person to pull themselves together" [17], a response inconsistent with MHFA principles. This enduring influence of cultural or intuitive norms highlights the limits of single-session training and reinforces the need for ongoing reinforcement.

Our study provides exploratory observations regarding differences in KAB scores according to time since training. While lower scores were observed among participants reporting longer intervals since MHFA training, the cross-sectional design does not allow these differences to be interpreted as direct evidence of skill decay. Alternative explanations, including cohort effects, differences in training implementation, opportunities for skill application, workplace support, refresher training, or other unmeasured factors, cannot be excluded. This pattern is consistent with findings in health education and learning science, particularly the "spacing effect," which shows that spaced learning supports long-term retention more

XSL•FO
RenderX

effectively than one-time exposure [34,35]. These results argue for the inclusion of refresher sessions as part of long-term MHFA implementation strategies, especially in large and diverse workforces.

Interestingly, 11.65% (545/4679) of our sample reported having received MHFA training—substantially higher than national averages (estimated at ~0.2% of the general population) [15]. This suggests a possible selection bias, but may also reflect higher interest, access, or perceived relevance of MHFA among public sector employees. Notably, 70.46% (384/545) of trained participants cited professional or academic motivations, reinforcing the relevance of MHFA for emotionally demanding roles and public service functions.

Sociodemographic gradients in KAB scores were consistent with prior findings. Women scored higher across all dimensions, in line with studies showing greater mental health literacy and empathy among women respondents [36,37]. Participants in higher professional categories (category A) and with higher education levels also showed stronger outcomes, likely reflecting greater exposure to psychosocial issues or prior training. Similar patterns were reported in KAB-focused studies among civil servants, including in the context of long COVID [38], or oral health literacy [39], underlining the structural dimensions that shape prevention capacities.

Taken together, these findings confirm the relevance of MHFA in occupational settings and provide strong support for its application in workforces. However, to ensure sustainable impact, training should be combined with targeted reinforcement strategies and equitable access across all staff categories.

## Limitations

Several limitations should be acknowledged. First, the cross-sectional nature of the study precludes causal inference regarding MHFA training effectiveness. Because participation in MHFA training was voluntary, self-selection cannot be excluded, and trained participants may have differed from untrained participants in baseline mental health literacy, motivation, or interest in mental health. Consequently, the observed differences in KAB scores may partly reflect preexisting characteristics rather than training effects. Although multivariable analyses adjusted for several sociodemographic variables, residual confounding and reverse causation remain possible. Longitudinal or pre- and poststudies would be required to better assess the causal impact of MHFA training.

Second, although the invitation was distributed to the entire recruitment frame of French civil servants who had agreed to receive email communications, the low participation rate (1.93%) raises concerns about selection bias, increasing the risk of self-selection and limiting population representativeness. This low participation rate is consistent with voluntary nationwide web-based surveys conducted without incentives and may also reflect the sensitive nature of mental health as a survey topic. Individuals who chose to participate may have differed systematically from nonparticipants with respect to mental health interest, literacy, previous training experiences, or personal exposure to psychological distress. Consequently, the sample may not fully represent the overall French civil servant population.

In addition, participation in MHFA training itself is voluntary. Individuals who attend such training are likely to differ from nontrained individuals in motivation, professional interest, empathy, or preexisting mental health knowledge. Therefore, the higher KAB scores observed among MHFA-trained participants cannot be interpreted as evidence of a causal training effect and may partly reflect self-selection. Although multivariable analyses adjusted for age, gender, educational level, and professional category, residual confounding due to unmeasured characteristics remains possible. Regarding incomplete questionnaires, although some statistically significant differences were observed between complete and incomplete respondents, the corresponding effect sizes were negligible to small (Multimedia Appendix 5), suggesting limited selection based on the observed baseline characteristics. Only a limited set of baseline variables was available for incomplete respondents, preventing the development of a robust response-propensity model. Consequently, inverse probability weighting would have been limited in its ability to account for potentially outcome-related noncompletion and would itself have required substantial assumptions about the missingness mechanism. However, because KAB outcomes were unavailable for participants who did not complete the questionnaire, we cannot exclude the possibility that complete-case estimates remain affected by outcome-related bias. Therefore, the associations should be interpreted as observed within a large volunteer sample rather than estimates that can be directly generalized to all French civil servants.

Third, the questionnaire was adapted from a previously developed instrument but was not formally psychometrically validated in this population. Consequently, the KAB scores should be interpreted as descriptive indicators of mental health–related knowledge, attitudes, and behaviors rather than as measurements derived from a validated psychometric scale.

Fourth, the study population consisted exclusively of French civil servants affiliated with a specific health insurance and prevention system and who had agreed to receive email communications. Consequently, the findings may not be directly generalizable to other occupational groups, private-sector employees, or populations from different health care, organizational, or cultural contexts.

Fifth, the use of self-reported data could introduce social desirability bias, particularly regarding attitudes or prosocial behaviors. The anonymity of the survey and validation of the questionnaire mitigate this risk, but it cannot be excluded.

Sixth, time since training was used as an indirect proxy for retention and did not capture frequency of skill application, refresher training, workplace support, or other factors that may influence the long-term maintenance of MHFA-related competencies.

Despite these limitations, this study provides valuable descriptive data on mental health literacy and supportive behaviors among civil servants and offers a relevant baseline for future longitudinal and intervention-based research.

RenderX

## Conclusions

This nationwide cross-sectional study highlights substantial heterogeneity in KAB related to psychological distress among French civil servants, with overall KAB levels remaining in the marginal range. Exposure to MHFA training was consistently associated with higher KAB scores, supporting its role as a public health literacy intervention in occupational settings. However, the observed attenuation of scores over time underscores the need to consider mental health competencies as a potentially declining dynamic rather than permanently acquired. Taken together, these findings support the relevance of integrating MHFA within broader and sustained prevention strategies, combining initial training with regular reinforcement mechanisms to strengthen mental health literacy. Their deployment in the civil service, and other workplace settings, would improve the collective capacity to respond to psychological distress, leading to greater social solidarity.

## Acknowledgments

The authors would like to thank all participants who responded to the questionnaire. The authors would also like to thank the authors of a previous similar study for sharing their questionnaires, especially Ilaria Montagni. The authors would also like to thank Union Régime Obligatoire Prévention Santé, a French health prevention organization that manages the compulsory health insurance scheme for civil servants, for distributing the questionnaire to their insured members, with special thanks to Marina Molin Orru, David Ollivier-Lannuzel, and José de Freitas. The authors did not use generative AI for this manuscript.

## Funding

The authors declared no financial support was received for this work.

## Abstract

**Background:** Prolonged sitting is an increasingly important public health concern, particularly in occupations that offer few opportunities for conventional exercise. Zero-time exercise (ZTEx) integrates brief muscle-engaging movements into daily routines without requiring dedicated time or equipment and may offer a practical way to interrupt prolonged sitting. However, the motivational, cognitive, and contextual factors associated with intention relevant to ZTEx adoption remain poorly understood.

**Objective:** This study examined the association between exercise motivation and general sedentary behavior reduction intention, used as a zero-time exercise–related intention proxy (ZTEx-IP), and assessed model-implied indirect associations involving general self-efficacy and perceived physical activity triggers among Chinese adults in sedentary occupations.

**Methods:** This cross-sectional survey included 790 adults working full-time in sedentary occupations across 20 provincial-level administrative divisions in China between May and September 2025. Eligible participants reported at least 6 hours of work-related sitting on a typical workday. Standardized questionnaires assessed exercise motivation, general self-efficacy, perceived physical activity triggers, and the ZTEx-IP. Multivariable regression and restricted cubic splines examined graded and nonlinear associations between exercise motivation and the ZTEx-IP. PROCESS Models 4 and 6 estimated covariate-adjusted direct and model-implied indirect associations using 5000 bootstrap resamples.

**Results:** Higher exercise motivation scores were associated with higher ZTEx-IP scores. Compared with participants in the lowest motivation tertile, those in the highest tertile had an adjusted score difference of 8.49 points (unstandardized regression coefficient, B=8.49, 95% CI 6.43-10.60; $P$<.001), and the association was nonlinear ($P$ for nonlinearity<.001). In the prespecified ordered model, exercise motivation retained a direct association with the ZTEx-IP (B=0.167, 95% CI 0.088-0.246). Model-implied indirect associations were observed through general self-efficacy (B=0.104, 95% CI 0.057-0.155), perceived physical activity triggers (B=0.157, 95% CI 0.110-0.205), and their prespecified ordering (B=0.025, 95% CI 0.013-0.039). Perceived triggers accounted for a larger increment in explained variance than general self-efficacy ($\Delta R^2$=0.054 vs 0.033), and the adjusted outcome model explained 37.6% of the variance in ZTEx-IP scores ($R^2$=0.376).

**Conclusions:** Among Chinese adults in sedentary occupations, exercise motivation was positively associated with the ZTEx-IP, with model-implied indirect associations involving general self-efficacy and perceived physical activity triggers. The statistical ordering of these associations does not establish that the constructs develop sequentially over time. The comparatively larger trigger-related estimate identifies contextual cue salience as a candidate mechanism for prospective testing but does not demonstrate intervention effectiveness. These hypothesis-generating findings provide a basis for workplace trials of contextually adapted, multicomponent strategies that evaluate actual ZTEx frequency, objectively measured sitting interruptions, adherence over time, and workplace acceptability.

## Introduction

Sedentary behavior is defined as any waking behavior characterized by an energy expenditure of 1.5 metabolic equivalents (METs) or less while sitting, reclining, or lying down [1]. Prolonged sitting has been associated with increased risks of dementia, cardiovascular disease, metabolic disorders, and all-cause mortality [2-4]. In China, approximately one-quarter of adults report sitting for more than 6 hours per day, and prolonged occupational sitting is increasingly common [5]. Given that work organization can limit opportunities for conventional exercise, feasible strategies for interrupting sitting without substantially disrupting routine tasks are needed. Zero-time exercise (ZTEx) refers to brief, simple, muscle-engaging movements performed as part of an existing daily activity, without a separate exercise session, specialized equipment, or additional scheduled time [6]. Examples include seated leg raises during desk work and shoulder retraction while typing. Unlike accumulated exercise, which divides physical activity into several discrete bouts, ZTEx is performed alongside occupational or household tasks. This feature may be particularly relevant to workers whose schedules or job demands limit participation in conventional exercise. Evidence that brief, lifestyle-integrated activity can improve cardiometabolic and functional outcomes further supports the potential value of incorporating movement into sedentary routines [7-9].

Research on ZTEx has largely examined its feasibility and preliminary health outcomes [10], while less is known about the psychosocial factors associated with intention to adopt it. Motivation, self-regulation, and perceived capability are established correlates of physical activity [11,12], but ZTEx may also depend on whether brief movement is perceived as feasible within an ongoing task. Workplace conditions such as time pressure, environmental cues, task structure, and organizational norms may therefore be especially relevant to this form of lifestyle-integrated activity [13]. Yet these factors have generally been studied separately, leaving their joint associations with intention relevant to ZTEx adoption unclear.

General sedentary behavior reduction intention and readiness to adopt ZTEx are conceptually related but not equivalent. Their overlap lies in the evaluation of interrupting sitting, perceived social expectations regarding such interruptions, perceived control over doing so, and willingness to change sedentary routines [14]. However, reducing sedentary behavior is a broad behavioral goal that may be pursued through standing, walking, conventional activity breaks, or ZTEx. ZTEx is a more specific means of pursuing this goal through brief muscle-engaging movements embedded within ongoing activities. The relationship between the constructs can therefore be understood as increasing behavioral specificity, from a general intention to reduce sedentary behavior, through willingness to interrupt a sitting episode and readiness to integrate movement into an ongoing activity, to performance of a defined ZTEx behavior in a particular context [15]. The zero-time exercise–related intention proxy (ZTEx-IP) is positioned at the broader end of this framework because it reflects general willingness and perceived control relevant to changing sedentary routines without specifying ZTEx as the means of change. ZTEx-specific readiness additionally involves beliefs about performing particular movements, knowledge of appropriate techniques, movement-specific confidence and outcome expectations, perceived feasibility and compatibility with ongoing tasks, and workplace appropriateness [16,17].

Because ZTEx is embedded within an ongoing activity, it must be initiated while another goal, such as completing a work task, is already active. This feature guided the selection of exercise motivation, general self-efficacy, and perceived physical activity triggers. Exercise motivation reflects the quality and internalization of the value placed on movement. This motivational quality is relevant when movement competes with the immediate convenience of sitting, habitual behavior, and task demands. Self-determination theory provides a theoretical account of this variation in motivational quality by distinguishing autonomous and controlled forms of regulation [18]. General self-efficacy represents a broader agentic resource for managing obstacles and competing demands. Social cognitive theory supports its inclusion because efficacy beliefs influence goal pursuit, effort, and persistence in the presence of impediments [19]. Perceived physical activity triggers represent the salience of cues and facilitators that make otherwise overlooked movement opportunities noticeable during work. This is particularly relevant when employees remain seated because their attention is absorbed by ongoing tasks. Workplace evidence identifies competing motivations, limited perceived control, task and organizational constraints, and missed or ignored cues as barriers to interrupting sitting. The three variables were therefore selected to represent motivational regulation, generalized perceived agency, and cue salience within the specific demands of lifestyle-integrated movement. They were not intended to capture all determinants of ZTEx adoption.

The capability, opportunity, motivation-behavior (COM-B) model and the Fogg behavior model provide complementary frameworks for organizing these factors at different explanatory levels rather than functioning as competing models. COM-B provides a system-level account in which behavior depends on motivation, capability, and opportunity [20,21]. At a broad conceptual level, exercise motivation relates to motivational resources, general self-efficacy to perceived psychological capability, and perceived physical activity triggers to the salience of cues and facilitators that signal opportunities for action. Nevertheless, the constructs measured in this study are not direct operational equivalents of these framework components. For ZTEx, capability also encompasses technique-specific

XSL•FO
RenderX

knowledge and movement skills, whereas opportunity encompasses task compatibility and workplace norms. The Fogg behavior model provides a more immediate account of behavioral initiation: a prompt is expected to elicit action only when sufficient motivation and ability are present at the same moment [22]. Thus, self-determination theory provides a theoretical account of motivational quality, social cognitive theory supports the role of generalized perceived agency, COM-B situates these factors within broader behavioral conditions, and the Fogg behavior model highlights the conditional role of prompts at the moment of action.

Therefore, this study aimed to examine the association between exercise motivation and the ZTEx-IP among Chinese adults in sedentary occupations and to evaluate model-implied indirect associations involving general self-efficacy and perceived physical activity triggers. We also characterized participants' sedentary behavior and physical activity patterns and examined whether the association between exercise motivation and the ZTEx-IP was graded or nonlinear. We hypothesized that higher exercise motivation would be positively associated with the ZTEx-IP and that the fitted models would yield positive indirect associations involving general self-efficacy and perceived physical activity triggers.

## Methods

### Design

This cross-sectional online survey examined contemporaneous associations among exercise regulation, general self-efficacy, perceived physical activity triggers, and the ZTEx-IP. Theory-informed parallel and ordered indirect-association analyses were used to quantify model-implied indirect associations. Because all variables were measured at the same time, these analyses were not intended to establish temporal or causal mediation. Reporting followed the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) checklist (Multimedia Appendix 1).

### Setting and Sample

Data were collected through an online questionnaire in China from May to September 2025. The study included participants from 20 of China's 34 provincial-level administrative divisions, covering eastern, central, and western regions. Recruitment used a multichannel convenience-sampling strategy. Recruitment information was distributed through workplace WeChat (Tencent Holdings Limited) groups, occupation-related online communities, and workplace or institutional contacts. Individual recruitment source was not recorded; therefore, channel-specific recruitment proportions could not be calculated. Self-reported work-unit information indicated participation from public-service institutions, enterprises, and other workplace settings. Organization size and ownership were not systematically recorded. A standardized recruitment notice described the study purpose, eligibility criteria, voluntary participation, confidentiality, approximate completion time, and the right to withdraw before submission. Contacts only forwarded the notice and questionnaire link and had no access to individual responses. The electronic questionnaire was administered through Wenjuanxing and accessed via a web link or QR code. Participants provided electronic informed consent before entering the survey. A standardized definition of ZTEx was presented before the ZTEx-related items. The inclusion criteria required (1) adults aged ≥18 years; (2) employed full-time in sedentary occupations, operationally defined as jobs predominantly involving seated work for ≥6 hours per working day with low energy expenditure (≤1.5 METs), consistent with the Sedentary Behaviour Research Network definition and commonly used cutoffs in occupational sedentary epidemiology; and (3) able to provide informed consent. Exclusion criteria eliminated individuals on long-term leave, with cognitive impairment affecting comprehension, or participating in concurrent behavioral intervention programs.

Of the 820 submitted questionnaires, 30 were excluded because missing data precluded calculation of at least one core scale score or analysis variable, leaving 790 questionnaires for analysis. Thus, 96.3% (790/820) of submitted questionnaires were included; this percentage represents analytic inclusion rather than a response rate because the number of individuals who received or viewed the recruitment information was unavailable. No item-level imputation was performed. Before data collection, sample-size planning used a pragmatic ratio of 10 to 20 participants per anticipated model parameter. Allowing 20% for unusable questionnaires yielded a recruitment target of 325 to 650 participants. Because sample-size requirements for indirect associations depend on path magnitudes and model characteristics [23,24], this heuristic was not regarded as a model-specific power calculation. A subsequent scenario-based Monte Carlo analysis of sample adequacy is reported in Multimedia Appendix 2.

### Data Collection Tools

#### *General Information Questionnaire*

The questionnaire was developed based on a literature review and study goals, covering 17 items and related sociodemographic and work characteristics. Variables included sex, age, educational attainment, monthly income, occupation category, job tenure, cumulative sedentary hours per day, musculoskeletal discomfort, recent health examination, chronic disease history, physical activity duration, exercise frequency and duration, use of wearable devices, and familiarity with ZTEx. For descriptive reporting, physical activity was separated based on context and intent. Incidental physical activity was defined as physical activity accumulated during work-related activities, household duties, transportation, and other routine daily activities, other than physical activity undertaken during a planned exercise session. Structured exercise was defined as a planned, intentional, and repetitive form of physical activity that was undertaken specifically with the aim of improving or maintaining health or physical fitness [25]. Frequency and duration were recorded separately for these 2 activity categories. Before answering the familiarity item, participants were shown the standardized definition of ZTEx. Familiarity was assessed with the single self-report item, "How familiar are you with zero-time exercise?" Responses were categorized as "not familiar," "somewhat familiar," or "very familiar" and retained in these categories for descriptive analyses. For the exploratory familiarity-restricted analysis, "somewhat familiar" and "very

XSL•FO
RenderX

familiar" were combined as "at least somewhat familiar," whereas participants who selected "not familiar" were excluded.

### *Adult Sedentary Behavior Reduction Intention Questionnaire*

The Adult Sedentary Behavior Reduction Intention Questionnaire was developed by Ye et al [26] from the theory of planned behavior to measure adults' intention to reduce sedentary behavior. It contains 4 dimensions: behavioral intention, attitude, subjective norms, and perceived behavioral control. The scale has 16 items, each rated on a 5-point Likert scale (1 to 5), with higher values showing greater intention to reduce sedentary behavior. In the absence of a validated ZTEx-specific intention measure, the questionnaire total score was operationalized as the ZTEx-IP. This operationalization was based on the conceptual overlap between reducing sedentary behavior and incorporating brief, routine-integrated movements into otherwise sedentary daily activities. However, the questionnaire assesses general sedentary behavior reduction intention rather than intention to perform ZTEx specifically; therefore, the outcome should be interpreted as a proxy indicator rather than a direct measure of ZTEx-specific intention. The validation study reported excellent internal consistency (Cronbach α=0.967) and strong construct validity, with subscale α ranging from 0.911 to 0.950. In this study, Cronbach α for this scale was 0.953.

### *Behavioral Regulation in Exercise Questionnaire*

The Behavioral Regulation in Exercise Questionnaire (BREQ-2) was developed by Markland and Tobin in 2004 to assess exercise motivation within self-determination theory [27]. It includes 5 dimensions: amotivation, external regulation, introjected regulation, identified regulation, and intrinsic motivation. The Chinese version contains 18 items rated on a 5-point Likert scale from 0 to 4. In this study, amotivation and external regulation items were reverse scored before all items were summed to create a composite score; higher scores represented a more self-determined motivational profile. The BREQ-2 captures relatively stable forms of behavioral regulation and motivational internalization rather than the momentary intensity of motivation immediately before an action, as conceptualized in the Fogg behavior model. Liu et al [28] translated and validated the Chinese version in 2015, reporting Cronbach α values ranging from 0.72 to 0.85 and good construct validity. Cronbach α was 0.882 in this study.

### *General Self-Efficacy Scale*

General Self-Efficacy Scale (GSES) was developed by Schwarzer and Jerusalem in 1995 to assess individuals' confidence in coping with challenges and controlling demanding situations [29]. The unidimensional scale contains 10 items rated from 1 to 4, with higher scores indicating greater general self-efficacy. Wang et al [30] translated and validated the Chinese version in 2001 [30], reporting Cronbach α=0.87, test-retest reliability $r$=0.83, and split-half reliability $r$=0.82. Cronbach α was 0.938 in this study. The GSES assesses generalized rather than ZTEx-specific self-efficacy and was therefore not treated as a direct operationalization of behavior-specific capability in the COM-B model. Instead, it was used as a theoretically relevant measure of generalized perceived agency within the proposed psychosocial model.

### *Physical Activity Triggers Questionnaire*

The Physical Activity Triggers Questionnaire (PATQ) was developed by Wang and Kang in 2022 to assess physical activity-related triggers [31]. It consists of 3 dimensions: spark, signal, and facilitator. The PATQ has 14 items measured on a 5-point Likert scale (1=strongly disagree, 5=strongly agree). The PATQ captures perceived exposure or receptivity to physical activity cues in daily life rather than brief prompts occurring immediately before a specific action. It was therefore used to examine cue-related associations with the other study variables. The original validation among Chinese university students reported strong internal consistency (Cronbach α=0.925), split-half reliability of 0.821, test-retest reliability of 0.860, and acceptable construct validity. Cronbach α was 0.934 in this study.

## Data Analysis

All statistical analyses were conducted using R (version 4.5.1; R Core Team) and IBM SPSS Statistics version 29.0 with the PROCESS macro. Scale-score distributions were assessed using the Shapiro-Wilk test. Categorical variables were summarized as frequencies and percentages, and scale scores as medians and IQRs (25th-75th percentiles). Internal consistency was evaluated using Cronbach α. Differences in the ZTEx-IP across participant characteristics were examined using Mann-Whitney U tests or Kruskal-Wallis H tests, as appropriate. The Benjamini-Hochberg procedure was applied to the 15 comparisons between-group comparisons; unadjusted and adjusted $P$ values are reported in Multimedia Appendix 3. Spearman rank correlations were used to examine associations among the 4 focal scores. Harman's unrotated single-factor analysis of the 58 core questionnaire items was used as a limited diagnostic for common method variance.

The adjustment set was defined using a combination of substantive considerations and nominal empirical screening. Candidate variables represented 4 relevant domains. Age and monthly income represented sociodemographic context; incidental physical activity duration and structured exercise frequency and duration represented existing movement patterns; wearable-device use represented potential exposure to activity monitoring and digital cues; and ZTEx familiarity represented prior awareness of the target strategy. The socioeconomic and activity-related rationale was informed by previous literature [32], whereas wearable-device use and ZTEx familiarity were included on substantive grounds because cue exposure and prior knowledge could be related to the focal study variables. To obtain a parsimonious adjustment set for this exploratory analysis, candidate variables meeting the nominal significance criterion (α=.05) in the initial unadjusted comparisons were retained. The resulting set comprised age, monthly income, incidental physical activity duration, structured exercise frequency, structured exercise duration, wearable-device use, and ZTEx familiarity. Monthly income met the nominal screening criterion before multiplicity adjustment (unadjusted $P$=.04), although the Benjamini-Hochberg–adjusted comparison was not statistically significant (adjusted $P$=.07). The

XSL•FO
RenderX

Benjamini-Hochberg procedure was used only for descriptive multiplicity control and did not redefine the adjustment set. The selected variables were treated as adjustment covariates rather than empirically established confounders. Age, income, incidental physical activity duration, structured exercise frequency and duration, and ZTEx familiarity were entered as ordinal category scores, whereas wearable-device use was entered as a binary indicator. Ordinary least squares regression was used to examine the association between exercise motivation and the ZTEx-IP. Motivation was modeled using sample-specific tertiles, with the lowest tertile as the reference and an ordinal term to test for trend. The continuous association was examined using a restricted cubic spline with knots at motivation scores of 33, 48, 54, and 72 and a reference score of 51; overall and nonlinear associations were tested.

Model-implied indirect associations were estimated using PROCESS Models 4 and 6. Model 4 specified general self-efficacy and perceived physical activity triggers as parallel intermediate variables, whereas Model 6 imposed the prespecified theory-informed ordering of exercise motivation, general self-efficacy, perceived physical activity triggers, and the ZTEx-IP to estimate the corresponding model-implied indirect association. The same covariates were included in every component equation. Direct, specific indirect, total indirect, and total associations were estimated using 5000 nonparametric percentile bootstrap resamples. A 95% bootstrap CI excluding 0 was considered statistical evidence of an indirect association. Unstandardized coefficients were the primary estimates, with standardized coefficients additionally reported for the focal associations. Model $R^2$ and overall $F$ statistics were reported. The incremental contribution of each intermediate variable was assessed using $\Delta R^2$ and Cohen $f^2$. Because all variables were measured concurrently, the indirect associations were interpreted as statistical decompositions of cross-sectional associations rather than evidence of temporal or causal mediation. Model assumptions were assessed using variance inflation factors and residual diagnostics, with HC3 heteroscedasticity-consistent SEs examined as a robustness analysis. Three theoretically motivated sensitivity analyses were prioritized: alternative outcome definitions using the behavioral intention subscale and a score excluding perceived behavioral control items, restriction to participants who were at least somewhat familiar with ZTEx, and an alternative ordering of general self-efficacy and perceived physical activity triggers. Additional regression diagnostics and technical robustness analyses are reported in Multimedia Appendices 4 and 5. Bootstrap-based sensitivity analyses used 5000 resamples. All sensitivity analyses were considered exploratory, and no additional multiplicity adjustment was applied.

### Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki, and ethical approval was granted by the Ethics Committee of Hunan Normal University (2025889). Before beginning the online questionnaire, participants received information about the study purpose, voluntary participation, data confidentiality, and their right to decline participation or withdraw before submission without penalty. All participants provided electronic informed consent before proceeding to the survey items. Participants received no financial or material compensation for participation. To protect participant privacy and confidentiality, the analytic dataset was deidentified before analysis by removing information that could identify individual participants or participating institutions. Results were reported in aggregate, data were used solely for the purposes of this study, and access was restricted to the research team.

## Results

### Descriptive Statistics

Of the 820 online questionnaire submissions received, 790 met the completeness requirements described in the “Methods” section and were included in the analyses, corresponding to an analytic inclusion proportion of 96.3% (790/820). Table 1 summarizes participants’ sociodemographic, occupational, and behavioral characteristics and their median ZTEx-IP scores. The sample was relatively balanced by sex, with female participants accounting for 56.6% (447/790), and 75.4% (596/790) of participants were younger than 40 years. Education and research professionals formed the largest occupational group (297/790, 37.6%). Most participants reported middle-income levels and had completed higher education.

[a]ZTEx-IP: zero-time exercise–related intention proxy.

[b]Incidental physical activity refers to movement accumulated through occupational duties, household tasks, transportation, and other routine daily activities outside planned exercise sessions. Structured exercise refers to planned, intentional, and repetitive physical activity undertaken to improve or maintain health or physical fitness. The presented *P* values were adjusted using the Benjamini-Hochberg procedure. Detailed test statistics, unadjusted *P* values, and Benjamini-Hochberg–adjusted results are provided in Multimedia Appendix 3.

[c]Benjamini-Hochberg.

[d]The 2025 average exchange rate was US $1=RMB 7.1875.

[e]ZTEx: zero-time exercise.

The median ZTEx-IP score was 59 (IQR 50-65.75). After Benjamini-Hochberg adjustment, differences remained statistically significant across age groups (adjusted *P*=.04), incidental physical activity duration (adjusted *P*=.001), structured exercise frequency (adjusted *P*<.001), structured exercise duration (adjusted *P*<.001), wearable-device use (adjusted *P*=.001), and ZTEx familiarity (adjusted *P*=.04). No statistically significant differences were observed by sex, educational attainment, occupation, job tenure, daily sedentary duration, musculoskeletal discomfort, health examination in the previous 6 months, or chronic disease status (all adjusted *P*>.05).

## Correlation Analysis

Spearman rank correlations were used to examine associations among exercise motivation, general self-efficacy, perceived physical activity triggers, and the ZTEx-IP (Table 2). All correlations were positive and statistically significant (all *P*<.001). Exercise motivation was positively correlated with general self-efficacy (ρ=0.347), perceived physical activity triggers (ρ=0.539), and the ZTEx-IP (ρ=0.371). General self-efficacy was positively correlated with perceived physical activity triggers (ρ=0.349) and the ZTEx-IP (ρ=0.378). Perceived physical activity triggers showed the strongest correlation with the ZTEx-IP (ρ=0.420).

XSL•FO
RenderX

**Table 2.** Spearman rank correlations among exercise motivation, general self-efficacy, perceived physical activity triggers, and the ZTEx-IP[a] (n=790)[b].

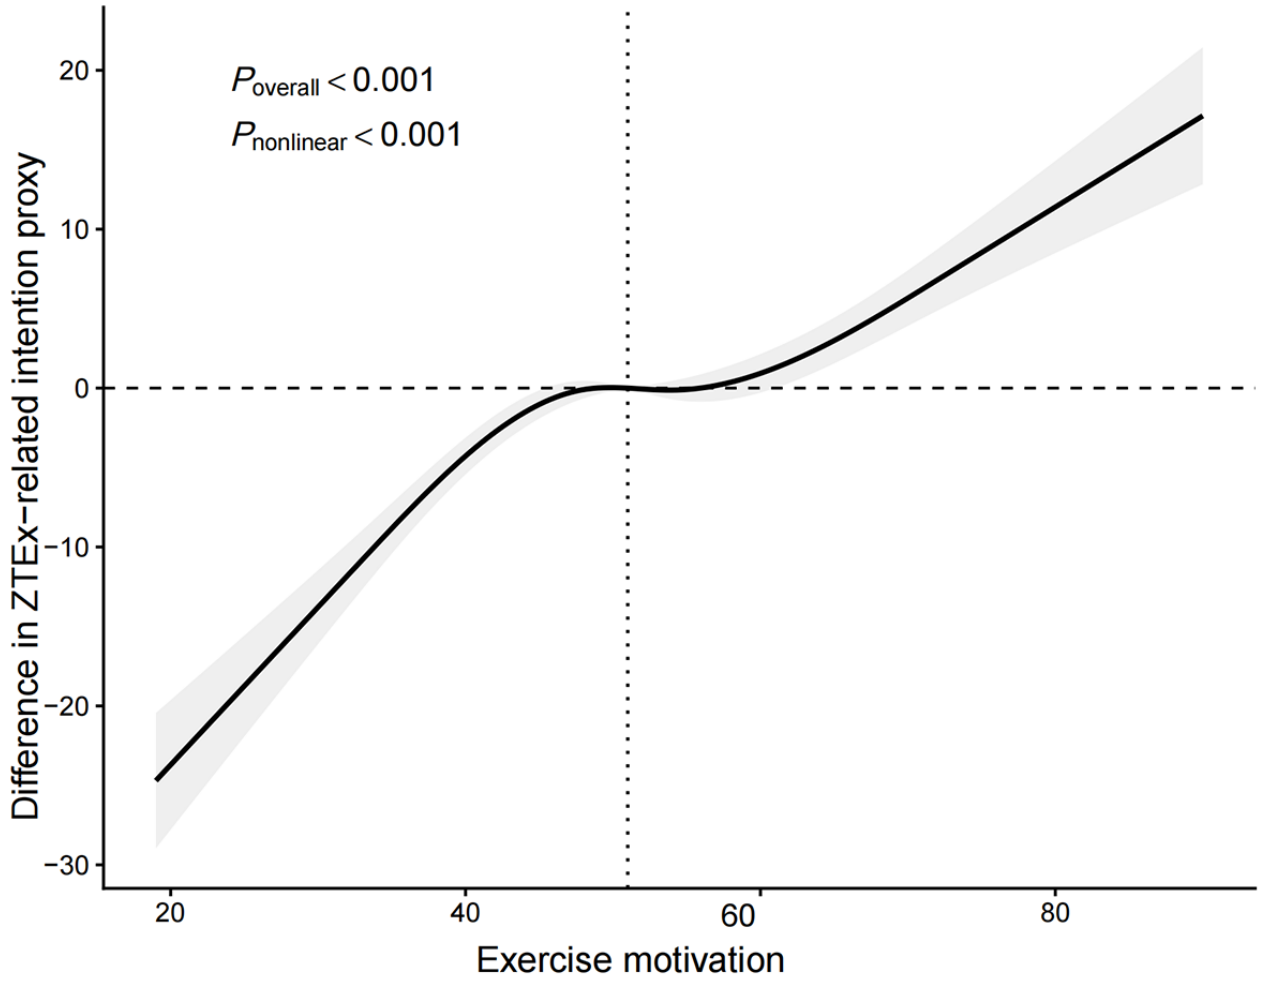
| Variable | Median (IQR) | 1 | 2 | 3 | 4 |
|---|---|---|---|---|---|
| Exercise motivation | 51 (44-56) | —[c] | | | |
| General self-efficacy | 29 (26-30) | .347[d] | — | | |
| Perceived physical activity triggers | 36 (28-43) | .539[d] | .349[d] | — | |
| ZTEx-IP | 59 (50-65.75) | .371[d] | .378[d] | .420[d] | — |

[a]ZTEx-IP: zero-time exercise–related intention proxy.

[b]Scale scores are presented as median (IQR). Values in the lower triangle are Spearman rank correlation coefficients (ρ). The ZTEx-IP was operationalized using the total score of the Adult Sedentary Behavior Reduction Intention Questionnaire.

[c]Self-correlations, which were not estimated.

[d]*P*<.001.



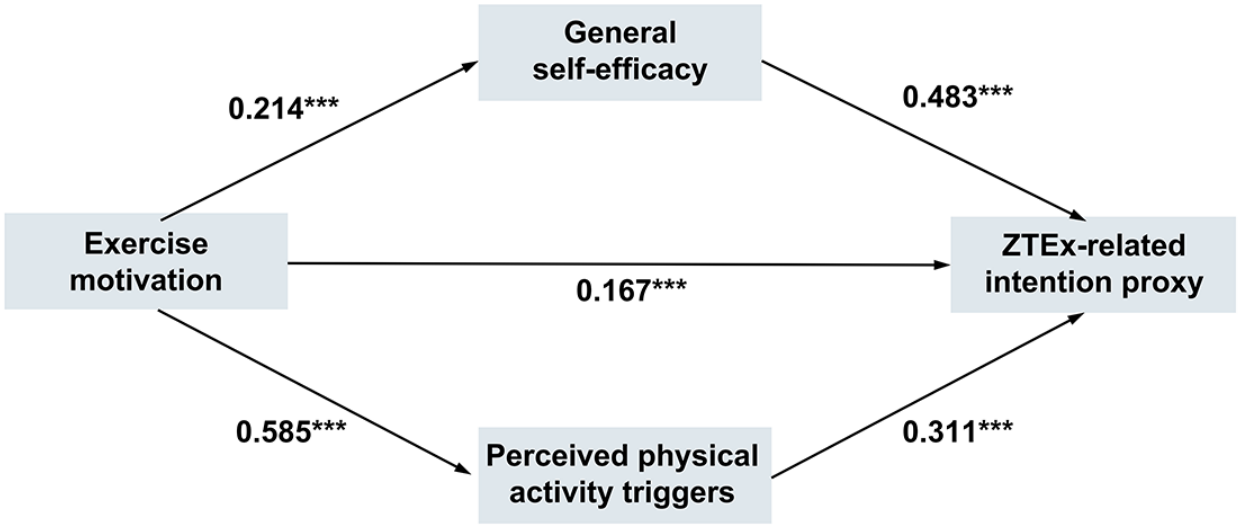
### Association Between Exercise Motivation and ZTEx-IP

Participants were categorized into tertiles according to their exercise motivation scores. In the unadjusted model, compared with participants in the lowest motivation tertile, those in the middle and highest tertiles had higher ZTEx-IP scores, with B coefficients of 5.58 (95% CI 3.60-7.56; *P*<.001) and 10.60 (95% CI 8.63-12.60; *P*<.001), respectively. After adjustment for age, income, incidental physical activity duration, structured exercise frequency, structured exercise duration, wearable-device use, and ZTEx familiarity, the corresponding B coefficients were 4.64 (95% CI 2.69-6.60; *P*<.001) and 8.49 (95% CI 6.43-10.60; *P*<.001), respectively (Multimedia Appendix 6). A significant positive trend was observed across increasing motivation tertiles (adjusted B for trend=4.25, 95% CI 3.22-5.28; *P*<.001). When exercise motivation was analyzed as a continuous variable, restricted cubic spline analysis showed a significant overall association with the ZTEx-IP (*P* overall<.001), with evidence of nonlinearity (*P* nonlinear<.001; Figure 1). Using an exercise motivation score of 51 as the reference value, the spline curve showed an overall increasing pattern, although the magnitude of the association varied across the motivation score range.

XSL•FO
RenderX

**Figure 1.** Restricted cubic spline analysis of the association between exercise motivation and the zero-time exercise–related intention proxy (ZTEx-IP) among Chinese adults in sedentary occupations. The solid line shows the multivariable-adjusted difference in the ZTEx-IP, and the shaded band shows the 95% CI. The vertical dotted line marks the reference motivation score of 51, at which the adjusted difference was set to 0; the horizontal dashed line indicates no difference from that reference. Negative values indicate lower adjusted ZTEx-IP scores relative to the reference and do not imply an inverse overall association. The model was adjusted for age, income, incidental physical activity duration, structured exercise frequency, structured exercise duration, wearable-device use, and zero-time exercise familiarity. Both the overall and nonlinear associations were statistically significant ($P$<.001 for each). ZTEx: zero-time exercise.

## Parallel Indirect-Association Analysis (PROCESS Model 4)



Before the indirect-association analyses, common method variance was assessed using Harman's single-factor test. All 58 core items from the BREQ-2, GSES, PATQ, and Adult Sedentary Behavior Reduction Intention Questionnaire were included. The first unrotated factor accounted for 31.93% of the total variance. This result did not indicate a predominant single factor, although the test cannot rule out common method bias. Full results are reported in Multimedia Appendix 7.

A parallel indirect-association model was fitted to estimate model-implied indirect associations involving general self-efficacy and perceived physical activity triggers. The model was adjusted for age, income, incidental physical activity duration, structured exercise frequency, structured exercise duration, wearable-device use, and ZTEx familiarity. The adjusted parallel indirect-association model is illustrated in Figure 2. Exercise motivation was positively associated with both general self-efficacy (B=0.214, SE 0.015, 95% CI 0.184-0.245; $P$<.001) and perceived physical activity triggers (B=0.585, SE 0.031, 95% CI 0.524-0.645; $P$<.001). In the outcome model, both general self-efficacy (B=0.483, SE 0.075, 95% CI 0.336-0.631; $P$<.001) and perceived physical activity triggers (B=0.311, SE 0.038, 95% CI 0.237-0.386; $P$<.001) were positively associated with the ZTEx-IP after adjustment for exercise motivation and covariates. The direct association between exercise motivation and the ZTEx-IP remained significant (B=0.167, SE 0.04, 95% CI 0.088-0.246; $P$<.001). Bootstrap analysis with 5000 resamples yielded nonzero indirect-association estimates involving general self-efficacy (B=0.104, bootstrap SE (BootSE)=0.026, 95% CI 0.056-0.158) and perceived physical activity triggers (B=0.182, BootSE=0.026, 95% CI 0.129-0.233). The total indirect association was also significant (B=0.286, BootSE=0.034, 95% CI 0.220-0.353). The adjusted outcome model explained 37.6% of the variance in the ZTEx-IP. Detailed adjusted Model 4 results are provided in Multimedia Appendix 8.

**Figure 2.** Adjusted parallel indirect-association model involving exercise motivation, general self-efficacy, perceived physical activity triggers, and the zero-time exercise–related intention proxy. Values are unstandardized regression coefficients. The model was adjusted for age, income, wearable-device use, incidental physical activity duration, structured exercise frequency, structured exercise duration, and zero-time exercise familiarity. ZTEx: zero-time exercise. ***$P$<.001.

## Ordered Indirect-Association Analysis (PROCESS Model 6)

PROCESS Model 6 was fitted to estimate model-implied indirect associations under the prespecified theory-informed ordering of exercise motivation, general self-efficacy, perceived physical activity triggers, and the ZTEx-IP. As shown in Table 3, exercise motivation was positively associated with both general self-efficacy (standardized regression coefficient, β=0.460, $P$<.001) and perceived physical activity triggers (β=0.487, $P$<.001), and general self-efficacy was positively associated with perceived physical activity triggers (β=0.170, $P$<.001). These coefficients were compatible with the prespecified statistical ordering, but they do not establish temporal precedence among the constructs. In the full model predicting the ZTEx-IP, exercise motivation (β=0.161, $P$<.001), general self-efficacy (β=0.216, $P$<.001), and perceived physical activity triggers (β=0.310, $P$<.001) all remained statistically significant. The adjusted outcome model explained 37.6% of the variance in the ZTEx-IP ($R^2$=0.376, $F_{10,779}$=46.995; $P$<.001). Compared with reduced models excluding each intermediate variable separately, general self-efficacy contributed an additional 3.3% of explained variance ($\Delta R^2$=0.033, Cohen $f^2$=0.053), whereas perceived physical activity triggers contributed an additional 5.4% ($\Delta R^2$=0.054, Cohen $f^2$=0.087). Complete model diagnostics and secondary technical robustness analyses are reported in Multimedia Appendix 4.

**Table 3.** Component equations for the prespecified ordered model (n=790)[a].

| Regression | | Model index | | Coefficients | |
|---|---|---|---|---|---|
| Dependent variable | Independent variable | $R^2$ | $F$ test ($df$) | β | $t$ test ($df$) |
| General self-efficacy | Exercise motivation | 0.269 | 35.997 (8, 781)[b] | 0.460 | 13.876 (781)[b] |
| Perceived physical activity triggers | Exercise motivation | 0.436 | 66.928 (9, 780)[b] | 0.487 | 14.960 (780)[b] |
| Perceived physical activity triggers | General self-efficacy | —[c] | — | 0.170 | 5.404 (780)[b] |
| ZTEx-IP[d] | Exercise motivation | 0.376 | 46.995 (10, 779)[b] | 0.161 | 4.150 (779)[b] |
| ZTEx-IP | General self-efficacy | — | — | 0.216 | 6.428 (779)[b] |
| ZTEx-IP | Perceived physical activity triggers | — | — | 0.310 | 8.239 (779)[b] |

[a]All 3 equations were adjusted for age, income, incidental physical activity duration, structured exercise frequency, structured exercise duration, wearable-device use, and ZTEx familiarity. β denotes a standardized coefficient. The focal continuous variables were analyzed using their original scale scores and standardized for presentation in this table. Ordered categorical covariates were entered as ordinal category scores, and wearable-device use was entered as a binary indicator.

### Bootstrap Estimation of the Ordered Indirect-Association Model

A percentile bootstrap analysis with 5000 samples was conducted to evaluate model-implied indirect associations under the prespecified ordering. As shown in Table 4, the total indirect association between exercise motivation and the ZTEx-IP was B=0.286 (BootSE=0.034, 95% CI 0.218-0.352). The three specific estimates involved (1) general self-efficacy alone (B=0.104, BootSE=0.025, 95% CI 0.057-0.155), (2) perceived physical activity triggers alone (B=0.157, BootSE=0.024, 95% CI 0.110-0.205), and (3) the prespecified ordered combination of general self-efficacy and perceived physical activity triggers (B=0.025, BootSE=0.007, 95% CI 0.013-0.039). All bootstrap CIs excluded 0. The direct association between exercise motivation and the ZTEx-IP also remained statistically significant (B=0.167, SE=0.040, 95% CI 0.088-0.246). Both the direct association and the model-implied indirect association estimates therefore differed from 0. The observed statistical pattern was consistent with the theory-informed ordering used in PROCESS Model 6. However, the cross-sectional estimates cannot determine whether self-efficacy precedes trigger perception, whether trigger perception enhances self-efficacy, or whether both are influenced by another unmeasured factor. Figure 3 presents standardized coefficients for the prespecified ordered model; its arrows indicate model specification and not temporal sequence.

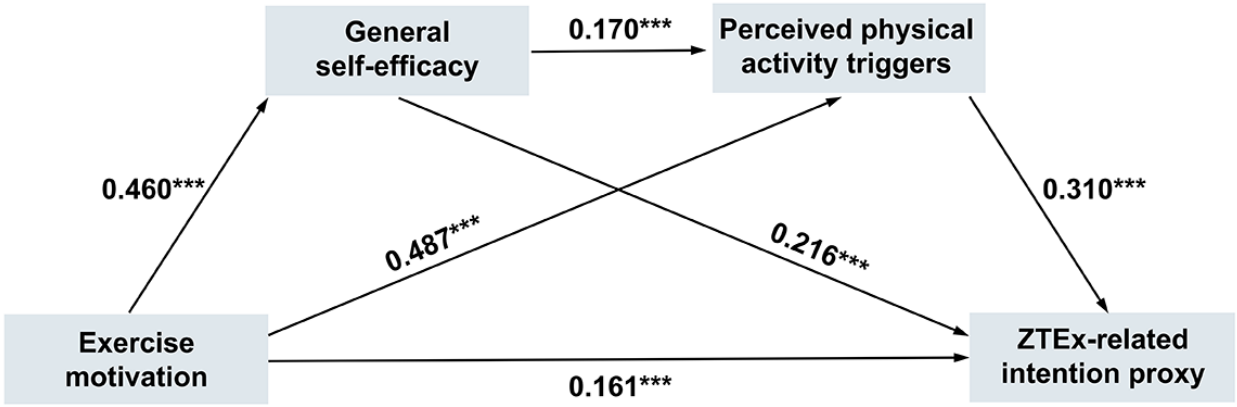

**Table 4.** Total, direct, and indirect associations between exercise motivation and the ZTEx-IP[a] involving general self-efficacy and perceived physical activity triggers (n=790)[b].

| Association component | B (SE) | 95% CI |
|---|---|---|
| Total association | 0.453 (0.034) | 0.385-0.520 |
| Direct association | 0.167 (0.040) | 0.088-0.246 |
| Total indirect association | 0.286 (0.034) | 0.218-0.352 |
| X → M1 → Y | 0.104 (0.025) | 0.057-0.155 |
| X → M2 → Y | 0.157 (0.024) | 0.110-0.205 |
| X → M1 → M2 → Y | 0.025 (0.007) | 0.013-0.039 |

[a]ZTEx-IP: zero-time exercise–related intention proxy.

[b]X: exercise motivation; Y: ZTEx-IP; M1: general self-efficacy; M2: perceived physical activity triggers; B: unstandardized coefficient. Indirect associations were estimated using 5000 bootstrap resamples and percentile 95% CIs. All equations were adjusted for age, income, incidental physical activity duration, structured exercise frequency, structured exercise duration, wearable-device use, and zero-time exercise familiarity.

**Figure 3.** Standardized coefficient diagram for the prespecified ordered model involving exercise motivation, general self-efficacy, perceived physical activity triggers, and the zero-time exercise–related intention proxy. Coefficients were adjusted for age, income, incidental physical activity duration, structured exercise frequency, structured exercise duration, wearable-device use, and zero-time exercise familiarity. Arrows indicate the imposed model specification and do not establish temporal sequence. ZTEx: zero-time exercise. ***$P$<.001.

### Theoretically Relevant Sensitivity Analyses

Analyses using the behavioral intention subscale or an outcome excluding perceived behavioral control items yielded positive direct and model-implied indirect associations, with the corresponding 95% CIs excluding 0. In the subgroup of participants who were at least somewhat familiar with ZTEx (n=187), the bootstrap CIs for both single-intermediate-variable associations and the total indirect association excluded 0, whereas the CIs for the direct and ordered indirect-association estimates included 0. An alternative variable ordering also yielded a nonzero ordered indirect-association estimate, reinforcing that the cross-sectional data could not identify a unique temporal order among the constructs. Complete numerical results and additional technical robustness analyses are reported in Multimedia Appendices 4 and 5.

## Discussion

### Principal Findings

In this study of 790 Chinese adults in sedentary occupations, higher exercise motivation was associated with higher ZTEx-IP scores. The association was graded and nonlinear across the observed motivation range. In both the parallel and ordered models, general self-efficacy and perceived physical activity triggers showed distinct model-implied indirect associations between exercise motivation and the ZTEx-IP. Perceived triggers had the larger specific indirect estimate and made the greater incremental contribution to explained variance, while the prespecified ordered term involving both intermediate variables yielded a smaller indirect estimate. Together, the adjusted variables explained 37.6% of the variance in the ZTEx-IP. The theoretically motivated sensitivity analyses retained the overall positive association pattern, although estimates in the ZTEx-familiar subgroup were less precise, and the alternative ordering confirmed that the cross-sectional data did not identify a unique temporal sequence. By considering these constructs in one model, the study extends prior work beyond isolated psychosocial correlates and highlights the joint relevance of motivational orientation, perceived agency, and cue-supportive contexts to readiness for brief, lifestyle-integrated movement.

### Interpretation, Comparison With Prior Work, and Implications

The graded association between exercise motivation and the ZTEx-IP is most plausibly interpreted as a relationship between a more self-determined regulatory profile and readiness to reorganize sedentary routines. The BREQ-2 assesses exercise regulation along an internalization continuum, capturing the quality and self-endorsement of motivation rather than the intensity of a momentary impulse [27,28]. This interpretation is consistent with evidence that perceived competence and more autonomous forms of regulation are recurrent correlates of physical activity [12]. The Chinese working-age context makes the finding particularly relevant. Half of Chinese adults aged 18-44 years report sitting for at least 6 hours per day [5], and longer sitting duration has been associated with a higher risk of major cardiovascular events among both manual and nonmanual workers [33]. For workers who find it difficult to set aside dedicated exercise time, an internalized value placed on movement may make brief bouts incorporated into existing routines more acceptable. The nonlinear pattern adds nuance but does not identify a threshold or plateau. Instead, it suggests that the strength of the motivation–ZTEx-IP association varies across the observed motivation range, providing a reason to test support tailored to workers' motivational profiles without imposing arbitrary cutoffs. The 37.6% of variance explained by the adjusted model falls within the broad range reported for theory-based models of behavioral and physical activity intentions [34]. Direct comparison should nevertheless be cautious because the present outcome includes several Theory of Planned Behavior domains. The unexplained variance may reflect factors not captured in the model, including job control, workload, habit, time availability, organizational norms, and access to feasible opportunities for movement [35,36].

The model-implied indirect associations show that exercise motivation, generalized perceived agency, and recognizable movement opportunities covaried within the prespecified statistical model. General self-efficacy reflects confidence in handling challenges across situations rather than efficacy for a particular ZTEx task [30]. From an affordance perspective, workers reporting greater agency may also be more likely to regard a task transition, reminder, or scheduled break as a usable opportunity for movement [37]. This is one theoretically plausible interpretation, not evidence that self-efficacy temporally precedes trigger perception. The larger trigger-related estimate is also plausible for a low-threshold strategy such as ZTEx, which requires little time, space, equipment, or technical skill. A cue is useful only when movement is feasible within the task and acceptable in the workplace. This point is especially relevant in Chinese workplaces, where time pressure and limited social support have been reported as barriers to sustained activity, while locally tested programs increasingly combine digital delivery with managerial, team-based, or interactive support [38-41]. Perceived triggers may therefore reflect both cue exposure and the perceived legitimacy of responding to a cue. The co-occurrence of motivation, perceived agency, and salient opportunity is compatible with COM-B and the Fogg behavior model, but neither framework determines temporal order in these data. Trigger perception might enhance self-efficacy; both constructs might reflect unmeasured influences such as job control or workplace culture, or reciprocal relations might operate. The observed statistical pattern was consistent with the theory-informed ordering used in PROCESS Model 6; however, longitudinal or intensive repeated-measures research is required to determine whether and how these constructs develop over time.

The relative estimates identify perceived trigger exposure, exercise motivation, and general self-efficacy as constructs for hypothesis-driven intervention research rather than as intervention components ready for implementation. In the prespecified ordered model, the specific indirect estimate involving perceived triggers exceeded that involving general self-efficacy (B=0.157 vs B=0.104), and triggers made the larger incremental contribution to explained variance ($\Delta R^2$=0.054 vs 0.033). Because these observational estimates relate perceived triggers to the ZTEx-IP, they do not demonstrate that delivered prompts or changes in workplace practices affect actual ZTEx behavior. A primary hypothesis for prospective evaluation is that context-sensitive prompts may help translate intention into objectively measured sitting interruptions and ZTEx performance. Future trials could also examine whether any such effect varies according to baseline motivation, self-efficacy, or occupational context. Evidence that workplace prompts have modest and heterogeneous effects [42-44] and that the effects of team communication vary according to message type and frequency [38] underscores the need to evaluate, rather than assume, the added value of particular delivery or organizational components. The present data cannot determine which components, delivery modes, or combinations are effective. Future workplace trials should prespecify occupation-specific

XSL•FO
RenderX

feasibility and safety criteria and assess objectively measured sitting interruptions, actual ZTEx frequency, adherence over time, and acceptability to workers and employers rather than intention alone [45].

## Limitations

This study had several strengths, including a relatively large and geographically diverse sample, standardized Chinese-language instruments with satisfactory internal consistency in the present sample, and extensive sensitivity analyses. Several limitations should nevertheless be considered. First, all variables were measured at one time point, so temporal precedence and causal relationships among exercise motivation, general self-efficacy, perceived physical activity triggers, and the ZTEx-IP could not be established. The model-implied indirect associations should therefore be understood as theory-informed decompositions of contemporaneous associations, not evidence of causal mediation. Reverse or bidirectional associations and alternative variable orderings remain possible [46-48]. Although the candidate variables were substantively motivated, the final adjustment set partly relied on nominal associations with the ZTEx-IP and was not derived from a prespecified causal graph. Outcome-based screening cannot identify confounding and may omit relevant variables with weak unadjusted associations. Residual confounding by workload, job control, workplace culture, or other excluded or unmeasured factors therefore remains possible. Second, the Adult Sedentary Behavior Reduction Intention Questionnaire has not been validated as a ZTEx-specific intention measure. It captures general willingness and perceived control regarding sedentary behavior reduction rather than intention to perform a specified ZTEx movement, and it does not directly assess ZTEx-specific knowledge, task feasibility, workplace appropriateness, or action planning [26]. This limitation is particularly important because 76.3% (603/790) of participants were unfamiliar with ZTEx and may have responded with reference to standing, walking, or other ways of interrupting sitting. Familiarity was measured with a single self-report item, and neither the standardized definition nor the sensitivity analyses could confirm ZTEx-specific understanding or construct validity. The ZTEx-IP should therefore be interpreted as a broad indicator of intention relevant to ZTEx adoption rather than a direct measure of ZTEx-specific intention. Future studies should develop and validate ZTEx-specific intention and readiness instruments. Third, although the instruments were reliable and theoretically relevant, they were not one-to-one operationalizations of COM-B or Fogg constructs. The BREQ-2 assesses the regulation and internalization of exercise motivation, the GSES assesses generalized perceived agency rather than confidence in performing ZTEx under specific work conditions, and the PATQ assesses perceived exposure to broad activity-related cues rather than prompts immediately preceding behavior [31]. Their differing behavioral and temporal referents further limit their correspondence with the proposed frameworks. Future research should use behavior-specific measures with aligned behavioral and temporal referents. Fourth, all principal variables were self-reported by the same participants at the same time. Common method variance, recall error, social desirability, and acquiescent responding may therefore have contributed to the observed associations. Although the first factor accounted for only 31.93% of the variance in Harman's single-factor analysis, this diagnostic cannot exclude common method bias [49]. Temporally separated or objective assessments would provide stronger protection against this bias. Fifth, the study assessed an intention proxy rather than actual ZTEx uptake, the frequency of sitting interruptions, or behavioral maintenance. Higher ZTEx-IP scores therefore cannot be assumed to translate into ZTEx adoption or sustained practice [45]. Future studies should combine ZTEx-specific intention measures with objective sitting assessments, ZTEx performance records, and longitudinal follow-up. Finally, multichannel online convenience sampling did not provide a population-based sampling frame or a response-rate denominator, and the recruitment source was not recorded at the individual level. Individuals with greater interest in health, exercise, wearable devices, or digital health, as well as those more active in workplace WeChat groups or occupation-related online communities, may have been more likely to participate. This self-selection may have yielded more favorable psychosocial score profiles and may limit the transportability of the observed score distributions, reliability estimates, and associations. Individuals with limited digital access or less engagement with online workplace networks may also have been underrepresented. Generalizability is further limited by the inclusion of only 14 adults aged 60 years or older and by differences in occupational constraints on sitting interruption, particularly for drivers. Nonsignificant subgroup differences should not be interpreted as evidence of equivalence because some estimates were imprecise. Occupation-specific heterogeneity should be examined in adequately represented, independently recruited samples.

## Conclusions

Among Chinese adults in sedentary occupations, higher exercise motivation, general self-efficacy, and more frequent perceived physical activity triggers were jointly associated with higher scores on the ZTEx-IP. Perceived triggers had the largest specific indirect estimate and incremental contribution, but the findings do not establish a unique causal or temporal sequence or demonstrate that modifying these factors would increase actual ZTEx behavior. More broadly, intention relevant to ZTEx adoption may reflect the alignment of motivational orientation, perceived agency, and recognizable opportunities within everyday work routines rather than motivation alone. By integrating these theoretically distinct factors within an occupational context, this study identifies an empirically supported pattern that can inform the formulation and prioritization of hypotheses for prospective intervention research. Specifically, the findings support testing whether multicomponent strategies combining autonomy-supportive motivational content, graded movement options, context-sensitive prompts, and appropriate organizational support can facilitate the translation of intention into behavior. Workplace trials should determine whether these components affect objectively measured sitting interruptions, actual ZTEx frequency, adherence and maintenance over time, and workplace acceptability across desk-based and safety-sensitive occupations. Thus, rather than providing evidence of intervention

XSL•FO
RenderX

effectiveness, the present study offers an empirically grounded and context-sensitive framework for advancing ZTEx research from intention-related associations to behavioral and intervention evaluation in Chinese occupational settings.

## Abstract

**Background:** People living with HIV are at increased risk for developing cancer, a leading cause of death in this population. The management of cancer in people living with HIV is particularly challenging, necessitating specialized, interdisciplinary care. However, insights into cancer care provision for people living with HIV in Germany remain scarce.

**Objective:** This study analyzed inpatient cancer care for people living with HIV, comparing treatment patterns and complications with those of an HIV-negative control group. Using claims data from 3 German university hospitals related to admissions between 2005 and 2022, we aimed to identify care disparities and provide evidence to support improved cancer management.

**Methods:** A customized federated approach was used to analyze inpatient claims data of patients across the 3 data-holding institutions. The data included demographics, diagnoses, procedures, and treatment codes as well as discharge information. Using nearest-neighbor matching, we analyzed demographic features, cancer diagnoses, anticancer therapies, and outcomes in people living with HIV and cancer and for a control group of HIV-negative patients with cancer.

**Results:** Among 162,380 patients, 907 (0.6%) were people living with HIV and cancer. The count of cancer diagnoses declined over time, particularly for AIDS-defining cancers (total cancer diagnoses: *P*=.001; AIDS-defining cancers: *P*=.002), with a shift toward older age at diagnosis. Compared with matched controls, people living with HIV and cancer had longer hospital stays, experienced more postchemotherapy complications (cancer with HIV: 64/907, 15.6%; cancer without HIV: 20/907, 5.5%; *P*<.001), and showed higher rates of metastasis after initial diagnosis (cancer with HIV: 128/267, 47.9%; cancer without HIV: 97/287, 33.8%; *P*<.001). People living with HIV and cancer also showed increased in-hospital mortality, although mortality declined

XSL•FO
RenderX

over time (*P*=.02). Our data suggested differences in documented therapy modalities between the compared groups, with people living with HIV and cancer receiving more chemo- and immunotherapy and less surgery.

**Conclusions:** Using federated analysis techniques, we were able to show that cancer diagnoses and mortality among people living with HIV in Germany have decreased over time; however, disparities in treatment and outcomes persisted as compared with HIV-negative patients with cancer. Our findings underscore the need for tailored, multidisciplinary care strategies to improve cancer management for this population.

## Introduction

Despite advances in treatment and prevention, HIV remains a major global health threat, with 39.9 million cases recorded worldwide in 2023 [1]. In Germany, HIV incidence has stabilized, and treated individuals no longer exhibit increased mortality, which is seen as a contributing factor to a rise in HIV prevalence [2]. The decline in AIDS-related deaths is largely attributed to effective antiretroviral therapy (ART) [3-6]. However, people living with HIV still face a significantly higher cancer risk, particularly for infection-related cancers. These occur approximately 30 times more frequently in female people living with HIV and up to 100 times more frequently in male people living with HIV as compared with the general population [7-10].

HIV-associated cancers in people living with HIV can be categorized as AIDS-defining (AD) and non–AIDS-defining (NAD), with AD cancers including Kaposi sarcoma, non-Hodgkin lymphoma, and invasive cervical cancer [11]. NAD cancers are further divided into virus-associated (virus-NAD) and non–virus-associated NAD types. Virus-NAD cancers linked to coinfections include lung, anal, vulvar, penile, oral, and pharyngeal cancers; Hodgkin lymphoma; and hepatocellular carcinoma [8,9,12,13].

Since the introduction of ART, the incidence of AD cancers has decreased, whereas the incidence of virus-NAD and non–virus-associated NAD cancers has increased [7,14,15]. Due to increased life expectancy, both virus-associated and non–virus-associated NAD cancers have become leading causes of death among people living with HIV, surpassing deaths directly attributable to HIV infection [5,16,17]. Although combination ART has improved survival and enables full-dose chemotherapy [18], managing cancer in people living with HIV remains complex. Immunosuppression, drug interactions with ART, and increased treatment toxicity pose significant challenges, requiring a multidisciplinary care approach involving oncology, hematology, infectious diseases, pharmacy, and supportive care specialists [19]. Given these complexities, people living with HIV and cancer may need to travel longer distances to access appropriate, specialized care.

While cancer epidemiology in people living with HIV is well-documented [7-10,12-15,19], evidence on cancer care in people living with HIV—particularly regarding treatment and outcomes—remains limited. Existing data, primarily from US registries, suggest that people living with HIV may receive cancer treatment less frequently than HIV-negative patients [20,21].

Using claims data from 3 German university hospitals, we analyzed inpatient cancer care for people living with HIV in Germany and compared it to that of an HIV-negative control group.

## Methods

### Study Data

This multicenter retrospective study used claims data collected under Section 21 of the German Hospital Fees Act (German: Krankenhausentgeltgesetz, KHEntgG). This law requires hospitals to report individual patient billing records to the federal institute for the hospital payment system (Institut für das Entgeltsystem im Krankenhaus). The data were sourced from data integration centers [22,23] of university hospitals in 3 large German cities (Frankfurt, Freiburg, and Munich).

The raw data included patient demographics and basic diagnostic- and treatment-related information (*International Statistical Classification of Diseases and Related Health Problems, Tenth Revision* [*ICD-10*]), as well as operation and procedure codes (Operationen- und Prozedurenschlüssel [OPS]; for more details, refer to Table S1 in Multimedia Appendix 1).

### Cohort Selection

Inclusion criteria required patients to be aged 18 years or older at the time of inpatient admission. The observation period was defined from January 1, 2005, to December 31, 2022. For inclusion, each patient also required at least 1 documented *ICD-10* code indicating either a cancer diagnosis or an HIV infection (Table S2 in Multimedia Appendix 1).

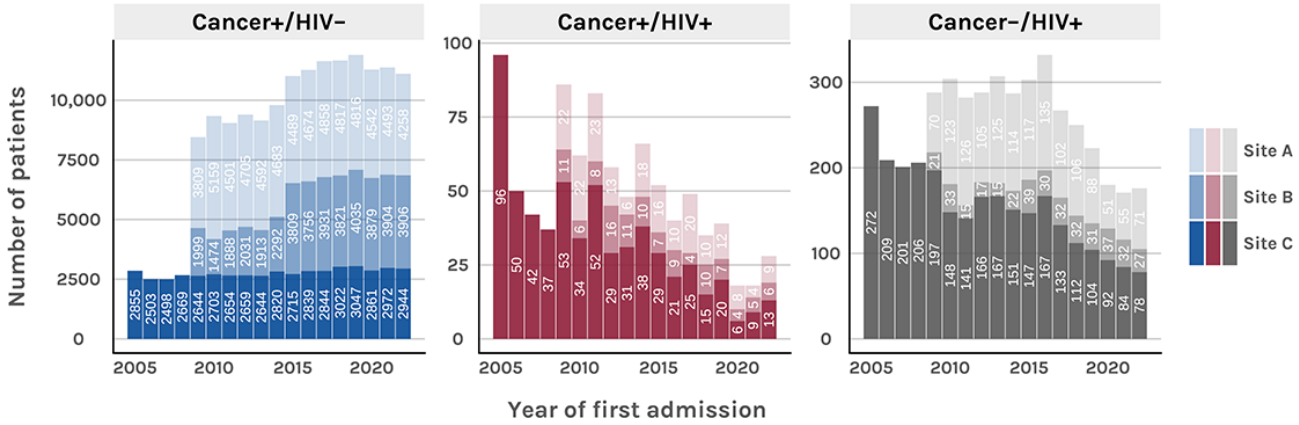
### Federated Data Analysis Approach

To analyze sensitive patient data distributed across multiple university hospitals, we used a federated approach; this means individual patient data were not transferred to a central computer to conduct pooled analysis. Instead, analysis scripts were sent to and executed locally at each participating hospital. Only aggregated or anonymized data were subsequently transferred to be jointly analyzed.

XSL•FO
RenderX

## Data Preprocessing and Patient Matching

A harmonized input data model (Table S3 in Multimedia Appendix 1) was developed to enable consistent and standardized analysis across study sites. Uniform value formats and restrictions were defined to ensure that only valid and consistent cases and data entries were included. A case was defined as a single hospitalization for a given patient. Using pseudonymized patient identifiers, individual hospital stays were linked to the same patient, allowing for multiple documented cases per patient during the observation period. Special focus was placed on plausibility checks to correctly classify main cancer and HIV diagnoses as well as therapeutic interventions (Tables S2, S4, and S5 in Multimedia Appendix 1). The data preprocessing resulted in a ready-for-analysis data model customized for the purpose of our study (Table S6 in Multimedia Appendix 1).



Included patients were categorized into 1 of 3 groups: cancer with HIV (cancer+/HIV+), cancer without HIV (cancer+/HIV–), and HIV without cancer (cancer–/HIV+) (Tables S2 and S5 in Multimedia Appendix 1). For patients with cancer, the first recorded cancer diagnosis was designated as the primary cancer diagnosis. For each patient group, frequencies of demographic and cancer-related, case-related, and therapy-related variables were summarized annually.

Patients in the cancer+/HIV+ group were matched with patients in the cancer+/HIV– group using 1:1 nearest-neighbor matching [24], based on age at cancer diagnosis, sex, year of cancer diagnosis, cancer topography group, presence of carcinoma in situ, and comorbidity score at the time of diagnosis (Table S7 in Multimedia Appendix 1). The comorbidity score was calculated using van Walraven weights for the Elixhauser comorbidity groups [25]. HIV infection and AIDS were assigned to a weight of zero, and cancer diagnoses beyond the primary diagnosis were considered comorbidities. Patient matching was performed to compare therapy-related data, including anticancer therapy frequencies, complications following chemotherapy (eg, transfer to the intensive care unit, dialysis, and mechanical ventilation), and outcomes (derived from the last recorded discharge reason) between the cancer+/HIV+ and cancer+/HIV– groups.

## Statistical Analysis

Relative frequencies of individual characteristics were calculated for each group across the entire study period (2005 - 2022). For matched group comparisons, *P* values from the Fisher exact test were calculated. Trend analyses were based on data from 2009 to 2022, the period for which data were available from all 3 sites (Figure 1). Poisson regression models were used to assess temporal trends in age at cancer diagnosis and cancer-related diagnoses within the cancer+/HIV+ group. When overdispersion was detected, negative binomial regression models were used as an alternative [26].

**Figure 1.** Number of patients in each defined group per year and per site (2005 - 2022).

For each regression model, the number of patients or diagnoses was used as the dependent variable, with the year of cancer diagnosis as the predictor. In contrast, for therapy-related trends, linear regression models were fitted using proportions as the dependent variable.

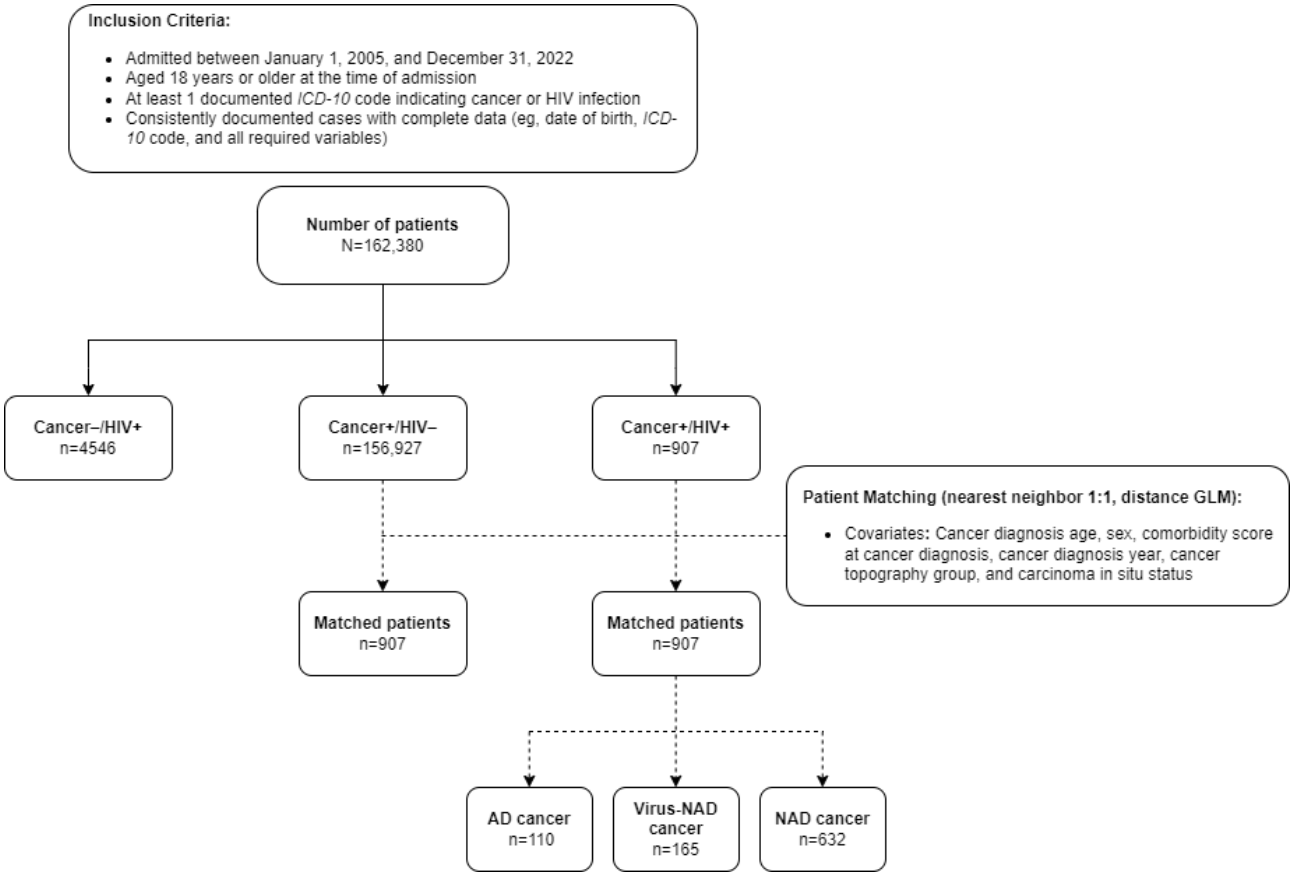
To assess travel distances for each patient group, the geographical distance between the centroid of each patient's postal code area at the time of first admission and the hospital location was estimated using the Haversine formula [27], providing an approximation of how far patients in the 3 subgroups traveled to receive care. Additionally, the catchment areas of the individual sites were visualized by mapping the distribution of patients to 3-digit postal code areas for each group (Figure S1 in Multimedia Appendix 1).

All statistical analyses were conducted using R (version 4.3.2; R Foundation for Statistical Computing) [28]. Nearest-neighbor matching was performed with the MatchIt package [24]. The Fisher exact test as well as linear and Poisson regression models were computed with the stats package [28], while negative binomial regressions were modeled using the MASS package [29]. Travel distances for the patient subgroups were calculated with the geosphere [27] and sf [30] packages.

## Ethical Considerations

This retrospective study was conducted after consultation with the responsible ethics committees (research ethics committee, Faculty of Medicine, Goethe University Frankfurt; 274/18; research ethics committee, University of Freiburg: 22-1279-S1-retro). In accordance with national law, no informed consent was obtained since only pseudonymized patient data was used for analysis. Furthermore, the federated data analysis

XSL•FO
RenderX



approach ensured data privacy through aggregation of individual-level data.

## Results

### Study Cohort

Between 2005 and 2022, a total of 162,380 eligible inpatients were recorded across all 3 sites and patient groups (Figure 2). Among these, 907 (0.6%) patients were classified as people living with HIV and cancer (cancer+/HIV+), exhibiting at least 1 *ICD-10* code from both diagnosis groups. A total of 156,927 (96.8%) patients had at least 1 cancer-related *ICD-10* code without an HIV diagnosis (cancer+/HIV–), while 4546 (2.8%) patients were identified as people living with HIV without cancer (cancer–/HIV+). Figure 1 shows the annual distribution of patients in each group by site.

**Figure 2.** Inclusion, grouping, and matching of patients with the respective number of patients. AD: AIDS-defining; *ICD-10: International Statistical Classification of Diseases and Related Health Problems, Tenth Revision*; GLM: generalized linear model; NAD: non–AIDS-defining; Virus-NAD: cancer associated with HIV infection but not considered AIDS-defining.

Patient demographics and admission-related characteristics for the 3 patient groups are displayed in Table 1. At the time of first admission, people living with HIV and cancer (cancer+/HIV+) were younger than HIV-negative patients with cancer (cancer+/HIV–), but older than people living with HIV without a cancer diagnosis (cancer–/HIV+). Fewer than one-quarter (214/907, 23.6%) of people living with HIV who have cancer were female.

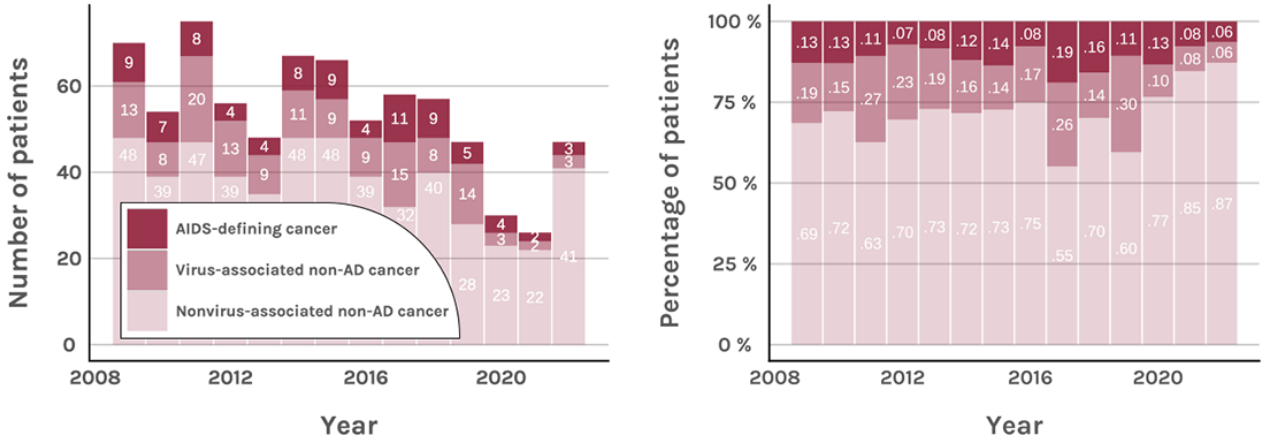
**Table .** Demographic and admission-related characteristics of the 3 patient groups (2005-2022).

| Characteristics | Cancer+/HIV– (n=156,927), n (%) | Cancer+/HIV+ (n=907), n (%) | Cancer–/HIV+ (n=4546), n (%) |
|---|---|---|---|
| Female patients | 72,231 (46.0) | 214 (23.6) | 1441 (31.7) |
| Age (years) at first relevant (cancer or HIV associated) admission | | | |
| 18 - 39 | 13,373 (8.5) | 176 (19.4) | 1781 (39.2) |
| 40 - 59 | 44,984 (28.7) | 536 (59.1) | 2204 (48.5) |
| 60 - 79 | 80,335 (51.2) | 192 (21.2) | 547 (12.0) |
| >80 | 18,235 (11.6) | 3 (0.3) | 14 (0.3) |
| Admission count per patient | | | |
| 1 | 58,444 (37.2) | 144 (15.9) | 2438 (53.6) |
| 2 - 4 | 62,840 (40.0) | 351 (38.7) | 1674 (36.8) |
| 5 - 10 | 27,877 (17.8) | 301 (33.2) | 356 (7.8) |
| More than 10 | 7766 (4.9) | 111 (12.2) | 78 (1.7) |
| Average length of stay per admission (days) | | | |
| Up to 7 | 77,096 (49.1) | 307 (33.8) | 2204 (48.5) |
| 7 - 14 | 49,898 (31.8) | 298 (32.9) | 1191 (26.2) |
| 14 - 30 | 23,194 (14.8) | 233 (25.7) | 835 (18.4) |
| More than 30 | 6739 (4.3) | 69 (7.6) | 316 (7.0) |



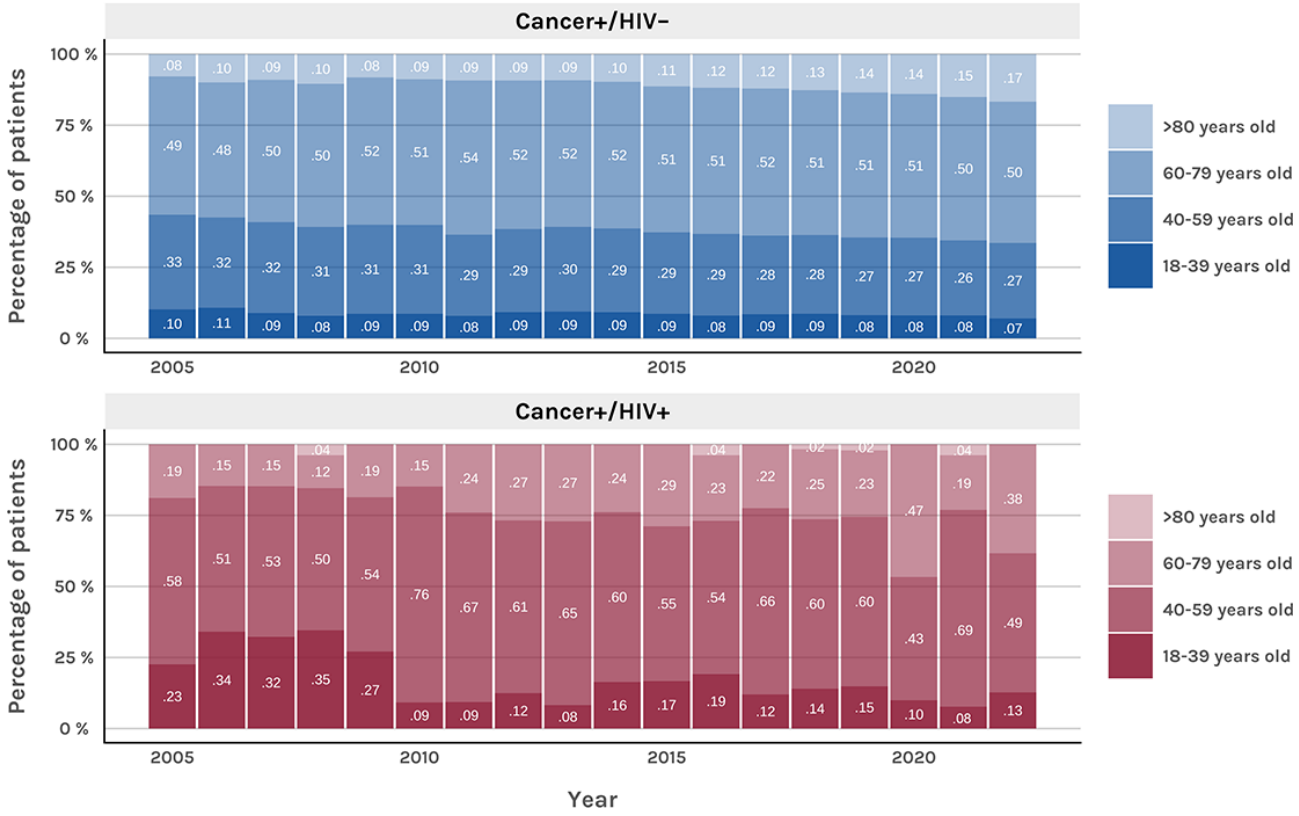
On average, patients in the cancer+/HIV+ group exhibited the highest admission frequencies among the 3 groups: 2 to 4 admissions in 38.7% (351/907), 5 to 10 admissions in 33.2% (301/907), and >10 admissions in 12.2% (111/907) of all observed patient histories.

## Cancer Incidence and Cancer Types in People Living With HIV

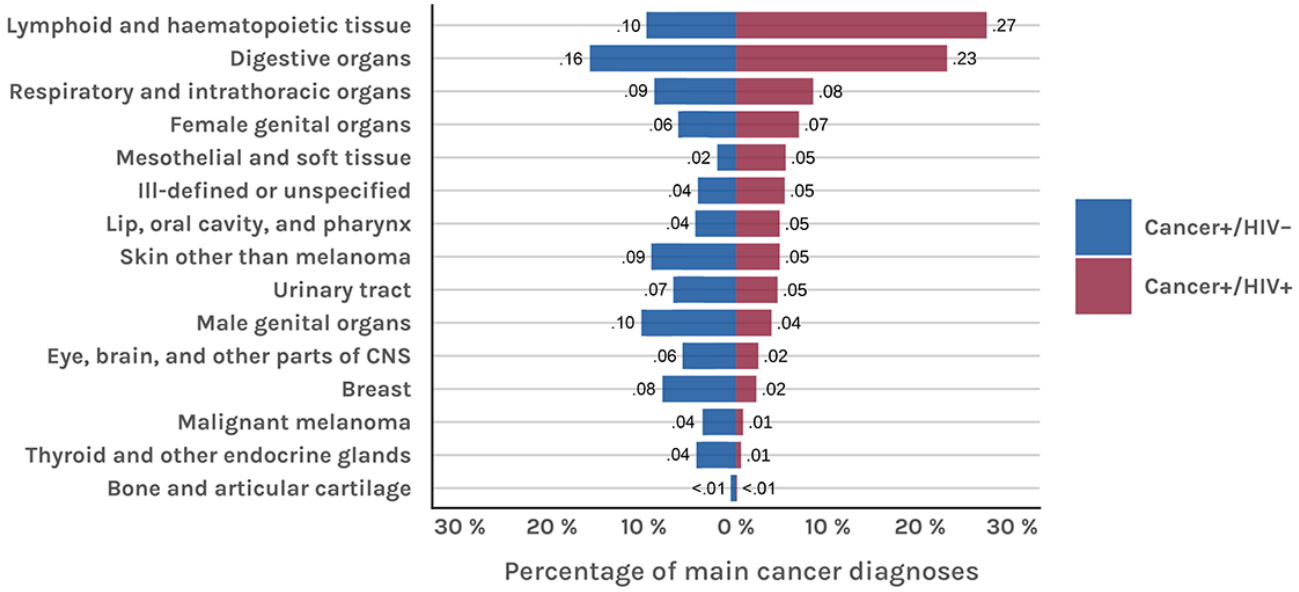
Among 907 patients with both diagnoses (cancer+/HIV+), the data suggest that 504 (55.6%) patients received HIV and cancer diagnoses simultaneously or within a short time interval. In 332 (36.6%) patients, the HIV diagnosis preceded the cancer diagnosis, whereas in 71 (7.8%) patients, the first recorded cancer diagnosis was documented before the HIV diagnosis (Table S8 in Multimedia Appendix 1).

While fluctuating over the observation period, the total number of cancer diagnoses in people living with HIV decreased significantly ($P$=.002). Among the cancer groups (AD, virus-NAD, and non–virus-associated NAD; Figure 3), the most notable decline was observed in the frequency of virus-associated NAD cancer diagnoses. In total, 110 (12.1%) diagnoses were classified as AD, 165 (18.2%) as virus-associated NAD, and 632 (69.7%) as non–virus-associated NAD. Among specific cancer subtypes, a significant reduction was observed in diagnoses involving lymphoid and hematopoietic tissues ($P$=.005), especially in non-Hodgkin lymphomas ($P$=.002) and nonfollicular lymphomas ($P$=.008).

**Figure 3.** Absolute frequencies and proportions of cancer categories in people living with HIV and cancer (2009-2022). AD: AIDS defining.



We observed an increase in the age at cancer diagnosis in both people living with HIV and HIV-negative patients with cancer (Figure 4). Consistent with this finding, regression analysis indicated a significant decrease in the proportion of patients younger than 60 years between 2009 and 2022 ($P$=.002).



XSL•FO
RenderX

**Figure 4.** Proportions of grouped age at cancer diagnosis in people living with HIV and cancer and (unmatched) HIV-negative patients with cancer (2005-2022).

A comparison of cancer topography frequencies between people living with HIV and cancer (cancer+/HIV+) and HIV-negative patients with cancer (cancer+/HIV–) is presented in Figure 5.

**Figure 5.** Most common cancer types in people living with HIV and cancer, sorted by frequency. CNS: central nervous system.

In the matched comparison between cancer+/HIV+ and cancer+/HIV–, results showed an overall comparable prevalence of metastasis; however, metastasis was present at time of cancer diagnosis more often in the cancer+/HIV– group, whereas patients in the cancer+/HIV+ group seemed to develop metastasis after initial diagnosis more often than their HIV-negative matches (cancer+/HIV+: 128/267, 47.9%; cancer+/HIV–: 97/287, 33.8%; *P*<.001).

## Anticancer Treatment of People Living With HIV

People living with HIV and cancer (cancer+/HIV+) received anticancer therapies at rates comparable to those of HIV-negative patients with cancer (cancer+/HIV–) but were more frequently treated with chemotherapy and immunotherapy, whereas patients in the cancer+/HIV– group seemed to have received more stem cell therapy (Table 2). Our results show a significant decrease in the use of chemotherapy in the

XSL•FO
RenderX

cancer+/HIV+ group between 2009 and 2022 (*P*=.02). People living with HIV and cancer presumably showed a higher rate of adverse events following chemotherapy than patients in the control group (cancer+/HIV+: 64/409, 15.6%; cancer+/HIV–: 20/361, 5.5%; *P*<.001). Additionally, the cancer+/HIV+ group was less frequently discharged home (516/713, 72.4%; *P*<.001) compared with the cancer+/HIV– group (583/714, 81.7%) and showed higher in-hospital mortality (cancer+/HIV+: 135/713, 18.9%; cancer+/HIV–: 90/714, 12.6%; *P*=.001).

**Table .** Comparison between people living with HIV and cancer and the matched patients with cancer without HIV.

| Characteristics | Cancer+/HIV–, n (%) | Cancer+/HIV+, n (%) | *P* value[a] |
|---|---|---|---|
| Metastasis occurrence (n=907) | | | |
| Metastasis documented | 287 (31.6) | 267 (29.4) | .33 |
| Metastasis at time of cancer diagnosis | 190 (66.2) | 139 (52.1) | <.001 |
| Metastasis after cancer diagnosis | 97 (33.8) | 128 (47.9) | <.001 |
| Therapy modalities (n=907) | | | |
| Any major therapy documented | 631 (69.6) | 639 (70.5) | .72 |
| Surgery | 285 (31.4) | 251 (27.7) | .09 |

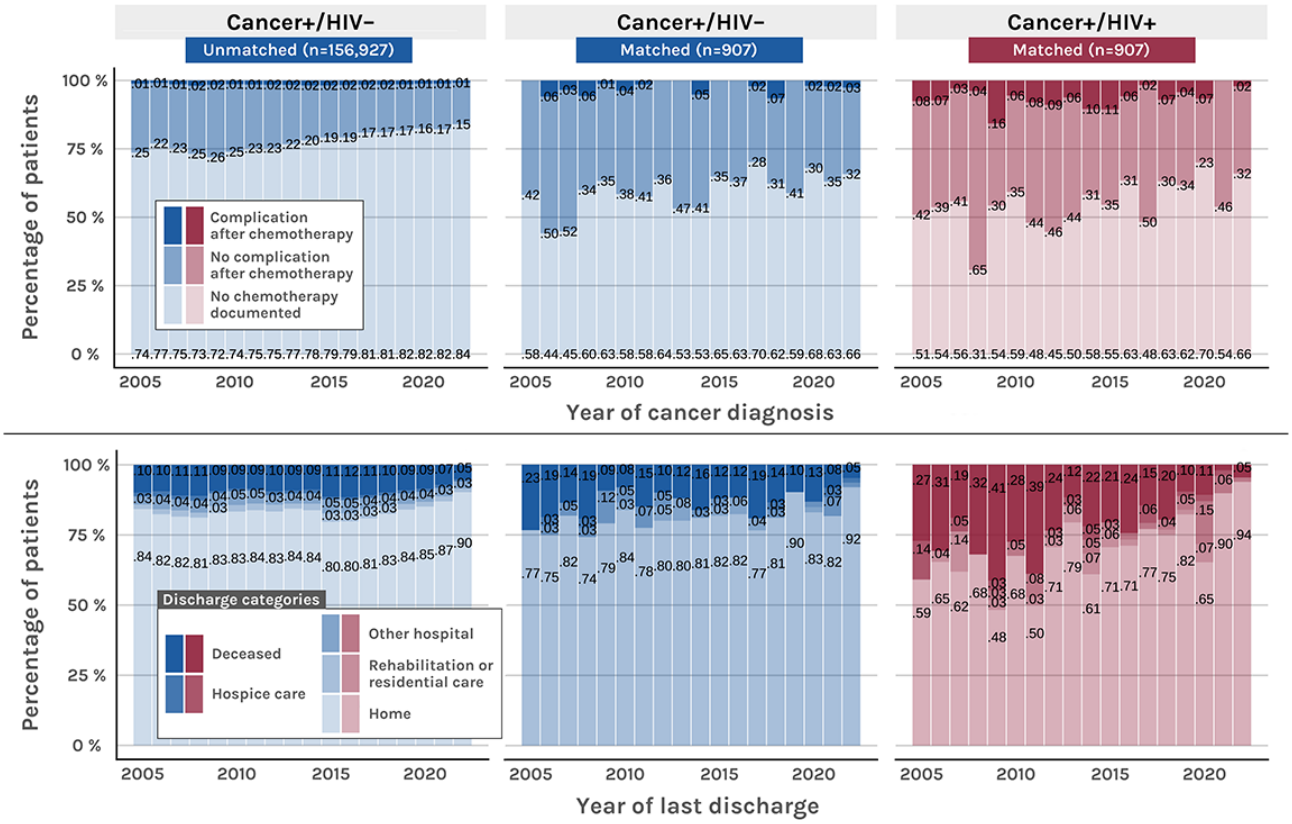
[a]*P* values were calculated using the Fisher exact test.

[b]Data were available from only 2 sites (n=714 for both groups).



[c]Data were available from only 2 sites (n=714 for cancer+/HIV– and n=713 for cancer+/HIV+).

Figure 6 depicts a comparison of temporal trends in complication rates after chemotherapy and discharge reasons across the total observed HIV-negative cancer population and the matched cancer groups.

XSL•FO
RenderX

**Figure 6.** Comparison of complication rates after chemotherapy and last documented discharge categories between unmatched cancer+/HIV– and matched cancer+/HIV– and cancer+/HIV+.

For more detailed results, refer to Tables S7, S8, and S9 in Multimedia Appendix 1. A visual abstract of the study is presented in Multimedia Appendix 2.

## Discussion

### Principal Findings

In this study, we examined epidemiological as well as treatment- and outcome-related characteristics of inpatients affected by HIV and cancer in 3 selected German university hospitals.

The overall number of cancer diagnoses in the cancer+/HIV+ group decreased between 2009 and 2022, primarily driven by a decline in AD cancers. This reduction was largely attributable to fewer cases of non-Hodgkin lymphomas, particularly within the nonfollicular lymphoma subgroup. Previous studies examining earlier observation periods found that following the introduction of ART, diagnoses of AD cancers, which had predominated in the early HIV era, began to decline, whereas NAD cancers became increasingly common over time [14,15].

The most frequently observed topographical categories in our study are consistent with those reported in previous research [8,10]. Lymphoma was the most frequent cancer diagnosis among people living with HIV, followed by cancers of the lung and bronchi, and the anus and anal canal. Previous studies have shown that, among NAD cancers, lung and anal cancers represent the greatest disease burden in high-income countries [31], which is in line with our findings. No increase over time was observed for typical age-related cancers, such as prostate cancer or malignant melanoma of the skin. However, it remains unclear whether this reflects stable incidence rates or a shift toward outpatient care.

The results showed an increase in the age at cancer diagnosis among people living with HIV, with fewer cases occurring in younger adults (<60 years). This trend could be explained by the decline in AD cancer diagnoses and is consistent with findings from previous studies [32]. Despite age matching, people living with HIV were diagnosed with cancer at younger ages compared with HIV-negative controls. This observation reflects the need for targeted screening strategies and emphasizes the importance of preventive measures for cancers linked to modifiable risk factors, such as smoking in the case of lung cancer [19,31] and human papillomavirus infection in cervical cancer [33].

Despite similar overall cancer treatment rates, people living with HIV received chemotherapy and immunotherapy more frequently but underwent slightly fewer surgical interventions. This disparity may be explained by differences in cancer type, stage at diagnosis, and tumor operability, as well as HIV-related factors such as immunosuppression, elevated postoperative infection risk, and potential interactions between ART and anesthesia [32,34]. Deviating from previous findings [19], cancers in our observed cohort of people living with HIV were more often diagnosed at premetastatic stages, which contradicts the lower prevalence of surgical therapy in this group.

Our findings highlight the need for improved posttreatment care. The longer and more frequent hospitalizations observed among people living with HIV and cancer require further investigation to determine whether they stem from greater

XSL•FO
RenderX

comorbidity burden or distinct clinical challenges associated with HIV infection.

Chemotherapy use during hospitalization declined among people living with HIV, suggesting a shift toward outpatient care [35,36]. To confirm this hypothesis, further analyses of outpatient care data are necessary. The study also showed a decrease in mortality among people living with HIV over time. Together, these trends suggest that cancer care and outcomes for people living with HIV have improved over the past 2 decades; however, additional research focusing on outpatient care is needed.

Contrary to our results, we initially hypothesized that people living with HIV and cancer would need to travel longer distances to access complex, multidisciplinary care. According to a recent study [37], HIV prevalence in Germany tends to be higher in urban compared with rural areas, which may explain shorter travel distances to urban university hospitals for people living with HIV in our study. Further research is needed to examine rural health care settings and to determine whether local care delivers comparable treatment outcomes or if traveling longer distances offers substantial benefits for specific patient groups like people living with HIV and cancer.

### Federated Data Analysis

The use of federated data analysis offered significant advantages, including improved data privacy by keeping sensitive patient information at its original site while enabling collaboration across multiple institutions. Nonetheless, challenges such as data heterogeneity, data inconsistencies, and technical limitations required repeated script adjustments for each center. This led to increased time and staffing costs, as well as minor discrepancies between site-specific results. Specialized federated analysis software such as DataSHIELD (DataSHIELD Research Project) [38] could mitigate these drawbacks but was not available in this study. All script modifications were recorded in a GitLab repository to maintain transparency and traceability.

### Limitations

A key limitation of this study is that the results cannot be generalized to the overall care of people living with HIV and cancer in Germany, as the analysis was based on data from 3 university hospitals representing the tertiary care sector. Further studies are needed to include nonuniversity hospitals and the outpatient sector.

Our study used large retrospective claims data, which the hospitals primarily documented for the purpose of billing services. Although data processing involved thorough plausibility checks, the risk that procedures or diagnoses were missing is high; furthermore, relevant information such as cancer staging and systemic therapy substances or dosage information was not part of the available data.

Sample size variations arose due to technical issues, leading to stratified analyses for the periods 2005 to 2008, 2009 to 2014, and 2015 to 2022 (Tables S6 and S7 in Multimedia Appendix 1). Other limitations include potential misclassification of disease onset and the inability to associate specific therapies with cancer types in patients with multiple diagnoses, both of which may have influenced the findings.

In our study, we chose to categorize malignancies as AD vs NAD. Different categorizations such as hematological vs solid tumors could have led to more nuanced insights. Further research should critically consider such decisions and potentially include multiple categorizations.

### Conclusions

Our study offers valuable insights into the inpatient care of people living with HIV and cancer in Germany, revealing shifts in cancer epidemiology and an aging patient population. Although the incidence of AD cancers has declined, people living with HIV continue to experience longer hospital stays and higher rates of posttreatment complications. Reduced mortality and inpatient chemotherapy use suggest that cancer care and outcomes for people living with HIV have improved over the past 2 decades; however, additional research focusing on outpatient care is needed.

The study also highlights the potential of federated data analysis for multicenter research, while emphasizing the need for standardized data collection to overcome technical challenges and data inconsistencies across sites.

## Acknowledgments

The authors would like to thank the participating university hospitals and their data integration centers for providing data and for their excellent cooperation. They also thank the German Cancer Consortium (DKTK) for partially funding this study.

During the preparation of this work, the authors used ChatGPT from OpenAI for proofreading. After using this tool, the authors reviewed and edited the content as needed and take full responsibility for the content of the publication.

## Funding

This study was funded in part by the German Cancer Consortium and in part by grant 01KX2121 (Network University Medicine). These funding sources were not involved in study design or the analysis and interpretation of the data.

## Data Availability

The datasets generated or analyzed during this study are not publicly available. We conducted a federated approach to data analysis, which means all individual-level patient data remain with the participating sites and are not publicly available due to health data privacy regulations. The aggregated data returned from site-specific analyses can be considered sufficiently anonymized.

XSL•FO
RenderX

Due to unclear use and access policies at the participating hospitals, these datasets are not made publicly available at this time; however, they can be provided by the corresponding author upon reasonable request.

## Abstract

**Background:** In the last 2 decades, there has been an increasing number of sexually transmissible enteric infection (STEI) outbreaks among gay, bisexual, or other men who have sex with men (GBMSM). There remain important gaps in our understanding of how STEI transmission is sustained that repeated collection of samples could help to address.

**Objective:** This study aimed to assess the feasibility and acceptability of longitudinal samples and epidemiological data collection among GBMSM accessing sexual health services (SHS) through a prospective cohort study.

**Methods:** GBMSM (≥16 years) accessing 2 SHS in Brighton and Sussex were recruited between May and October 2022. Participants provided an initial rectal swab and optional fecal sample and completed an online baseline questionnaire. Weekly follow-up questionnaires and rectal swabs were collected for a further 11 weeks. Sexually transmitted infection (STI) surveillance data were pseudonymously linked to provide additional clinical and demographic information. Selected participants were invited to take part in an optional one-to-one interview. We assessed the number completing study procedures, characteristics of those completing procedures and not, and representativeness of the study sample alongside facilitators and barriers from interviews. A chi-square test was used to compare groups.

**Results:** Overall, 193 participants were recruited. Half (100/193, 51.8%) provided a baseline rectal swab, with a third (34/100, 34.0%) of them providing all 12 swabs. Alongside the baseline swab, 76.0% (76/100) provided the optional fecal sample. Just over a third (71/193, 36.8%) of participants completed a baseline questionnaire, with a fifth (15/71, 21.1%) providing all follow-up questionnaires. Interviews (n=21) found that participation was motivated by the feeling of giving something back for services received and a perceived indirect benefit to self. The study was generally accepted, with over half reflecting on the perceived ease of participation and relatively simple tasks that could be easily integrated into normal routine with an element of flexibility.

XSL•FO
RenderX

Most participants were satisfied with the 12-week study length, and having a definitive end point aided the ability to assess if they would be able to participate. Barriers to completing the study procedures included not being aware of what was required, particularly for the follow-up questionnaires. Suggested improvements included concise and easier-to-read instructions, with a section to clearly list out the key procedures of the study. SMS text messaging reminders were sent, but these were seen with variable utility and interpreted in different ways (eg, personal or generic reminders or thank you messages).

**Conclusions:** This study has provided evidence that longitudinal rectal swab sampling and data collection for research purposes are feasible and acceptable among GBMSM attending SHS. This provides an innovative way to address important knowledge gaps about STEI transmission, which will help inform public health measures for infection control. Tangible insights from this pilot can also inform the design of similar studies in other settings.

sexually transmitted diseases; sexually transmitted enteric infection; gay, bisexual, or other men who have sex with men; longitudinal sampling; acceptability; feasibility

## Introduction

Enteric pathogens are classically transmitted by ingesting food or water contaminated by fecal matter, causing gastroenteritis, hepatitis, and malabsorption [1]. Over the past 50 years, it has been recognized that these pathogens can also be transmitted directly from person to person during sexual activity. Gay, bisexual, or other men who have sex with men (GBMSM) are particularly at risk of sexually transmissible enteric infections (STEIs) through sexual behaviors such as oral-anal sex (rimming), oral sex, scat play, or indirectly through oral sex after anal sex [1,2]. Transmission is likely also facilitated amongst groups of GBMSM in dense sexual networks through chemsex, group sex, and the use of sexual networking applications [3,4].

The number of reported STEI outbreaks among GBMSM globally has increased [1,5-7], with circulating strains often associated with antimicrobial resistance (AMR) [8-10], causing a growing public health concern. Antimicrobial-resistant STEIs, including *Campylobacter* spp. and Shiga toxin–producing *Escherichia coli*, and extensively drug-resistant *Shigella* spp., have all been reported, compromising management with antimicrobials [11]. Previous studies have suggested that the acquisition of AMR determinants could be linked to selection pressure from high levels of antimicrobial use in GBMSM for treating bacterial sexually transmitted infections (STIs) [8,12]. However, these mechanisms are not fully understood, and other factors, such as the gut microbiota, may also play a role in the development and severity of gastrointestinal disease and the transfer of AMR genes [13].

There also still remain important gaps in our understanding about the duration of STEI carriage and infectiousness and how this might contribute to sustained transmission of STEIs in GBMSM sexual networks. An analysis of *Shigella* spp. isolates from symptomatic adult men from the general population reported a median time interval of 23.5 days (range 6 - 176 days; IQR 8 - 70) between isolates recovered from the same individual [14], suggesting possible persistent, recurrent, or recrudescent infection or carriage (as no intervening clinical data were available). This highlights the need for longitudinal studies with matched questionnaire data, such as symptom status, the type or duration of reported symptoms, any antimicrobials taken, and any sexual partners or specific sexual behaviors.

Other studies have shown that asymptomatic carriage may play a key role in sustaining transmission of enteric pathogens among specific sexual networks of GBMSM [12,15,16] and may be a significant barrier to effective control. A meta-analysis provided estimates of prevalence of STEIs among asymptomatic GBMSM, ranging from 0.3% to 3.8% [17]. The analysis included 6 studies, of which only 2 explored potential risk factors, one from Melbourne, Australia, where STEI detection was associated with insertive oral-anal sex and group sex [16], and one from London, United Kingdom, where STEI detection was associated with having 5-9 new sexual partners in the last 3 months (as compared to 0-1 new partners), a bacterial STI in the last year, and the use of HIV pre-exposure prophylaxis (PrEP) or living with HIV [12]. While these studies contributed to our wider understanding of STEI transmission and the importance of certain sexual practices, they were cross-sectional and did not provide information on duration of carriage and did not include detailed information on gastrointestinal symptoms, antimicrobial treatment, or travel history.

Thus, there is a need to better understand the factors that might be sustaining transmission of, and the development of AMR in, enteric pathogens among sexual networks of GBMSM to inform the development, targeting, and delivery of clinical and public health measures that control transmission. To address these knowledge gaps, a possible study design is the repeated collection of fecal samples and/or rectal swabs, in addition to clinical and behavioral data, over a period of several months. The longitudinal samples could be sequenced and compared to study within-host evolution [18] and transmission pathways [19]. As a first step toward addressing the knowledge gaps, we conducted a mixed methods observational pilot study of sexually transmitted enteric infections among GBMSM (STEIM). We aimed to assess the feasibility and acceptability of longitudinal rectal swab sample and epidemiological data collection among GBMSM attending sexual health services (SHSs). Here we describe the characteristics of participants, completion of study procedures, and facilitators and barriers to completing the study.

## Methods

### Study Design

We conducted a longitudinal, observational prospective cohort study among GBMSM that accessed 2 SHSs in Brighton and Sussex between May 23 and October 11, 2022, with samples collected from May 26, 2022, to January 24, 2023. This region of England has high numbers of diagnoses of STEIs in GBMSM [20], making it a suitable setting for the pilot. Participants were asked to consent to provide an initial rectal swab and optional fecal sample and complete a baseline questionnaire upon enrollment. Follow-up questionnaires and rectal swabs were collected at weekly intervals for a further 11 weeks. Samples were sent to the Gastrointestinal Bacteria Reference Unit at the UK Health Security Agency (UKHSA) and tested for a range of enteric pathogens, and results were linked to questionnaire responses. Where participants provided specific informed consent, study data were linked pseudonymously (without using direct identifiers such as name or date of birth) to the national GUMCAD STI Surveillance System using unique clinic and patient numbers [21]. Selected participants were invited to take part in an optional one-to-one interview to discuss their experience of the study. These were conducted between October 2022 and March 2023.

### Study Setting

The study took place within Brighton and Sussex at SHSs provided by University Hospitals Sussex NHS Foundation Trust. In England, SHSs are free and confidential, and they are available to anyone regardless of whether the person is resident in the local area.

### Study Population

All men (cis or transgender), transgender women, or gender-diverse people, aged 16 years or older, who attended the participating SHSs during the study period and reported sex with a man (cis or transgender) or nonbinary person assigned male at birth in the previous 3 months were eligible. The study excluded those not able to provide informed consent and/or complete the study procedures due to English language or literacy. Those unable to use or access a suitable mobile device or internet were also excluded. The study aimed to recruit a representative sample of GBMSM attending the SHSs for routine STI screening or care, regardless of symptoms.

### Recruitment

All eligible participants who attended for routine sexual health care during the study period were to be approached for recruitment by SHS staff. The participation information sheet (PIS) provided for recruitment was available online during recruitment, along with the study protocol, to provide more information to potential participants.

Where eligible SHS attendees declined to participate, SHS staff were asked to complete a separate screening log to document the reasons for declining without recording personal data. Informal insights from SHS staff provided further information on the feasibility and acceptability of recruitment.

SHS staff contacted participants who agreed to be contacted about participating in a one-to-one interview. Purposive sampling was used initially to ensure representation across ages and different levels of participation in study procedures. The invite was extended to all consenting participants in the latter stages of the study.

### Sample Size

A recruitment target of 200 participants was set, based on our estimates of how many GBMSM attend the SHSs and how many will agree to participate in the time frame set for the study. No formal sample size calculation was completed, as the pilot was designed to inform sample size calculations for future larger studies. We aimed to conduct up to 20 interviews, with this estimated to be a sufficient number to reach saturation of issues related to acceptability and feasibility [22,23].

### Study Procedures

At enrollment, participants were provided with 12 rectal swabs and a fecal sample collection kit, including prepaid envelopes. For completion of the first rectal swab (the baseline rectal swab), there was the option to provide a concurrent fecal sample on the same day. After baseline, a rectal swab was to be returned each week for a further 11 weeks. Participants recorded the date of collection on the sample tube before posting.

Separate web-based questionnaires were completed at enrollment (baseline) and at each weekly follow-up. The surveys were hosted on a secure remote server (Snap Surveys Ltd) and were completed using personal digital devices. The access links to the questionnaires were available through the study web page; participants were required to enter their unique study ID only. For those who agreed to it, one-to-one interviews were also conducted to understand how best to minimize barriers and better facilitate participation and retention in the study.

For participants who gave consent, a weekly email or SMS text message reminder about the study procedures was sent on the same day every week (the day that they were recruited). Participants could choose the day of the week they completed the procedures and could continue to take part in the study even if they did not provide all the requested samples. Providing an incentive to participants was explored during the study design phase, and the decision was made not to pursue this given the study was a pilot and the aim was to assess feasibility and acceptability, including barriers and motivators for taking part. The concept of incentives was explored during the interviews.

### Data Sources and Outcomes

The data sources included behavioral and clinical data from the baseline and follow-up questionnaires; the baseline questionnaire was longer (median 8.3 minutes to complete) and had a longer look-back period than the weekly follow-up questionnaire (median 2.8 minutes to complete; Table 1 and Multimedia Appendices 1 and 2). The questionnaires did not contain any standardized tools or instruments; however, they were developed by drawing upon questionnaires used in other studies [24,25], and comprehension and clarity of the questions were checked during the study design phase.

**Table .** Overview of data collected and look-back periods for the baseline and follow-up questionnaires for the sexually transmitted enteric infections among gay, bisexual, or other men who have sex with men (GBMSM; sexually transmitted enteric infections among GBMSM [STEIM]) study.

| Data collected | Baseline questionnaire | Look-back period | Follow-up questionnaire | Look-back period |
|---|---|---|---|---|
| Reason for attending SHS[a] when recruited | Yes | N/A[b] | N/A | N/A |
| HIV-related factors | | | | |
| HIV status and date of most recent test | Yes | No time limit | No | N/A |
| Antiretroviral treatment (living with HIV) | Yes | No time limit | No | N/A |
| Viral load count (living with HIV) | Yes | No time limit | No | N/A |
| HIV Pre-exposure prophylaxis (PrEP; HIV negative) | Yes | No time limit | No | N/A |
| Sexual behavior | | | | |
| Number of sexual contacts (and additional information on partners, for example new or casual) | Yes | 3 months | Yes | 1 week |
| Type of sex | Yes | 3 months | Yes | 1 week |
| Frequency of condom use | Yes | 3 months | Yes | 1 week |
| Drug use before or after sex | | | | |
| Use and frequency of listed drugs before or during sex | Yes | 3 months | Yes | 1 week |
| Injection drug use | Yes | 3 months | Yes | 1 week |
| Antibiotic use | | | | |
| Consumption of antibiotics for any reason | Yes | 3 months | Yes | 1 week |
| Use of antibiotics as STI[c] prophylaxis | Yes | 3 months | Yes | 1 week |
| Gastrointestinal symptoms | | | | |
| Gastrointestinal symptoms and duration | Yes | 3 months | Yes | 1 week |
| Sexual contacts with gastrointestinal symptoms | Yes | 3 months | Yes | 1 week |
| Other contacts (eg, household) with gastrointestinal symptoms | Yes | 3 months | Yes | 1 week |
| Travel | | | | |
| Travel outside the United Kingdom | Yes | 3 months | Yes | 1 week |
| New sexual partners while abroad | Yes | 3 months | Yes | 1 week |

[a]SHS: sexual health service.

[b]N/A: not applicable.

[c]STI: sexually transmitted infection.

One-to-one interviews were conducted using a semistructured topic guide. This was developed collaboratively and designed to allow for data on participation motivation, research experience, understanding of compliance with and the acceptability of study requirements and procedures, barriers and facilitators to study participation and retention, and suggestions for improvement for subsequent research to be collected. Interviews were conducted by one member of the STEIM study team (D Reid) and were conducted as remote audio or video interviews using Microsoft Teams. All interviews

XSL•FO
RenderX

were also transcribed through Microsoft Teams, with transcriptions reviewed by the interviewer. As this was a pilot study, interviews were not piloted beforehand.

Additional clinical and demographics information was sourced from GUMCAD. GUMCAD is the mandatory surveillance system for STIs in England and collects data on STI tests and diagnoses from all publicly commissioned SHSs [21]. For consenting participants, pseudonymous linkage to GUMCAD data was conducted to provide additional clinical and demographic information, including recent STI diagnoses (*Chlamydia trachomatis, Neisseria gonorrhoeae,* or *Treponema pallidum* [primary, secondary, or early latent] at enrollment and in the past 12 months); HIV status; HIV PrEP use; sexual orientation; ethnicity and country of birth; and patient residence to allow for determination of index of multiple deprivation (IMD).

Outcomes of the study included the number and proportion of participants providing samples and questionnaires at various time points throughout the study, for example, how many completed baseline procedures and how many completed all weeks; description of the characteristics of the study population; comparison of the characteristics of participants who did and did not return samples and questionnaires; whether the study population was representative of all GBMSM attending the SHSs during the study period; and facilitators and barriers to the study as drawn out from the one-to-one interviews. Qualitative interview results were used to contextualize the quantitative results and to provide a full picture of the acceptability and feasibility of the pilot study.

## Data Management and Analysis

All quantitative data were managed and analyzed using Microsoft Excel and STATA (v17; StataCorp LLC). Qualitative data were analyzed using NVivo (20; Lumivero).

GUMCAD records were linked to the enrollment log using a deterministic linkage approach based on participants' patient number, SHS attended, and SHS attendance date. Data matches were accepted where the GUMCAD SHS attendance date was within 30 days of the participant enrollment date, but information on concurrent STI diagnosis at baseline was only included where the dates matched exactly. After records were linked, the GUMCAD patient number was dropped. The GUMCAD data were subsequently linked to the laboratory testing results and questionnaire responses using the study ID. Where responses from the questionnaire differed from GUMCAD data on the same topic, the questionnaire response was used for analysis (being the most up-to-date and less subjective to clinician or coder bias) and replaced the input from GUMCAD. When the date of collection of rectal swabs was not provided (254/949, 26.8%), the date of receipt at UKHSA was used.

Summary metrics, such as the median number of samples returned, were used to assess the feasibility of longitudinal rectal swab collection and completion of self-administered questionnaires. Participant characteristics were analyzed and summarized using data from GUMCAD and questionnaires. To minimize the risk of deductive disclosure, in some cases, small numbers (1-4 inclusive) were masked and referred to as "<5" or groups containing small numbers have been aggregated. The characteristics of participants enrolled in the study who did and did not return at least one sample or completed questionnaire were compared using the chi-square test.

The representativeness of the study sample was ascertained by comparing the demographic characteristics, obtained from the GUMCAD data, to participating SHS attendees during the study period, excluding the study participants, who reported as GBMSM; the chi-square test was used for statistical comparisons.

An analytic "framework" approach [26] was used to analyze the interview transcripts. Initial deductive and inductive thematic codes were derived using the interview topic guides and 3 transcripts by 2 members of the STEIM study team (D Reid and DO). Wider themes were discussed to agree on all themes and coding structure before the agreed codes were then applied to all transcripts (by D Reid) and data were charted, summarized, and interpreted. As this was a pilot study, we did not formally assess saturation, and the number of interviews was set in advance.

## Ethical Considerations

This study was reviewed and approved by the London and South East NHS Research Ethics Committee (Reference 21/LO/0891) and the University Hospitals Sussex NHS Foundation Trust Research and Development department. Written informed consent was obtained from all participants prior to participation (Multimedia Appendix 3), and participants could withdraw from the study at any time. Those willing to take part in an optional one-to-one interview completed a separate interview consent form (Figure S1 in Multimedia Appendix 4). In addition, consent for (1) linkage to GUMCAD data, (2) residual study samples to be stored for future ethically approved research studies, (3) text or email reminders to be sent about completing the follow-up procedures each week, and (4) participating in the one-to-one interview was recorded. All four of these tasks were optional to agree to. All data were pseudonymized using a unique study identifier before sending to researchers, so they did not have access to personal identifying information. No images are provided in the manuscript or supplementary material that would allow identification of individual participants. No type of incentive was given to participants.

During the study design phase, cognitive interviews with GBMSM were used to explore general interest and acceptability of the study proposal and methodology as part of the patient and public engagement and involvement strategy. The interviews also explored acceptability, comprehension, and clarity of the participant information documents and questionnaires. Suggestions for improvement to methods and study materials were incorporated.

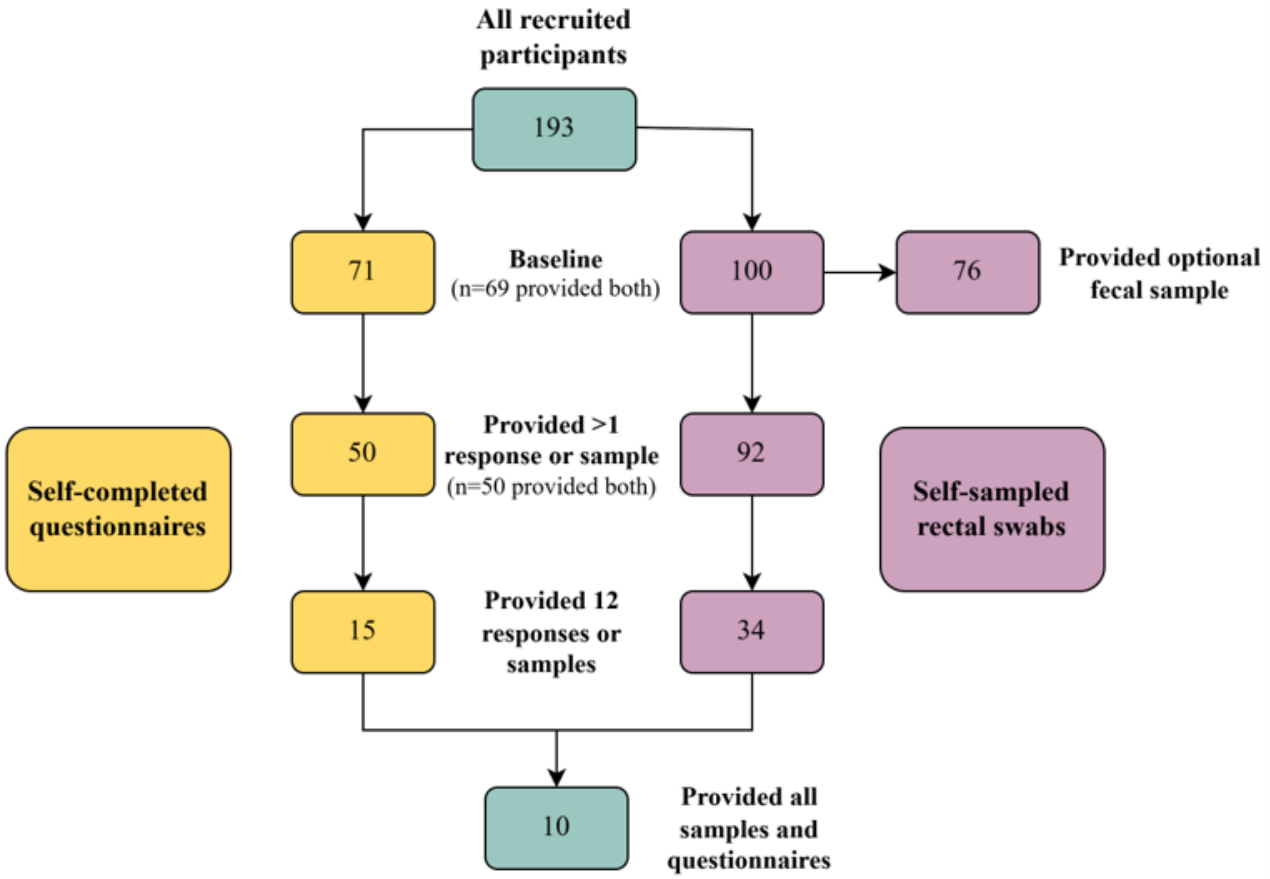
# Results

## Quantitative Results



### *Recruitment and Study Completion Rates*

Overall, 193 people were recruited into the STEIM study between May 23, 2022, and October 11, 2022 (96.5% of the planned 200 to be recruited). Screening logs were completed for 23 eligible SHS attendees who did not agree to take part; not having the time or capacity to participate was cited as a reason by half (12/23), often due to travel abroad or relocating (7/12). Others perceived they had too few recent sexual partners or had not engaged in specific sexual behaviors to be suitable for the study (7/23), lacked access or proficiency using the internet (n<5), or did not want to provide the samples required (n<5). Half (12/23, 50%) of the screening log entries were from the Sussex SHS. Informal discussions with SHS staff indicated that the screening log was not routinely completed, meaning a lack of accurate records of those declining to participate. They also highlighted that the most frequently heard refusal was a lack of interest in participating. Other reasons included being put off by rectal swabbing and the lack of returned diagnostic results.

Most participants were recruited at the SHS in Brighton (168/193, 87.0%), the largest SHS in the study area. Baseline questionnaires were completed by 71 participants (71/193, 36.8%), among which most were recruited while attending for a vaccination (28/71, 39.4%), a general sexual health check (22/71, 31.0%), and/or to receive HIV PrEP (20/71, 28.2%). Informal discussions with SHS staff suggested that recruitment was often conducted during mpox vaccination clinics (the opening of recruitment coincided with the start of the mpox outbreak in the United Kingdom in the summer of 2022).

Of those recruited, 51.8% (100/193) provided a baseline rectal swab (Figure 1), among which 34.0% (34/100) provided all 12 swabs (Figure S2 in Multimedia Appendix 4 shows more details), with a median of 11 rectal swabs submitted (IQR 5-12). Those providing all 12 swabs did so over 11-23 weeks, with 9 participants providing swabs for 14 or more weeks. Among these participants, 76.0% (76/100) also provided an optional fecal sample. Of those who completed a baseline questionnaire, 21.1% (15/71) completed all follow-up questionnaires (Figure 1) over 11-15 weeks. There were 11 participants who submitted follow-up questionnaires but no baseline; these participants were not included in completed questionnaire counts, and most submitted 3 or fewer questionnaires (7/11, 63.6%), with only one submitting all follow-up questionnaires.

**Figure 1.** Flowchart of sexually transmitted enteric infections among gay, bisexual, or other men who have sex with men (GBMSM; sexually transmitted enteric infections among GBMSM [STEIM]) study participant recruitment and participation by study component (self-completed questionnaires and self-sampled rectal swabs and fecal sample).

RenderX

### *Feasibility of Data Linkage*

Most participants (188/193, 97.4%) agreed to GUMCAD data linkage, and linkage was successful for 97.9% (184/188). Of the 102 participants with a baseline sample and/or questionnaire, 98.0% (100/102) agreed to linkage, and 98% (98/100) were successfully linked to a GUMCAD record. Demographic data were obtained for all of those successfully linked; concurrent STI diagnosis at baseline was available for 97.3% (179/184) of participants.

### *Characteristics of Study Participants*

Most study participants were UK-born (141/184, 76.6%) and of white ethnicity (171/184, 92.9%; Table 2), with a median age of 43 years (IQR 33-52). At baseline, most participants were not known to be living with HIV (134/184, 72.8%), of which 47.8% (64/134) were taking HIV PrEP. While only 5.0% (9/179) of participants were diagnosed with a bacterial STI on the day of enrollment, 38.0% (70/184) had a bacterial STI diagnosed in the previous year.

[a]Data obtained from routine returns to the GUMCAD STI surveillance system and baseline questionnaire entries, where eligible for the study participants only.

[b]Study participants were eligible if reporting sex with a man (cis/transgender) or nonbinary person assigned male at birth in the past 3 months; as this same level of detail on sexual partners is not available in GUMCAD, the comparison is made to all male individuals with sexual orientation reported as gay or bisexual in GUMCAD data rather than explicitly those reporting sex with a man in the past 3 months.

[c]SHS: sexual health service.

[d]N/A: not applicable.

[e]All other ethnic groups include groupings for those of Asian ethnicity, Black ethnicity, mixed ethnicity, and any other ethnicity. These data were aggregated into one group due to small data points.

[f]All other regions of birth include groupings for those born in the Caribbean, Central and South America, North America, Europe, South Asia, sub-Saharan Africa, and any other region. These data were aggregated into one group due to small data points.

[g]PrEP: pre-exposure prophylaxis.

[h]Concurrent or previous STI was considered as *Chlamydia trachomatis*, *Neisseria gonorrhoeae*, or *Treponema pallidum* (primary, secondary, or early latent) diagnosis.

[i]STI: sexually transmitted infection.

From the baseline questionnaires, the most common number of sexual partners in the previous 3 months was between 2 and 4 (29/71, 40.8%; Table 3). During that time, very few participants had used STI prophylaxis (taken antimicrobials immediately before or after sex to prevent STIs other than HIV; 2/71, 2.8%; missing data n=1, 1.4%), and a majority of participants (69.0%, 49/71) reported gastrointestinal symptoms, with diarrhea being most common (42/49, 85.7%) followed by mucus and/or blood in feces (23/49, 46.9%). Just under half (31/71, 43.7%) had traveled abroad, and about a third (10/31, 32.3%) of those reported sex abroad.

[a]STI: sexually transmitted infection.

[b]GI: gastrointestinal

Nearly half (89/193, 46.1%) of participants did not complete questionnaires or provide samples after initial recruitment. These participants had similar characteristics to those who did provide samples and/or questionnaires (Table S1 in Multimedia Appendix 4). However, participants who provided completed samples or questionnaires were more likely to be from the least deprived IMD quintiles (*P*=.004). Participants returning samples or questionnaires, and who were not known to be living with HIV, were more likely to be taking HIV PrEP (46.5% vs 21.2%; *P*=.001) and less likely to be diagnosed with a concurrent bacterial STI at enrollment (2.1% vs 8.3%; *P*=.06).

### *Representativeness of Study Population*

Recruited participants were representative of GBMSM attending the participating SHSs within the study period for most characteristics. Most GBMSM attending the participating SHSs were also UK-born (76.0%) and of White ethnicity (88.2%; Table 2), with a median age of 43 (IQR 33-54) years. However, more study participants were taking HIV PrEP (34.8% vs 14.3%; *P*<.001) and more had experienced a bacterial STI in the previous year (38.0% vs 20.3%; *P*<.001) compared to all GBMSM attending the SHSs.

## Qualitative Results

### *Characteristics of Interview Participants*

Most participants (153/193, 79.3%) agreed to be contacted for an interview, with 21 participants completing interviews. Interviewees were slightly older on average than all participants, ranging from 28 to 76 years old with a median of 49 (IQR 43-55) years, compared to a median of 43 (IQR 33-52) years for all participants. Most interviewees reported some pre-STEIM research participation (17/21), and they had better completion of study procedures than the overall study participants, with almost all interviewees submitting a fecal sample (20/21) and all submitting one or more rectal swabs.

### *Motivations for Study Participation*

Qualitative findings from interviews showed that the context in which participants were recruited may have motivated many

XSL•FO
RenderX

to consider joining the study, with most interviewees mentioning concurrent receipt of mpox vaccination or other valued services:

> *I'm really grateful for having the monkeypox vaccine so quickly and because of that, I'm going to take part in this slightly uncomfortable study as my way of giving something back.*

Taking part in STEIM was perceived as a welcome opportunity for many to give back to SHSs.

Almost all participants referred to indirect benefits to self through helping others or achieving a collective benefit for peers. More than half (12/21) of the interviewees suggested they were interested in the STEIM study or studies related to gut health or the sexual health of gay men more generally. The relative novelty of a sexual health study focused on gut infections was appealing and interesting to many. Two participants did mistakenly expect that tests on their samples that identified an infection would be communicated either to medical staff or themselves and therefore incorrectly inferred a potential direct benefit in early diagnosis and potential treatment.

All interviewees had some initial discussion with one or more SHS staff members before agreeing to participate. Staff members who were known, trusted, and enthusiastic about the study encouraged participation. Reassurances that tasks were not onerous and perceptions of staff as knowledgeable and able to provide ongoing support or advice also promoted a decision to participate.

Many participants noted that an incentive to take part would not personally be a motivator to take part in the study, but the acceptability of an incentive offer was reported by a majority. Financial incentives were mentioned, and it was suggested that these should be easy to use, useful, small, and targeted at those in need. Some participants suggested they may also be incentivized by receiving study results instead of a monetary reward; from one participant,

> *I'm never going to say no to money, but it's ok if someone wants to give you money for the thing. But I'd be happy if it was just a general, either like a feedback, personal health monitoring thing or seeing the sort of results of the study. So, seeing what it's accomplishing, hearing sort of updates on what the research is finding.*

### *Facilitators and Barriers to Participation and Completion of Procedures*

Over half of interview participants expressed no reservations about participating in the study, reflecting on the perceived ease of participation and relatively simple and not onerous tasks. From one participant,

> *Once you get into it, it was very straightforward and easy. You know, I think for me; do the sample, fill in the survey, 5 minutes, not an issue, you know and, tick the box and job done. Really.*

Study time requirements and potential disruption to normal life were important considerations for more than half, though generally assessed as acceptable. A few participants related that a definite study end point aided them in assessing the time required when considering other commitments such as work or holidays. Most were highly satisfied with the 12-week pilot length, a majority (16/21) of whom felt it was a preferable maximum. Three months is a period most felt they could commit to participate and in which interest and remembering tasks could be maintained. From one participant, "*Probably about this [length] would have been the longest. I wouldn't have done it if it was much more*." However, half the participants (11/21) would consider a longer study duration, and a third reported that they would consider 6 months to 1 year, and a small minority may consider an indefinite period.

The ability to integrate and routinize the study into participants' lives facilitated participation. The flexibility to choose a preferred day of the week to complete the study procedures, with allowances and leeway of a day or 2, was appreciated and reported as useful. Many participants recounted the ease of taking rectal swabs as part of their morning routine or in posting samples soon after on the way to work, during a walk, or when passing a postbox. The weekly repetition of tasks helped to aid memory, and over half the participants discussed the utility of setting their own reminders, alarms, or in-diary tasks positively.

Many discussed the variable or limited utility of text reminders sent by the clinic. These texts sometimes came on a different day from that set by the participant and were perceived in different ways as reminders, either targeted personally or automatic and generic or as thanks or acknowledgment of completion and receipt of samples. These interpretations were influenced by whether they arrived before or after the day that samples were taken, posted, or received and by previous interpretations or expectations. The utility of these texts was enhanced if they were seen to improve a sense of study connection and engagement, which participants suggested might be increased by a personal rather than generic focus, being tailored to tasks and including messages of appreciation for participation as well as feedback on study findings.

Reception to the PIS and other written instructions was mixed, with participants often suggesting improvements to these. In reading the PIS, some participants reported that they missed aspects of the study methodology or were left uncertain and made suggestions for step-by-step instructions or bullet points of the key tasks.

> *I think the way that it's all presented, a patient information sheet, it's quite sort of quite a lot of dense information and lots of separate paragraphs. […] Just too much text and I think I could have done with a little reminder right at the top, maybe at the top of that just bullet points like every week, one bullet saying take your swab and send it off and then another bullet point saying complete the questionnaire.*

### *Facilitators and Barriers to Rectal Swab and Stool Sample Collection*

The ability to provide the specimens at home, allowing for privacy and saving time and potential SHS visits, was appreciated and desired. One interviewee stated,

XSL•FO
RenderX

> *… I think the fact that I could do it myself and post them in was one of the things that convinced me it would be fine to do it.*

Interviews suggested that there were differences in the interpretation of the end point of the study; most interviewees reported believing that the end point was when all swab samples were submitted, but others identified 12 weeks as an end point even if some samples were missed, which was the intended outcome.

Instructions for rectal swab collection were described as useful for understanding procedures, and those for stool sample collection detailed best practices, though many men described using methods of collection that were slightly adapted to suit their own situation and resources, for example, using a toilet paper nest or a Tupperware container. Most interview participants were happy to provide rectal swabs, relating a perception of rectal swab collection that was relatively simple.

There was less general acceptance for the fecal samples. Interview participants perceived stool sample collection as more difficult than rectal swabbing. They discussed difficulties, such as disgust in handling feces, less familiarity with collection, requirements to follow body processes and timings, and more complexity in planning and execution. This included needing a private toilet and more complex requirements for preparing and taking the sample, getting the sample into the correct container in the required amount without contamination, and disposing of or cleaning equipment or containers. Overall, a quarter of participants (5/21) felt it was a difficult thing to do; the rest were relatively comfortable while also acknowledging less ease and greater effort were required than in taking rectal swabs [1].

### *Facilitators and Barriers to Questionnaire Completion*

Interviews confirmed that the aspect of the study that proved the most challenging or difficult to complete as instructed was the online weekly questionnaires. No participant reported returning a questionnaire on the same day every week for a consecutive 12-week period, and almost a third (6/21) reported being unaware of a requirement to complete a weekly questionnaire at all. From one participant,

> *Oh, I didn't get that because I think when I read and I got information, I thought there only was one questionnaire at the start of the study and then you only send samples.*

Some of the men interviewed were not aware of online questionnaire requirements, though they reported reading participant information detailing them. Suggestions were made for improved instructions, including greater clarity on requirements for weekly questionnaire completion, less densely presented but more concise information, bullet points with study requirements, and use of less formal and more readable language.

Among participants who completed the questionnaires, this was facilitated by online links or QR codes in study information, text reminders, or self-bookmarking the site of the weekly questionnaire. From one interviewee,

> *[…] But then I got a text that day thanking me for taking part in the study which had the link embedded which is really useful because I couldn't remember what the hell the name of it was.*

The content and length of the questionnaires were largely acceptable to those who were aware of and completed one or more questionnaires.

> *The length as in. Uh, yeah [...] I found it pretty straightforward and easy, in fact, I wish I'd known about it earlier. I would have probably done it more regularly if I'd known how easy it was.*

Overall, participants expressed comfort with the content of questions, and their assessments suggested a reasonable understanding or acceptance that questions were included because they would be useful and appropriate to the study.

A couple of interviewees related some irritating repetition in individual surveys or in having to answer questions when little had changed in their behavior from preceding weeks and may prefer a more concise way of indicating as such, for example, a "No change" option that would result in skipping most of the questions. Others suggested they would appreciate improvements to layout and legibility, particularly on mobile screens.

> *[…] I tried to do [the questionnaire] on my phone again, but it was just impossible. It was just far too small.*

## Discussion

The STEIM study design was feasible to implement and largely acceptable in an SHS-attending GBMSM population in Brighton and Sussex. The study team was successful in recruiting a study population of the target size that was broadly representative of GBMSM attending the participating SHSs. Just under half of participants provided more than one rectal swab, and many provided weekly or nearly weekly swabs. Questionnaire completion was less complete than swab return. Insights from qualitative interviews identified barriers and facilitators that could be addressed in a future implementation of the study design, and many made suggestions for improving participant-facing study materials. For example, participants reported not being aware of the need for regular questionnaire completion and being surprised about how easy they were to complete, which could be addressed by improved study information and communication.

Our findings align with other research involving the recruitment of GBMSM to provide self-completed questionnaires and a biological sample; one study recruiting GBMSM at a central London SHS to complete a questionnaire and collect biological samples for human papillomavirus testing had a high acceptance rate of 81.4% [27], while the Gay Men's Sexual Health Survey in Scotland recorded a response rate of 65.2% for the survey aspect, with 80.4% of those surveyed providing an optional oral fluid specimen [28]. Our findings are particularly encouraging given the longitudinal sampling component of STEIM.

XSL•FO
RenderX

Qualitative interviews highlighted that the innovation of the study, especially given the focus on gut health, was appealing to many and may have helped with recruitment. Altruism is a common facilitator for participation in a study [29], and the feeling of giving something back was also a driver for participation in this study, with some recruitment happening in vaccination clinics responding to the 2022 mpox outbreak in England. This was a special circumstance, but linking recruitment to valued services may be beneficial for future studies.

Perceived personal benefits are also a common facilitator [29]. However, the study design did not provide individual sample test results, which could present a possible barrier to participation. Two participants reported being motivated to participate because they expected to receive diagnostic test results. It will be important to better emphasize that this is not the case for future recruitment or to develop mechanisms to explore feedback in future studies, especially as it was suggested that receiving results, both individual sample and overall study results, may incentivize participants to complete the study.

A large proportion of participants did not complete any study procedures after enrollment. Other studies have documented similar problems. For example, in Positive Voices, a national survey of people living with HIV, 90% of individuals accepted the initial survey invitation, but only 23% completed it [24]. Unfortunately, limited data were available to understand the drop-off in this study, with no qualitative interviews conducted with these participants. Demographic analysis showed that those who completed study procedures were more likely to have taken HIV PrEP or to live in the least deprived IMD quintile, highlighting more routine use of SHSs; a desire for reciprocity of valued services or high socioeconomic status might facilitate taking part. Future studies must address this challenge, potentially through better public engagement work or through improving the study procedures based on feedback from this pilot. While the lack of financial offers was not highlighted as a barrier to participation in the interviews, with no interviews conducted with those who did not complete procedures, it is possible that financial incentives could help give higher overall participation and retention for future studies, especially for those living in more deprived areas, who were less likely to complete study procedures. The potential drop-off should also be accounted for in future sample size calculations.

Participant engagement with questionnaires was challenging, with 36.8% of participants completing a baseline and only 15 participants completing all follow-up questionnaires, less than half the number who provided rectal swabs for the whole study. Qualitative interviews revealed low awareness of questionnaires, especially the requirement for weekly completion, and this will be a focus for future iterations. Concise, bulleted instructions of the key steps might help improve participant understanding and completion rates. Optimizing mobile access and completion of the questionnaire could also improve engagement, for example, by using the mobile surveys feature of Snap Surveys Ltd.

SMS text messaging sent to participants as reminders to complete study procedures had variable utility, with mixed understanding as to whether they were reminders or were a thank you instead. A meta-analysis showed varied usefulness of reminders in promoting participant engagement with online surveys [30]. The utility of SMS text messaging increased if they were seen to improve a sense of study connection and engagement, which participants suggested might be done by a more personal focus and tailoring to specific tasks. In other studies, personalized reminder messages have been discussed as a useful tool to generate extra responses and encourage reluctant participants [31].

There was better engagement with the return of rectal swabs, with over half of those returning one swab returning 10 or more swabs. This might be because rectal swab sampling was easier to incorporate into daily routines, as highlighted by qualitative interviews. Qualitative interviews also revealed that most participants were satisfied with the 12-week study length and that the definitive end point supported decision-making on the ability to participate, further suggesting that this type of longitudinal sampling is feasible. Patient familiarity with the rectal swab procedure, a routine form of testing in SHS [32], may also have contributed to acceptability in this cohort.

Even so, few of the interviewees at the time of the interview had fully completed the study procedures, and none completed them on the same day every week. This indicates that, although feasible and acceptable, competing life tasks and the unpredictability of weekly routines still limit participation in a longitudinal study. It will be important to ensure that participants are aware there is flexibility and that they can complete weekly procedures on different days or miss one week (or a couple) and still provide important participation.

There are some limitations to the STEIM study. Regarding recruitment, estimating recruitment success relied on the completion of study screening logs, which were not routinely done, leading to possibly overestimated recruitment success. Participants were required to have sufficient English language and literacy skills and access to a mobile device and the internet to be able to complete the study procedures, and most participants were recruited from Brighton SHS, making this essentially a single-center study. Together, this limits the generalizability of the study, the demographics of the recruited individuals, and the participant experience. Based on experience from other studies [25], we were confident that online data collection methods were acceptable to most SHS attendees in this population, and within the time and financial constraints of our pilot study, it was not possible to translate materials into different languages or supply alternatives to digital devices. However, these options should be explored for future studies to increase the generalizability of the study and the representativeness of those who complete study procedures. Additionally, the STEIM study had specific eligibility criteria, such as having had a recent sexual partner, which, at that time, could not be compared to national STI surveillance data. Therefore, representativeness was compared to the overall population and may explain the higher frequency of recent STIs and taking HIV PrEP in the study cohort. Interview participants had all returned at least one questionnaire and rectal swab, which limited our qualitative insights on barriers to completing study procedures.

XSL•FO
RenderX

Overall, based on the findings from this pilot study, we recommend that future studies (1) provide a user-friendly outline of the study requirements at the beginning of the participant instruction sheet that clearly lays out the expectation of the participant over the study period through concise bulleted instructions, with an emphasis on the weekly questionnaire alongside the swab; (2) modify SMS text messaging reminders so that they improve a sense of connection to the study, for example, are tailored to specific tasks, and are clearly phrased to serve as reminders of study procedures and what those procedures are; (3) optimize the questionnaires for use on mobile phones; (4) consider participation incentives, which could include financial incentives and/or reports on study results; and (5) keep and emphasize the element of flexibility to the study procedures so that they can be integrated into normal routine.

In conclusion, this phase of the STEIM study has provided evidence of the feasibility and acceptability of the study methods, as well as tangible insights to inform the design of future similar studies involving longitudinal rectal swabs and self-reported data collection for STEI-related studies as well as for studies in other sexual health patient populations and outside of this setting. This pilot has provided innovative results in the field of STEIs; previous research studies for exploring risk factors for and transmission of STEIs (in the United Kingdom) have been cross-sectional in nature [12,15] and, to our knowledge, this is the first study that is longitudinal. This type of study is needed to address important gaps in our understanding of STEI transmission, which can then be used to inform appropriately targeted clinical and public health interventions for infection control.

## Acknowledgments

The authors thank all staff at the participating clinics that enabled recruitment, and the study participants. We would also like to acknowledge the support of the NIHR Clinical Research Network. We acknowledge members of the National Institute for Health and Care Research Health Protection Research Unit (NIHR HPRU) in Blood Borne and Sexually Transmitted Infections (BBSTI) Steering Committee: Professor Caroline Sabin (HPRU Director), Dr John Saunders (UKHSA Lead), Professor Catherine Mercer, Dr Hamish Mohammed, Professor Greta Rait, Dr Ruth Simmons, Professor William Rosenberg, Dr Tamyo Mbisa, Professor Rosalind Raine, Dr Sema Mandal, Dr Rosamund Yu, Dr Samreen Ijaz, Dr Fabiana Lorencatto, Dr Rachel Hunter, Dr Kirsty Foster and Dr Mamooma Tahir.

## Abstract

**Background:** While prior studies have examined structural and individual-level barriers to pre-exposure prophylaxis (PrEP) uptake, little is known about the psychological mechanisms underlying resistance to PrEP, particularly among high-risk groups. The status quo bias (SQB) theory provides a theoretical framework for understanding why individuals may resist beneficial health innovations.

**Objective:** The aim of this study was to examine the associations between SQB and PrEP resistance intention among Chinese men who have sex with men (MSM) and to test whether condom-use inertia moderated these relationships.

**Methods:** We conducted a cross-sectional online survey among 1022 MSM in China from November 2024 to February 2025. Theory-guided multi-item measures were constructed to capture key dimensions of SQB. Their internal consistency and construct validity were examined using confirmatory factor analysis prior to regression modeling. Multiple linear regression models assessed main effects and moderation effects, adjusting for sociodemographic and behavioral covariates.

**Results:** A total of 1022 MSM were included in the final analysis (mean age 29.6 y); the majority identified as homosexual (767/1022, 75.1%) and were unmarried (896/1022, 87.7%). Regression analyses revealed that transition costs were positively associated with PrEP resistance intention (β=0.26, 95% CI 0.17-0.35; *P*<.001), while social norms were negatively associated (β=–0.19, 95% CI –0.27 to –0.12; *P*<.001). Condom-use inertia significantly moderated both associations, amplifying the positive relationship between transition costs and resistance (β=0.04, 95% CI 0.01-0.09; *P*=.03) and enhancing the negative association of social norms (β=–0.05, 95% CI –0.09 to 0.00; *P*=.04). Subgroup analyses showed that the amplifying effect of condom-use inertia on transition costs was particularly evident among participants with postgraduate education (β=0.13, 95% CI 0.01-0.26; *P*=.04). Conversely, its strengthening effect on social norms was more pronounced among MSM 30 years or younger (β=–0.11, 95% CI –0.17 to –0.04; *P*=.001) and those identifying as homosexual (β=–0.07, 95% CI –0.12 to –0.02; *P*=.01).

**Conclusions:** This study suggests that SQB is an important psychological barrier to PrEP adoption among Chinese MSM. The moderating role of condom-use inertia highlights the relevance of habitual condom-use routines in shaping PrEP resistance. Behaviorally informed strategies that reduce transition costs and leverage social norms may help mitigate resistance and improve PrEP uptake.

## Introduction

According to the latest statistics from the World Health Organization, an estimated 40.8 million people were living with HIV at the end of 2024, and approximately 1.3 million people acquired HIV in the same year [1]. Men who have sex with men (MSM) continue to be among the populations at highest risk for HIV infection, with a relative risk estimated to be 23 times higher than that of the general population [2,3]. In the ongoing global public health effort to end the HIV epidemic, pre-exposure prophylaxis (PrEP) has emerged as a milestone biomedical intervention. Evidence shows that when taken as prescribed, PrEP can reduce the risk of HIV acquisition among MSM by approximately 99% [4]. Nevertheless, despite its enormous potential to reshape the trajectory of the HIV epidemic, the implementation and scale-up of PrEP continue to encounter considerable challenges.

Implementing and promoting PrEP uptake among MSM remains a considerable challenge. Although studies estimate that over 66.7% of MSM in China express willingness to use PrEP, the actual uptake rate remains below 10% [5,6]. Existing research has focused on 2 broad categories of barriers to PrEP willingness or uptake. On the structural level, a large body of literature highlights obstacles such as limited health care access, high out-of-pocket costs, and service delivery gaps [7,8]. On the psychosocial level, researchers have emphasized the role of factors such as stigma, perceived HIV risk, and self-efficacy [9-11]. While crucial metrics like PrEP willingness and uptake measure the presence of a positive inclination or a final behavior, they may not fully capture the active psychological processes underlying the rejection of PrEP. This specific failure to adopt PrEP among those who need it most underscores the limitations of "willingness" as a construct and necessitates a new focus on the cognitive and behavioral factors driving active resistance intention.

From the perspective of status quo bias (SQB) theory, individuals often prefer preserving their current circumstances, even when alternative options offer greater benefits [12]. This study focuses on 2 principal mechanisms, drawn from SQB theory, that may explain this phenomenon: rational decision-making and psychological commitments [13]. Rational decision-making implies that individuals conduct a cost-benefit analysis before transitioning to a new HIV prevention strategy [13]. Transition costs refer to the burdens associated with adopting a new practice; when such costs outweigh the perceived benefits, individuals are likely to maintain the status quo [14]. In the context of PrEP, these transition costs may present a significant barrier to adoption, including the time and financial investments required for behavioral adjustments, such as medical consultations, regular HIV testing, and the establishment of consistent medication routines [15-17]. For example, Katz et al [18] reported that high-risk women in Kenya experienced difficulties initiating PrEP due to professional scheduling conflicts, educational disruptions, and prohibitive transportation expenses.

Psychological commitment reflects prevailing social norms [19]. In HIV prevention, social norms refer to the collective expectations and shared attitudes within MSM communities regarding PrEP usage. Previous studies suggest that the willingness of MSM to use PrEP is significantly influenced by perceived social approval or disapproval from significant others [20,21]. Specifically, the attitudes and opinions of family members, peers, and healthcare providers can influence the perceptions and decisions of MSM regarding PrEP [22,23]. When individuals are embedded in social networks that actively endorse or discuss PrEP use, these positive normative cues can help counteract status quo tendencies and encourage PrEP uptake [24,25].

Rather than arising from reflective cost-benefit analyses, inertia reflects an automatic reliance on established behavioral patterns and a natural resistance to change [26,27]. While condoms remain a cornerstone of HIV prevention, their effectiveness is often compromised by inconsistent use—a well-documented risk factor, particularly among high-risk MSM [28]. PrEP is a critical supplement to HIV prevention for this high-risk group. However, adopting this biomedical paradigm triggers cognitive resistance. For example, Han et al [29] found that individuals who preferred and consistently used condoms as a method of HIV prevention were significantly less willing to consider PrEP adoption. Similarly, previous research has shown that MSM with high self-efficacy regarding condom use were less likely to contemplate using PrEP [11]. Building on these insights, while recognizing the underexplored relationship between SQB and behavioral inertia, we hypothesize that condom-use inertia moderates this interplay, such that the influence of factors like transition costs and social norms becomes more pronounced among individuals with higher levels of inertia.

Although a growing body of research has explored barriers to PrEP adoption and willingness, few studies have explicitly examined PrEP resistance intention through a behavioral economics lens. Moreover, the potential influence of condom-use inertia has received little empirical attention. Guided by SQB theory, this study examines how transition costs and perceived social norms are associated with PrEP resistance intention among Chinese MSM and tests whether condom-use inertia conditions these associations.

## Methods

### Study Design and Participant Recruitment

We conducted this cross-sectional study using an anonymous, web-based questionnaire deployed via Sojump, a widely used online survey platform in China, and reported the online survey in accordance with the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) (Checklist 1). We collected data from November 29, 2024, to February 11, 2025. Participants were recruited through convenience and snowball sampling. The research team developed recruitment materials, including digital posters and standardized outreach messages, which were disseminated through the WeChat official accounts of collaborating community-based organizations (CBOs) and local Centers for Disease Control and Prevention. Guangdong served as the initial dissemination hub because the core CBO partner responsible for launching recruitment was based there. To implement snowball sampling, participants were encouraged

XSL•FO
RenderX

to share the survey link with their peers. As a result, recruitment extended beyond the initiating hub and ultimately reached multiple regions across mainland China, including Guangdong, Hubei, Shandong, Jiangsu, Sichuan, and Shanghai.

Eligible participants were those who met the following inclusion criteria: aged 18 years or older, identified as cisgender male, had a history of sexual activity with other men, were self-reported HIV-negative or unaware of their HIV status, and provided electronic informed consent before beginning the survey. We excluded participants who declined to consent or were deemed unable to complete the survey due to severe psychiatric illness or significant cognitive impairment, as determined by self-report or investigator assessment. We restricted participation to cisgender MSM to preserve conceptual and measurement consistency because the study constructs and items were developed to capture PrEP-related resistance and condom-use routines in this population and have not been validated for transgender and gender-diverse participants.

Before accessing the questionnaire, potential participants viewed an electronic informed consent page that described the study investigator, the study's purpose, and the estimated survey duration (about 15 min). The consent page also explained what information would be collected, that responses would be stored on a secure, password-protected server managed by the study team, that only authorized investigators would have access, and that the data would be used solely for scientific research. Participants could proceed to the survey only after actively indicating consent (eg, selecting an "I agree" option). Participants whose responses passed the logic-consistency and attention-check procedures received 30 yuan (about US $5) as a token of appreciation for their time.

To ensure data quality, the questionnaire incorporated embedded attention-check items and logic-consistency checks. Of 1311 submitted responses, 257 failed quality control and were excluded, leaving 1054 responses. We then removed 32 duplicate entries identified using the phone numbers submitted with the questionnaire, resulting in 1022 unique participants included in the final analysis (Multimedia Appendix 1). Phone numbers were collected solely for duplicate checking and were removed from the analytic dataset after screening. The survey platform also required completion of mandatory items before submission, minimizing missing data.

The present study focuses on PrEP resistance intention and incorporates multiple covariates and interaction testing. An a priori power analysis using G*Power 3.1.9.7 indicated that, for a multiple linear regression model with $\alpha$=.05 and up to 20 predictors, a sample of 157 participants would be required to detect a medium effect ($f^2$=0.15) with 80% power, whereas 1064 participants would be required to detect a small effect ($f^2$=0.02). The final analytic sample of 1022 participants fell between these 2 benchmarks, suggesting adequate power to detect effects in the small-to-medium range in the primary regression models. However, smaller interaction effects and exploratory subgroup analyses should be interpreted cautiously.

## Ethical Considerations

We obtained ethical approval for this study from the Institutional Review Board of Shenzhen University (protocol PN-202400070). All participants provided informed consent electronically before accessing the survey. The survey was administered anonymously online. Phone numbers were collected only for duplicate screening and compensation purposes and were removed from the analytic dataset after screening. All data were stored on a password-protected server accessible only to the research team and were used solely for research purposes. Participants whose responses passed the quality-control procedures received 30 Yuan (about US $5) as compensation.

## Measures

### *Study Constructs and Measurement*

We operationalized the key study constructs using theory-guided, multi-item measures informed by the behavioral economics framework of SQB [13] and by prior empirical literature on PrEP adoption barriers among MSM [15-17,21-25,30,31]. We adapted all items to suit the cultural and behavioral context of the target population and refined them through expert consultation and pilot testing [32]. Participants rated all items on a 7-point Likert scale, ranging from 1 (strongly disagree) to 7 (strongly agree). We then calculated the final score for each dimension as the arithmetic mean of its corresponding items. Table 1 summarizes the study constructs and their items. These constructs were analyzed as distinct measures (outcome, predictors, and moderator) rather than as subscales of a single instrument.

XSL•FO
RenderX

**Table .** Study constructs and items.

| Study constructs | Items |
|---|---|
| Transaction costs | |
| TC1 | It would take a lot of time and effort for PrEP[a]-related physical exams. |
| TC2 | I would spend a lot of money if I were to switch to using PrEP. |
| TC3 | There would be health-related side effects if I were to switch to using PrEP. |
| TC4 | Switching to using PrEP could result in unexpected hassles. |
| Social norms | |
| SN1 | My doctors/community outreach workers think I should use PrEP. [reverse-coded item] |
| SN2 | My family/friends think I should use PrEP. [reverse-coded item] |
| SN3 | My sex partners think I should use PrEP. [reverse-coded item] |
| Condom-use inertia | |
| I will continue using condoms for preventing HIV… | |
| CI1 | …simply because it is what I have always done. |
| CI2 | …I enjoy doing so. |
| CI3 | …even though I know it is not the best way of doing things. |
| Resistance intention | |
| RI1 | I oppose the idea of using PrEP as a strategy to prevent HIV. |
| RI2 | I will not start using PrEP for preventing HIV. |
| RI3 | I will not comply with the medical instructions to use PrEP for preventing HIV. |

[a]PrEP: pre-exposure prophylaxis.

### *Primary Outcome*

The primary outcome variable, PrEP resistance intention, was assessed using 3 items designed to capture individuals' intentions to resist the adoption and use of PrEP. These items reflect a spectrum of resistance, ranging from general attitudinal opposition to the change to specific behavioral intentions to reject both the adoption process and the medication regimen. We calculated the outcome score as the mean of the 3 items, with higher scores indicating stronger resistance intentions.

### *Explanatory Variables*

We focused on 2 theoretically salient dimensions of SQB as the main explanatory variables: transition costs and perceived social norms. These dimensions reflect distinct psychological mechanisms that may contribute to resistance to behavioral change. Transition costs included 4 items covering concerns about time, financial burden, side effects, and potential hassles associated with PrEP uptake [15-17]. We assessed social norms using 3 reverse-coded items that evaluated perceived approval of PrEP use from key referents, such as health care workers, friends, and sexual partners [21-25]. We reverse-coded these items so that higher values reflected more supportive norms, consistent with the hypothesized protective association.

### *Moderator Variable*

Condom-use inertia, reflecting an inertial reliance on behavioral persistence, was measured using 3 items. These items explored the behavioral, affective, and cognitive tendencies of individuals to continue using condoms for HIV prevention, even in cases where condom use might be perceived as suboptimal [9,29,33]. Higher scores indicated more substantial condom-use inertia.

### *Covariates*

We selected covariates based on prior empirical evidence identifying their relevance to PrEP-related decision-making and their potential roles as confounding factors [34,35]. Demographic characteristics included age, sexual orientation, marital status, education level, and monthly income. Sexual behavior–related variables included the number of regular male sexual partners and the number of casual male sexual partners reported in the past 6 months. We also included substance use as a behavioral covariate. We asked participants whether they had used any of a list of commonly reported substances within the previous 12 months, specifically in sexual contexts. The checklist included marijuana, cocaine, opium ("white powder"), methamphetamine, poppers, ecstasy, lysergic acid diethylamide, psilocybin, and gamma-hydroxybutyrate or gamma-butyrolactone. We dichotomized responses, coding any substance use during sex as 1 ("yes") and no reported use as 0 ("no").

## Statistical Analysis

We used descriptive statistics to summarize participants' demographic and behavioral characteristics. We reported means and SDs for continuous variables and presented categorical variables as frequencies and proportions. Psychometric evaluation and regression analyses were conducted in the same analytic sample (N=1022). To support the subsequent regression analyses, we evaluated the measurement properties of the

XSL•FO
RenderX

theory-guided multi-item constructs. Because the factor structure was specified a priori based on theory, we conducted confirmatory factor analysis (CFA) to evaluate construct validity. We assessed internal consistency using Cronbach α and composite reliability. We examined convergent validity using standardized factor loadings and average variance extracted (AVE) from CFA, and we tested discriminant validity using the Fornell-Larcker criterion by comparing the square root of each construct's AVE with its correlations with other constructs. We then computed mean scores for all constructs and conducted Pearson correlation analyses to examine the bivariate associations between transition costs, social norms, condom-use inertia, and PrEP resistance intention.

To identify factors associated with PrEP resistance intention, we conducted hierarchical linear regression analyses in 3 steps. Model 1 estimated the main associations between transition costs, social norms, and condom-use inertia and PrEP resistance intention, while adjusting for sociodemographic and behavioral covariates. Model 2 added the transition costs × condom-use inertia interaction, and Model 3 added the social norms × condom-use inertia interaction. We mean-centered continuous predictors before creating interaction terms to reduce multicollinearity and facilitate interpretation. We reported standardized coefficients (β), 95% CIs, and *P* values. We assessed model fit using multiple criteria, including $R^2$, adjusted $R^2$, and nested model *F* tests, to determine whether interaction terms significantly improved the model fit. We performed all analyses using Stata 17 (StataCorp LLC). Statistical significance was set at $P<.05$ (2-tailed). For exploratory 3-way interaction analyses, *P* values between .05 and .10 were treated as marginal evidence and interpreted cautiously [36,37].

## Results

### Participants' Sociodemographic Characteristics

The final analytical sample consisted of 1022 Chinese MSM with a mean age of 29.6 (SD 7.6) years. The sample was predominantly homosexual-identified (767/1022, 75.1%), never married (896/1022, 87.7%), and well educated, with 87.8% (897/1022) holding a bachelor's degree or higher. Regarding monthly income, over one-third (369/1022, 36.1%) earned more than 8000 Yuan (about US $1157) monthly, while 13.3% (136/1022) earned less than 3000 Yuan (about US $434). Participants reported diverse sexual partnership patterns: 57.4% (587/1022) had 1 regular male partner, while 69.8% (714/1022) reported having casual partners in the past 6 months. Nearly one-quarter (253/1022, 24.8%) reported substance use during sexual activities (Table 2).

## Measurement Properties of Study Constructs

To support the regression analyses, we assessed the measurement properties of the theory-guided constructs. CFA demonstrated acceptable model fit for the measurement model ($\chi^2_{79}$=523.8, $P$<.001; root mean square error of approximation=0.074, 90% CI 0.068 to 0.08; standardized root mean square residual=0.058; comparative fit index=0.947; Tucker-Lewis index=0.930) (Multimedia Appendix 2). All constructs demonstrated acceptable internal consistency and convergent validity. Internal consistency was excellent for PrEP resistance intention (Cronbach α=0.93) and good for condom-use inertia (α=.86), social norms (α=.85), and transition costs (α=.83). Composite reliability values exceeded 0.80 for all constructs. AVE values surpassed the 0.50 threshold, supporting convergent validity (Figure 1).

XSL•FO
RenderX

**Figure 1.** Discriminant validity assessment based on the Fornell-Larcker criterion. AVE: average variance extracted; PrEP: pre-exposure prophylaxis; SQRT: square root.

## SQB Variables by PrEP Resistance Intention

Bivariate correlations revealed consistent associations (Multimedia Appendix 3). Transition costs (mean 4.7, SD 1.1) showed a small-to-medium positive correlation with PrEP resistance intention (mean 3.2, SD 1.6; $r$=0.21; $P$<.001), indicating that higher perceived switching costs to PrEP were associated with greater resistance. Social norms (mean 3.8, SD 1.2) showed a negative correlation of similar magnitude ($r$=–0.21; $P$<.001), suggesting that supportive social environments were associated with lower resistance. Condom-use inertia (mean 4.9, SD 1.3) showed a statistically significant but practically small association with resistance ($r$=0.08; $P$=.008), suggesting that its primary role might be as a moderator rather than a direct predictor.

## Main and Moderation Analysis of PrEP Resistance Intention

Table 3 presents the results of the multiple linear regression models. In model 1, both SQB dimensions were significantly associated with PrEP resistance intention after adjusting for covariates. Transition costs were positively associated with PrEP resistance intention (β=0.26, 95% CI 0.17-0.35; $P$<.001). Social norms showed a comparable negative association (β=–0.19, 95% CI –0.27 to –0.12; $P$<.001), with more supportive normative environments linked to lower PrEP resistance intention. Condom-use inertia showed no significant direct association (β=–0.01, 95% CI –0.08 to 0.07; $P$=.80), supporting its hypothesized role as a moderator rather than a direct predictor of resistance intention.

[j]N/A: not applicable.

Both hypothesized interactions were statistically significant, supporting the moderating role of condom-use inertia in SQB mechanisms. The transition costs × condom-use inertia interaction was significant (β=0.04, 95% CI 0.01-0.09; *P*=.03),

XSL•FO
RenderX

indicating that the positive association between transition costs and resistance intention was stronger among individuals with higher condom-use inertia. The social norms × condom-use inertia interaction was also significant (β=–0.05, 95% CI –0.09 to 0; *P*=.04), indicating that the negative association between supportive social norms and PrEP resistance intention was more pronounced among MSM with high condom-use inertia.

### Moderating Role of Condom-Use Inertia Across Subgroups

Table 4 summarizes the patterns of these moderation effects across various subgroups. The amplifying influence of condom-use inertia on transition costs was particularly pronounced among several subgroups, including participants who were divorced, separated, or widowed (β=0.28, 95% CI 0.13-0.43; *P*<.001), those with a postgraduate degree (β=0.13, 95% CI 0.01-0.26; *P*=.04), individuals with 1 regular male partner (β=0.08, 95% CI 0.01-0.15; *P*=.02), and participants reporting no substance use (β=0.07, 95% CI 0.01-0.12; *P*=.01).

## Discussion

### Principal Findings

This study examines the psychological mechanisms underlying resistance to PrEP adoption among Chinese MSM, focusing on key dimensions of SQB—transition costs and social norms—and the moderating role of condom-use inertia. Our findings show that both dimensions of SQB are significantly associated with PrEP resistance intention, with condom-use inertia playing a notable moderating role across psychological pathways. This study also highlights the heterogeneity of decision-making processes within MSM populations and may help explain why resistance to PrEP adoption persists despite increasing accessibility. These insights move beyond identifying descriptive barriers to illuminating the specific cognitive and behavioral processes at play, informing the design of behaviorally informed public health strategies.

This study provides empirical evidence on associations between SQB-related factors and PrEP resistance intention among MSM. Our findings suggest that PrEP resistance intention was higher among individuals reporting high transition costs, specifically in terms of time investment, financial costs, and potential side effects. National guidelines recommend HIV testing 1 month after PrEP initiation and quarterly follow-up thereafter, including renal and liver function monitoring [38]. Previous studies indicate that obtaining PrEP through licensed clinics in China is often perceived as time-consuming, requiring multiple visits for testing, prescription, and follow-up [8,39]. Limited provider availability has led some MSM to seek PrEP through informal channels (eg, Dài-Gòu), raising concerns about drug safety [39]. In addition, PrEP in China is largely paid for out of pocket, including medication and required clinical monitoring, and cost has consistently been reported as a major barrier among MSM [40]. Conversely, a supportive social environment was associated with lower resistance, highlighting the inverse relationship with perceived social norms. This pattern aligns with previous literature linking transition costs and normative factors to PrEP-related attitudes and behaviors [24,25,41], and our study extends this work by explicitly framing the outcome as PrEP resistance intention, providing more comprehensive evidence on the active rejection process.

We also identified condom-use inertia as a significant psychological moderator in PrEP decision-making. Although habitual condom use is protective and remains essential for preventing a wide range of sexually transmitted infections, a strong reliance on this established routine may be associated with psychological friction when individuals consider adding or transitioning to PrEP. This friction may relate to the cognitive stability and predictability associated with long-standing habits [42,43]. In this context, condom-use inertia may act as a powerful cognitive filter that reinforces the status quo and amplifies the perceived costs of behavioral change [44,45]. Our findings indicated that men with entrenched condom-use habits perceived the costs and hassles of initiating PrEP as significantly more burdensome, which was associated with greater resistance. Therefore, addressing inertia may help reduce the extent to which established condom-use routines are associated with PrEP resistance.

Paradoxically, this same inertia also amplified the positive association with social norms, suggesting a dual-amplifier mechanism. Individuals with strong habits appear particularly responsive to normative cues, potentially because such cues can penetrate habitual cognitive filters more effectively than informational messages alone [46]. This finding suggests the moderating role of inertia: it strengthens resistance to change when signals support maintaining existing condom routines, yet enhances receptiveness when signals favor PrEP adoption. This dual-amplifier mechanism is particularly relevant for MSM who meet clinical criteria for PrEP, including those with higher sexual activity, multiple recent partners, or increased HIV exposure risk. For these groups, PrEP does not replace condoms but provides supplementary HIV-specific protection where condom effectiveness may be inconsistent or challenged by real-world sexual practices [47].

Exploratory subgroup analyses suggested that the moderating role of condom-use inertia varies across demographic and behavioral profiles. The interaction between condom-use inertia and transition costs was more pronounced among participants with a postgraduate degree, MSM with 1 regular partner, and those reporting no substance use. For example, among participants with higher education, prior research suggests a higher likelihood of reporting consistent condom use [48]. When condom-use inertia is high, PrEP may be perceived as unnecessary and more burdensome to initiate and maintain, magnifying perceived transition burdens and being linked to higher PrEP resistance intention. Along similar lines, MSM reporting one regular partner or no substance use may perceive condoms as sufficiently protective for their current risk profile; high condom-use inertia may therefore make PrEP-related transition costs seem less justified, reinforcing PrEP resistance intention. This suggests that rigid behavioral routines may heighten the psychological burden of initiating PrEP among these groups. Strategies consistent with the MINDSPACE (Messenger, Incentives, Norms, Defaults, Salience, Priming, Affect, Commitments, Ego) framework, such as simplified defaults for PrEP initiation, streamlined refill procedures, and increased salience of concrete PrEP benefits, may help mitigate perceived transition barriers [49,50]. For instance, PrEP eligibility screening or counseling could be embedded within routine HIV and sexual health services using an opt-out default, which may reduce initiation friction. Follow-up and refills could be streamlined (eg, 1-click scheduling, prefilled forms, and automated reminders), which may lower perceived time and hassle costs [51,52].

In contrast, the interaction between condom-use inertia and social norms was most evident among younger MSM, homosexual-identified men, unmarried individuals, those with a bachelor's degree, and MSM with multiple regular partners, with inertia appearing to strengthen the negative association with social norms. Younger MSM and homosexual-identified men are often more embedded in MSM peer networks and community interactions, where HIV prevention information, attitudes, and behavioral modeling circulate more frequently [53]. Condom-use inertia may reflect the cumulative effects of

XSL•FO
RenderX

prior prevention socialization, including repeated reinforcement of condom-related norms, skills, and confidence within peer and sexual networks [54,55]. Within this normative context, individuals anchored in condom-use routines may be more responsive to supportive social endorsement, which may increase the perceived acceptability and feasibility of PrEP and lower resistance intention. Accordingly, norm-based nudges could increase the visibility of supportive norms in MSM social spaces by communicating descriptive and injunctive norms that normalize PrEP consideration. Credible messengers, including peer leaders, PrEP-experienced MSM, and trusted clinicians, may further strengthen normative influence and enhance the perceived feasibility of initiation and persistence [56,57].

### Limitations

Several limitations of this study should be considered when interpreting the results, and these also point to directions for future research. First, this study employed a cross-sectional design, with all variables measured at a single time point. Although this design can identify associations between variables, it does not allow for temporal ordering or causal inference. Second, the sample for this study was drawn from the Chinese cultural and demographic context. While the findings provide valuable localized insights into the PrEP decision-making process among this group, their generalizability may be limited. The factors influencing SQB, such as the nature of social norms and the specific components of transition costs, may differ significantly across other cultural, social, and healthcare system contexts. Third, our reliance on online convenience and snowball sampling limits generalizability to all MSM in China. Recruitment via partner CBO or Centers for Disease Control and Prevention channels and peer sharing likely over-sampled younger, urban, and highly educated individuals, potentially under-representing MSM with lower educational attainment who may differ in HIV prevention knowledge, digital health literacy, and access to PrEP services. Finally, we assessed the prespecified measurement structure using CFA and standard discriminant validity checks; however, we did not conduct exploratory factor analysis or validate the measurement model in an independent sample. Future studies should replicate the factor structure in separate samples and consider incorporating exploratory factor analysis to further evaluate construct dimensionality and strengthen the psychometric evidence base.

### Conclusion

This study applied the theory of SQB to explain PrEP resistance intention, offering a novel theoretical perspective and empirical tools for understanding the intention-behavior gap in public health. Crucially, we identified the moderating role of condom-use inertia, highlighting the cognitive friction involved in shifting from established condom-based routines to new prevention methods. In conclusion, our findings confirm that SQB is an important yet often overlooked factor associated with PrEP adoption among MSM. Integrating insights from behavioral economics into HIV prevention strategies has significant theoretical and practical importance for addressing challenges in PrEP promotion and for informing more effective public health interventions.

## Acknowledgments

We express our sincere gratitude to the Social Entrepreneurship for Sexual Health team for their invaluable efforts in data collection for this study. We are also deeply grateful to all the participants who generously gave their time and shared their perspectives; this research would not have been possible without their participation. Generative artificial intelligence was used only for limited English grammar and language editing. All scientific content, interpretation, and references were reviewed and verified by the authors, who take full responsibility for the manuscript.

## Funding

This work was supported by the Ministry of Education of the People's Republic of China Project of Humanities and Social Sciences (grant 24YJC840051), the Natural Science Foundation of Shaanxi Province (grant 2025JC-YBQN-1106), the Fundamental Research Funds for the Central Universities (grant SK2026027), the Ministry of Science and Technology of the People's Republic of China (grants 2022YFC2304900 and 2022YFC2304905), and the National Key Research and Development Program of China (grants 2022YFC2505100 and 2022YFC2505103). The funders had no role in the study design, data collection, analysis, data interpretation, manuscript writing, or the decision to submit the paper for publication.

## Data Availability

The data presented in this study are not publicly available due to privacy and ethical restrictions related to the sensitive nature of the information collected from marginalized populations. Deidentified data may be available upon reasonable request from the corresponding author.

## Abstract

**Background:** Adherence to antiretroviral therapy (ART) during pregnancy is critical for maternal health and the prevention of vertical HIV transmission. In Uganda, where HIV prevalence remains high, pregnant women living with HIV face intersecting structural and psychosocial challenges, including stigma, food insecurity, and limited social support. Although each factor has been linked to ART nonadherence, less is known about how these factors co-occur within individuals and jointly shape vulnerability to nonadherence during pregnancy.

**Objective:** This study used latent profile analysis to identify empirically derived psychosocial vulnerability profiles reflecting the co-occurrence of stigma, food insecurity, and limited social support among pregnant women living with HIV in Uganda and examine whether profile membership is associated with ART adherence.

**Methods:** We conducted a cross-sectional analysis of 167 pregnant women living with HIV recruited from 6 health facilities in Uganda between June and December 2020. Measures included experienced HIV stigma, internalized HIV stigma, household food insecurity, and interpersonal social support. Latent profile analysis identified psychosocial profiles, and linear regression models assessed associations between profile membership and ART adherence, adjusting for sociodemographic covariates.

**Results:** A 2-class solution provided the best model fit (entropy=0.93). The higher-risk profile (75/167, 45.1%) was characterized by increased experienced stigma (mean score 1.97, SE 0.05), higher internalized stigma (mean score 2.66, SE 0.07), severe food insecurity (mean score 7.53, SE 0.20), and lower social support (mean score 2.06, SE 0.04). The lower-risk profile (92/167, 54.9%) showed significantly lower internalized stigma (mean score 2.32, SE 0.04; $P<.001$), lower experienced stigma (mean score 1.72, SE 0.05; $P<.001$), minimal food insecurity (mean score 0.82, SE 0.15; $P<.001$), and slightly higher social support (mean score 2.14, SE 0.04; $P<.001$). Membership in the higher-risk profile was associated with significantly lower ART adherence compared with membership in the lower-risk profile (B=0.88; β=0.40, 95% CI 0.02-0.78; $P=.04$).

**Conclusions:** Distinct psychosocial profiles are meaningfully associated with ART adherence among pregnant women living with HIV in Uganda. By moving beyond single-risk models, these findings demonstrate the added value of person-centered analytic approaches for identifying subgroups of pregnant women living with HIV exposed to clustered psychosocial and structural vulnerabilities. The findings underscore the need for multicomponent, person-centered interventions that simultaneously address stigma, food insecurity, and limited social support rather than treating these challenges in isolation. Identifying empirically derived vulnerability profiles provides a targeted framework for prioritizing high-risk subgroups and informing contextually appropriate intervention design. Addressing these intersecting vulnerabilities is essential for improving maternal ART adherence and supporting efforts to prevent vertical HIV transmission in high-burden settings.

## Introduction

Although HIV prevention and treatment coverage have expanded across sub-Saharan Africa (SSA), Uganda continues to shoulder a high HIV burden [1,2]. An estimated 1.5 million Ugandans live with HIV, 57% of whom are women [1]. Against this backdrop, pregnancy and the early postpartum period are particularly consequential for maternal health and prevention of vertical transmission [3,4]. Accordingly, consistent antiretroviral therapy (ART) adherence during this window is essential [4-6]. Uganda has adopted HIV treatment for all, a World Health Organization strategy that provides lifelong ART to all people living with HIV, including pregnant and breastfeeding women living with HIV regardless of clinical stage or CD4 T-lymphocyte count [6-9]. However, nonadherence remains common, particularly during the postpartum period. Evidence from Uganda and SSA indicates that up to one-third of women miss doses of ART, thereby increasing the risk of virologic failure and mother-to-child transmission [6,10-12].

In this context, a complex array of structural and psychosocial factors undermines ART adherence among pregnant and postpartum women living with HIV in Uganda [10]. HIV-related stigma remains one of the most pervasive barriers to sustained engagement in care [1,13,14]. Stigma operates at multiple levels: externalized stigma (discrimination, rejection, and social exclusion by others) and internalized stigma (self-directed shame, guilt, and diminished self-worth) [15,16]. Women living with HIV frequently report experiencing stigma from family members, community figures, and health care providers, which discourages disclosure and contributes to social withdrawal and disengagement from care [17,18]. Internalized stigma is also associated with increased depressive symptoms and reduced treatment self-efficacy among people entering HIV care, factors that can undermine ART adherence during pregnancy and the early postpartum period [19-21].

Beyond stigma, household food insecurity is another critical, often underappreciated barrier to optimal ART adherence among pregnant and postpartum women living with HIV. Recent phone survey data show that 48% of Ugandan households experience moderate food insecurity and 11% experience severe food insecurity, with the highest burden in rural areas [22]. For women managing HIV during pregnancy, food insecurity magnifies the challenges of chronic illness by intensifying common ART side effects such as nausea, dizziness, and gastrointestinal discomfort when medications are taken without food [23,24]. These amplified side effects discourage adherence, increase depressive symptom severity, and compromise viral suppression [25,26]. Food insecurity also heightens psychological stress, limits care seeking, and undermines social participation and economic independence, thereby reinforcing HIV-related stigma [25,27]. Collectively, these pathways elevate the risk of suboptimal adherence during pregnancy and the early postpartum period.

Importantly, interpersonal social support can buffer the harmful effects of stigma and food insecurity on HIV-related outcomes. Longitudinal studies in rural Uganda and western Kenya demonstrate that emotional and instrumental support reduce the impact of food insecurity on depression and improve ART adherence [28,29]. Peer-based interventions, including peer mother counseling and online support groups, have also shown promise in improving adherence and disclosure among pregnant and postpartum women living with HIV in Uganda [30,31]. However, such support is not universally accessible. Qualitative research has documented that many women experience relationship conflict, lack of disclosure, and rejection following an HIV diagnosis, which limits their access to emotional or practical assistance [17,32].

Despite this evidence, while stigma, food insecurity, and social support have each been studied individually as predictors of ART adherence [33-35], their co-occurrence and interaction remain poorly understood among pregnant and postpartum women in SSA [36,37]. Traditional variable-centered approaches such as early regression models [38] often examine these predictors in isolation and may overlook how multiple adversities interact to shape adherence outcomes [39]. Syndemic frameworks emphasize the synergistic clustering of social and structural challenges, which may amplify risk beyond the sum of individual effects [39,40]. Person-centered methods such as latent profile analysis (LPA) offer a rigorous approach to identifying subgroups of individuals who share similar constellations of psychosocial characteristics [41].

Accordingly, LPA has been increasingly applied in HIV research to detect syndemic vulnerability profiles and adherence-related behavioral patterns among adults in diverse contexts, including SSA [42-44]. However, its use among pregnant and postpartum women remains limited, particularly in high-burden, resource-constrained settings. Applying LPA in this context may uncover subgroups of women disproportionately affected by overlapping stressors and inform more targeted, tailored interventions.

This study addresses this gap by applying LPA to identify vulnerability subgroups among pregnant women living with HIV in Uganda based on 4 theoretically and empirically grounded indicators: experienced HIV stigma, internalized HIV stigma, household food insecurity, and perceived interpersonal social support. We then examined whether profile membership was associated with ART adherence adjusting for sociodemographic covariates. We hypothesized that members of higher-risk profiles, characterized by greater stigma and food insecurity combined with lower levels of support, would report significantly lower ART adherence compared with members of lower-risk profiles. By identifying distinct constellations of co-occurring risk factors, this study aimed to inform more targeted and contextually appropriate interventions to improve maternal adherence and advance Uganda's progress toward achieving its 95-95-95 targets.

# Methods

## Data, Participants, and Procedures

Data were drawn from a larger longitudinal study examining factors that influence retention in HIV care among pregnant and postpartum women in Uganda. Details of the parent study design and data collection procedures have been reported elsewhere [45]. Participants were recruited from 6 participating health care facilities through a clinic-based recruitment process. Midwives and nurses involved in routine antenatal and HIV care served as initial points of contact and systematically identified potentially eligible women during routine clinic visits. Eligibility criteria included living with HIV, being in the third trimester of pregnancy, and enrollment in an ART or prevention of mother-to-child transmission program.

Women who met the eligibility criteria and expressed interest were referred to trained study staff, who provided a detailed explanation of the study, confirmed eligibility, obtained written informed consent, and administered baseline questionnaires. Baseline data collection took place between June and August 2020. Approximately 3 months later, participants were recontacted to complete follow-up assessments, including additional sociodemographic and ART adherence–related measures, between October and December 2020. Recruitment was intentionally anchored in late pregnancy, when women are approaching delivery and facing heightened clinical, psychosocial, and structural demands, to facilitate follow-up into the early postpartum period in the parent longitudinal study.

This analysis used baseline data only and was conducted as a cross-sectional study. Baseline assessment during the third trimester provided a uniform and clinically salient time point, capturing psychosocial and structural vulnerabilities during a period of heightened relevance for ART adherence and prevention of vertical HIV transmission. Restricting analyses to baseline data minimized heterogeneity related to postpartum transitions and allowed for the identification of contemporaneous psychosocial vulnerability profiles prior to delivery. Longitudinal findings from the parent study examining postpartum outcomes have been reported previously [45].

## Ethical Considerations

This study was conducted in accordance with the principles of the Declaration of Helsinki and was reviewed and approved by the Institutional Review Board of the University of California, San Francisco (approval 20-30261), and the Mbarara University of Science and Technology Research Ethics Committee (approval MUREC 1/7). Written informed consent was obtained from all participants prior to enrollment. Participants did not receive compensation for their participation. Participant confidentiality was maintained throughout the study, and all data were deidentified prior to analysis and stored securely, with access restricted to authorized study personnel. This analysis used data from an approved parent study, and all ethics approvals and consent procedures were conducted as part of the original study protocol [45].

## Measures

### Overview

All study measures were administered by trained research staff with experience working with pregnant women living with HIV in Uganda. Instruments were selected based on prior use in HIV research and conceptual relevance to the study objectives. The measures were reviewed and piloted prior to data collection to ensure clarity and contextual appropriateness for the study population. Participants were provided with assistance as needed during questionnaire administration to support comprehension.

### Internalized HIV Stigma

Internalized HIV stigma was assessed using the Internalized Stigma of HIV/AIDS Tool [46], a 10-item measure previously used in HIV research, including studies conducted in SSA, in which respondents rate each statement on a 5-point Likert scale ranging from “strongly disagree” to “strongly agree.” Items prompt participants to reflect on their self-perceptions and feelings since receiving an HIV diagnosis. Example items include “I feel blemished” and “I feel ashamed about having HIV/AIDS.” We calculated mean scores, with higher scores indicating greater internalized HIV stigma. In this sample, the scale demonstrated good internal consistency (Cronbach $\alpha$=0.81).

### Experienced HIV Stigma

Experienced HIV stigma was assessed using the Externalized Stigma of HIV/AIDS Tool (ESAT), a 10-item measure capturing participants’ experiences of stigma and discrimination from others in response to their HIV status. The ESAT was adapted from the Internalized Stigma of AIDS Tool to capture enacted or experienced HIV-related stigma, which is conceptually distinct from internalized stigma. Participants rate each statement on a 5-point Likert scale ranging from “strongly disagree” to “strongly agree.” Example items include “I have been excluded from social events” and “I have been verbally abused or ridiculed.” Average scores were calculated, with higher scores indicating greater experienced HIV stigma. In this sample, the scale demonstrated good internal consistency (Cronbach $\alpha$=0.74). The full list of ESAT items is provided in Multimedia Appendix 1.

### Household Food Insecurity

Household food insecurity was measured using items from the Household Food Insecurity Access Scale (HFIAS) [47], which assesses household food access over the previous 30 days. The HFIAS includes paired items that first assess the presence of specific food insecurity conditions (“yes” or “no”) and, if endorsed, follow with questions assessing frequency. In this analysis, only the dichotomous HFIAS items assessing the presence of food insecurity conditions were used. The corresponding frequency follow-up items were not included because participants who responded “no” to the initial presence questions did not provide frequency data, resulting in substantial missingness on the frequency items. Dichotomous items were coded as 0 (“no”) or 1 (“yes”) and summed to create a composite score reflecting the number of food insecurity conditions endorsed, with higher scores indicating greater household food

XSL•FO
RenderX

insecurity. Internal consistency for this composite was high (Cronbach α=0.96)

### *Interpersonal Social Support*

Perceived interpersonal social support was assessed using the Interpersonal Support Evaluation List–12 [48], a widely used and psychometrically validated measure of perceived availability of social resources. The Interpersonal Support Evaluation List–12 consists of 12 items rated on a 4-point Likert scale (0="definitely false"; 3="definitely true"). Sample items include "If I were sick, I could easily find someone to help me with my daily chores" and "There is someone I can turn to for advice about handling problems with my family." Item scores were averaged to yield a composite score, with higher scores indicating greater perceived interpersonal social support. In this study, the Cronbach α was 0.71, suggesting acceptable reliability.

### *ART Adherence*

ART adherence was assessed using 3 items from the Center for Adherence Support Evaluation Adherence Index [49], which capture common adherence challenges. Participants responded to the following three items: (1) "How often do you feel that you have difficulty taking your HIV medications on time?" (response options: "never," "rarely," "most of the time," and "all of the time"); (2) "On average, how many days per week would you say that you missed at least one dose of your HIV medications?" (response options: "every day," "4‐6 days/week," "2-3 days/week," "once a week," "less than once a week," and "never"); and (3) "When was the last time you missed at least one dose of your HIV medications?" (response options: "within the past week," "1‐2 weeks ago," "3‐4 weeks ago," "between 1 and 3 months ago," "more than 3 months ago," and "never"). Responses across these 3 items were coded and summed to create an ART adherence composite score ranging from 3 to 16, with higher scores indicating more optimal adherence to ART. The Cronbach α was calculated as 0.76, suggesting good internal reliability.

### Data Analysis

Descriptive statistics were calculated for all study variables. LPA was conducted to identify unobserved subgroups (latent classes) of participants based on 4 continuous indicators: experienced HIV stigma, internalized HIV stigma, food insecurity, and interpersonal support. Model selection (the number of profiles) was guided by multiple fit indexes: the Akaike information criterion (AIC), Bayesian information criterion (BIC), consistent AIC, sample size–adjusted BIC, and classification likelihood criterion. Higher model fit was indicated by lower values of these indexes. Model interpretability and entropy values (ranging from 0 to 1) were also used to assess classification accuracy, with higher values indicating more precise assignment of individuals to latent classes. In determining the optimal number of classes, parsimony and fit indexes were balanced with conceptual clarity and class separation. Parameter estimates (means, variances, and SEs) for each class were extracted and compared across latent profiles to describe group characteristics.

Next, we conducted a linear regression analysis to examine the association between the latent classes and optimal ART adherence adjusting for age, educational status of both women living with HIV and their partners, religion, place of residence, partners' HIV status, and perceived financial status. All independent variables, including covariates, were entered simultaneously into the model. All analyses were cross-sectional and performed using Jamovi (version 2.3) [50].

Because participants were recruited through clinic-based sampling rather than a probability-based survey design, no survey weights were applied in the analyses. The study sample was not intended to be nationally representative, and therefore, weighting procedures designed to correct for unequal selection probabilities or population-level inference were not appropriate. All analyses were conducted using unweighted data, consistent with prior clinic-based studies of pregnant women living with HIV in similar settings. The analytic focus was on identifying within-sample psychosocial vulnerability profiles rather than producing population-level prevalence estimates.

## Results

### Descriptive Statistics

A total of 167 pregnant women living with HIV were included in the analysis. As shown in Table 1, the mean age was 28.01 (SD 6.14; range 17-45) years. Most participants (124/167, 74.3%) reported being in a relationship and living with a partner. Regarding educational level, most (118/167, 70.7%) indicated primary school education as their highest level. When asked about their partners' educational level, 47.0% (77/164) reported primary school education, whereas 19.5% (32/164) indicated that they did not know. Most participants (96/166, 57.8%) identified as Protestant, and most (141/166, 84.9%) lived in rural areas. Slightly more than half (84/160, 52.5%) reported that their partner was HIV positive, whereas others reported that their partner was HIV negative (46/160, 28.7%) or that they did not know their partner's status (30/160, 18.8%). Finally, most participants (139/166, 83.7%) described their financial situation as poor or not enough. Mean scores were 1.84 (SD 0.47; range 1.00‐4.20) for experienced stigma, 2.48 (SD 0.54; range 1.40‐3.80) for internalized stigma, 3.88 (SD 3.65; range 0‐9) for food insecurity, 2.11 (SD 0.38; range 0.75‐3.00) for interpersonal social support, and 14.5 (SD 2.31; range 7‐16) for ART adherence.

### LPA Results

LPA was conducted to identify distinct subgroups of participants based on their scores on the selected indicators (ie, experienced HIV stigma, internalized HIV stigma, food insecurity, and interpersonal support). Competing models with 2 and 3 latent classes were compared. The results suggest that model fit indexes favored the 2-class solution over the 3-class solution. Specifically, the 2-class model had the lowest values for the AIC (1408), BIC (1449), consistent AIC (1462), and sample size–adjusted BIC (1407), all indicating better fit. The 2-class model also exhibited higher entropy (0.93) compared with the 3-class model (0.82), suggesting more accurate classification of individuals into latent classes. Although the 3-class model had slightly better classification likelihood (classification likelihood criterion=1411 vs 1384 for the 2-class model), this was not sufficient to outweigh the superior overall fit of the 2-class solution. Taken together, these criteria support the 2-class model as the most parsimonious and best-fitting solution.

As shown in Figure 1, there were 2 latent classes that emerged. Class 1 (higher-risk profile; 75/167, 45.1%) was characterized by greater experienced HIV stigma (mean 1.97; SE 0.05), higher internalized HIV stigma (mean 2.66; SE 0.07), high food insecurity (mean 7.53; SE 0.20), and lower interpersonal support (mean 2.06; SE 0.04). In contrast, class 2 (lower-risk profile; 92/167, 54.9%) showed slightly lower experienced HIV stigma (mean 1.72; SE 0.04), lower internalized HIV stigma (mean 2.32; SE 0.05), much lower food insecurity (mean 0.82; SE 0.15), and slightly higher interpersonal support (mean 2.14; SE 0.04). All differences between classes were statistically significant ($P$<.001). These findings indicate 2 interpretable and distinct profiles of pregnant women living with HIV in Uganda, differing substantially in structural and psychosocial vulnerability.

**Figure 1.** Profile plot of latent classes.

### Linear Regression Analysis

A linear regression analysis was conducted to examine the association between latent profile membership (lower-risk profile vs higher-risk profile) and optimal ART adherence while adjusting for the covariates. Latent class membership emerged as a significant predictor of ART adherence. Specifically, compared with women living with HIV in the lower-risk profile (class 2), those in the higher-risk profile (class 1) reported significantly lower levels of optimal ART adherence ($B$=0.88; β=0.40, 95% CI 0.02-0.78; $t_{133}$=2.07; $P$=.04). These results suggest that latent profiles capturing structural and psychosocial vulnerabilities are meaningfully associated with ART adherence above and beyond key demographic and contextual factors.

## Discussion

### Principal Findings

This study aimed to identify psychosocial vulnerability profiles among pregnant women living with HIV in Uganda and examine their associations with ART adherence during pregnancy. Consistent with these objectives, we identified 2 empirically

XSL•FO
RenderX

distinct vulnerability profiles that differed significantly in levels of HIV stigma, food insecurity, and interpersonal social support and were significantly associated with ART adherence. Women living with HIV in the higher-risk profile, characterized by higher experienced and internalized HIV stigma, severe food insecurity, and lower interpersonal support, reported significantly lower ART adherence relative to their lower-risk counterparts. The converging of HIV stigma and food insecurity within the high-risk group suggests a pattern of intersecting stressors that may amplify psychological distress, impair medication adherence, and disrupt care engagement during the perinatal period.

These results align with syndemic theory, which posits that co-occurring adversities can interact synergistically to undermine health behaviors [39,40]. Unlike prior variable-centered studies, our LPA demonstrates how stigma, food insecurity, and social support co-occur to shape distinct vulnerability profiles. Our findings are consistent with those of prior Ugandan studies showing that stigma undermines ART adherence [51], food insecurity disrupts treatment consistency [52], and social support facilitates adherence [53]. Similar associations have been reported in neighboring countries, where stigma [54], food insecurity [55], and family support [56] have been identified as critical determinants of adherence. Our study extends this literature by highlighting how these factors co-occur within subgroups of pregnant women living with HIV, thereby highlighting heterogeneity in vulnerability that is obscured when determinants are examined individually. By situating our results within this evidence, we not only show alignment with prior work but also advance understanding by demonstrating the buffering role of interpersonal support, a dimension often overlooked in previous analyses. This person-centered perspective provides a more nuanced understanding of vulnerability among pregnant women living with HIV and complements prior studies that have examined these factors in isolation.

Our findings also underscore the need for interventions that address intersecting structural and psychosocial vulnerabilities identified in the higher-risk profile. Multicomponent approaches that respond to both material needs and social stressors are likely to be most effective in this context. In Uganda, the Friends for Life Circles peer group program combined peer mother mentoring, community ART distribution, and income-generating support, resulting in improved postpartum retention and engagement in care [57]. The program's design allowed peer mothers to provide psychosocial support and role modeling, whereas community-based ART delivery reduced barriers such as transport costs and clinic waiting times. The inclusion of income-generating activities further addressed underlying economic vulnerability, helping women sustain care engagement [57]. In Kenya, the Shamba Maisha [58,59] livelihood intervention provided small loans, farming tools, and agricultural and financial training to people living with HIV. Participants reported reduced internalized stigma and improved psychosocial well-being, attributed to increased economic productivity and a regained sense of social value [58,59]. By improving household food security and restoring participants' economic agency, the intervention not only strengthened material conditions but also enhanced social standing within the community [58,59].

Together, these examples highlight the role of economic empowerment in creating conditions that enable ART adherence and demonstrate the value of integrated, context-sensitive strategies that simultaneously address food insecurity, HIV stigma, and limited social support. Building on this evidence, future HIV interventions in Uganda should consider integrating community-based delivery models such as mentor mothers and community health workers with nutritional assistance. Potential strategies include food vouchers to meet immediate dietary needs and agricultural subsidies to support sustainable household food production, particularly in rural communities where subsistence farming is common. Conditional food support linked to engagement in antenatal HIV care may further help disrupt the cycle of poverty, stigma, and disengagement from care among pregnant women living with HIV.

Food insecurity may exacerbate stigma-related stress through multiple interacting pathways. Physiologically, taking ART without sufficient food intake has been linked to intensified side effects, which may undermine treatment adherence and persistence [60]. Psychologically, food insecurity contributes to depressive symptoms and reduced self-efficacy, particularly in rural Ugandan settings where poverty and HIV stigma are closely intertwined [25]. Interpersonally, social support serves a protective function by providing emotional reassurance and practical assistance, including help with medication adherence, clinic attendance, and disclosure [61]. Our findings align with these mechanisms: participants in the lower-risk latent profile reported higher levels of perceived support, suggesting that even modest increases in interpersonal support may buffer the adverse effects of structural and psychosocial stressors. This interpretation is further supported by meta-analytic evidence indicating that social support is a consistent facilitator of ART adherence among pregnant and breastfeeding women across SSA [62,63].

Although this study advances the HIV literature by applying a person-centered analytic approach during a critical perinatal period and integrating both structural and psychosocial determinants of ART adherence, several limitations should be noted. First, although the data were drawn from a longitudinal cohort, this analysis was cross-sectional. This limits causal inference, making it unclear whether stigma, food insecurity, and social support influence ART adherence or whether nonadherence may exacerbate these vulnerabilities. Future studies should use longitudinal or implementation science designs to clarify temporal and causal relationships. Second, ART adherence was assessed via self-report, which may be subject to recall and social desirability biases. Incorporating objective measures such as electronic dose monitoring or pharmacy refill records should strengthen adherence measurement in future research. Third, our analysis did not include other relevant determinants of adherence, such as depressive symptoms, intimate partner violence, or transportation barriers, which may further refine vulnerability profiles. Fourth, because the study sample was relatively small and recruited from rural health facilities, the findings may not be generalizable to urban populations or other regions.

XSL•FO
RenderX

Replication with larger and more diverse samples is warranted to strengthen external validity. Future research should also assess whether additional profiles emerge in larger and more diverse samples.

Although the data were collected in 2020, the structural and psychosocial challenges examined in this study, including HIV-related stigma, food insecurity, and limited social support, remain persistent barriers to ART adherence among pregnant women in Uganda and other high-burden settings. In addition, shifts in the global HIV funding landscape toward more constrained and efficiency-focused models heighten the importance of person-centered approaches that can identify and prioritize subgroups facing clustered vulnerabilities, thereby supporting more targeted and sustainable intervention strategies.

### Conclusions

This study highlights the need to urgently address intersecting psychosocial and structural challenges that compromise ART adherence among pregnant women living with HIV. Identifying latent vulnerability profiles offers a targeted framework for directing limited resources to those at greatest risk of disengagement. Intervention strategies should be grounded in the lived experiences of pregnant women living with HIV and must address overlapping adversities rather than treating risks in isolation. Integrated approaches that combine HIV stigma reduction, nutritional support, and strengthened social networks are essential for efforts to promote maternal health and prevent vertical HIV transmission. By demonstrating how these determinants cluster within identifiable subgroups, our findings underscore the value of person-centered methods for guiding intervention design. Addressing these vulnerabilities is essential not only for advancing Uganda's progress toward the 95-95-95 targets but also for informing global strategies to improve maternal and child health outcomes in high-burden settings.

## Abstract

**Background:** Despite policy-level progress, implementation of oral HIV preexposure prophylaxis (PrEP) remains limited in Latin America. In Peru, men who have sex with men (MSM) account for most new HIV diagnoses, yet uptake remains low. Widespread smartphone ownership and the use of digital platforms present an opportunity to expand access through mobile health (mHealth) interventions. However, limited data exist on user preferences to guide the design of mHealth tools in Spanish-speaking Latin American settings.

**Objective:** This study aimed to assess preferences for mHealth features to support PrEP engagement among Peruvian MSM and their association with PrEP cascade stages.

**Methods:** We conducted a cross-sectional online survey (June-August 2023) among 600 HIV-negative MSM residing in Peru (median age 29, IQR 24-35 years), recruited via Facebook, Instagram, WhatsApp (Meta Platforms, Inc), and Grindr (Grindr LLC). The survey assessed communication platform use, interest in mHealth features measured on a 4-point Likert scale, and PrEP cascade stages. Exploratory factor analysis (principal axis factoring with Promax rotation) identified domains of mHealth preferences, from which median domain scores were calculated. Bivariate analyses used chi-square tests and Wilcoxon rank sum tests. Multivariable logistic regression models (α=.05), with covariates selected using stepwise procedures from candidate sociodemographic and behavioral variables, estimated associations between each domain score and PrEP cascade stages, each modeled as a separate binary outcome.

**Results:** Nearly all participants (589/600, 98.2%) reported owning a smartphone. WhatsApp was the most frequently used and preferred platform for PrEP support, with 547 (91.2%) reporting frequent use and 302 (50.3%) ranking it first. Exploratory factor analysis identified three mHealth preference domains: informational support (Cronbach α=0.94), self-management tools (Cronbach α=0.94), and interactive communication (Cronbach α=0.91). Among participants, 483 (80.5%) had decided to use PrEP, 190 (31.7%) had sought PrEP, and 109 (18.2%) had initiated PrEP. Higher informational support was associated with the decision to use PrEP (adjusted odds ratio [aOR] 4.54, 95% CI 3.36 - 6.28; *P*<.001), seeking PrEP (aOR 1.43, 95% CI 1.10 - 1.89; *P*=.001), and PrEP initiation (aOR 1.64, 95% CI 1.16 - 2.44; *P*=.009). Self-management tools showed similar associations with the decision to use PrEP (aOR 3.23, 95% CI 2.51 - 4.22; *P*<.001), seeking PrEP (aOR 1.34, 95% CI 1.06 - 1.70; *P*=.02), and PrEP initiation (aOR 1.49, 95% CI 1.11 - 2.05; *P*=.01). Interactive communication was associated with the decision to use PrEP (aOR 2.74, 95% CI 2.15 - 3.53; *P*<.001) but not with initiation.

**Conclusions:** Preferences for mHealth features were associated with engagement at multiple stages of the PrEP cascade among MSM in Peru. Informational support features demonstrated the most consistent associations with cascade engagement. These findings provide empirical evidence on user-prioritized digital functions that could support early engagement in HIV prevention services in a Latin American implementation context. Integrating culturally tailored mHealth tools within widely used platforms such as WhatsApp may strengthen early PrEP cascade engagement and support scalable digital strategies for HIV prevention in Peru and similar settings.

## Introduction

Despite important gains in HIV prevention, HIV remains a pressing public health concern across Latin America, with a disproportionately high incidence among gay, bisexual, and other men who have sex with men (MSM), as well as transgender women [1]. In Peru, these populations account for the vast majority of new HIV diagnoses, reflecting persistent gaps in prevention services and structural inequities [2].

Oral preexposure prophylaxis (PrEP) is an evidence-based intervention to prevent HIV acquisition [3]. Although many Latin American countries have begun integrating PrEP into their public health policies, uptake remains limited and uneven [4]. In Peru, fewer than 8000 individuals were using PrEP among an estimated 140,000 who could benefit by 2025 [5]. Gaps along the PrEP cascade, including seeking, initiation, and adherence, underscore the need for scalable, user-centered approaches to support delivery.

Digital communication technologies are widely used among MSM in Latin America [6]. Social media, mobile apps, and geosocial networking platforms are common sources of both social connection and health information [7-9]. This widespread engagement presents opportunities to integrate digital solutions, such as mobile health (mHealth) apps, messaging platforms, social media–based tools, and AI-enabled chatbots, into HIV prevention efforts.

Globally, mHealth interventions have shown promise in promoting HIV testing, linkage to care, and engagement with HIV prevention services, including PrEP uptake and adherence [10-12]. Randomized trials of mHealth apps in the United States have demonstrated measurable effects on HIV testing and progression along the PrEP cascade. For example, HealthMindr-PrEP (Emory University) [13] increased PrEP uptake overall, particularly among individuals with baseline PrEP indications. In a national randomized trial among young sexual minority men, MyChoices (Keymind) [14] increased HIV testing compared with standard prevention services, whereas LYNX (APT Mobility) [14] showed a nonsignificant increase in testing; neither intervention significantly increased PrEP initiation. Other trials have focused on adherence and retention among individuals using PrEP. SMS text messaging–based interventions such as PrEPmate (WelTel Inc) [15] and iTAB (University of California San Diego) [16] improved visit retention and some adherence outcomes, while app-based tools such as the Amsterdam PrEP app (Amsterdam PrEP Project/H-TEAM) [17], PrEP-iT! (San Diego State University) [18], P3 (Florida State University) [19], and DOT Diary (AiCure LLC) [20] demonstrated signals of improved adherence. Messaging platforms have also been leveraged for adherence support, including reminder systems delivered through WeChat (Tencent Mobile International Limited) [21] and weekly text messaging interventions implemented in Brazil [22].

Additional approaches target service navigation and demand generation. Clinic-integrated platforms such as JomPrEP (JomPrEP study team) [23,24] enable HIV self-testing, teleconsultation, and rapid PrEP initiation through mobile interfaces, while digital peer-navigation tools such as PrEPresent (Florida State University) [25] support engagement with PrEP services. Decision-support tools such as MyPrEP (University of Washington) [26] have also been developed to help individuals assess HIV risk and evaluate whether PrEP is appropriate before clinical consultation, and have been associated with improved early PrEP persistence in a randomized trial. AI-enabled chatbot–based conversational agents are also emerging as digital prevention tools. For example, Amanda Selfie (PrEP1519 study team) [27], MYHIV365 (Yale University) [28,29], and CHIA (Brown University) [30] deliver automated HIV prevention information and counseling through interactive chat interfaces and have demonstrated usability and acceptability in early testing phases. Formative work further highlights the importance of culturally tailored design; SaludFindr (Emory University) [31] was developed to address barriers to PrEP uptake among Latino sexual minority men in the United States, and DOT Diary and PrEPmate have been adapted to support adherence among linguistically diverse populations [32]. Ongoing trials such as Combine [33] are also evaluating mobile interventions designed to increase HIV testing and PrEP initiation among underserved populations, including rural MSM in the southern United States.

While this body of work reflects substantial innovation, most evaluated interventions have been implemented in high-income settings, and evidence specific to Latin American health care systems remains limited, particularly for Spanish-speaking populations. Although Spanish is widely spoken in Latin America, communication norms, health system navigation pathways, and colloquial vocabulary vary across countries, potentially limiting the direct transferability of digital tools developed elsewhere [34]. Because these contextual factors may influence how digital interventions are understood and used, assessing user preferences is an important first step before developing or adapting existing mHealth tools for Peru and similar Latin American settings.

To address this gap, we conducted a survey among MSM in Peru to characterize communication technology use and assess preferences for mHealth features to support PrEP engagement. We examined whether interest in distinct domains of mHealth support was associated with engagement in three PrEP cascade stages: (1) decision to start PrEP; (2) actively seeking PrEP services; and (3) PrEP initiation. We hypothesized that greater interest in specific mHealth domains would be associated with a higher likelihood of having reached these stages. Because these stages represent distinct behavioral transitions, digital supports may operate differently at each stage. While grounded in the Peruvian context, these findings may inform the design of culturally responsive, user-centered interventions to improve

XSL•FO
RenderX

PrEP engagement across Latin America, with appropriate adaptations for local settings.

## Methods

### Study Design

We conducted a cross-sectional online survey between June 16 and August 31, 2023, to explore the use of communication technologies and preferences for mHealth features to support HIV prevention among Peruvian MSM. The study followed the Journal Article Reporting Standards for quantitative research [35].

### Participant Selection

Respondents were recruited using convenience, nonprobability sampling through paid advertisements on Instagram, Facebook, Grindr, and via unpaid standard posts ("organic content") shared on social media and WhatsApp groups managed by participating HIV and AIDS service organizations. Recruitment materials targeted MSM aged 18 years and older residing in Peru.

Participants accessed the survey through a secure link and completed it using their own internet-connected electronic devices; no data subsidies were provided. The survey platform required an active internet connection; offline completion was not supported. Electronic informed consent was required before initiating the survey. The survey instrument was administered in Spanish using standard Peruvian terminology reviewed for clarity and cultural appropriateness. Responses were anonymous, and participants were allowed to skip any question they did not wish to answer.

To ensure data integrity, responses were restricted to one submission per IP address, and IP addresses, timestamps, and completion times were reviewed to identify duplicate, automated, or implausibly rapid entries; none were identified.

### Measures and Covariates

#### *Survey Design*

The 34-item survey included multiple-choice and Likert-scale questions covering sociodemographic and behavioral characteristics, achieved stages in the HIV prevention cascade (refer to Variable Definitions for operational definitions) [36,37], smartphone and internet access, frequency of use of communication channels (eg, phone calls, SMS text messaging, WhatsApp, social media, and internet browsing), and preferences for features of mHealth tools designed to support PrEP use.

#### *mHealth Feature Preferences*

To assess preferences for mHealth tools to support PrEP use, participants were presented with a series of 11 potential features and asked to rate their level of interest in each. The stem question read, "How interested would you be in receiving the following types of PrEP-related support through your mobile phone?" Responses were collected on a 4-point Likert scale, ranging from "Not interested" to "Very interested." The list of features was developed based on existing literature and used human-centered design by refining items through input from community partners to ensure local relevance and clarity [15,20,26,32].

The features covered both informational and behavioral support functions. Informational items included general PrEP education (eg, what PrEP is, how it works, and how to take it), more detailed information (eg, whether someone is a good candidate, side effects, and steps to start) [26], and logistical details (eg, where PrEP is offered, clinic hours, frequency of visits, and cost). Behavioral support features included reminders for PrEP appointments and pill-taking, interactive communication through a virtual assistant or a real person [15], and several app-based tools: push notifications to take PrEP, a daily pill tracker, a sexual activity log, and a feature that assesses whether the user is currently protected from HIV based on their reported pill use and sexual behavior [20].

#### *Exploratory Factor Analysis*

To identify latent constructs representing participant preferences for mHealth features, we conducted an exploratory factor analysis (EFA) on 11 items assessing interest in different functionalities of hypothetical mHealth PrEP support tools [38,39]. Before the EFA, data suitability was evaluated using the Kaiser-Meyer-Olkin measure of sampling adequacy and Bartlett test of sphericity. We used principal axis factoring with Promax (oblique) rotation, given the expected correlation among features. The number of factors retained was based on eigenvalues >1.0, scree plot inspection, parallel analysis, and conceptual clarity. Resulting factors were used to generate composite scores that represented core domains of mHealth tool interest, which were then used in regression analyses.

#### *Variable Definitions*

##### Preferred Communication Channel Category

The preferred communication channel category for PrEP support was defined according to the participant's most preferred platform for receiving PrEP-related communication. "Traditional channels" referred to phone calls or SMS text messaging, which do not require smartphone-specific apps. "Digital channels" included WhatsApp, a customized PrEP app, or other messaging or social media platforms such as Telegram (Telegram FZ-LLC), Messenger and Instagram (Meta Platforms, Inc), or TikTok (ByteDance Ltd), all of which require a smartphone and an internet connection.

##### PrEP Cascade Outcomes

PrEP cascade outcomes reflected 3 distinct stages of engagement in the HIV prevention cascade [36,37], selected for their proximity to PrEP uptake and their potential to be directly influenced by mHealth interventions. The decision to use PrEP was defined as responding "Yes" or "Probably yes" to the question "Have you decided to start using PrEP?" Sought PrEP referred to self-reported attempts to obtain PrEP from a clinic or provider. PrEP initiation was defined as having ever started PrEP, including both current and past use.

##### Sociodemographic and Behavioral Covariates

Sociodemographic covariates included age (<25 years vs ≥25 years; based on regional PrEP implementation evidence showing lower engagement among younger individuals [40]), educational

XSL•FO
RenderX

level (elementary and secondary vs post-secondary), monthly income (<1000 Peruvian soles [PEN; 1000 PEN=US $268 as of August 15, 2023], equivalent to the minimum monthly wage at the time of the study [41], vs ≥1000 PEN), and city of residence (Metropolitan Lima vs other cities). Behavioral variables referred to the past 6 months and included self-perceived HIV risk (yes or no), engagement in anal sex (yes or no), number of anal sex partners (≤5 vs>5), condom use (always vs not always), transactional sex (yes or no), and recent bacterial sexually transmitted infection (STI) diagnosis (chlamydia, gonorrhea, or syphilis; yes or no).

### Statistical Analysis

#### *Analytic Sample Determination*

The analytic sample included participants who completed all exposure and outcome measures. Respondents who reported being assigned female at birth, identified as a gender other than cisgender male, or self-reported living with HIV were excluded from the analytic sample. No missing data were observed among the 600 participants included in the analysis; therefore, complete-case analysis was performed.

#### *Descriptive Statistics*

We summarized participant characteristics using frequencies and percentages for categorical variables and medians with IQRs for continuous variables given nonnormal distributions. Group comparisons used 2-tailed chi-square tests or Fisher exact tests when expected cell counts were <5. Continuous variables were compared using Wilcoxon rank sum tests. To compare preferences across digital communication platforms, we used pairwise 2-tailed Wilcoxon signed-rank tests on participant rankings, applying Bonferroni correction for multiple comparisons. Statistical significance was defined as $\alpha$=0.05.

#### *Logistic Regression Analyses*

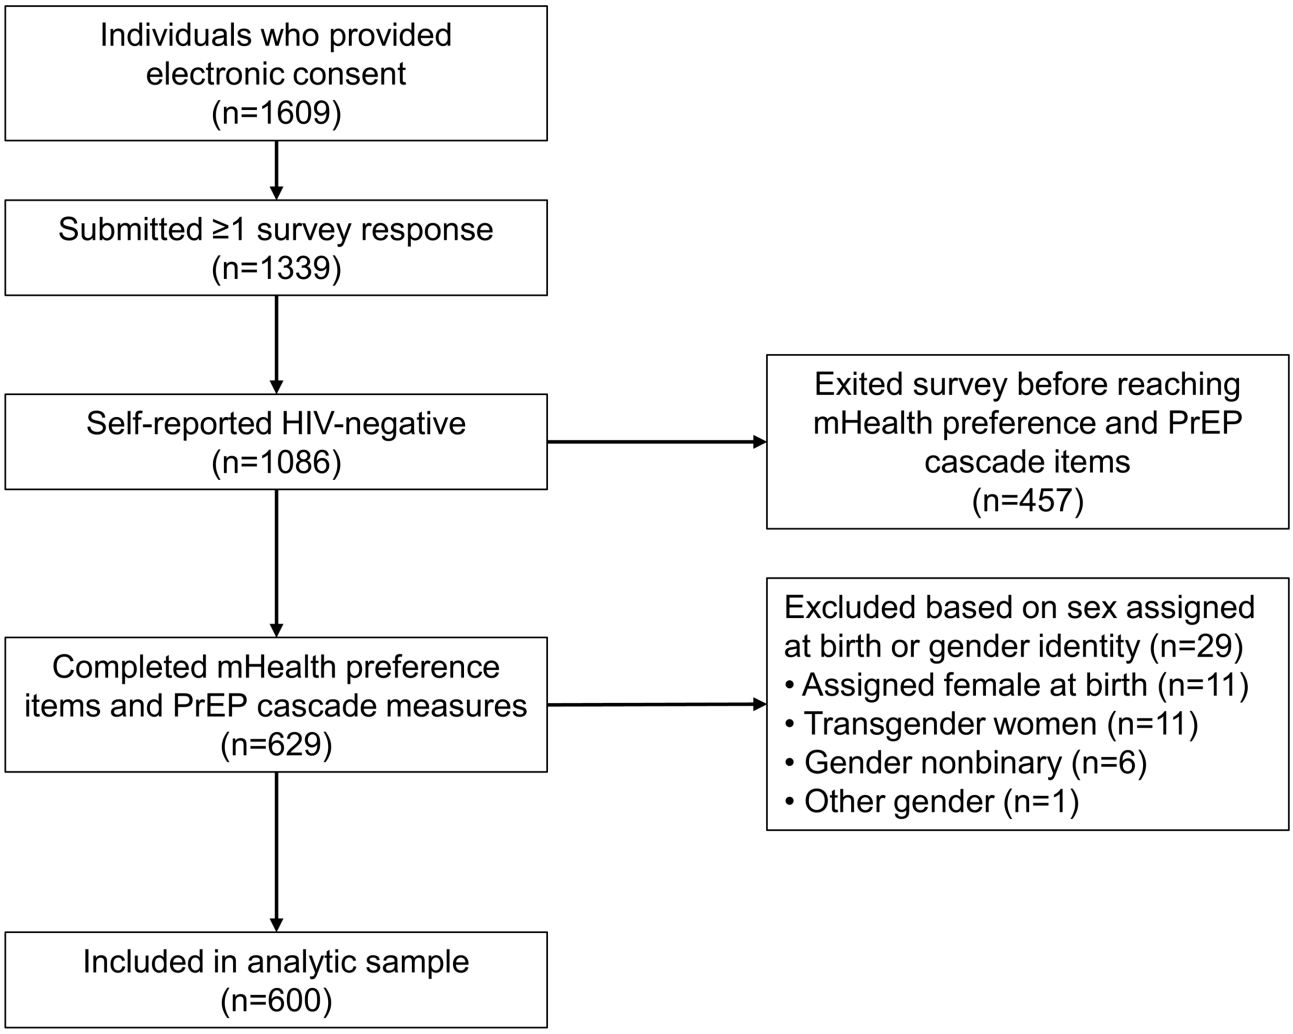
We conducted bivariate and multivariable logistic regression analyses with a logit link to examine associations between interest in mHealth tool features and engagement at 3 distinct stages of the HIV prevention cascade. Interest in mHealth features was operationalized using median composite scores derived from EFA. Each PrEP cascade outcome was modeled independently to reflect conceptually distinct dimensions of PrEP engagement with potentially different determinants. Because the cascade stages were assessed cross-sectionally and were not strictly sequential in all participants, we modeled each stage as a separate binary outcome rather than imposing hierarchical or conditional restrictions that would reduce sample size and could introduce selection bias. This approach allowed us to estimate associations with having reached each cascade stage without assuming temporal ordering or monotonic progression across stages.

For each outcome, stepwise selection based on the lowest Akaike Information Criterion was first applied to sociodemographic and behavioral variables to identify relevant covariates independently for each PrEP cascade stage. Akaike Information Criterion was used to balance model fit and parsimony while reducing the risk of overfitting. Variance inflation factors were examined to assess multicollinearity, with all retained covariates having variance inflation factor <2. The selected variables were then used to adjust separate multivariable logistic regression models for each mHealth composite factor score. Results are presented as odds ratios and adjusted odds ratios (aORs), with 95% CI. As a sensitivity analysis, multinomial logistic regression models were fitted, treating each cascade stage as a categorical outcome to assess whether associations observed in stage-specific models were consistent when modeled jointly. All analyses were conducted using R version 4.3.1 (R Foundation for Statistical Computing).

### Ethical Considerations

The informed consent form and survey instrument (Multimedia Appendix 1) were reviewed and approved in Spanish by the Comité Institucional de Bioética de Vía Libre (approval 9008 - 2023 a). Electronic informed consent was obtained before survey access, and a waiver of documentation of written informed consent was issued to preserve participant anonymity. Participants indicated consent by selecting “I agree” before accessing survey items. The consent form clearly stated that the survey was intended for adult MSM living in Peru, and self-identification was confirmed upon accepting the consent. No personally identifying information was collected, and IP addresses were used solely for duplicate detection. All data were stored on secure, password-protected servers accessible only to the research team. Participation was voluntary, and respondents could skip any question or exit the survey at any time without penalty. No financial compensation was provided. Upon completion, participants received information on HIV prevention services and resources. No identifiable images or personal data are included in this paper.

## Results



### Participant Flow

Of the 1609 individuals who provided informed consent, 1339 submitted at least one survey response. Among these, 1086 self-reported being HIV-negative and were retained for further screening. A total of 457 respondents were excluded because they did not complete the required exposure or outcome items due to survey dropout before reaching those sections. Compared to those with incomplete surveys, respondents who completed the full survey were older (median 29.0, IQR 24.0 - 35.0 years vs median 27, IQR 21.0 - 33.0 years; *P*<.001), more likely to reside in Metropolitan Lima (473/629, 75.2% vs 262/457, 57.3%; *P*<.001), have postsecondary education (494/629, 78.5% vs 328/457, 71.8%; *P*=.01), report higher perceived HIV risk (455/629, 72.3% vs 263/457, 60.9%; *P*=.001), and report more than 5 anal sex partners in the past 6 months (177/629, 35.3% vs 69/457, 25%; *P*=.005). There were no significant differences in sex, gender identity, income, or behavioral characteristics. We further excluded 29 respondents who did not identify as cisgender men, resulting in a final analytic sample of 600 HIV-negative MSM who completed the survey. Participant flow is summarized in Figure 1.

XSL•FO
RenderX

**Figure 1.** Participant flow diagram for a cross-sectional online survey assessing communication technology use and preferences for mobile health (mHealth) features to support HIV preexposure prophylaxis (PrEP) engagement among HIV-negative men who have sex with men in Peru (June 16-August 31, 2023).

## Participant Characteristics

Participants were primarily recruited through organic content on social media and WhatsApp groups (305/600, 50.8%), followed by paid advertisements on Instagram or Facebook (216/600, 36%) and on Grindr (79/600, 13.2%) (Table S1 in Multimedia Appendix 2). The median age in the final analytic sample was 29 (IQR 24 - 35) years, with 152 (25.3%) aged <25 years. Most participants had completed postsecondary education (479/600, 79.8%), and 403 (67.2%) reported a monthly income exceeding 1000 PEN. A total of 450 (75%) resided in Metropolitan Lima. In the past 6 months, 476 (79.3%) engaged in anal sex, 354 (59%) reported condomless sex, and 168 (28%) reported a recent bacterial STI diagnosis. Additionally, 95 (15.8%) engaged in transactional sex, and 440 (73.3%) perceived themselves to be at risk for HIV.

Engagement along the PrEP cascade varied. While 518 (86.3%) participants expressed interest in using PrEP and 483 (80.5%) had made the decision to use it, fewer had taken steps to access it. A total of 190 (31.7%) had sought PrEP, 109 (18.2%) had initiated it, and only 43 (7.2%) were currently using PrEP with self-reported good adherence.

## Communication Behaviors

Smartphone ownership was nearly universal (589/600, 98.2%). Participants reported frequent use of multiple digital platforms, with WhatsApp emerging as the most widely used platform; 547 (91.2%) participants reported using it multiple times per day or throughout the day. Frequent use of internet browsers (498/600, 83%) and social media (405/600, 67.5%) was also common. Phone calls remained widely used, with 432 (72%) participants reporting several calls per day or all-day use. In contrast, SMS text messaging was less popular, with only 193 (32.2%) participants reporting similarly frequent use (Figure S1 in Multimedia Appendix 2).

## Preferred Channels for PrEP Support

Participants expressed a strong preference for receiving PrEP-related support through digital channels. As shown in Figure 2, WhatsApp was the most preferred platform, with 302 (50.3%) participants ranking it as their top choice (Figure S2 in Multimedia Appendix 2). This preference was statistically stronger than for any other channel (all adjusted $P<.001$). Preferences across the remaining platforms also differed significantly in nearly all pairwise comparisons. The only exceptions were the comparisons between the customized PrEP

XSL•FO
RenderX

app and SMS text messaging (adjusted *P*=.24), and between other chat apps and phone calls (adjusted *P*=.07). When platforms were categorized as digital vs traditional, 450 (75%) participants selected digital channels (WhatsApp, other chat platforms, or a customized PrEP app) as their most preferred platform for receiving PrEP support, while only 150 (25%) participants ranked traditional channels (SMS text messaging or phone calls) as their top choice.

**Figure 2.** Mean rank scores of preferred communication channels for receiving HIV preexposure prophylaxis–related support among HIV-negative men who have sex with men in Peru (cross-sectional online survey, June 16-August 31, 2023; N=600). Lower mean rank scores indicate greater preference for each communication channel. mHealth: mobile health; PrEP: preexposure prophylaxis.

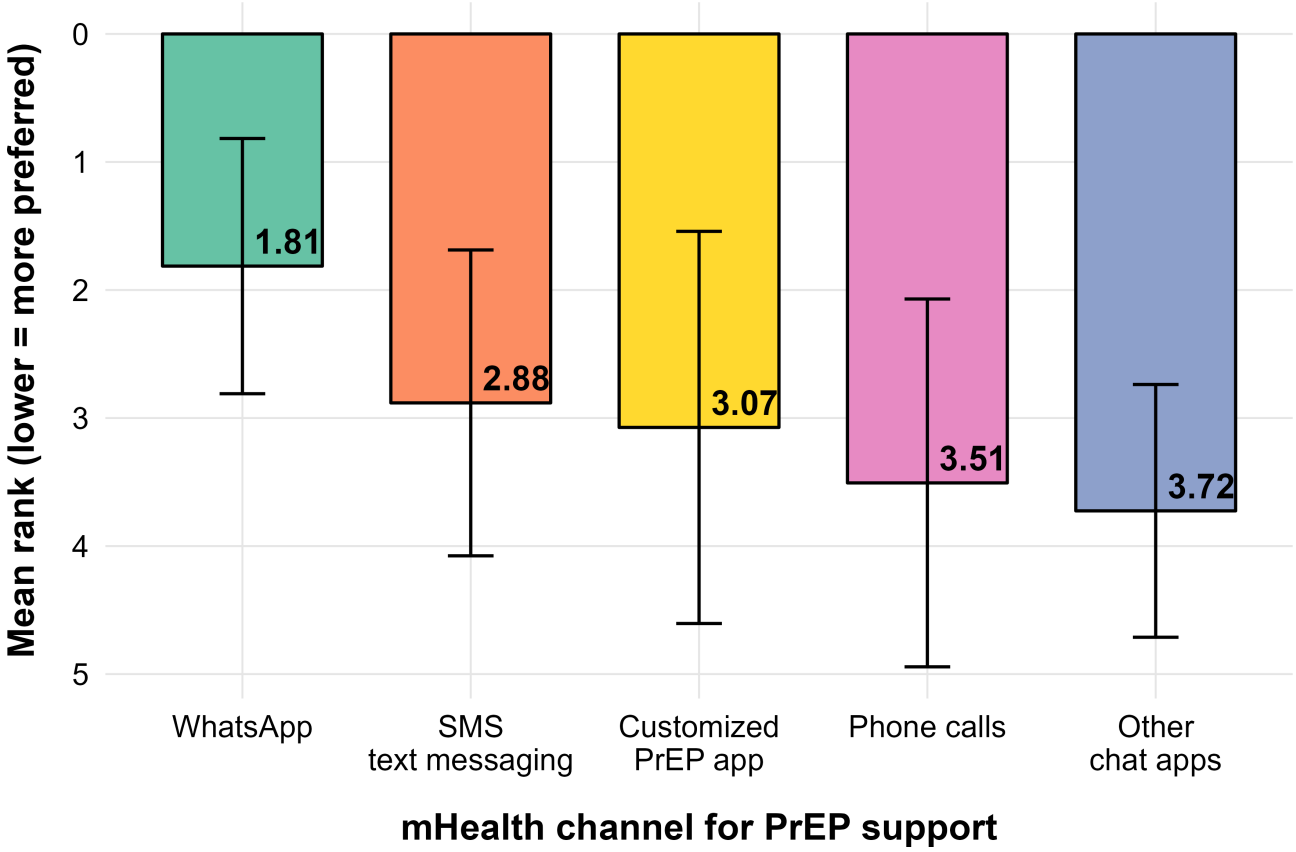


Table 1 provides sociodemographic and behavioral characteristics by preferred communication channel category for PrEP support. Compared to participants who preferred traditional channels, those who preferred digital channels were more likely to reside in Metropolitan Lima (352/450, 78.2% vs 98/150, 65.3%; *P*=.002) and to report having more than 5 anal sex partners in the past 6 months (137/450, 30.4% vs 32/150, 21.3%; *P*=.03). Participants preferring digital channels were also significantly more likely to own a smartphone (448/450, 99.6% vs 141/150, 94.0%; *P*<.001). Other characteristics, including age, income, education level, recruitment method, perceived HIV risk, STI history, and condom use, did not differ significantly between groups.

XSL•FO
RenderX

[a]mHealth: mobile health

[b]PrEP: preexposure prophylaxis.

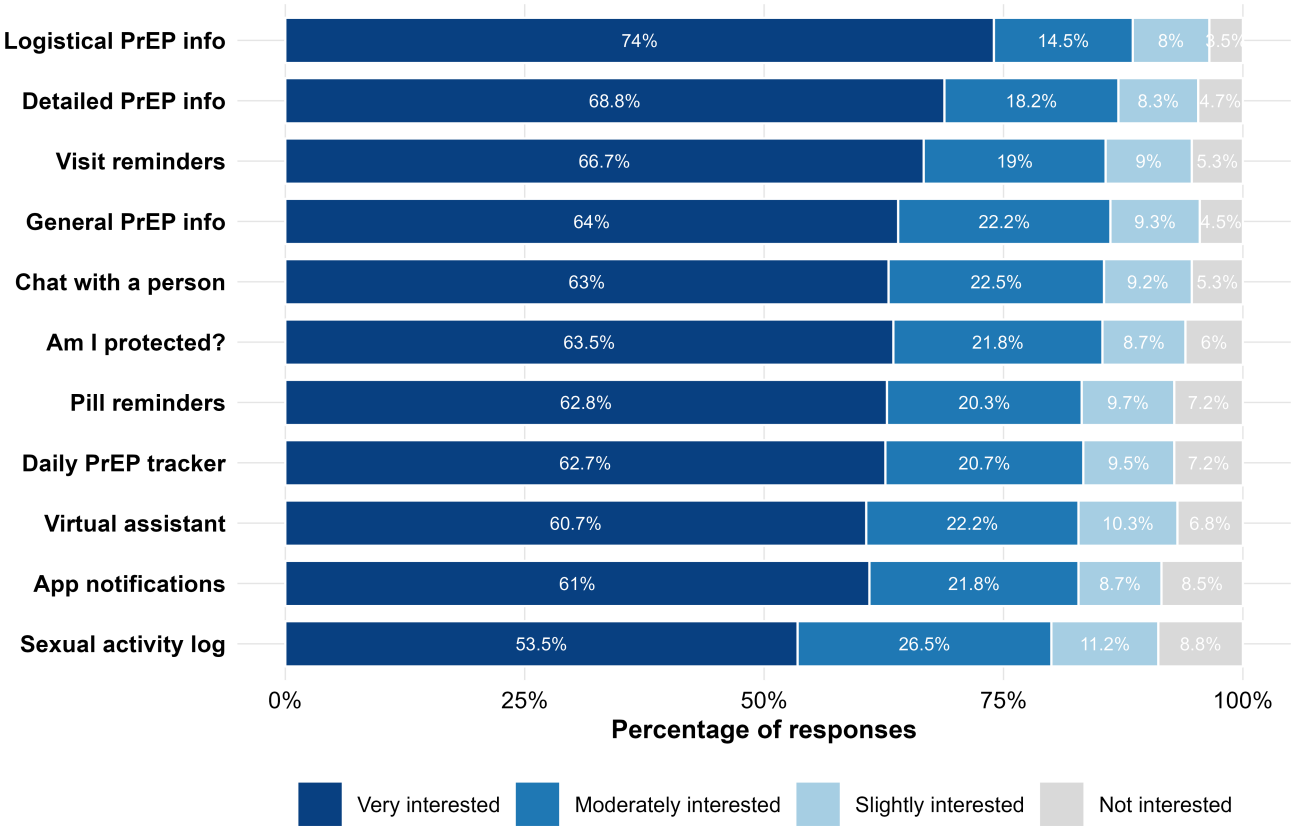
[c]Includes phone calls and SMS text messaging.

[d]Includes WhatsApp, a customized PrEP app, and other messaging platforms (eg, Telegram, Messenger, Instagram, TikTok).

[e]*P* values correspond to chi-square tests, except where expected cell counts were <5, in which case Fisher exact test was used.

[f]PEN: Peruvian soles (1000 PEN approximately US $268 as of August 15, 2023).

[g]Organic content refers to standard posts shared via the participating HIV and AIDS service organizations' social media accounts and WhatsApp groups for study recruitment, without paid promotion.



[h]Behavioral variables refer to the past 6 months.

[i]STI: sexually transmitted infection (chlamydia, gonorrhea, or syphilis).

## Preferences for mHealth Tool Features for PrEP Support

Overall, interest was high across mHealth features for PrEP support (Figure 3 and Figures S4 and S5 in Multimedia Appendix 2). The most frequently endorsed feature was logistical information, such as the locations where PrEP is offered, clinic hours, frequency of visits, and cost, with 444 (74%) reporting they were "very interested." This was followed by detailed PrEP information, including whether someone is a good candidate, possible side effects, and the steps required to initiate PrEP (413/600, 68.8%), appointment reminders (400/600, 66.7%), and general PrEP information, such as what PrEP is, how it works, and how to take it (384/600, 64%). Features such as chatting with a person (378/600, 63%), pill reminders (377/600, 62.8%), a daily PrEP tracker (376/600, 62.7%), and a virtual assistant (364/600, 60.7%) also generated strong interest. App notifications (366/600, 61%) and the "Am I protected?" feature (381/600, 63.5%) were similarly well rated. The sexual activity log received the lowest endorsement, though over half of participants (321/600, 53.5%) still indicated they were "very interested."

**Figure 3.** Distribution of participant-reported interest in specific mobile health features to support HIV preexposure prophylaxis use among HIV-negative men who have sex with men in Peru (cross-sectional online survey, June 16-August 31, 2023; N=600). Bars represent the proportion of respondents selecting each Likert-scale category (not interested, slightly interested, moderately interested, and very interested), and segments sum to 100% per feature. PrEP: preexposure prophylaxis.

## EFA of mHealth Tool Features for PrEP Support

The Kaiser-Meyer-Olkin measure indicated excellent sampling adequacy (0.93), and the Bartlett test of sphericity was significant ($\chi^2_{55}$=7582.29; *P*<.001), supporting the suitability of the data for factor analysis. The EFA of the 11 items yielded a 3-factor solution explaining 81% of total variance and demonstrating high internal consistency for each factor (Table 2). The three domains were interpreted as:

1. Informational support (Cronbach α=0.94) included features providing educational content and logistical guidance related to PrEP. This factor encompassed general PrEP

XSL•FO
RenderX

information, more detailed content about candidacy and side effects, logistical details such as service locations and costs, and visit reminders.

2. Self-management tools (Cronbach α=0.94) captured interest in tools for daily adherence and self-monitoring. It included pill reminders, app notifications, a daily PrEP tracker, a sexual activity log, and the "Am I protected?" feature.
3. Interactive communication (Cronbach α=0.91) reflected a preference for real-time, 2-way support, whether through chatting with a person or a virtual assistant.

**Table .** Exploratory factor analysis[a] of participant-reported interest in mHealth[b] features to support HIV PrEP[c] use among HIV-negative men who have sex with men in Peru (cross-sectional online survey, June 16-August 31, 2023; N=600).

| Items | Self-management tools (Cronbach α=0.94), factor loadings | Informational support (Cronbach α=0.94), factor loadings | Interactive communication (Cronbach α=0.91), factor loadings |
|---|---|---|---|
| General information about PrEP (eg, how it works, who it is intended for) | —[d] | 0.80 | — |
| Detailed medical information about PrEP (eg, side effects, lab tests, and dosing) | — | 0.95 | — |
| Logistical information on where and how to get PrEP (eg, nearby clinics, schedules, and costs) | — | 0.90 | — |
| Reminders for upcoming clinic appointments | — | 0.63 | — |
| Daily pill-taking reminders or dosing alerts | 0.51 | — | — |
| Push notifications from the app with updates or support | 0.94 | — | — |
| Daily tracker to monitor PrEP use | 0.92 | — | — |
| Log to record recent sexual activity (number of partners, condom use, etc) | 0.74 | — | — |
| Feature estimating HIV protection based on reported pill use and sexual activity | 0.65 | — | — |
| Virtual assistant (chatbot) providing automatic responses | — | — | 0.54 |
| Option to chat with a real person for support or questions | — | — | 0.96 |

[a]Principal axis factoring with Promax (oblique) rotation. All retained factors had eigenvalues >1.0 and were supported by scree plot and parallel analysis. No substantial cross-loadings (>0.40 on more than one factor) were observed.

[b]mHealth: mobile health.

[c]PrEP: preexposure prophylaxis.

[d]Factor loadings <0.40 are not displayed for clarity.

Median scores were skewed toward the upper end of the scale, reflecting generally high levels of interest across all mHealth domains, with scores of 4.00 (IQR 3.00 - 4.00) for informational support and interactive communication, and 3.80 (IQR 3.00 - 4.00) for self-management tools. Even among participants who were unsure or not interested in PrEP at the time of the survey, interest in mHealth tools remained moderate to high, with median scores of 3.00 (IQR 2.00 - 3.50) for informational support, 2.70 (IQR 1.80 - 3.60) for self-management tools, and 3.00 (IQR 2.00 - 4.00) for interactive communication. As expected, interest was significantly higher among those who were currently interested in using PrEP, with median scores of 4.00 (IQR 3.50 - 4.00), 3.80 (IQR 3.00 - 4.00), and 4.00 (IQR 3.00 - 4.00) across the respective domains (all *P*<.001).

## Association Between Interest in mHealth Tool Features for PrEP Support and PrEP Cascade Stages

### *Decided to Use PrEP*

Participants who had decided to use PrEP (483/600, 80.5%) were more likely than those who were unsure or had not decided (117/600, 19.5%) to reside in Metropolitan Lima (375/483, 77.6% vs 75/117, 64.1%; *P*=.002), perceive themselves at risk for HIV (382/483, 79.1% vs 58/117, 49.6%; *P*<.001), report anal sex in the past 6 months (392/483, 81.2% vs 84/117, 71.8%; *P*=.03), and have more than 5 anal sex partners (148/483, 30.6% vs 21/117, 17.9%; *P*=.006). In adjusted analyses, greater interest in informational support (aOR 4.54, 95% CI 3.36 - 6.28; *P*<.001), self-management tools (aOR 3.23, 95% CI 2.51 - 4.22; *P*<.001), and interactive communication (aOR 2.74, 95% CI

XSL•FO
RenderX

2.15 - 3.53; *P*<.001) was associated with higher odds of having decided to use PrEP. Full results are provided in Table 3.

**Table .** Associations between interest in mHealth[a] feature domains and decision to use HIV PrEP[b] among HIV-negative men who have sex with men in Peru (cross-sectional online survey, June 16-August 31, 2023; N=600).

| Characteristics | Decided to use PrEP[c] | | Bivariate | Multivariable[d] |
|---|---|---|---|---|
| | Exposed, n/N (%) | Reference, n/N (%) | OR[e] (95% CI) | aOR[f] (95% CI) |
| Age ≥25 years | 366/448 (81.7) | 117/152 (77.0) | 1.34 (0.85 - 2.07) | —[g] |
| Postsecondary education | 389/479 (81.2) | 94/121 (77.7) | 1.24 (0.75 - 2.00) | — |

### *Sought PrEP*

Participants who had sought PrEP (190/600, 31.7%) were more likely than those who had not (410/600, 68.3%) to be aged 25 years or older (158/190, 83.2% vs 290/410, 70.7%; *P*=.001), have postsecondary education (161/190, 84.7% vs 318/410, 77.6%; *P*=.04), reside in Metropolitan Lima (161/190, 84.7% vs 289/410, 70.5%; *P*<.001), report condomless sex (124/190, 65.3% vs 230/410, 56.1%; *P*=.03), have more than 5 anal sex partners (72/190, 37.9% vs 97/410, 23.7%; *P*<.001), engage in transactional sex (41/190, 21.6% vs 54/410, 13.2%; *P*=.009), and report a recent STI diagnosis (68/190, 35.8% vs 100/410,

XSL•FO
RenderX

24.4%; *P*=.004). In adjusted analyses, higher interest in informational support (aOR 1.43, 95% CI 1.10 - 1.89; *P*=.001) and self-management tools (aOR 1.34, 95% CI 1.06 - 1.70; *P*=.02) was associated with having sought PrEP, whereas the association with interactive communication was marginal (aOR 1.25, 95% CI 1.00 - 1.57; *P*=.053). Full results are provided in Table 4.

### *Multinomial Sensitivity Analyses*

As a sensitivity analysis, we fit multinomial logistic regression models treating PrEP cascade stage as a 4-level categorical outcome (not decided, decided only, sought PrEP, and initiated PrEP), using "not decided" as the reference category. The distribution of cascade stages was as follows: not decided (101/600, 16.8%), decided only (285/600, 47.5%), sought PrEP only (105/600, 17.5%), and initiated PrEP (109/600, 18.2%). Associations were broadly consistent with the stage-specific logistic regression models (Table 6).

**Table .** Multinomial analysis[a] of associations between interest in mHealth[b] feature domains and engagement across stages of the HIV PrEP[c] cascade among HIV-negative men who have sex with men in Peru (cross-sectional online survey, June 16-August 31, 2023; N=600).

| Multinomial analysis | Decided only vs not decided, aRRR[d] (95% CI) | Sought PrEP vs not decided, aRRR (95% CI) | Initiated PrEP vs not decided, aRRR (95% CI) |
|---|---|---|---|
| PrEP cascade stage vs not decided (each mHealth domain entered separately) | | | |
| Score: informational support[e] | 4.18 (2.97 - 5.87)[f] | 3.02 (2.04 - 4.49)[f] | 4.18 (2.65 - 6.57)[f] |
| Score: self-management tools[e] | 3.25 (2.42 - 4.35)[f] | 2.57 (1.82 - 3.64)[f] | 3.31 (2.27 - 4.83)[f] |
| Score: interactive support[e] | 2.93 (2.20 - 3.89)[f] | 2.26 (1.62 - 3.17)[f] | 2.45 (1.74 - 3.44)[f] |
| All mHealth scores in one model (mutually adjusted) | | | |
| Score: informational support[e] | 2.99 (1.67 - 5.34)[f] | 2.44 (1.22 - 4.89)[g] | 3.37 (1.58 - 7.19)[h] |
| Score: self-management tools[e] | 1.49 (0.84 - 2.64) | 1.50 (0.76 - 2.95) | 2.03 (0.99 - 4.16) |
| Score: interactive support[e] | 0.98 (0.57 - 1.70) | 0.85 (0.45 - 1.60) | 0.63 (0.33 - 1.20) |

[a]Multinomial models were adjusted for prespecified sociodemographic and behavioral covariates (age category, income, education, location, perceived HIV risk, number of anal sex partners, recent STI diagnosis, and transactional sex) included simultaneously in all models. Models in the upper panel include each mHealth domain score entered separately. Models in the lower panel include all three mHealth domain scores simultaneously (mutually adjusted).

[b]mHealth: mobile health.

[c]PrEP: preexposure prophylaxis.

[d]aRRR: adjusted relative risk ratio.

[e]mHealth domain scores were derived from exploratory factor analysis using principal axis factoring with Promax rotation and entered as continuous variables in regression models.

[f]$P<.001$.

[g]$P<.05$.

[h]$P<.01$.

In models including each mHealth domain separately, higher scores were strongly associated with engagement in more advanced cascade stages compared with not having decided to use PrEP. For example, for each 1-unit increase in the informational support score, the relative risk of being in the decided-only, sought, and initiated stages was approximately 3- to 4-fold higher compared with the not-decided stage, with similar magnitudes observed for the self-management tools and interactive support scores. When all 3 domain scores were included simultaneously, the informational support score remained independently associated with more advanced cascade stages relative to the not-decided stage, whereas associations for the self-management tools and interactive support scores were attenuated, suggesting shared variance across domains. When cascade stages were rereferenced to examine adjacent contrasts, domain scores were strongly associated with the contrast between decided-only and not decided but were not significantly associated with transitions from decided-only to sought PrEP or from sought PrEP to initiated PrEP.

## Discussion

### Principal Findings

In this cross-sectional survey of HIV-negative MSM in Peru, we found near-universal smartphone ownership and a strong preference for digital communication platforms, particularly WhatsApp, for receiving PrEP-related support. Interest in informational support, self-management tools, and interactive communication features was high overall. Greater interest in these mHealth domains was associated with engagement across the PrEP cascade. Informational support and self-management features demonstrated consistent associations with all 3 stages, whereas interactive communication features were associated only with the decision stage. Associations were strongest for the decision stage and more modest for later stages. Sensitivity analyses using multinomial models showed similar overall patterns.

These findings are consistent with prior evidence suggesting that mHealth interventions can support engagement with HIV prevention services. A recent meta-analysis of randomized controlled trials reported that digital interventions improve HIV testing and PrEP adherence and show emerging effects on PrEP

XSL•FO
RenderX

uptake [42]. Similarly, a systematic review among MSM concluded that digital tools are generally feasible and acceptable and may support engagement across the PrEP continuum when culturally tailored and user-centered [43]. Together, this body of evidence underscores the potential role of mHealth as an entry point into prevention services that can be integrated with offline initiation and follow-up within differentiated service delivery models [24,44]. Our findings extend this literature by identifying which types of digital support may be most salient at different stages of PrEP engagement. In particular, the stage-specific associations observed in our analyses provide insight into when digital supports may be most useful within the PrEP cascade.

The stronger associations at the decision stage, compared with the more modest associations at later stages, suggest that digital features may be particularly salient during early phases of PrEP engagement. At these stages, individuals may be evaluating their HIV risk, learning about prevention options, and determining whether and how to access services. Digital tools delivered through widely used communication platforms could therefore help translate risk awareness into concrete prevention decisions by providing accessible information about eligibility, service availability, and pathways to PrEP initiation. In contrast, progression through later cascade stages, such as seeking services and initiating PrEP, may depend more heavily on structural and health system factors, including service accessibility, appointment availability, and provider interactions.

Informational support demonstrated the strongest and most consistent associations across the PrEP cascade stages examined in this study, underscoring the continued importance of accurate, accessible, and actionable information about PrEP. Features that clarify where and how to obtain PrEP, including service locations, clinic hours, costs, and eligibility criteria, may be particularly relevant in contexts where program expansion is ongoing. Despite expansion of PrEP services in Peru, uncertainty about access pathways may persist. Digital informational tools may help address these barriers by centralizing prevention information and simplifying service navigation. For example, decision-support and navigation platforms such as MyPrEP [26], SaludFindr [31], and PrEPresent [25] have been designed to help users assess PrEP eligibility, locate services, and connect with prevention programs. Clinic-integrated platforms such as JomPrEP [23,24] extend these functions by combining informational resources with service navigation features, including HIV self-testing support, teleconsultation, and streamlined pathways for PrEP initiation, within a mobile interface. In the Peruvian context, similar tools could be adapted to incorporate location-specific service directories, appointment scheduling, and referral pathways. Emerging approaches, including the integration of generative artificial intelligence to dynamically update service directories, eligibility guidance, and prevention information, may further enhance scalability and timeliness of such tools [45-47], although their effectiveness in real-world PrEP delivery settings warrants evaluation.

Likewise, self-management tools including pill reminders, adherence trackers, protection status calculators, and sexual activity logs were also associated with greater engagement across the PrEP cascade, suggesting that users value tools that support adherence, routine formation, and ongoing self-monitoring. These functionalities are designed to support adherence and ongoing engagement after initiation, and evidence from mobile interventions in other settings suggests they can be feasible and acceptable to users. For example, tools such as PrEPmate [15], iTAB [16], the Amsterdam PrEP app [17], PrEP-iT! [18], P3 [19], and DOT Diary [20] incorporate adherence reminders, monitoring systems, or behavioral feedback features and have demonstrated high usability and feasibility, with some studies reporting improvements in PrEP adherence. In the Peruvian context, similar tools could be adapted with appropriate cultural and linguistic tailoring. Core features such as reminders and simplified adherence tracking could also be integrated into widely used messaging platforms. Emerging digital approaches may facilitate scalable adaptation; however, their effectiveness and implementation feasibility should be evaluated within local health system contexts.

By contrast, interactive communication features appeared to be most relevant earlier in the cascade, with the strongest association observed for the decision to use PrEP. This pattern suggests that personalized, bidirectional communication may support individuals as they explore PrEP and clarify uncertainties. Digital conversational tools, including AI-enabled chatbots, have been proposed as scalable mechanisms to deliver tailored prevention information and facilitate service navigation while operating continuously and triaging more complex inquiries to human providers [48]. Early implementations of chatbot-based HIV prevention tools such as Amanda Selfie [27] and CHIA [30] have demonstrated feasibility and user acceptability in pilot studies. MYHIV365, a chatbot-based digital intervention developed in Malaysia to support HIV prevention among MSM, integrates conversational guidance on HIV testing, PrEP awareness, and risk reduction with culturally tailored content designed to address stigma and informational barriers [28,29]. Early evaluations have reported high usability and acceptability, suggesting that conversational agents may provide a scalable mechanism to deliver prevention information and support decision-making in stigmatized or resource-constrained settings.

Because such conversational systems can be deployed through widely used messaging platforms such as WhatsApp, they may offer a practical approach to delivering interactive prevention support within existing communication ecosystems. The widespread and frequent use of WhatsApp observed in our sample further supports the feasibility of this approach. Nearly all participants owned smartphones and reported frequent use of WhatsApp for daily communication, consistent with prior reports documenting the central role of messaging platforms in digital health engagement across diverse settings [8,28,49-52]. In contexts such as Peru, where developing and maintaining dedicated health applications may be resource-intensive for public health systems, leveraging existing communication platforms may offer a pragmatic strategy for delivering scalable interactive prevention support. Earlier work among MSM in Lima reported substantially lower smartphone access in 2015 [7], suggesting that the rapid expansion of digital connectivity over the past decade may enable broader implementation of messaging-based prevention tools. As conversational

XSL•FO
RenderX

technologies evolve, integrating AI-enabled chatbots with clinical messaging workflows may provide scalable models for delivering personalized PrEP guidance and follow-up within routine prevention services.

The potential value of these digital supports will likely depend on how well they align with local communication habits, user preferences, social norms, health system capacity, and service pathways. Adapting mHealth tools for the Peruvian context by embedding local clinical pathways, incorporating culturally and linguistically appropriate content, and integrating with widely used platforms may enhance their relevance across different stages of the PrEP cascade. Prior Spanish-language adaptations of digital HIV interventions have demonstrated the feasibility of this approach and underscore the importance of aligning tools with local communication norms and service structures [31,32]. Together, these considerations support the development of contextually grounded digital strategies rather than the direct transplantation of tools developed for other health system environments.

In addition to linguistic and service-delivery adaptation, digital tools may also be relevant because they can address barriers related to privacy and anticipated stigma. Although stigma was not directly measured in this study, prior research in Peru indicates that discrimination and discomfort in health care settings remain important barriers to PrEP uptake [53-55]. Digital support tools have been proposed as an implementation strategy to reduce structural and interpersonal barriers by allowing individuals to access information and decision support more privately [12,56]. By offering discreet engagement with credible sources and supportive communication, mHealth approaches may lower some perceived barriers to initial PrEP exploration. Digital support strategies should be viewed as complementary to, rather than replacements for, broader efforts to address stigma within health care systems.

Beyond individual feature preferences, our findings also have implications for how digital supports might be embedded within broader PrEP delivery models. Two relevant approaches are online-to-offline linkage models and telePrEP. The high level of interest in digital support features observed in this study is consistent with the potential relevance of online-to-offline approaches for PrEP delivery. In these models, individuals are initially engaged through digital platforms such as targeted messaging, educational content, or virtual navigation, and subsequently linked to in-person services through facilitated referrals, electronic appointment systems, or digital vouchers [57]. Such models may be particularly pertinent in settings where the geographic concentration of services and perceived stigma create barriers to in-person engagement [58,59]. The Adam's Love online-to-offline model in Thailand, which increased HIV testing and PrEP uptake through integrated online counseling and streamlined clinic check-in processes, illustrates how digital engagement can be operationalized within routine service delivery [60]. Adaptation of similar models to the Peruvian context would require integration with local service pathways and evaluation of their feasibility and impact.

TelePrEP represents a complementary strategy within differentiated service delivery models [56]. By incorporating virtual consultations, remote prescribing, and home-based monitoring, telePrEP has been proposed as a mechanism to expand access for individuals who prefer remote care or who reside in areas with limited clinic availability [61]. Integration of mHealth features such as messaging-based reminders, adherence tracking, and location-specific informational support into telePrEP platforms may facilitate continuity between digital engagement and clinical services. In combination, online-to-offline approaches and telePrEP models illustrate how digital strategies could be configured to support more flexible and geographically inclusive PrEP delivery frameworks in Peru. Formal evaluation would be needed to determine their effectiveness and scalability within the national health system.

As access to long-acting PrEP expands, including twice-yearly lenacapavir, which has been approved in the United States and recommended by the World Health Organization as an additional PrEP option [62,63], priorities for digital support may shift toward earlier stages of the prevention cascade. Because twice-yearly injectable PrEP reduces daily adherence demands compared with oral regimens, digital tools may become increasingly relevant for awareness, risk appraisal, demand generation, and linkage to services, while still supporting safety monitoring and follow-up. Ongoing research is also evaluating lenacapavir formulations administered at extended intervals [64], which could further reduce adherence-related barriers and increase the relative importance of timely, localized information regarding eligibility, service availability, cost, and evolving guidance. Integration of these informational and navigation functions into widely used platforms such as WhatsApp may support engagement as long-acting options become available, while maintaining pathways to human support.

This study has several limitations. First, the cross-sectional online survey design likely oversampled individuals who are urban and digitally connected, which may limit generalizability to populations with more limited internet access and to other groups not included in this analysis. Second, all measures were self-reported, including behavioral indicators and interest in digital features, which may be subject to recall or reporting bias. Although anonymous online surveys may reduce social desirability bias [65], measurement error remains possible. Third, interest was assessed for hypothetical mHealth features rather than actual tool use or clinical outcomes and therefore observed associations with PrEP cascade stages should not be interpreted as evidence of effectiveness. Fourth, the cross-sectional design precludes causal inference regarding the directionality of associations. Finally, stigma was not directly measured and therefore could not be examined as a mediator or moderator of digital engagement preferences.

These limitations underscore the need for prospective implementation research to evaluate the feasibility, acceptability, and effectiveness of specific mHealth interventions within diverse Peruvian settings. Implementation science frameworks may provide structured guidance for adapting and evaluating digital tools in real-world contexts [51,66]. By identifying which domains of digital support are most strongly associated with engagement at different stages of the PrEP cascade, our findings offer practical guidance for designing user-centered digital

XSL•FO

strategies to strengthen HIV prevention delivery in Peru and similar settings.

## Conclusions

In summary, this study provides novel, stage-specific evidence on digital preferences that may support PrEP engagement in a Latin American implementation context. Informational support and self-management tools were consistently associated with engagement across multiple stages of the PrEP cascade, whereas interactive communication features appeared most relevant during early decision-making phases. Among these domains, informational support emerged as the most consistent correlate of reaching more advanced cascade stages, highlighting the importance of accessible and actionable information in facilitating progression along the prevention continuum. These findings extend the existing literature by identifying which digital functions may be most salient at different points in the prevention cascade.

From a public health perspective, the near-universal smartphone ownership and strong preference for WhatsApp suggest that culturally tailored, messaging-based digital strategies aligned with specific cascade stages could be feasibly integrated within differentiated service delivery models, including telePrEP and online-to-offline frameworks. As long-acting PrEP options expand and delivery models evolve, contextually adapted mHealth tools may help align prevention services with users' communication practices and complement efforts to address structural barriers to engagement. Rigorous implementation research is needed to determine their effectiveness, scalability, and sustainability within Peru's national PrEP program and similar health system environments.

## Acknowledgments

We thank the Community Engagement Unit of the Peru Clinical Trials Unit for their contributions to language review and community validation of the survey instrument. Generative artificial intelligence tools were not used in any portion of the paper preparation.

## Funding

This work was supported by the National Institute of Allergy and Infectious Diseases, National Institutes of Health (R01AI177082; FLA), and the Fogarty International Center of the National Institutes of Health (D43TW010540; JAG-C).

## Data Availability

The anonymized dataset analyzed during this study is available from the corresponding author upon reasonable request.

## Authors' Contributions

JAG-C led the conceptualization, data curation, formal analysis, investigation, methodology, project administration, visualization, and writing (original draft of the paper). KAK contributed to formal analysis and methodology and provided cosupervision alongside SB, with JS serving as the local supervisor and FLA as the senior supervisor. DLGG-Q supported investigation and project administration. All authors contributed to writing (review and editing of the paper), with JAG-C leading revisions.

## Abstract

**Background:** HIV incidence continues to disproportionately affect sexual and gender minority (SGM) individuals in Latin America. Pre-exposure prophylaxis (PrEP), including long-acting products, urgently need scaling up in the region. Understanding PrEP modality preferences can help design effective implementation.

**Objective:** This study examined willingness to use different PrEP modalities and an HIV vaccine among SGM individuals aged 18 years or older from Brazil, Mexico, and Peru and factors associated with willingness to use 4 PrEP modalities.

**Methods:** We conducted a cross-sectional online survey in 2021; participants were recruited via apps (Grindr and Hornet) and social media (Facebook, Instagram, and WhatsApp). We used multivariate Poisson regression with robust variance ($\alpha$=.05) to estimate prevalence ratios, identifying differences in willingness to use daily oral, event-driven oral, monthly oral, and bimonthly injectable PrEP. Models were constructed for each PrEP modality and adjusted for age, country, race, education, income, HIV risk score, HIV testing, and HIV risk perception. Variables were retained in the final adjusted models regardless of statistical significance.

**Results:** Among 16,951 respondents, 10,385 (61.3%) were Brazilian, 4996 (29.5%) Mexican, and 1570 (9.3%) Peruvian. Median age was 32 (IQR 26-39) years. Among the total respondents, 12,621 (74.4%) were willing to use monthly oral PrEP; 11,153 (65.8%) daily oral PrEP; 10,212 (60.2%) bimonthly injectable PrEP; and 14,044 (82.8%) an HIV vaccine. Only 6442 (38%) were willing to use event-driven oral PrEP. In Brazil, 6082 (66.8%) were willing to use daily oral, 3162 (36.1%) event-driven, 7640 (74.9%) monthly oral, and 6450 (63.3%) injectable PrEP; in Mexico, 3242 (67.8%) daily oral, 1958 (41%) event-driven, 3728 (76.5%) monthly oral, and 2805 (57.5%) injectable PrEP; in Peru, 799 (53.1%) daily oral, 584 (39.9%) event-driven, 830 (62.5%) monthly oral, and 610 (45.9%) injectable PrEP. In multivariable models, willingness to use each of the 4 PrEP modalities was positively associated with high self-perceived HIV risk (adjusted prevalence ratios [aPRs] 1.10-1.25) and higher HIV Incidence

XSL•FO
RenderX

Risk Index scores (aPRs 1.08-1.22). Having lower education was associated with lower willingness for monthly oral and bimonthly injectable PrEP (aPR=0.93, 95% CI 0.89-0.97 and aPR=0.94, 95% CI 0.90-0.99, respectively). Never having been tested for HIV and testing more than 6 months ago were associated with lower willingness for daily oral PrEP (aPR=0.89, 95% CI 0.83-0.95 and aPR=0.95, 95% CI 0.91-0.99, respectively) and bimonthly injectable PrEP (aPR=0.80, 95% CI 0.74-0.86 and aPR=0.90, 95% CI 0.86-0.94, respectively).

**Conclusions:** Our results suggest a strong preference for long-acting formulations, including monthly oral and bimonthly injectable, among SGM individuals in Latin America. Further research is needed to address gaps in the understanding of prevention modalities. As additional PrEP modalities are included in HIV prevention programs, the development of accessible tools and community-based strategies will be essential to support informed PrEP choices and ensure equitable implementation across the region.

## Introduction

In 2024, an estimated 2.5 million people were living with HIV in Latin America [1]. Latin America is one of the few regions where HIV incidence has risen, with a 13% increase from 2010 to 2024 [2]. The incidence of HIV remains disproportionately higher among sexual and gender minority (SGM) individuals, who accounted for 66% of cases in Latin America in 2022. HIV prevalence among gay, bisexual, and other men who have sex with men (MSM) and transgender persons aged 15 to 49 years (2019-2023) was 10% and 9.5%, respectively [3]. Additionally, a study conducted in Brazil and Peru found high annualized HIV incidence among SGM individuals not using pre-exposure prophylaxis (PrEP; 3.9%, 95% CI 2.9-4.9), with higher incidence among participants from Peru, those aged 18 to 30 years, and those reporting lower incomes [4].

Currently, the World Health Organization (WHO) recommends daily or on-demand oral emtricitabine 200 mg and tenofovir disoproxil fumarate 300 mg (FTC/TDF), long-acting injectable cabotegravir (CAB-LA), long-acting injectable lenacapavir (LEN), and the dapivirine vaginal ring as effective HIV PrEP modalities [5]. As of July 2024, a total of 152 countries worldwide had adopted WHO recommendations on PrEP into their national guidelines, and 12 countries had adopted policies for CAB-LA [6]. In Latin America, oral PrEP was implemented as part of public policy in most countries, with Brazil initiating the provision of PrEP through the public health system (Sistema Único de Saúde [SUS]) in 2017, Mexico in 2021, and Peru in 2023 [7-9]. In 2024, a total of 286,862 persons were using PrEP in the region, with Brazil accounting for 58% of them [10]. In addition to regional disparities, more is needed to reach those who are at higher vulnerability to HIV. During the ImPrEP study, the largest PrEP implementation study in Latin America, younger participants, those who were Black or of mixed race (*pardo* or *mestizo*), those with lower educational attainment, and transgender women had higher HIV incidence and increased odds of discontinuing PrEP, lower adherence, and reduced persistence [11-13]. Similarly, PrEP uptake and persistence are worse among younger, Indigenous, and Black Brazilians according to Brazilian national data [14]. In response to implementation concerns with existing oral PrEP regimens, long-acting products need to be offered and accessible to those who need them most.

In 2021, CAB-LA was shown to be a highly effective alternative to daily oral FTC/TDF for HIV prevention among cisgender women, cisgender MSM, and transgender women [15,16]. Recently, subcutaneous LEN, administered twice yearly, was superior to FTC/TDF among cisgender women and SGM individuals in the phase 3 PURPOSE 1 and PURPOSE 2 clinical trials [17,18]. The frequency of administration of CAB-LA and LEN, bimonthly or biannually, respectively, is attractive for people who have difficulty adhering to an oral pill regimen. However, barriers to implementing injectable PrEP must be considered, including cost-effectiveness, staffing and other implementation constraints, acceptability and preferences among potential users, factors influencing timely attendance at injection visits, the prolonged subtherapeutic pharmacokinetic effect, and the feasibility of alternative administration sites [19,20]. While CAB-LA and LEN are not widely available in Latin America, Brazil is conducting the ImPrEP CAB Brasil and the ImPrEP LEN Brasil studies to evaluate the implementation of CAB-LA and LEN for SGM individuals aged 18 to 30 years in the public health system [21-23].

Different PrEP technologies, such as monthly oral, infusion of monoclonal antibodies, topical microbicides, and other long-acting products, are being developed [20,24]. For instance, subdermal implants have several advantages, such as easy removal; biodegradability; minimal health care system interaction; lower daily dosage; and more consistent, predictable drug release [20,25]. Islatravir delivered through a subdermal implant demonstrated promise as a potentially effective and well-tolerated approach for HIV prevention [26].

PrEP urgently needs to be scaled-up among SGM individuals in Latin America, including the provision of long-acting products, such as CAB-LA and LEN [3]. In this sense, understanding the willingness to use PrEP modalities could provide information for future adaptations or implementation of HIV prevention policies. We aimed to describe willingness to use different PrEP modalities and an HIV vaccine among SGM individuals in Brazil, Mexico, and Peru. We also assessed factors associated with willingness to use 4 PrEP modalities

XSL•FO
RenderX

(daily oral, event-driven oral, monthly oral, and bimonthly injectable).

## Methods

### Study Design

A cross-sectional online survey was conducted between April and August 2021 among individuals who self-identified as SGM individuals and aged 18 years or older from Brazil, Peru, and Mexico. Respondents were recruited using a convenience sampling approach through advertisements on dating apps, such as Grindr (3236/16,943, 19.1%) and Hornet (6400/16,943, 37.8%), and social media platforms, such as Facebook (3374/16,943, 19.9%), Instagram (2994/16,943, 17.7%), and WhatsApp (431/16,943, 2.5%), as well as other online sources (508/16,943, 3%). Each advertisement included a link to the survey website, where participants were provided with detailed information about the study aims, procedures, and confidentiality measures. Those who provided their electronic informed consent were able to access and complete a computer-based questionnaire that included information on sociodemographics, behavior, HIV testing, and prevention. We excluded participants who reported living with HIV.

Anonymity was ensured by not collecting any personally identifiable information. The survey platform prevented multiple submissions from the same device using browser cookies and IP restrictions. Participants were permitted to select only 1 response option per question to ensure data consistency and avoid multiple selections.

### Variables

#### *Outcomes*

Participants were asked to report their willingness to use each of the PrEP modalities using the following question: “Considering that all PrEP modalities are available, how likely would you be to use them?” with answers recorded using a 4-point Likert scale: very unlikely, unlikely, likely, and very likely. “Very likely” answers were classified as “willing,” following the definition from previous studies [27,28]. We evaluated willingness to use the following PrEP modalities: daily oral, event-driven oral, monthly oral, bimonthly injectable in the gluteal muscle, daily topical, event-driven topical, patch, implant, infusion of monoclonal antibodies, and subcutaneous monoclonal antibodies. We also inquired whether participants were willing to use a vaccine to prevent HIV. Only factors associated with 4 PrEP modalities (daily oral, event-driven oral, monthly oral, and bimonthly injectable) were reported, as these were currently available, implemented, or under investigation in Latin America when the survey was launched.

#### *Sociodemographics*

For gender identity, participants answered the question “What gender do you currently identify with?” with the following possible options: cisgender man, cisgender woman, transgender woman, transgender man, queer or nonbinary, and other. Age was categorized as 18 to 24, 25 to 30, and more than 30 years. Ethnicity or race was classified as White, mixed race (*pardo* or *mestizo*), and Black, Asian, Indigenous, or other. Level of education was dichotomized as complete secondary education or less (lower education) and more than secondary education (higher education). Regarding individual monthly income, we considered the minimum wage per country in 2021 (Brazil: US $213 per month, Mexico: US $215 per month, and Peru: US $257 per month) and dichotomized as minimum wage or less (lower income) and more than minimum wage (higher income).

#### *Perceived Risk of HIV Acquisition, HIV Incidence Risk Index, and HIV Testing*

The perceived risk for HIV was evaluated using the question “Considering your current sexual practices, in your opinion, what is your risk of acquiring HIV in the next 12 months?” which was recategorized as low (none, low, or moderate) and high (high, or certainty of infection). The HIV Incidence Risk Index (HIRI) was constructed by combining sexual behavior and substance use variables, as described previously [29]. Scores equal to or greater than 10 were considered as “engaging in high HIV sexual exposure.” Regarding HIV testing, participants answered the question “When was the last time you took an HIV test?” which was categorized as never, 6 months or less, and more than 6 months.

### Ethical Considerations

Ethics approval for the study was obtained from the respective ethical review boards in each country. In Brazil, the study was approved by the Institutional Review Board of Instituto Nacional de Infectologia Evandro Chagas-FIOCRUZ (CAAE 82021918.0.0000.5262); in Mexico, by the Research Ethics Committee of the National Institute of Psychiatry Ramón de la Fuente Muñiz (CEI/C/038/2018); and in Peru, by the Ethical Committee for Research with Human Subjects at Universidad Peruana Cayetano Heredia (101460). All participants signed electronic informed consent form before initiating the study. No personally identifiable information was collected, except IP addresses, which were used exclusively for quality control purposes (duplicate entry prevention) and were not linked to survey responses. Data were stored on secure servers and analyzed in deidentified form. We provided no compensation to participants.

### Statistical Analysis

Statistical analyses were conducted using Stata (version 18.0; StataCorp). Frequencies and percentages of sociodemographic and behavior characteristics and HIV testing were compared by country (Brazil, Mexico, and Peru) using the $\chi^2$ test. We also described these variables according to the willingness to use 4 PrEP modalities (daily oral, event-driven oral, monthly oral, and bimonthly injectable) for each country. Descriptive analyses were based on observed data.

Missing data were assessed using Little's MCAR (missing completely at random) test, which indicated that the data were not missing completely at random ($\chi^2_{121}$=5239; $P$<.001). Therefore, missing values in outcome and covariate variables were handled using multiple imputation by chained equations under the assumption of missing at random. Binary variables were imputed using logistic regression models and multinomial variables using multinomial logistic regression models. A total

XSL•FO
RenderX

of 20 imputed datasets were generated, and parameter estimates were combined using the Rubin rules.

We conducted multivariate Poisson regression models with robust variance to estimate adjusted prevalence ratios (aPRs) and 95% CIs for willingness to use each PrEP modality (daily oral, event-driven oral, monthly oral, and bimonthly injectable). Models were adjusted for covariates selected a priori (age, country, race, education, income, HIRI score, HIV testing, and HIV risk perception). Variables were retained in the final adjusted models regardless of statistical significance.

## Results

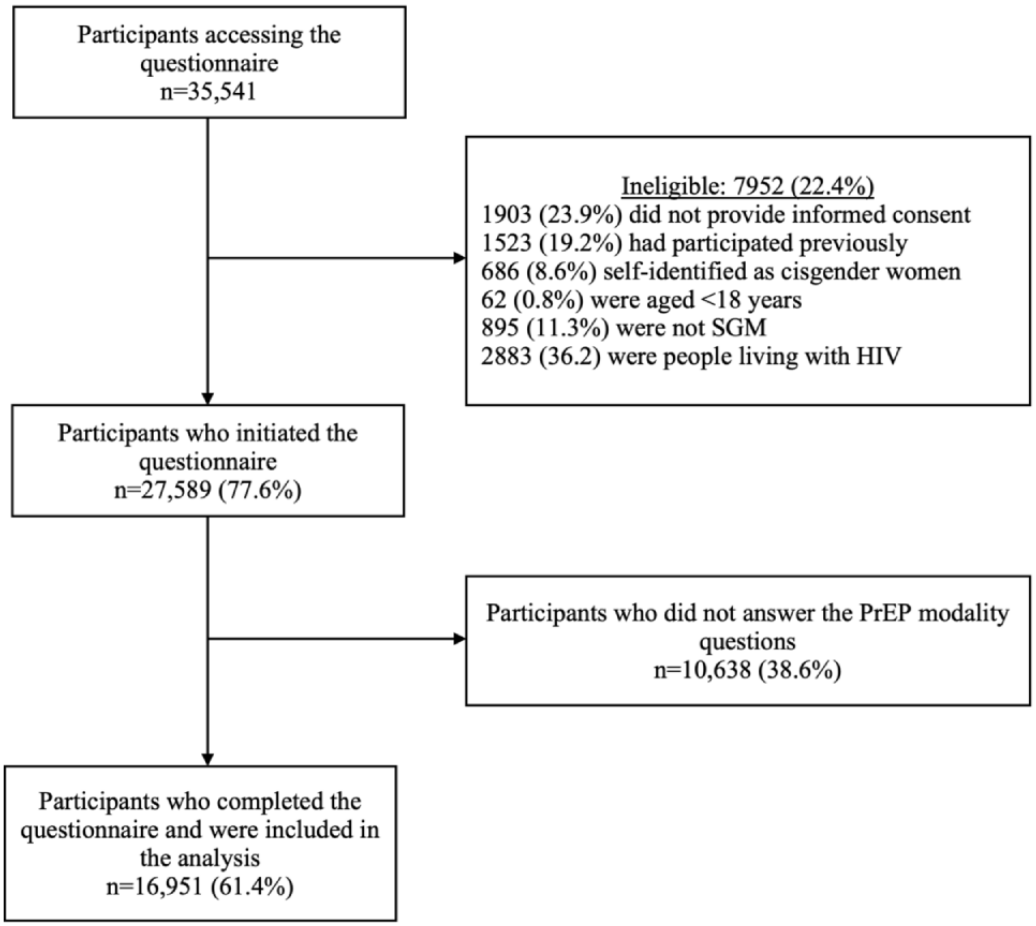
A total of 35,541 individuals accessed the online questionnaire, of whom 7952 (22.4%) were ineligible for the following reasons: 1903 (23.9%) did not provide informed consent, 1523 (19.2%) had participated previously, 686 (8.6%) self-identified as cisgender women, 62 (0.8%) were younger than 18 years, 895 (11.3%) were men who did not self-identify as SGM individuals, and 2883 (36.2%) reported living with HIV (Figure 1). Among 27,589 eligible individuals, 10,638 (38.6%) were excluded for not answering questions about PrEP modalities. Overall, 16,951 (61.4%) respondents were included in this analysis; 10,385 (61.3%) Brazilians, 4996 (29.5%) Mexicans, and 1570 (9.3%) Peruvians. Among these, 16,183 (95.5%) self-identified as cisgender men, 99 (0.6%) as transgender women, 60 (0.4%) as transgender men, 423 (2.5%) as nonbinary or queer persons, and 165 (1%) as other. Median age was 32 (IQR 26-39) years; almost half of the respondents (7483/16,285, 46%) self-declared mixed race, and more than three-quarters (12,627/16,509, 76.5%) received more than 1 minimum wage per month (higher income). In addition, 10,379 (61.2%) respondents were identified as having high HIV sexual exposure according to the HIRI, 1961 (11.6%) had never been tested for HIV, and 6688 (39.6%) had their last HIV test more than 6 months ago.

Study population characteristics were compared by country (Table 1). More Peruvians (164/1570, 10.5%) self-identified as transgender or nonbinary persons compared with Brazilians (224/10,384, 2.2%) and Mexicans (379/4996, 7.6%) and were aged 18 to 24 years (Peru: 716/1570, 45.6%; Mexico: 1057/4996, 21.2%; Brazil: 1304/10,385, 12.6%). Regarding race, most Brazilians (5873/10,385, 56.5%) self-defined as White, while most Mexicans (3249/4330, 75%) and Peruvians (1109/1570, 70.6%) self-identified as mixed race. Most individuals in Brazil and Mexico received more than minimum wage monthly (8179/10,385, 78.8% and 3738/4729, 79%, respectively) compared with Peru (710/1395, 50.9%). In addition, more Peruvians (180/1194, 15.1%) perceived themselves to be at high risk of acquiring HIV compared with Brazilians (964/10,385, 9.3%) and Mexicans (439/4996, 8.8%); conversely, more Brazilians (6676/10,385, 64.3%) had high HIV sexual exposure according to HIRI scale compared with Mexicans (2965/4996, 59.4%) and Peruvians (738/1570, 47%). Additionally, a higher proportion of Peruvians (328/1550, 21.2%) had never been tested for HIV compared with Mexicans (757/4972, 15.2%) and Brazilians (876/10,385, 8.4%).

Regarding PrEP modalities, most of the respondents were willing to use monthly oral PrEP (12,621/16,951, 74.4%), daily oral PrEP (11,153/16,951, 65.8%), and bimonthly injectable PrEP (10,212/16,951, 60.2%), while only 38% (6442/16,951) were willing to use event-driven PrEP. Other PrEP modalities received lower willingness levels: 25.1% (4109/16,398) for daily topical, 25.6% (4202/16,398) for event-driven topical, 31.7% (5204/16,399) for a patch, 35.9% (5885/16,398) for an implant, 28.4% (4660/16,397) for infusion monoclonal antibodies, and 31.3% (5139/16,398) for subcutaneous monoclonal antibodies. Additionally, 82.8% (13,579/16,398) of participants reported willingness to use an HIV vaccine. Figure 2 shows the percentages of willingness to use these less common PrEP modalities and an HIV vaccine in each country.

We also found country-level differences in the willingness to use at least one of the 4 PrEP modalities evaluated (daily oral, event-driven oral, monthly oral, and bimonthly injectable). Mexicans reported the highest overall willingness (4449/4903, 90.7%), followed by Brazilians (8965/10,034, 89.4%) and Peruvians (1195/1423, 84%). Within each country, there were substantial differences in the willingness to use each of these 4 PrEP modalities. Peruvians were less willing to use daily oral (799/1506, 53.1%), monthly oral (830/1328, 62.5%), and bimonthly injectable (610/1328, 45.9%) compared with Brazilians (daily oral: 6082/9106, 66.8%; monthly oral: 7640/10,197, 74.9%; bimonthly injectable: 6450/10,197, 63.3%) and Mexicans (daily oral: 3242/4784, 67.8%; monthly oral: 3728/4875, 76.5%; bimonthly injectable: 2805/4875, 57.5%). Willingness to use event-driven PrEP was lower for Brazilians (3162/8761, 36.1%).

In all 3 countries, cisgender MSM were more willing to use monthly oral PrEP compared with transgender or nonbinary participants (Table 2). In Brazil (4376/5780, 75.7%) and Mexico (619/788, 78.6%), White individuals were more willing to use monthly oral PrEP, while in Peru (610/951, 64.1%), mixed-race individuals showed higher willingness. In Mexico (469/788, 59.5%) and Peru (80/168, 47.6%), White participants were more willing to use bimonthly injectable PrEP, whereas in Brazil (884/6450, 64.7%), Black, Asian, or Indigenous individuals showed greater willingness. In Brazil and Mexico, daily oral PrEP was more preferred among individuals with lower education (2165/6082, 68.7% and 983/1429, 68.8%, respectively) and lower income (1368/2032, 67.3% and 664/969, 68.5%), while in Peru, it was more preferred among participants with higher education (519/958, 54.2%) and income (378/671, 56.3%). In Brazil and Mexico, participants who had an HIV test within the past 6 months showed greater willingness to use monthly oral PrEP (4148/5462, 75.9% and 1576/2010, 78.4%, respectively), while in Peru, this modality was more preferred by people who had an HIV test more than 6 months ago (313/491, 63.8%).



In the multivariable analysis (Table 3), willingness to use each of the 4 evaluated PrEP modalities was positively associated with high HIV self-perceived risk and higher HIRI scores. Peruvian respondents showed lower willingness to use 3 modalities (daily oral: aPR=0.81, 95% CI 0.75-0.87; monthly oral: aPR=0.84, 95% CI 0.78-0.91; and injectable: aPR=0.76, 95% CI 0.69-0.83). Mexican and Peruvian respondents reported higher willingness to use event-driven oral PrEP (aPR=1.14, 95% CI 1.08-1.22 and aPR=1.11, 95% CI 1.01-1.22,

XSL•FO
RenderX

respectively) compared with Brazilian respondents. Having secondary education or less was associated with lower willingness to use monthly oral and bimonthly injectable PrEP (aPR=0.93, 95% CI 0.89-0.97 and aPR=0.94, 95% CI 0.90-0.99, respectively). Having a minimum wage or less was associated with lower willingness for bimonthly injectable PrEP (aPR=0.95, 95% CI 0.90-1.00). Never having been tested for HIV and testing for more than 6 months ago were associated with lower willingness to use daily oral PrEP (aPR=0.89, 95% CI 0.83-0.95 and aPR=0.95, 95% CI 0.91-0.99, respectively) and bimonthly injectable PrEP (aPR=0.80, 95% CI 0.74-0.86 and aPR=0.90, 95% CI 0.86-0.94, respectively).

## Discussion

### Principal Findings

In this paper, we provide information about willingness to use PrEP modalities and an HIV vaccine among SGM individuals from 3 countries in Latin America. Overall, participants were more interested in monthly oral PrEP, with daily oral and bimonthly injectable PrEP also being widely accepted and event-driven oral PrEP being the least preferred. Most participants reported willingness to use an HIV vaccine. Participants perceiving themselves at higher HIV risk and engaging in higher HIV sexual exposure were more willing to use all 4 PrEP modalities. Individuals with lower education were less willing to use long-acting PrEP (monthly oral and bimonthly injectable). Participants who had never tested for HIV or had been tested more than 6 months ago were less willing to use daily oral PrEP and bimonthly injectable. Our study provides insight into PrEP preferences among SGM individuals in Latin America and can guide the implementation of new PrEP modalities in prevention programs.

Higher willingness to use monthly oral and bimonthly injectable PrEP indicates a preference for long-acting formulations among SGM individuals in Latin America. In a discrete-choice experiment conducted in Brazil, SGM individuals preferred long-acting PrEP requiring less frequent dosing (monthly, bimonthly, or annually) as long as efficacy and side effects were similar or lower than those of oral PrEP [30]. Additionally, participants did not show a stronger preference for annual dosing compared with monthly or bimonthly dosing [30]. Previous studies identified injectable PrEP as the most preferred modality; however, they did not consider monthly oral PrEP as an option [31-33]. Currently, monthly oral PrEP is not available, although MK-8527, a novel investigational nucleoside reverse transcriptase translocation inhibitor, is under evaluation as an alternative to daily oral PrEP [34]. Two phase 3 clinical trials (EXPrESSIVE 10 and 11) are investigating the efficacy, safety, and tolerability of MK-8527 monthly compared with daily oral PrEP (FTC/TDF) among cisgender women and SGM individuals in several regions, including Latin America [35].

Long-acting injectables have been considered highly acceptable among SGM populations for HIV prevention [36]. This is corroborated by findings from a survey conducted among 3665 Brazilian SGM individuals in 2024 [37]. In the ImPrEP CAB Brasil study, most participants (83%) chose CAB-LA over daily oral PrEP [38]. Long-acting injectables offer potential advantages, such as reducing the frequency of clinic visits and improving adherence compared with daily oral PrEP [39]. Our study also revealed that individuals with lower education were less willing to use long-acting PrEP formulations, similar to findings related to injectable PrEP in Brazil [31]. This suggests that people using PrEP need accessible information to better understand the important features of these modalities.

Daily oral PrEP was also widely accepted; however, Peruvians were less likely to be willing to use this modality compared with Brazilians and Mexicans. This result is consistent with results from the ImPrEP study, which reported lower persistence and adherence to daily oral PrEP among MSM and transgender women from Peru compared with Brazil [11,12]. Possible contributing factors included low awareness of oral PrEP, HIV-related stigma during sexually transmitted infection clinic visits, and concerns about medication efficacy and side effects [27]. These concerns may be more noticeable with newer PrEP modalities, particularly long-acting formulations, due to the lack of information and perceived loss of autonomy in administration, which may contribute to a preference for the daily oral modality [33,40]. Additionally, familiarity with and routine use of a daily oral pill could also have contributed to this preference [40].

Differences among countries may also reflect structural and contextual barriers. Brazil and Mexico incorporated daily oral PrEP into their public health systems in 2017 and 2021, respectively, and have since implemented large-scale, community-supported programs that promote familiarity with and confidence in PrEP [8,41]. In contrast, the Peruvian Ministry of Health initiated offering oral PrEP to populations at high vulnerability for HIV in 2023 [9]. This delayed implementation, with limited-service availability, may have reduced visibility and accessibility among potential users. Strengthening PrEP implementation in Peru through decentralized service delivery, stigma reduction initiatives, and targeted communication campaigns could help improve uptake and promote more equitable access across the region.

Event-driven oral PrEP was the least acceptable among our participants. This finding aligns with previous studies [31,32], except for a study conducted in the United States, in which MSM reported that most of condomless anal sex events are either infrequent or can be anticipated [42]. In contrast, participants in the ImPrEP study showed low interest in switching from daily oral to event-driven oral PrEP [43]. Reasons included that fewer than 25% reported having sex less than 2 days per week (indicating infrequent sex), most were satisfied with the daily regimen, considered event-driven PrEP a difficult regimen to follow, and had concerns about its efficacy and anxiety about their own HIV risk [43].

Individuals who perceived themselves at high risk for HIV and who were engaging in high HIV sexual exposure were more likely to use any PrEP modality. A high perceived risk of HIV has been identified as a facilitator of PrEP acceptability and willingness to use it [44-46]. For example, in Mexico, transgender women reported a high willingness to use daily oral PrEP (95.5%) if they had high HIV risk perception [47]. Additionally, Torres et al [31] reported that higher HIRI scores increased the willingness of use injectable PrEP, while lower HIRI scores were associated with a preference for event-driven PrEP in Brazil and Mexico. In another Latin American study, Assaf et al [48] found that a higher risk for HIV was associated with PrEP awareness in Brazil but not among MSM in Mexico and Peru. Importantly, a study from Brazil [27] found that PrEP awareness was associated with willingness to use it, indicating the importance of continuous education campaigns about HIV prevention, including current and future PrEP modalities.

PrEP modalities involving topical agents, patches, implants, and monoclonal antibodies received lower willingness to use compared with the oral and injectable modalities. In contrast,

XSL•FO
RenderX

HIV vaccines were widely accepted by participants. Many of these alternative PrEP formulations are still in the clinical research phase [20,49], while no HIV vaccine has been efficacious to date. Limited awareness of the options still under study could have generated distrust. However, previous study from South Africa have reported high acceptability of topical agents among different populations, including SGM individuals [49]. Although there is currently no approved HIV vaccine, the MOSAICO study (HPX3002/HVTN706) enrolled Latin American participants before being discontinued due to lack of efficacy [50]. Nevertheless, previous studies from Brazil found a high willingness to use a hypothetical effective HIV vaccine, even if it was not free of charge [51,52].

We acknowledge that this study has certain limitations. Participants were recruited through dating apps and social media platforms and accessed the online survey using smartphones or other internet-connected devices. This recruitment strategy was appropriate for reaching SGM communities but may have introduced selection bias by excluding individuals with limited digital access, meaning that our sample may not be representative of all SGM individuals in Latin America, Brazil, Mexico, or Peru. Additionally, the cross-sectional design of our study limited our ability to establish causality. Notably, when the data were collected in 2021, only daily oral PrEP was available in these countries. However, oral PrEP information was more widely disseminated in Brazil, where it had been included in their public health care system since 2017 [41]. Finally, all responses were based on participants' self-reports, and social desirability bias may have occurred; however, online anonymous data collection may have reduced this bias. It is also important to note that "willingness" reflects hypothetical acceptability and may not directly translate into actual intention or behavior, which should be considered when interpreting these findings.

## Conclusions

We found that SGM individuals from Latin America were more willing to use long-acting PrEP, including monthly oral and bimonthly injectable PrEP, but daily oral PrEP was also highly accepted. Further research and education are needed to better understand and address the gaps in knowledge about prevention modalities. The availability of additional choices to better address the prevention needs of SGM populations could empower individuals to use these methods. As additional PrEP modalities are included in HIV prevention programs, the development of accessible tools and community-based strategies will be essential to support informed PrEP choices and ensure equitable implementation across the region.

## Acknowledgments

The authors express their gratitude to all study participants for their time and participation in this study. HV-R, CG-D-B, and DD-S thank the National Council of Humanities, Sciences and Technologies for acknowledging them as members of the National Researchers System. These results were presented in part as a poster presentation at the AIDS 2022 Conference in Montreal, QC. Artificial intelligence was not used in any portion of the manuscript writing.

## Funding

This project was made possible through Unitaid's funding and support. Unitaid accelerates access to innovative health products and supports their scale-up by countries and partners. Unitaid is a hosted partnership of the World Health Organization. TST was supported by the National Council of Technological and Scientific Development (CNPq; 304417/2025-4 and 405558/2025-2) and the Carlos Chagas Filho Foundation for Research Support in the State of Rio de Janeiro (FAPERJ; E-26/201.270/2022). BG was supported by CNPq (313265/2023-2) and FAPERJ (E.26/200.946/2022).

## Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

## Conflicts of Interest

None declared.

## Abstract

**Background:** Human papillomavirus (HPV) is one of the most common sexually transmitted infections worldwide. Despite the availability of effective vaccines, uptake remains suboptimal in many settings, including Saudi Arabia, where cultural sensitivities, limited awareness, and vaccine hesitancy have been documented. Educational interventions grounded in behavioral theory, such as the information-motivation-behavioral skills (IMB) model, can help address informational and motivational barriers to HPV vaccination.

**Objective:** This study aimed to evaluate the impact of an educational intervention in improving HPV vaccination decision-making among women in Northern Saudi Arabia.

**Methods:** A quasi-experimental design (pretest-posttest with a control group) was used among women attending primary health care centers in the Northern Border Region of Saudi Arabia. A total of 380 participants, 190 in the control group and 190 in the intervention group, completed surveys at baseline (T1), 1-week post intervention (T2), and a 3-month follow-up (T3), assessing HPV-related knowledge, health awareness, attitudes, and vaccination intentions. The educational intervention consisted of a culturally adapted, evidence-based, 45-minute interactive group session delivered in primary health care centers.

**Results:** Study retention was excellent (380/389, 97.7%). At the 3-month follow-up, intervention participants demonstrated medium to large effect size improvements compared with controls: knowledge (adjusted β=0.84, 95% CI 0.53-1.15; $P$<.001; Cohen $d$=0.45, medium effect), health awareness (β=0.88, 95% CI 0.53-1.23; $P$<.001; $d$=0.44, medium effect), attitude (β=0.70, 95% CI 0.42-0.98; $P$<.001; $d$=0.38, medium effect), and vaccination intentions (β=0.86, 95% CI 0.60-1.12; $P$<.001; $d$=0.82, large effect). Exploratory subgroup analyses found no significant effect modification by age, education, or health literacy (all interaction $P$>.10), suggesting consistent intervention effects across demographic characteristics.

**Conclusions:** This culturally tailored educational intervention was effective in improving HPV-related knowledge, attitudes, health awareness, and vaccination intentions among women in Northern Saudi Arabia. Given the well-documented intention-behavior gap in vaccination uptake, future research should incorporate verified vaccine initiation and completion outcomes, along with longer follow-up, to assess whether enhanced intentions translate into actual vaccine uptake.

## Introduction

### The Global Challenge of Human Papillomavirus as a Non-HIV Sexually Transmitted Infection in Women

Human papillomavirus (HPV) is the most prevalent non-HIV sexually transmitted infection (STI) globally, and most sexually active individuals will acquire HPV during their lifetime [1-3]. Among women, persistent infection with high-risk oncogenic HPV types is a necessary cause of cervical cancer. It contributes to a broader spectrum of anogenital and oropharyngeal cancers, creating a substantial preventable burden across the life course [3-5]. HPV vaccination offers a critical opportunity for primary prevention of an STI-related cancer, with high efficacy against vaccine-type infection and intraepithelial neoplasia when administered before exposure [5-7]. Among young adult women beyond routine childhood immunization schedules, HPV vaccination is often positioned as a preference-sensitive decision requiring individualized counseling, yet vaccine coverage remains insufficient in many settings [8,9].

Incomplete vaccine uptake reflects both individual-level barriers (knowledge, attitudes, and motivation) and structural barriers (access, cost, and provider recommendation). While system-level changes are essential, individual-level educational interventions remain necessary to address modifiable cognitive and motivational barriers, particularly in contexts where structural access exists but is underused [9,10]. Individual barriers include limited awareness and misinformation, perceived stigma associated with STI prevention, low confidence in vaccine safety, concerns about fertility and long-term harms, and the "intention-behavior gap," the well-documented phenomenon in which individuals express willingness yet do not translate intention into action [11-13]. These factors are particularly relevant for women's health in culturally conservative contexts where sexual health discussions carry social stigma.

### HPV Vaccination Challenges in Saudi Arabia: Epidemiological Context and Cultural Barriers

In Saudi Arabia, cervical cancer incidence is comparatively low but nonnegligible: the Information Centre on HPV and Cancer (ICO)/International Agency for Research on Cancer (IARC) country fact sheet [14] estimates approximately 358 new cases and approximately 179 deaths annually, with an age-standardized incidence rate (ASR) of approximately 2.8 per 100,000 women and ranking eighth among cancers in women overall and in those aged 15 to 44 years. Recent registry-based analyses also show regional variation, with Makkah consistently reporting the highest rates, followed by Riyadh and the Eastern Region, and a favorable shift toward earlier stage at diagnosis between 2005 and 2019 (increase in localized-stage diagnoses; decline in unknown stage), underscoring geographic and stage heterogeneity relevant to prevention strategies [15,16]. The Saudi Cancer Registry (under the National Cancer Center, Saudi Health Council) continues to publish periodic incidence reports and program updates, improving data quality for planning and evaluation [17].

Regarding vaccine policy and access, the Saudi Ministry of Health (MOH) health-education pages recommend HPV vaccination for adolescents (girls and boys) at ages 11 to 12 years (can start at age 9 years) and catch-up through age 26 years, aligning with international guidance; adults aged 27 to 45 years may benefit on a case-by-case basis. Since 2022, public communications from MOH and independent evaluations have described school-based campaigns introducing HPV vaccination for early adolescents, with media notices highlighting the importance of early vaccination and a multicohort school-based rollout reported in 2022 (with subsequent years' activity). Importantly, official, centralized MOH fee schedules for HPV vaccine are not published; doses delivered within school-based/public programs are provided at no charge to families, whereas private-sector prices are not standardized or publicly listed by MOH/Saudi Food and Drug Authority (SFDA) [18].

Contemporary studies in Saudi Arabia consistently demonstrate low HPV vaccine uptake despite rising awareness. For example, a 2023-2024 national survey found that although 60.85% of Saudi women had heard of HPV, only 8.25% had received the vaccine, and more than 70% expressed willingness, highlighting a clear intention-behavior gap [19]. Similarly, recent cross-sectional research shows that Saudi women continue to report fear of side effects, doubts about vaccine effectiveness, and low positive perceptions, indicating persistent informational and motivational barriers to HPV prevention efforts [20]. Among younger populations, such as nursing and medical students, studies report poor HPV knowledge, limited understanding of screening, and low vaccination rates, with over 70% unvaccinated, despite relatively high awareness [21,22].

Although overall awareness has significantly increased following Saudi MoH campaigns, HPV-related behaviors remain suboptimal. A national comparison from 2022 to 2024 documented a rise in HPV awareness from 38.8% to 71.1%, yet cervical cancer screening uptake remained low, with only 25.8% of women reporting ever having a Pap smear [23]. Cultural and social dynamics further shape preventive behaviors: barriers such as perceived lack of necessity, abstinence-based reasoning, safety concerns, and misconceptions about who the vaccine is "appropriate" for continue to impede uptake [24]. In family-centered decision contexts, parental acceptance of HPV vaccination is strongly influenced by education level, health care worker status, and especially receiving a recommendation from the MoH or clinicians, demonstrating how social and institutional cues shape women's access to preventive care [24-26].

Shared decision-making (SDM) principles may require adaptation in this context, as women's health care decisions often involve family consultation and are influenced by clinician paternalism [27-29]. Educational interventions can support SDM

XSL•FO
RenderX

by strengthening women's knowledge and confidence to engage in vaccine discussions, ask questions, and express preferences to clinicians [30,31]. Therefore, this study aims to improve determinants of informed vaccination decisions, a foundational step toward SDM-compatible counseling.

### Educational Interventions, Theoretical Frameworks, and Evidence Gaps

Educational interventions have repeatedly demonstrated effectiveness in improving HPV-related knowledge, attitudes, and vaccine acceptance [11,32]. However, many interventions lack cultural tailoring and do not address context-specific concerns such as fertility misconceptions, stigma, and family influence, and they often fail to incorporate behavioral theory to explain how information converts to lasting motivation and action [11,33,34]. Ensuring equitable reach requires evaluating whether interventions maintain effectiveness across differing levels of health literacy, as literacy-related disparities substantially affect the ability to process health information and may reduce the intervention's public health impact [35-37].

The information-motivation-behavioral skills (IMB) model proposes that behavior change is driven by accurate, actionable information, motivation (personal and social), and the behavioral skills needed to execute decisions, an especially relevant structure for vaccine uptake behaviors that require navigating appointments, consent, and follow-through [38,39]. IMB-based educational interventions have improved HPV vaccination-related outcomes in other contexts, including web-based education among female college students [40]. Yet, within Saudi Arabia and the broader Middle Eastern region, many studies remain cross-sectional, focus on university settings, or assess knowledge and hesitancy without testing scalable, culturally adapted, primary care–compatible intervention models [20,41]. Additionally, registry and international sources emphasize that although overall cervical cancer incidence is low, regional disparities and ongoing cases justify prevention efforts, particularly in high-population regions such as Makkah and Riyadh.

### Study Rationale, Objectives, and Research Questions

This study addresses these gaps directly by evaluating a culturally tailored educational intervention to improve HPV vaccination decision-making among women in Northern Saudi Arabia. This study makes 3 distinct contributions. First, it addresses HPV vaccination as both an informational challenge and an SDM implementation challenge, where women's concerns, stigma, and family/social context must be addressed to support informed and values-concordant decisions [27,29,30]. Second, it applies a behavioral theory lens (IMB) to structure how education targets the specific mechanisms most plausibly linked to vaccine initiation behaviors [38,39]. Third, it focuses on a Saudi setting where published evidence indicates persistent gaps in knowledge and uptake and where culturally tailored prevention strategies are needed to reduce HPV-related disease burden among women [4,19,20]; contemporaneous national and international data further justify the focus, citing current case counts, regional variation, and active public health efforts.

### Research Questions

Research question 1 assesses whether a culturally tailored, IMB-based educational intervention improves HPV-related knowledge, health awareness, attitudes, and vaccination intentions among women in Northern Saudi Arabia compared to standard care. Research question 2 assesses whether intervention effects are sustained at 3-month follow-up. Research question 3 assesses whether intervention effects vary by age, education level, health literacy, or prior vaccination experience.

### Hypotheses

Hypothesis 1 states that intervention participants will demonstrate significantly greater improvements in all 4 outcome domains compared to controls at post-intervention and 3-month follow-up. Hypothesis 2 states that effects will be sustained (no significant decay) between postintervention and 3-month assessments. Hypothesis 3 states that intervention effects will not significantly differ across demographic subgroups (consistent effectiveness).

## Methods

### Study Design

A quasi-experimental design (pretest-posttest with a control group), with a pragmatic, nonrandomized allocation approach, was used due to operational constraints within the primary health care (PHC) system that precluded individual-level randomization, combined with concerns about contamination between intervention and control participants within the same clinic sessions. Outcomes were assessed at 3 time points: baseline (T1), approximately 1 week after the intervention session (T2), and 3 months after baseline (T3). The study is reported in accordance with the Transparent Reporting of Evaluations with Nonrandomized Designs (TREND) statement for nonrandomized evaluations of behavioral and public health interventions; a completed TREND checklist is provided in Multimedia Appendix 1. Causal language is used cautiously given the nonrandomized design, and effect estimates are interpreted as associations consistent with an intervention effect.

### Participants and Setting

#### *Eligibility Criteria*

Women who were currently pregnant were excluded because HPV vaccination is typically deferred until the postpartum period and because pregnancy-related clinical contexts could have introduced heterogeneity in decision urgency and confounded intervention effects. Additional exclusion criteria were (1) health care professionals or trainees likely to have specialized knowledge of HPV vaccination (eg, nursing, medical, or public health students or staff involved in health services), (2) current participation in another vaccine-related study, (3) cognitive impairment limiting informed consent or questionnaire completion, and (4) completion of the full HPV vaccination series. Numbers of women screened, excluded, and enrolled are reported in the Participant Flow and Retention section, in line with reporting standards for nonrandomized studies.

XSL•FO
RenderX

### *Recruitment and Enrollment*

The study was implemented between December 2025 and May 2026 in 4 PHCs in the Northern Border Region, Saudi Arabia. Women attending the participating PHCs for routine services were approached by trained female research staff, screened for eligibility, and invited to participate; written informed consent was obtained from all enrolled women. Enrollment counts are reported in the Participant Flow and Retention section.

### *Allocation Procedure (Nonrandom)*

Allocation was nonrandom and based on clinic scheduling/time of attendance to maximize feasibility and minimize disruption to routine PHC operations. Women attending designated morning clinic sessions at participating sites were invited to join the intervention arm, whereas women attending afternoon clinic sessions served as the control arm.

### *Threats to Internal Validity*

Nonrandom, time-based allocation introduces potential selection bias, as timing of clinic attendance can correlate with employment status, caregiving responsibilities, health-seeking motivation, and socioeconomic factors. We prospectively collected and adjusted for key sociodemographic and health covariates (Outcome Measures section) to address measured confounding, but unmeasured factors associated with clinic attendance timing (eg, health motivation, urgency of care-seeking) could confound intervention effects. To quantify the magnitude of potential bias, standardized differences were calculated for all baseline covariates (Table 1), and sensitivity analyses were conducted (Statistical Analysis section). Although standardized differences <.10 suggested minimal observed imbalance across measured characteristics, causal inference remains limited, and estimates are interpreted as associations consistent with an intervention effect rather than as definitive causal effects. To minimize contamination, intervention and control sessions were scheduled on different days when feasible, and participants were asked not to share educational materials with other clinic attendees. Clinic staff provided routine care to both groups without knowledge of study arm allocation to the extent possible in this pragmatic trial. Participants and facilitators were not blinded to group allocation, which is inherent to the delivery of an educational intervention in a nonrandomized design. T3 telephone interviewers were partially blinded, as described in the Data Collection Procedures section.

[e]Knowledge and attitudes scores are linearly transformed from the original scales (0-9 and 1-5, respectively) to a 1-7 scale for comparability across outcomes.

XSL•FO
RenderX

### *Retention and Follow-Up*

Participant flow, retention, and completeness of follow-up are reported in the Participant Flow and Retention section. Baseline characteristics were compared between participants who completed all assessments and those lost to follow-up; results of this comparison between participants who completed follow-up vs those who did not are provided in Multimedia Appendix 2. All 380 participants included in the analytic sample completed follow-up within the prespecified window; the final 3-month interview was completed on May 30, 2026, and no further follow-up assessments were undertaken after that date.

## Sample Size

Sample size was estimated using G*Power 3.1 for repeated-measures ANOVA with within-between interaction. The primary test was the $F$ test of the group × time interaction in a 2 (group) × 3 (time) mixed design, for which the test statistic follows a noncentral $F$ distribution with numerator $df = (2 - 1)(3 - 1) = 2$ and denominator $df = 2(N - 2)$, with sphericity assumed (ε=1). Assuming a moderate effect size ($F$=0.25, equivalent to Cohen $d$≈0.50), an α of .05, power of 0.80, a total of 3 measurement time points, and a within-subject correlation of 0.5, the sample size required was 82 participants per group. Anticipating 20% attrition, we targeted 103 per group (n=206). Actual enrollment (n=389) substantially exceeded this target, providing adequate power for primary analyses.

Although the achieved sample provides sufficient power for main effects, the exploratory subgroup analyses (Statistical Analysis section) were not formally powered and should be interpreted as hypothesis-generating: interaction tests require approximately 4 times the sample size of main-effect tests, and with 190 participants per group, statistical power for detecting subgroup interactions was estimated at 40% to 50%.

## Intervention Development and Implementation

### *Theoretical Framework*

The intervention was grounded in the IMB model [30], which proposes that health behavior adoption is driven by (1) accurate and accessible information, (2) motivation (personal and social), and (3) behavioral skills needed to translate decisions into action. The IMB model has been applied to sexual health behaviors and preventive decision-making, including STI prevention [42,43].

### *Patient and Public Involvement*

#### Cultural Adaptation

A structured cultural adaptation framework consisting of 4 phases was used, developed with input from the target population and stakeholders (patient and public involvement): (1) information gathering through focus groups with 32 women from the target population and interviews with 15 stakeholders, including PHC clinicians (n=8), community health workers (n=4), and women's health advocates (n=3), to identify context-specific barriers (eg, STI stigma, HPV/HIV confusion, fertility concerns, and preference for gender-concordant delivery); (2) preliminary adaptation and development of culturally congruent messaging and delivery strategies; (3) pilot testing with 20 women to refine clarity, acceptability, and session length, after which the session was reduced from 60 minutes to 45 minutes and terminology was revised to replace "sexually transmitted" with "virus that can cause cancer" in several sections to reduce stigma (pilot acceptability rating 4.6/5.0 for clarity and 4.8/5.0 for cultural appropriateness); and (4) refinement and finalization of materials and delivery protocols.

All intervention materials (session scripts, facilitator guides, and the Arabic pamphlet) were developed in Arabic by the bilingual study team and back-translated into English to verify content fidelity; discrepancies identified during back-translation were resolved by consensus before pilot testing.

#### Intervention Content and Delivery

The intervention consisted of a 45-minute interactive group session delivered in private rooms within PHCs to groups of 10 to 15 participants, facilitated by 2 trained female health educators.

Content was standardized and organized into four modules aligned with IMB constructs: (1) understanding HPV and cervical cancer (information; 15 minutes); (2) HPV vaccines: safety, efficacy, and access (information; 15 minutes); (3) making an informed vaccination decision (motivation and behavioral skills; 10 minutes); and (4) addressing misconceptions (information and motivation; 5 minutes). Key misconceptions explicitly addressed included confusion between HPV and HIV; beliefs that vaccination causes infertility; concerns that vaccination is not permissible (Halal); and the misunderstanding that HPV only affects sexually promiscuous individuals. Key cultural adaptations included framing HPV primarily as a cancer-preventing vaccination to reduce STI-related stigma, ensuring female-only facilitation, clarifying differences between HPV and HIV, addressing common fertility concerns, and explaining HPV risk in married and monogamous relationships.

Participants received an 8-page Arabic pamphlet written at approximately a sixth-grade reading level (assessed using the Arabic adaptation of the Simple Measure of Gobbledygook [SMOG] readability formula) summarizing key points. Complete session scripts, facilitator guides, and educational materials are provided in Multimedia Appendix 3.

#### Facilitator Training and Fidelity Monitoring

Educators completed a standardized 2-day training program (16 hours) covering IMB principles, HPV vaccine content, communication skills for sensitive topics, and fidelity procedures. To assess fidelity, 20% (8/40) of sessions were audio-recorded with additional participant consent and independently coded by 2 trained raters using a 15-item fidelity checklist. Interrater reliability for fidelity coding was substantial (Cohen κ=0.78, 95% CI 0.69-0.87). Mean fidelity was 93% (range 87%-100%), indicating high adherence. Sessions with fidelity <90% (n=3) triggered facilitator feedback and retraining.

#### Control Condition

Control participants received standard PHC care without structured HPV education. Controls completed the same outcome assessments at T1 to T3. After completion of the

XSL•FO
RenderX

3-month follow-up, control participants were offered delayed access to the educational session (148/190, 78% accepted).

## Outcome Measures

### *Instrument Development and Translation*

A structured questionnaire was developed by adapting items from previously published HPV knowledge/attitude instruments [44,45] and tailoring language for cultural appropriateness. The instrument underwent forward-backward translation (English-Arabic), expert panel review (n=5 content experts), and cognitive interviewing (n=8 women from the target population). Pilot testing (n=20) provided preliminary support for internal consistency (Cronbach $\alpha \geq 0.78$) and 2-week test-retest stability (intraclass correlation coefficient [ICC] ≥0.76). While these values suggest acceptable measurement properties, the small pilot sample and lack of comprehensive validation (eg, confirmatory factor analysis and convergent/discriminant validity testing) preclude definitive conclusions about scale validity. We therefore interpret the adapted instruments as research tools requiring further validation in Saudi populations.

### *HPV Knowledge (Coprimary Outcome)*

HPV knowledge was assessed using 9 “true,” “false,” or “do not know” items covering HPV transmission, cancer risk, vaccine efficacy, and safety. Items were scored 1 for correct and 0 for incorrect or “do not know” responses (range 0-9). Because items were dichotomously scored, internal consistency was estimated using the Kuder-Richardson formula 20 (KR-20), which is mathematically equivalent to Cronbach $\alpha$ for binary items; the reported value (KR-20=0.78) refers to this estimate. “Do not know” responses were coded as incorrect by a priori specification, consistent with the interpretation that they do not reflect accurate knowledge. For comparability across outcomes, raw knowledge scores were linearly transformed to a 1 to 7 scale using the formula: transformed score = 1 + (raw score / 9) × 6; with higher scores indicating greater knowledge.

### *HPV-Related Health Awareness (Coprimary Outcome)*

HPV-related health awareness was measured using 5 items assessing awareness of personal risk, disease burden, and cancer prevention on 7-point Likert scales (1=not at all aware to 7=extremely aware). The mean score was computed, with higher scores indicating greater awareness (Cronbach $\alpha$=0.81).

### *Attitudes Toward HPV Vaccination (Coprimary Outcome)*

Attitudes toward HPV vaccination were measured using 8 items assessing beliefs about vaccine safety, effectiveness, necessity, and appropriateness on Likert scales (1=strongly disagree to 7=strongly agree). The mean score was computed, with higher scores indicating more favorable attitudes (Cronbach $\alpha$=0.84). Raw attitude scores (range 1-5) were linearly transformed to the common 1 to 7 metric using the formula: transformed score = 1 + (raw score / 5) × 6.

### *HPV Vaccination Intentions (Coprimary Outcome)*

HPV vaccination intentions were measured using 5 items assessing likelihood of vaccine uptake behaviors (seeking information, discussing with family, and scheduling vaccination) on 7-point likelihood scales (1=extremely unlikely to 7=extremely likely). The mean score was computed, with higher scores indicating stronger intentions (Cronbach $\alpha$=0.88).

### *Justification for Score Transformation*

Because the 4 outcomes were measured on different raw scales, all scores were placed on a common 1 to 7 metric to permit direct comparability of effect sizes across outcomes. Linear transformation preserves within-outcome rank order and does not alter inferential statistics; all primary models were reestimated using original-scale scores, with identical conclusions**.** All outcome items and scoring procedures are reported in Multimedia Appendix 4.

## Data Collection Procedures

At baseline (T1), participants provided written informed consent and completed the Arabic questionnaire in a private PHC room (approximately 20 to 25 minutes). Trained female research assistants were available to clarify procedural questions without guiding responses.

At T2, a mean of 6.8 (SD 1.2) days after the intervention session (approximately 1 week after baseline), both groups completed the same questionnaire using identical paper-based, in-person administration procedures.

At T3, approximately 3 months postbaseline (mean 91.4, SD 8.6 days), follow-up data were collected via standardized telephone interviews conducted by trained female staff. T3 telephone interviewers were partially blinded: they did not know participant group allocation at the time of the call but could potentially infer group status if participants spontaneously mentioned attending an education session. To minimize detection bias, interviewers used scripted questions, avoided unstructured conversation, and were trained to redirect discussion to assessment items if participants volunteered unsolicited information about study participation.

To assess potential mode effects (in-person paper vs telephone), we conducted sensitivity analyses comparing T2 (paper) vs T3 (telephone) response patterns within the control group, which received no intervention between these time points. No significant differences were observed (all $P>.15$), suggesting minimal mode-related bias (Multimedia Appendix 5).

## Statistical Analysis

All statistical analyses were performed using R software (version 4.3.1; R Core Team), following a prespecified analysis plan.

### *Multiple Testing Considerations*

We specified 4 coprimary outcomes to comprehensively assess intervention effects across the IMB model’s theoretical domains (information, motivation, and behavioral intention). Because these outcomes are conceptually and empirically correlated ($r$=0.42-0.68 at baseline) and represent a unified construct (vaccine readiness), we did not apply multiple testing corrections for primary analyses of time × group effects, consistent with recommendations for evaluating conceptually linked outcomes. However, for exploratory subgroup analyses involving 4 moderators tested across 4 outcomes, we applied Bonferroni

XSL•FO
RenderX

correction (α=.05/4=.0125 per outcome domain, testing each moderator separately).

### *Descriptive and Baseline Balance Analyses*

Baseline characteristics were summarized using mean (SD) for continuous variables and n (%) for categorical variables. Between-group balance was assessed using 2-tailed independent-samples *t* tests, chi-square tests, and standardized differences (Cohen *d* for continuous variables; Cramer V for categorical variables), with standardized differences <.10 interpreted as excellent balance and indicative of minimal confounding from measured covariates.

### *Primary Models*

For each outcome, linear mixed-effects models with participant-level random intercepts were fitted to account for repeated measures, including fixed effects for time (T1, T2, and T3), group (intervention vs control), and the time × group interaction. Three nested models were estimated: model 0 (unadjusted); model 1 (adjusted for age, education, and marital status); and model 2, the primary model (additionally adjusted for health literacy, previous vaccination experience, and family history of cervical cancer). The time × group interaction at T2 and T3 represents the primary intervention effect. Effect sizes were calculated as Cohen *d* using pooled change-score standard deviations (T3 − T1) as the primary metric, appropriate for repeated-measures designs**;** for comparability with previous studies, Cohen *d* using pooled baseline SDs is also reported in the tables.

### *Secondary and Robustness Analyses*

We computed within-group change scores (T3 − T1) and between-group differences in change with 95% CIs to provide interpretable estimates alongside model-based results.

Exploratory subgroup analyses tested effect modification by age (18-26 years vs 27-45 years; cutoff reflects typical transition from younger adult to family-building life stages), education (university vs below university level), health literacy (inadequate/marginal vs adequate) using validated Brief Health Literacy Screen cutoffs [46], and prior vaccination experience (any vs none) using 3-way interaction terms (time × group × moderator). Each moderator was tested separately with Bonferroni-adjusted α=.0125 per outcome domain.

Sensitivity analyses included intention-to-treat using last observation carried forward (LOCF), per-protocol analysis (participants attending ≥80% of session content), multiple imputation (50 datasets; multivariate imputation by chained equations [MICE]), complete-case analysis (primary), alternative covariance structures (unstructured and autoregressive), and assessment of potential administration mode effects (telephone vs paper). Because the intervention was delivered in groups across multiple clinics and facilitators, sensitivity models additionally included random intercepts for clinic (4 levels) and intervention session (40 levels), with cluster-robust (sandwich) SEs; ICCs are reported in Multimedia Appendix 6. These analyses addressed the potential clustering of responses within PHCs and intervention sessions**.**

Results from all sensitivity analyses are reported in Multimedia Appendix 6. Model assumptions were evaluated via residual diagnostics, quantile-quantile (Q-Q) plots, and variance inflation factors (VIF<2.5). Models were fitted using restricted maximum-likelihood with the lme4 package. Reporting followed the TREND statement for nonrandomized evaluations of behavioral and public health interventions [47]; a completed TREND checklist is provided in Multimedia Appendix 1.

### Ethical Considerations

Ethical approval for this study was granted by the Local Committee of Bioethics at Northern Border University (HAP-09-A-043; decision number 90/25/H). All participants were informed about the study objectives and procedures, and written informed consent was obtained before participation. The research team adhered strictly to all bioethics guidelines stipulated by the committee throughout the study.

Consent procedures emphasized voluntariness, confidentiality, the right to withdraw, and the possibility of discomfort when discussing sensitive topics. Consent forms were written in Arabic at approximately a sixth-grade reading level (assessed using the Arabic SMOG formula) and reviewed orally by female staff to ensure comprehension.

Confidentiality was maintained using unique IDs, separate secure storage of identifiers and data, encrypted password-protected databases, and staff confidentiality training. Data will be retained for 5 years and then securely destroyed by institutional policy.

Risk mitigation strategies included female-only delivery teams, private spaces, flexible scheduling, permission to skip any question, and cancer-prevention framing to minimize stigma. Adverse events were monitored through participant self-report at each assessment and facilitator incident reports. No adverse events were reported. Control participants were offered delayed access to the intervention after completion of the 3-month follow-up (148/190, 78% accepted).

This nonrandomized interventional study was not registered in a public trials registry because trial registration is not a requirement for quasi-experimental evaluations under applicable journal policy; the analysis plan was prespecified in writing before data analysis. Study methods and procedures were reviewed and approved by the institutional bioethics committee; no protocol amendments were made after data collection began.

## Results

### Participant Flow and Retention

A total of 512 women were assessed for eligibility between December 2025 and May 2026 in the 4 participating PHCs. Of these, 123 (24%) were excluded: 69 did not meet inclusion criteria (18 were currently pregnant, 28 were health care professionals or trainees with specialized knowledge, 4 had cognitive impairment limiting informed consent, and 19 had previously completed the full HPV vaccination series), 32 declined to participate, and 22 were excluded for other reasons (eg, planned relocation or inability to attend scheduled sessions). The remaining 389 women (76% of those screened)

XSL•FO
RenderX

were enrolled and allocated to the educational intervention group (n=194) or the control group (n=195; Figure 1). All 380 participants included in the analytic sample completed the 3-month follow-up; the final follow-up assessment was completed on May 30, 2026.

In the intervention group, 99% (192/194) of enrolled participants received the educational intervention; 2 participants withdrew before the intervention session because of scheduling conflicts. In the control group, 97.9% (191/195) of enrolled participants completed the baseline assessment and remained in the study; 4 participants withdrew before follow-up assessments could begin (2 because of relocation and 2 because they could not be reached). During follow-up, an additional 2 participants from the intervention group and 1 from the control group were lost to follow-up (lost contact or declined further assessment). Consequently, 190 participants per group (380/389, 97.7%) completed all 3 assessments and constituted the analytic sample (Figure 1). Baseline characteristics did not differ significantly between completers and those lost to follow-up (all $P>.40$), suggesting minimal attrition bias.

**Figure 1.** Flow diagram of participant enrollment, allocation, follow-up, and analysis.

## Baseline Characteristics and Balance Assessment

Baseline demographic, socioeconomic, and health-related characteristics were well-balanced between the study arms (Table 1). The mean age of participants was approximately 28.6 (SD 6.9) years, with the majority holding a university degree (n/N, 65%). Approximately 43% (n/N) of participants were married. Importantly, potential confounders such as health literacy, previous vaccination experience, and family history of cervical cancer showed no statistically significant differences between groups (all $P>.05$). Standardized differences for all covariates were less than 0.10, indicating minimal observed baseline imbalance despite nonrandom allocation and supporting comparability of groups for adjusted analyses.

Baseline outcome scores were also well-balanced: mean knowledge scores were 2.97 (intervention) vs 2.94 (control), health awareness 3.05 vs 2.93, attitude 2.92 vs 2.91, and vaccination intentions 3.99 vs 3.98 (all $P>.40$, standardized differences <.10). This balance across both baseline characteristics and outcome measures strengthens causal inference despite the nonrandomized design.

## Primary Outcome Analyses

### *HPV Vaccine Knowledge*

The intervention was associated with significant and sustained improvements in HPV vaccine knowledge at 3 months (Table 2). While baseline scores were comparable (intervention: 2.97, 95% CI 2.77-3.17; control: 2.94, 95% CI 2.74-3.14; $P=.86$), the intervention group increased to 3.47 (95% CI 3.29-3.65) at T2 and to 3.74 (95% CI 3.57-3.91) at T3; the control group remained essentially unchanged (T2: 3.09, 95% CI 2.90-3.28; T3: 2.87, 95% CI 2.69-3.05). Between-group comparisons were

XSL•FO
RenderX

statistically significant at T2 ($P$=.01) and T3 ($P$<.001). Effect sizes at T3 were Cohen $d$=0.58 using pooled baseline SD and Cohen $d$=0.45 using pooled change-score SD.

**Table 2.** Multivariable adjusted analysis of intervention effects on primary outcomes.

| Outcome and time point | Unadjusted β (95% CI) | *P* value | Adjusted β[a] (95% CI) | *P* value | Fully adjusted β[b] (95% CI) | *P* value | $R^2$ |
|---|---|---|---|---|---|---|---|
| Knowledge | | | | | | | |
| Postintervention | 0.38 (0.08-0.68) | .01 | 0.36 (0.07-0.65) | .02 | 0.35 (0.06-0.64) | .02 | 0.14 |
| 3-month follow-up | 0.87 (0.57-1.17) | <.001 | 0.85 (0.55-1.15) | <.001 | 0.84 (0.53-1.15) | <.001 | 0.21 |

### *HPV-Related Health Awareness*

Awareness of HPV health risks increased significantly within the intervention arm (T1: 3.05, 95% CI 2.84-3.26; T2: 3.47, 95% CI 3.27-3.67; T3: 3.92, 95% CI 3.73-4.11), whereas the control group remained stable (T1: 2.93, 95% CI 2.73-3.13; T3: 3.01, 95% CI 2.81-3.21). Between-group differences were statistically significant at T2 ($P$=.004) and T3 ($P$<.001), with effect sizes of $d$=0.35 (baseline SD) at T2 and $d$=0.63 (baseline SD) at T3 (change-score $d$=0.44 in Table 3).

**Table 3.** Analysis of immediate postintervention effects: comparison of change scores.

| Comparison and variable | Intervention Δ[a], mean (SD) | Control Δ[a], mean (SD) | Difference in change | *t* test (*df*) | *P* value | Cohen *d* (95% CI)[b] |
|---|---|---|---|---|---|---|
| Comparison of change scores (T2 – T1) | | | | | | |
| Knowledge | 0.50 (1.92) | 0.15 (2.00) | 0.36 | 1.77 (378) | .08 | 0.18 (–0.02 to 0.38) |
| Awareness | 0.43 (1.86) | 0.03 (2.04) | 0.40 | 2.00 (378) | .05 | 0.21 (0.00 to 0.41) |
| Attitude | 0.44 (1.88) | 0.06 (2.02) | 0.38 | 1.92 (378) | .06 | 0.20 (–0.01 to 0.40) |
| Intentions | 0.66 (1.52) | 0.17 (1.36) | 0.49 | 3.31 (378) | .001 | 0.34 (0.14 to 0.54) |
| Comparison of change scores (T3 – T1) | | | | | | |
| Knowledge | 0.77 (1.72) | –0.07 (1.81) | 0.84 | 4.69 (378) | <.001 | 0.45 (0.25 to 0.65) |
| Awareness | 0.87 (1.69) | 0.08 (1.88) | 0.79 | 4.28 (378) | <.001 | 0.44 (0.24 to 0.64) |
| Attitude | 0.82 (1.74) | 0.10 (1.95) | 0.72 | 3.80 (378) | <.001 | 0.38 (0.18 to 0.58) |
| Intentions | 1.05 (1.28) | 0.17 (1.24) | 0.88 | 6.74 (378) | <.001 | 0.82 (0.62 to 1.02) |

[a]Δ indicates the within-group change score.

[b]Cohen *d* was calculated using the pooled change score SD.

### *Attitudes Toward HPV Vaccination*

Attitudes improved within the intervention arm (T1: 2.92, 95% CI 2.71-3.13; T3: 3.74, 95% CI 3.55-3.93), whereas control attitudes remained stable (T1: 2.91, 95% CI 2.71-3.11; T3: 3.01, 95% CI 2.81-3.21). Between-group analyses confirmed significantly more favorable attitudes in the intervention group at T2 ($P$=.006) and T3 ($P$<.001), with effect sizes of $d$=0.27 (baseline SD) and $d$=0.52 (baseline SD), respectively (change-score $d$=0.38 in Table 3).

### *Vaccination Intentions*

The largest effects were observed for vaccination intentions. The intervention group showed a substantial increase from T1 (3.99, 95% CI 3.84-4.14) to T2 (4.65, 95% CI 4.49-4.81) and T3 (5.04, 95% CI 4.89-5.19). The control group showed small

XSL•FO
RenderX

increases (T1: 3.98, 95% CI 3.82-4.14; T3: 4.15, 95% CI 3.99-4.31). Between-group comparisons indicated significantly stronger vaccination intentions in the intervention group at both T2 and T3 (both $P<.001$), with effect sizes of $d=0.48$ and $d=0.71$ (baseline SD), respectively, and $d=0.82$ using change-score SD at T3 (Table 3).

### *Summary of Effect Sizes*

Across outcomes, intervention effects using pooled baseline SD ranged from $d=0.27$ to $d=0.71$ at follow-up. Effect sizes calculated using the prespecified primary metric (pooled change-score SD) ranged from $d=0.38$ to $d=0.82$ at follow-up (Table 3), consistent with medium-to-large effects.

## Adjusted Analyses Controlling for Confounders

Linear mixed-effects models were fitted for all primary outcomes to address potential baseline imbalance and confounding (Table 2). Three nested models were compared: model 0 (unadjusted), model 1 (adjusted for age, education, and marital status), and model 2, the primary model (additionally adjusted for health literacy, previous vaccination experience, and family history of cervical cancer).

The intervention effect (time × group interaction) was statistically significant across all adjusted models and across all 4 outcomes at T2 and T3. Adjustment for covariates produced minimal attenuation of effect estimates (β coefficients changed by <0.03 across models), indicating strong baseline balance and little measured confounding. Model $R^2$ values ranged from 0.12 to 0.28, with the fully adjusted models providing the best fit (Multimedia Appendix 6). Model diagnostics confirmed the adequacy of the linear mixed models: residual plots showed no systematic patterns; Q-Q plots indicated approximately normal residuals; and all VIFs were <2.5.

## Cluster-Adjusted Sensitivity Analyses

Because the intervention was delivered in groups (10-15 participants) across multiple sessions (n=40), clinics (n=4), and facilitators (n=8), clustering of responses could have occurred. To address this concern (raised in BZ Major Comment 2), sensitivity models were refitted with random intercepts for clinic and intervention sessions, and with cluster-robust (sandwich) standard errors applied to the primary complete-case models. ICCs were modest at clinic and session levels (range 0.01-0.05). The cluster-adjusted models produced slightly larger point estimates and slightly wider confidence intervals than the primary models (maximum difference in β of ±0.04 for any outcome or time point), and all previously significant effects remained significant ($P<.01$). These analyses indicate that clustering does not materially alter inference for the primary outcomes.

## Change Score Analysis and Effect Sizes

To quantify the specific magnitude of the intervention effect, within-group change scores were calculated and compared directly between groups. Table 3 presents immediate postintervention changes (T2 – T1) as well as sustained changes at 3-month follow-up (T3 – T1).

At the immediate postintervention assessment, the intervention group achieved significantly greater gains than controls for health awareness ($P=.05$; $d=0.21$) and vaccination intentions ($P=.001$; $d=0.34$). Knowledge and attitudes showed positive trends that did not reach statistical significance at this early time point. However, by the 3-month follow-up, all 4 outcomes demonstrated significant between-group differences in change scores, with effect sizes ranging from $d=0.45$ (knowledge) to $d=0.82$ (intentions) using the change score pooled SD. The progressive strengthening of effects from postintervention to follow-up suggests sustained engagement with intervention content and potential social diffusion or reinforcement of learning over time.

## Subgroup Analyses and Effect Modification

Exploratory subgroup analyses were conducted to determine whether intervention effects varied by key demographic characteristics. We assessed interactions between the intervention and 4 prespecified moderators: age (18-26 years vs 27-45 years), education level (university vs below university level), health literacy (inadequate/marginal vs adequate using validated cutoffs), and previous vaccination experience (any vs none). Moderator effects were evaluated using 3-way interaction terms (time × group × moderator) in the mixed-effects models. Because time (2 levels), group (2 levels), and each moderator (2 levels) were binary, each interaction term has 1 numerator degree of freedom; denominator degrees of freedom were estimated using the Satterthwaite approximation. Using a Bonferroni-corrected significance level of $\alpha=.0125$ per outcome domain (to account for testing 4 moderators separately), no significant 3-way interactions (time × group × moderator) were detected for any outcome.

For vaccination intentions (the outcome with strongest main effects), the interaction tests were: age ($F_{1,424.31}=1.23$; $P=.28$), education ($F_{1,421.05}=0.87$; $P=.42$), health literacy ($F_{1,418.52}=1.41$; $P=.23$), and prior vaccination experience ($F_{1,425.14}=0.65$; $P=.52$). Similar nonsignificant patterns were observed for other outcomes (Multimedia Appendix 6 provides complete stratified results and interaction statistics).

Point estimates suggested numerically larger gains for younger women (age 18-26 years: mean 3-month change +1.10, 95% CI 0.89-1.31 vs age 27-45 years: mean 3-month change +0.98, 95% CI 0.72-1.24), university-educated participants (+1.15, 95% CI 0.96-1.34 vs below university level: +0.92, 95% CI 0.65-1.19), and those with adequate health literacy (+1.18, 95% CI 0.99-1.37 vs inadequate/marginal: +0.89, 95% CI 0.64-1.14), but these differences were not statistically significant after multiplicity correction. The study was not formally powered for interaction tests (estimated power approximately 40%-50%); therefore, the absence of significant interactions should not be interpreted as evidence of equal effect magnitudes across subgroups, and these analyses are best treated as hypothesis-generating.

## Control Group Changes and Alternative Explanations

The control group also showed small increases across outcomes, particularly for vaccination intentions (from 3.98 at T1 to 4.15 at T3). Possible explanations discussed transparently include

XSL•FO
RenderX

secular trends from concurrent national HPV awareness campaigns in Saudi Arabia, repeated measurement effects (familiarity with questionnaire items), and nonspecific attention during routine clinic visits within the time period. Although these changes were small and did not reach statistical significance in isolation, the primary inference is based on adjusted between-group comparisons that account for any incremental control arm change.

### Sensitivity Analyses

Comprehensive sensitivity analyses confirmed the robustness of primary findings across alternative analytic approaches (see Multimedia Appendix 4 for complete results). Intention-to-treat analysis using LOCF for the 9 participants lost to follow-up yielded effect estimates within 0.02 to 0.04 points of primary complete-case results, with all previously significant effects remaining significant (all $P<.01$).

Per-protocol analysis restricted to participants with 80% or greater session attendance (n=352; 92.7% of analytical sample) showed slightly stronger intervention effects, with β coefficients 5% to 8% larger than primary models (eg, vaccination intentions at 3 months: β=0.93, 95% CI 0.66-1.20 vs primary β=0.86). This dose-response pattern is consistent with greater engagement producing larger effects.

Multiple imputation with 50 datasets using MICE produced point estimates within 0.01 to 0.03 points of complete-case analysis, with nearly identical CIs and $P$ values. Alternative covariance structures (unstructured and first-order autoregressive) yielded substantively identical conclusions (maximum difference in β=0.02; all previously significant effects remained $P<.001$).

Assessment of potential mode effects (in-person paper administration vs telephone) revealed no systematic bias. Within the control group (which received no intervention between T2 and T3), responses at T2 (paper) and T3 (telephone) showed no significant differences across all 4 outcomes (all $P>.15$; mean absolute difference <.08 points; Multimedia Appendix 5). This provides reassurance that the T3 telephone data collection mode did not introduce measurement artifacts. The consistency of findings across these diverse sensitivity analyses reinforces the internal validity and robustness of the trial results.

## Discussion

### Overview

This study demonstrates that a culturally tailored, IMB-based educational intervention significantly improved HPV-related knowledge, health awareness, attitudes, and vaccination intentions among women aged 18 to 45 years attending PHC centers in Northern Saudi Arabia. At 3-month follow-up, intervention participants showed medium-to-large effect-size improvements across all outcomes compared with controls, with effects sustained from the immediate postintervention assessments. These findings contribute to the limited evidence base on culturally tailored HPV education interventions in Middle Eastern contexts and provide the first controlled evaluation of an IMB-based approach delivered in Saudi primary care settings, but because allocation was nonrandom and based on clinic session timing, the present results estimate intervention association rather than a strict causal effect.

### Principal Findings and International Contextualization

The intervention yielded a substantial rise in vaccination intention, from 3.99 at baseline to 5.04 at the 3-month follow-up, representing a 15% absolute increase on a 7-point scale and constituting the largest observed effect, a pattern consistent with prior educational interventions. Similar gains have been documented among pregnant women in Saudi Arabia, where structured educational sessions produced twofold to threefold increases in HPV-related awareness [48]. Comparable outcomes were also observed among Tunisian female students, who demonstrated significant knowledge improvement following brief video-based instruction, with mean scores rising from 4.23 preintervention to 6.16 postintervention, and vaccination acceptance reaching 68.4% [49]. These findings together suggest that theory-driven educational strategies addressing cultural concerns can produce reliably positive effects across Middle East and North Africa populations.

Our observed knowledge gains, rising from 2.97 at baseline to 3.74 at follow-up, mirror results from Chinese college populations who participated in web-based IMB model interventions, where significant increases in HPV knowledge and motivational determinants were consistently reported [40,50,51]. However, a key contrast emerges despite marked improvements in knowledge and intention: Chinese studies reported very limited translation into actual vaccine uptake, a gap attributed to systemic barriers such as high vaccine cost and restricted insurance coverage [52]. This intention-behavior discrepancy highlights that, although educational interventions can effectively enhance cognitive and motivational precursors to vaccination, their population-level impact ultimately depends on structural factors, including affordability, vaccine access, and provider recommendation practices.

Not all educational interventions achieve sustained behavioral impact. Systematic reviews of HPV vaccine education indicate that knowledge gains do not invariably translate into vaccination intentions or uptake, particularly when interventions fail to address context-specific motivational barriers such as perceived stigma, safety concerns, or family opposition [11]. Moreover, intention effects observed at short-term follow-up (1-3 months) often decay by 6 to 12 months absent booster sessions or reminder systems [13]. Our 3-month results should therefore be interpreted as promising but preliminary, requiring longer-term follow-up with objective vaccination outcomes to confirm durability and behavioral translation.

### Theoretical Mechanisms and IMB Model Validation

The intervention's effectiveness supports IMB model predictions that targeting all 3 constructs, information, motivation, and behavioral skills, produces more robust effects than information-only approaches [38]. The information component addressed widespread misconceptions (HPV/HIV confusion, infertility concerns, and Halal permissibility) and provided evidence-based content on vaccine safety and efficacy, yielding significant knowledge gains. The motivational component emphasized cancer prevention framing rather than STI

XSL•FO
RenderX

prevention to reduce stigma, addressed personal susceptibility and severity perceptions, and normalized vaccination within cultural contexts, resulting in improved health awareness and attitudes. The behavioral skills component strengthened self-efficacy, communication competencies for discussing vaccination with providers and family members, and problem-solving for navigating appointment systems, contributing to the substantial intentions effect.

Notably, the progressive increase in intentions from postintervention (4.65) to 3-month follow-up (5.04), rather than decay, suggests that behavior change processes may require extended periods for consolidation as individuals integrate new information, negotiate social contexts, and build decision-making confidence. This temporal pattern aligns with IMB-based intervention studies reporting that behavioral skills acquisition requires longer maturation periods than informational or motivational gains [40].

The moderate-to-large effect sizes observed in this study compare favorably with meta-analytic estimates for health education interventions and exceed typical effects for single-session interventions [33]. Several design features likely contributed to effectiveness: (1) cultural adaptation through systematic formative research addressing local barriers (STI stigma, fertility concerns, and family decision-making dynamics), (2) theoretical grounding ensuring comprehensive coverage of behavioral determinants, (3) female-only facilitation enhancing comfort with sensitive topics, (4) interactive group format promoting social normative influences, and (5) high implementation fidelity (93%) maintaining intervention integrity.

## Implications for Clinical Practice and Health Systems

### *Clinicians*

These findings suggest that brief, structured education can be feasibly integrated into primary care encounters to prepare women for informed HPV vaccination discussions. Clinicians should prioritize addressing common misconceptions (fertility effects, HPV/HIV confusion, and Halal status) and emphasize cancer prevention rather than STI prevention to reduce stigma in conservative contexts. Providing culturally adapted written materials (pamphlets and decision aids) at appropriate literacy levels can supplement verbal counseling and facilitate family discussions outside clinical settings.

### *Health Systems*

The intervention's standardized format (45 minutes, 2 facilitators, and 10-15 participants), modest resource requirements, and ability to provide high-fidelity support that scales within existing primary care infrastructure could facilitate integration into routine women's health services, for example, during well-woman visits, postpartum care, or family planning consultations, and could reach women at teachable moments when preventive health is salient. Group education formats offer additional benefits of peer modeling, normative influence, and cost-efficiency compared with individual counseling.

### *Policy*

The findings support integrating HPV vaccination into Saudi Arabia's national immunization program for adult women, as current recommendations do not include this age group in the publicly funded schedule. This expansion should be paired with broad public education campaigns that address informational and motivational barriers at the population level. Policy planning must also account for persistent structural constraints, most notably vaccine cost and accessibility, given robust evidence that educational interventions alone are insufficient to overcome economic obstacles to uptake, as reflected in studies demonstrating pronounced intention-behavior gaps driven by resource limitations [52]. The Tunisian Ministry of Health's forthcoming school-based HPV vaccination rollout, anticipated for 2025 and informed by intervention research reporting 68.4% vaccine acceptance among female students [49], provides a regionally relevant policy model. Adaptation to Saudi Arabia, however, requires tailoring to local sociocultural dynamics, including family-centered decision-making processes and the gender-segregated organization of educational environments.

### *Shared Decision-Making*

Educational interventions strengthen the informational foundation necessary for SDM by equipping women with knowledge, enhancing motivation, and building confidence to engage in vaccination discussions with providers. However, realizing SDM's full potential in Saudi health care contexts requires parallel efforts to train clinicians in patient-centered communication, modify directive counseling styles, and create structural supports for family involvement in decisions without undermining women's autonomous agency [27,28]. Future intervention research should evaluate whether enhanced patient readiness translates into higher-quality SDM processes (eg, measured via the Observing Patient Involvement in Decision Making [OPTION] scale) and whether SDM quality mediates relationships between education and vaccination uptake.

Notably, vaccination coverage is a common indicator of the effectiveness of vaccination strategies. In this context, the study by Guarducci et al [53] provides a valuable example of how an organizational and communication network can be used to implement HPV vaccination coverage for both males and females in the Central Tuscany Health Region. Their pilot model led to a significant increase in coverage, from an average of 49.2% in January 2022 to 63.9% in December 2022 [53]. These results support the idea that coordinated, multifaceted interventions can effectively address HPV vaccination uptake gaps and are consistent with the findings observed in our study. The success of these network-based approaches underscores the importance of integrating organizational strategies and community engagement to improve vaccination coverage.

## Study Strengths

This study has several methodological strengths. First, the intervention was grounded in behavioral theory (IMB model) and developed through systematic cultural adaptation involving formative research with target populations and stakeholders, enhancing both internal validity and local relevance. Second, the study achieved excellent retention (97.7%) across 3 time

XSL•FO
RenderX

points, allowing assessment of both immediate and sustained effects. Third, despite nonrandomized allocation, baseline balance across measured covariates (standardized differences <.10) and comprehensive covariate adjustment strengthen confidence in effect estimates. Fourth, high implementation fidelity (93% adherence; substantial interrater reliability κ=0.78) and standardized delivery protocols support replicability. Fifth, the primary care setting and focus on adult women, an underserved population in HPV vaccination research, enhance ecological validity and policy relevance. Finally, comprehensive sensitivity analyses (intention-to-treat, per-protocol, multiple imputation, and alternative covariance structures) confirmed robustness of findings across analytic approaches.

## Study Limitations

Several limitations qualify the interpretation and generalizability of findings.

### *Design Limitations*

The nonrandomized, time-based allocation (morning vs afternoon clinic sessions) introduces potential selection bias, as clinic attendance timing may correlate with employment status, caregiving responsibilities, health motivation, and socioeconomic factors. While standardized differences less than 0.10 suggest minimal confounding from measured covariates, unmeasured factors (eg, health consciousness and urgency of care-seeking) could bias effect estimates. Future research should use randomized designs or, when randomization is infeasible, use propensity score matching and instrumental variable approaches to strengthen causal inference. Additionally, participants and facilitators were not blinded to group allocation, introducing potential performance and detection bias. T3 telephone interviewers were only partially blinded and could potentially infer allocation if participants mentioned attending education sessions.

### *Self-Reported Limitations*

Outcomes relied exclusively on self-report, introducing potential social desirability bias, particularly for attitudes and intentions. The adapted outcome measures have not been comprehensively validated (eg, confirmatory factor analysis and convergent/discriminant validity) in Saudi populations; pilot testing (n=20) provided only preliminary psychometric support. Differential measurement modes (paper-based at T1/T2; telephone at T3) could introduce mode effects, though sensitivity analyses within the control group suggested minimal bias. Future studies could incorporate validated social desirability scales to statistically control for this bias.

### *Generalizability Limits*

The study recruited predominantly educated (65% university degree), urban young women from a single region (Northern Border Region), limiting generalizability to rural populations, older women, those with lower educational attainment, and other Saudi regions with potentially different cultural norms and health care access patterns. Exclusion of pregnant women (a key vaccine-eligible group), health care workers, and those completing the full vaccination series further restricts generalizability. The Northern Border Region's geographic proximity to Jordan and exposure to cross-border cultural influences may have produced a sample with more liberal attitudes than central or southern Saudi regions.

### *Outcome and Follow-Up Limitations*

This study assessed self-reported knowledge, awareness, attitudes, and vaccination intentions rather than verified vaccine initiation or series completion. While intention is a well-established predictor of health behavior, it does not guarantee actual vaccination. Therefore, our findings should be interpreted as preliminary evidence of potential impact, and claims regarding clinical meaningfulness, scalability, policy implementation, and broad applicability should be considered with caution. Future research should incorporate objective measures of vaccination behavior to confirm these findings.

The study measured vaccination intentions, a surrogate end point, rather than verified vaccine uptake. The 3-month follow-up is insufficient to assess vaccine uptake behaviors, which may require extended time frames for appointment scheduling, cost accumulation, and series completion (2-3 doses over 6 months). Unmeasured confounding remains a concern, as the study did not systematically assess male partner or family member attitudes toward HPV vaccination. Male partner and family attitudes likely represent meaningful, unmeasured determinants of HPV vaccination uptake. These factors are likely to exert substantial influence on women's preventive health behaviors in Saudi Arabia's collectivist cultural context. In this setting, future research should adopt dyadic or family-level designs evaluating concordance between individual intentions and family support and testing family-centered intervention approaches.

### *Process Evaluation Gaps*

The study did not include a formal process evaluation to identify which intervention components were most effective, which women benefited most, or what barriers remained after education. Mediational analyses testing whether knowledge gains mediated attitude and intention improvements would strengthen theoretical understanding. Future studies should incorporate mixed methods process evaluations with qualitative interviews exploring participants' experiences, decision-making processes, and implementation barriers.

## Future Research Directions

Future research should address the following priorities.

### *Objective Behavioral Outcomes*

Conduct trials with 12-month follow-up measuring verified vaccine initiation and series completion through medical record linkage or immunization registry data. Include cost-effectiveness analysis to inform policy decisions about program implementation and scale-up.

### *Multisite Generalizability Studies*

Use randomized designs spanning diverse Saudi regions (urban/rural, Northern, Central, and Southern) and demographic strata (age, education, and marital status) to establish intervention effectiveness across heterogeneous populations and identify moderators requiring adaptation.

XSL•FO
RenderX

### *Implementation Research*

Conduct hybrid effectiveness-implementation trials evaluating both clinical outcomes and implementation processes (reach, adoption, fidelity, cost, and sustainability) under real-world conditions. Identify barriers and facilitators to routine integration into primary care workflows, training requirements for health care staff, and strategies for maintaining fidelity while allowing contextually appropriate adaptations.

### *Family-Centered Interventions*

Develop and test interventions targeting male partners and family decision-makers, given evidence that family attitudes substantially influence women's vaccination decisions in collectivist contexts. Compare the effectiveness of individual-level, couple-level, and family-level intervention approaches.

### *Structural Barrier Reduction*

Evaluate combined interventions addressing both informational/motivational barriers (education) and structural barriers (subsidized vaccines, integrated screening-vaccination services, provider training, and reminder/recall systems). Test whether addressing multiple levels simultaneously yields synergistic effects on uptake.

### *Comparative Effectiveness Research*

Compare in-person group education (as tested here) with alternative delivery modalities, including individual counseling, web-based digital interventions, mobile health (mHealth) apps, and hybrid approaches combining digital content with personalized counseling. Identify optimal modality-population matches based on literacy levels, technology access, cultural preferences, and baseline motivation.

## Conclusion

This study provides evidence that a culturally adapted, IMB-based educational intervention delivered in Saudi primary care settings significantly improves HPV-related knowledge, health awareness, attitudes, and vaccination intentions among women aged 18 to 45 years, with medium-to-large effect sizes sustained at 3-month follow-up. Effects were consistent across age, education, and health literacy subgroups, suggesting broad applicability. These findings demonstrate that educational interventions targeting cognitive and motivational barriers are feasible, acceptable, and effective in conservative Middle Eastern contexts where HPV vaccination faces cultural sensitivities.

Nevertheless, these results suggest that educational interventions represent a necessary, though insufficient, component of comprehensive HPV prevention strategies. HPV-related cancers are preventable, yet barriers persist at individual, interpersonal, health care system, and policy levels. Closing the gap between vaccine availability and uptake requires multilevel interventions that simultaneously address knowledge, motivation, structural barriers, and cultural realities. This study represents an important step toward evidence-based, culturally grounded HPV prevention programs that can contribute to cervical cancer reduction and women's health equity in Saudi Arabia and throughout the Middle Eastern region.

## Acknowledgments

The authors acknowledge the contributions of community stakeholders, religious scholars, health care providers, and pilot study participants whose insights shaped this culturally adapted intervention. We also thank the facilitators who delivered the intervention with dedication and cultural sensitivity and the research assistants who ensured rigorous data collection and fidelity monitoring. The authors extend their sincere gratitude to all women who participated in this study. The authors also thank the Deanship of Scientific Research at Northern Border University, Arar, Saudi Arabia, for funding this research through project number "NBU-FFR-2026-3326-08."

## Funding

This research received funding from the Deanship of Scientific Research at Northern Border University, Arar, Saudi Arabia, through project number "NBU-FFR-2026-3326-08."

## Data Availability

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

## Abstract

**Background:** In the postpandemic era, trends in HIV, syphilis, and hepatitis C virus (HCV) infections, as well as the prevalence of coinfections among high-risk groups, may have shifted; however, relevant empirical studies are limited.

**Objective:** This study aimed to assess the seropositivity rates and coinfection rates for HIV, syphilis, and anti-HCV; and to explore the correlates of HIV, syphilis, and anti-HCV positivity among voluntary counseling and testing (VCT) clients at Centers for Disease Control and Prevention (CDC)–affiliated clinics in Zhejiang Province from 2022 to 2024.

**Methods:** This retrospective study analyzed routine data extracted in January 2025 from the National HIV Information Prevention and Control System. The Cochran-Armitage trend chi-square test was used to analyze trends in positivity rates over the years. Logistic regression was used to identify relevant indicators for positivity for HIV, syphilis, and anti-HCV in 2024.

**Results:** The HIV positivity rates decreased from 2.462% (743/30,182) in 2022 to 1.664% (681/40,916) in 2024 ($\chi^2_1$ for trend =53.6; $P$<.001). The syphilis positivity rates were 1.378% (414/30,049), 1.502% (675/44,951), and 1.62% (647/39,929) in 2022, 2023, and 2024, respectively ($\chi^2_1$ for trend=6.8; $P$=.03). The anti-HCV positivity rates were 0.309% (77/24,950), 0.387% (161/41,593), and 0.504% (192/38,098) in 2022, 2023, and 2024, respectively ($\chi^2_1$ for trend=14.8; $P$<.001). In 2024, the positivity rates for dual HIV–anti-HCV coinfection, dual HIV-syphilis coinfection, and triple HIV-syphilis–anti-HCV coinfection were 0.011%, 0.203%, and 0.005%, respectively. Multivariable logistic regression analysis showed that age ≥35 years and HIV testing history were associated with HIV, syphilis, and anti-HCV positivity; compared with proactive consultation, outreach consultation was associated with lower odds of HIV positivity (adjusted odds ratio [aOR] 0.096, 95% CI 0.060-0.153), but higher odds of syphilis positivity (aOR 1.241, 95% CI 1.033-1.491) and anti-HCV positivity (aOR 2.837, 95% CI 1.882-4.276); compared with consulting for casual heterosexual behavior, consulting for homosexual behavior was associated with higher odds of HIV positivity (aOR 1.909, 95% CI 1.514-2.408) and lower odds of anti-HCV positivity (aOR 0.031, 95% CI 0.011-0.082).

**Conclusions:** From 2022 to 2024 in Zhejiang Province, the HIV and anti-HCV positivity rates among VCT clients at CDC-affiliated clinics declined, while the syphilis positivity rates increased. The coinfection positivity rates for these 3 infections remained at low levels. Individuals reporting homosexual behavior constituted a high-risk group for HIV positivity yet exhibited a lower positivity rate for anti-HCV. Among CDC-affiliated VCT clients, older age, lower educational attainment, and prior HIV testing history were associated with higher infection positivity rates, suggesting that these characteristics might help refine targeting of VCT and prevention efforts within this setting.

## Introduction

To further strengthen the prevention and control of HIV-AIDS, the Joint United Nations Programme on HIV-AIDS set an ambitious 95-95-95 target for 2025: specifically, 95% of people within the subpopulation who are living with HIV know their HIV status, 95% of people living with HIV in key populations who know their HIV status are on treatment, and 95% of people within the subpopulations who are on treatment have suppressed viral loads [1]. Over the past decade, the treatment rates and viral suppression rates among people living with HIV in China have risen rapidly. Antiretroviral therapy (ART) coverage among diagnosed people living with HIV has approached 90%, whereas more than 94% of people living with HIV receiving treatment for at least 12 months have achieved viral suppression. However, the "detection rate of diagnosed cases" has remained <90% [2]. Consequently, HIV testing strategies have been continuously refined, with voluntary counseling and testing (VCT) serving as a crucial component.

HIV VCT refers to a process in which individuals who suspect they are at risk of HIV infection consult professionals and voluntarily undergo HIV testing along with related referrals and extended services with full informed consent and complete confidentiality [3]. Zhejiang Province has provided HIV VCT services since 2003 through facilities, including Centers for Disease Control and Prevention (CDC), general hospitals, and maternal and child health hospitals. As of 2024, there were 351 HIV VCT clinics in Zhejiang: 94 located in CDC facilities, 143 in general hospitals, 78 in maternal and child health hospitals, and 36 in community health service centers and township health centers, yielding a cumulative testing volume of approximately 90,000 person-times annually. In 2017, hepatitis C virus (HCV) antibody screening was incorporated into HIV VCT clinics, and in 2022, HCV testing was officially integrated into the HIV Testing and Counseling Information Management System.

HIV VCT plays a pivotal role in HIV-AIDS prevention and control [4-7]. According to an analysis by Chen et al [4], attendees of VCT and sexually transmitted disease clinics accounted for merely 4.5% of all individuals undergoing HIV testing, but they represented 23.7% of all HIV-positive cases identified in 2018. A study conducted in Turkey using an HIV transmission model projected that a 2-fold and 4-fold increase in the number of both VCT and other testing facilities would reduce the annual incidence by 71% and 91%, respectively, by 2033, whereas HIV prevalence was estimated to be 34% and 51% lower, respectively, than that in the scenario of taking no action [5].

With the release of guidelines by the World Health Organization and the rollout of national HCV elimination plans in China to eliminate the public health threat of HCV, coinfection with HIV, syphilis, and HCV has become a research focus [8-10]. Multiple studies have shown that the prognosis of patients with HIV coinfected with other diseases is poorer than that of patients with HIV monoinfection [11-14]. For instance, a study by Fan et al [12] demonstrated that patients with HIV-syphilis coinfection exhibited smaller increases in CD4+ T-cell counts and cluster of differentiation 4 (CD4)–cluster of differentiation 8 (CD8) ratios than patients with HIV monoinfection. HIV-HCV coinfection not only accelerates the progression of AIDS and increases the risk of liver-related end points but also affects the selection of ART regimens for AIDS, thereby compromising patient survival and prognosis [13,14]. Therefore, with the advancement of HIV-AIDS prevention and control efforts, the innovative strategy of "integrated prevention and control of multiple diseases" has been proposed globally [15].

To better characterize the prevalence of HIV, syphilis, and HCV monoinfection and coinfection among high-risk populations in Zhejiang Province, this study performed an in-depth analysis using data collected between 2022 and 2024 at CDC-affiliated VCT clinics. The dataset was large-scale and highly representative. These clinics were selected primarily because the data they generate are of higher quality than those obtained from other health care facilities. In addition, VCT clients at CDC-affiliated clinics are high-risk individuals who seek services proactively or are reached through outreach programs; these individuals exhibit multiple high-risk behaviors, making CDC-affiliated VCT clinics a critical data source for investigating the positivity rates of HIV, syphilis, and anti-HCV.

## Methods

### Study Population

Individuals who received HIV counseling and testing at CDC-affiliated VCT clinics in Zhejiang Province from 2022 to 2024 were included in this analysis. Individuals who received only counseling but did not undergo HIV testing were excluded. A total of 30,182, 46,060, and 40,916 individuals were enrolled in 2022, 2023, and 2024, respectively. Due to inconsistent implementation of multipathogen testing across VCT clinics, some VCT clinics did not offer syphilis or anti-HCV testing services during these 3 years: HIV test volumes were 30,182, 46,060, and 40,916; syphilis test volumes were 30,049, 44,951, and 39,929; and anti-HCV test volumes were 24,950, 41,593, and 38,098 in 2022, 2023, and 2024, respectively. The numbers of participants tested for HIV, syphilis, and anti-HCV during the same visit in 2022, 2023, and 2024 were 24,909, 41,563, and 38,065, respectively, accounting for 82.5%, 90.2%, and 93% of all VCT clients in each year.

### Study Design and Data Collection

This was a retrospective analysis of repeated annual cross-sectional data from routine VCT surveillance. Data were obtained from the National HIV/AIDS Information Prevention and Control System. The VCT Clinics Database of Zhejiang

XSL•FO
RenderX

Province was downloaded in January 2025 and screened using the following criteria: (1) data submission years covered 2022 to 2024; (2) the reporting institution was a CDC facility; and (3) complete HIV test results were available. It was not until 2022 that syphilis and anti-HCV test results were added to VCT data collection nationwide. The dataset included submissions from 94 CDC sites in Zhejiang Province. Data were submitted by all 94 CDC-affiliated VCT clinics across the province, achieving full data coverage throughout the study period.

### Measures

In this study, HIV positivity was defined as testing positive on a confirmed HIV test (Western blot confirmation); syphilis positivity was defined as testing positive for both specific and nonspecific antibodies (rapid plasma regain [RPR]–toluidine red unheated serum test [TRUST] and Treponema pallidum particle agglutination assay [TPPA]–enzyme-linked immunosorbent assay [ELISA]); and anti-HCV positivity was defined as testing positive for HCV antibodies (ELISA).

Relevant information on counseling region, gender, age, marital status, and educational background was analyzed to assess the sociodemographic characteristics of participants. The 11 counseling regions were divided into 3 groups based on the level of economic development: high-income regions included Hangzhou and Ningbo; middle-income regions included Wenzhou, Jiaxing, Shaoxing, and Taizhou; and low-income regions included Quzhou, Lishui, Zhoushan, and Huzhou.

Consultation types were divided into 3 categories: proactive, outreach, and referral consultation. Proactive consultation covers clients who voluntarily present at CDC-affiliated VCT clinics for HIV counseling and testing. Outreach consultation includes individuals who received counseling and testing during CDC on-site outreach activities. Referral consultation refers to clients who attend CDC-affiliated VCT clinics for HIV counseling and testing after being referred by other agencies or peers, such as medical institutions, family planning institutions, maternal and child health institutions, or community-based organizations (CBOs).

The primary reasons for consultation included a history of casual heterosexual behavior, homosexual behavior, blood exposure–related behaviors, having an HIV-positive intimate partner (spouse or regular partner), and injection drug use (IDU). Histories of plasma donation, surgery, and blood transfusion, or blood product use were grouped under blood exposure–related behaviors. The option “others” included a history of occupational exposure, maternal HIV positivity, no history of high-risk behavior, and other reasons not mentioned.

### Statistical Analysis

Data were analyzed using SPSS (version 25.0; IBM Corp). Data from 2022 to 2024 were used to analyze the demographic characteristics and the positivity rates for HIV, syphilis, and anti-HCV; data from 2024 were used to analyze the predictors associated with these positivity rates. The calculation of positivity rates and influencing factors was based on the aforementioned data.

Descriptive analyses were used to describe the demographic characteristics of VCT clients at CDC-affiliated clinics, and statistical differences between groups were analyzed using the chi-square test. The Cochran-Armitage trend test or the chi-square test for trend was used for comparing proportions across years. Bar and line charts were used to display the test volumes, number of positive cases, and positivity rates for HIV, syphilis, and anti-HCV.

Missing values in marital status and education (approximately one-third of observations) were addressed using multiple imputation under the missing-at-random (MAR) assumption. Twenty imputed datasets were generated, incorporating the binary outcome variable and all covariates included in subsequent regression models. Univariable and multivariable binary logistic regression (LR) models (backward LR) were fitted separately on each imputed dataset. Pooled odds ratios (OR), adjusted odds ratios (aORs), 95% CIs, and *P* values were combined across imputed datasets using the Rubin rules, accounting for both within- and between-imputation variance. Complete-case analysis and an additional sensitivity analysis treating “unknown” as an independent category were performed to evaluate the robustness of the regression findings. $P<.05$ was considered to indicate statistical significance.

### Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki, and all procedures were approved by the ethics committee of the Zhejiang Provincial Center for Disease Control and Prevention (2026-038-01). Ethics approval for the waiver of informed consent was granted because the data were routinely collected by province-wide VCT clinics for daily clinical service delivery, rather than collected specifically for a research project.

## Results

A total of 30,182, 46,060, and 40,916 VCT clients were enrolled at CDC-affiliated clinics in Zhejiang Province in 2022, 2023, and 2024, respectively. In 2024, the proportions of individuals in high-income, middle-income, and low-income regions were 27.7% (n=11,335), 53% (n=21,671), and 19.3% (n=7910), respectively. Of these clients, 78.8% (n=32,228) were male, 52.1% (n=21,305) were aged 35 years, and 39.8% (n=16,267) were married. In total, 19.6% (n=8000) had a college education or higher. Of all respondents, 74.1% (n=30,307) received proactive consultation, 21.7% (n=8893) received outreach consultation, and 4.2% (n=1716) received referral consultation. For consultation reasons, 43% (n=17,601) consulted for homosexual behavior, followed by casual heterosexual behavior (n=11,972, 29.3%) and HIV-positive intimate partners (n=2077, 5.1%). Differences in these characteristics among the 3 years were statistically significant ($P<.05$; Table 1).

As shown in Figures 1 to 3, an analysis of the positivity rates for HIV, syphilis, and anti-HCV from 2022 to 2024 revealed the following: the HIV positivity rates decreased from 2.462% (743/30,182) in 2022 to 1.664% (681/40,916) in 2024, with a significant difference according to the Cochran-Armitage trend test ($\chi^2_1$ for trend=53.6; $P<.001$; Figure 1). Between 2022 and 2024, the syphilis positivity rates were 1.378% (414/30,049),

XSL•FO
RenderX

1.502% (675/44,951), and 1.62% (647/39,929), respectively, with a significant difference according to the chi-square test for trend ($\chi^2_1$ for trend=6.8; *P*=.03; Figure 2). The anti-HCV positivity rates were 0.309% (77/24,950), 0.387% (161/41,593), and 0.504% (192/38,098) in 2022, 2023, and 2024, respectively, with a significant difference according to the chi-square test for trend ($\chi^2_1$ for trend=14.8; *P*<.001; Figure 3).

From 2022 to 2024, the positivity rates for dual HIV-syphilis coinfection were 0.3% (90/30,049), 0.249% (112/44,951), and 0.203% (93/39,929), respectively; those for dual HIV–anti-HCV coinfection were 0.012% (3/24,950), 0.002% (1/41,593), and 0.011% (4/38,098), respectively; and the positivity rates for triple HIV-syphilis–anti-HCV coinfection were 0.008% (2/24,909), 0% (0/41,563), and 0.005% (2/38,065), respectively (Table 2).

The results of univariable and multivariable analyses of factors associated with HIV, syphilis, and anti-HCV positivity are shown in Table 3.

Compared with high-income regions, middle-income regions had higher odds of HIV positivity (aOR 1.388, 95% CI 1.161-1.660) and anti-HCV positivity (aOR 3.568, 95% CI 1.924-6.615), while low-income regions had lower odds of HIV positivity (aOR 0.411, 95% CI 0.301-0.561). Female participants had a lower likelihood of HIV infection (aOR 0.511, 95% CI 0.385-0.676). The odds of HIV, syphilis, and anti-HCV positivity all rose with advancing age. Compared with unmarried clients, being married was associated with lower odds of HIV positivity (aOR 0.565, 95% CI 0.432-0.738) and higher odds of anti-HCV positivity (aOR 5.109, 95% CI 2.904-8.990).

Compared with participants with junior high school education or below, those with senior high school (aOR 0.455, 95% CI 0.356-0.583) or college education or above (aOR 0.646, 95% CI 0.515-0.811) had lower odds of HIV positivity; those with senior high school (aOR=0.665, 95% CI 0.541-0.818) or college education or above (aOR=0.734, 95% CI 0.584-0.922) had lower odds of syphilis positivity; and those with senior high school (aOR=0.448, 95% CI 0.254-0.792) or college education or above (aOR=0.392, 95% CI 0.228-0.672) had lower odds of anti-HCV positivity. Compared with proactive consultation, outreach consultation was associated with lower odds of HIV positivity (aOR 0.096, 95% CI 0.060-0.153), but higher odds of syphilis positivity (aOR 1.241, 95% CI 1.033-1.491) and anti-HCV positivity (aOR 2.837, 95% CI 1.882-4.276). Referral consultation was associated with higher odds of HIV positivity (aOR 1.632, 95% CI 1.249-2.131) and anti-HCV positivity (aOR 31.869, 95% CI 20.557-49.406).

Compared with participants seeking consultation for casual heterosexual behavior, those consulting for homosexual behavior had higher odds of HIV positivity (aOR 1.909, 95% CI 1.514-2.408) and lower odds of anti-HCV positivity (aOR 0.031, 95% CI 0.01-0.082). Participants consulting as intimate partners of HIV-positive individuals had higher odds of HIV positivity (aOR 3.526, 95% CI 2.546-4.882). Those consulting for IDU had higher odds of anti-HCV positivity (aOR 30.495, 95% CI 15.584-59.672).

Participants who had never been tested for HIV had higher odds of HIV positivity (aOR 1.455, 95% CI 1.208-1.754), syphilis positivity (aOR 1.294, 95% CI 1.105-1.516), and anti-HCV positivity (aOR 2.943, 95% CI 2.069-4.187).

## Discussion

### Prevalence of HIV, Syphilis, and Anti-HCV and Coinfection

From 2022 to 2024, the HIV positivity rates among VCT clients at CDC-affiliated clinics in Zhejiang Province decreased from 2.462% to 1.664%. This positivity rate was higher than the national average of 0.82% for VCT clinics in 2022 [16]. A study conducted in Chiang Mai Province, Thailand, found that the HIV positivity rates among individuals attending fixed-site and mobile VCT services were 5.6% and 2.6%, respectively [17]. The findings of this study indicated an overall decreasing trend in the newly reported HIV positivity rates, which were consistent with the downward trend in the overall HIV epidemic in Zhejiang Province.

This study showed that the syphilis positivity rates among VCT clients at CDC-affiliated clinics increased from 1.378% in 2022 to 1.62% in 2024. The reported incidence of syphilis in Zhejiang Province was 35.23 per 100,000 in 2022, with a decreasing trend from 2016 to 2022 [18]. The positivity rates observed in this study were higher than those reported in other regions of China and in studies conducted in the United States (2016-2023) and the United Kingdom [19-21].

The results of this study demonstrated that the anti-HCV positivity rates among VCT clients at CDC-affiliated clinics increased from 0.309% in 2022 to 0.504% in 2024. This rate was lower than the 1.8% reported for VCT clinics in Beijing [22] and the 1.5% reported by Conway [23] among CDC clients at community-based clinics across multiple European countries in 2018. The positivity rates for anti-HCV in Zhejiang Province showed a decreasing trend, with rates of 5.13 per 100,000, 3.97 per 100,000, and 3.61 per 100,000 in 2022, 2023, and 2024, respectively.

A study conducted among female sex workers in South China reported that the positivity rates for dual syphilis–anti-HCV, HIV-syphilis, HIV–anti-HCV, and triple HIV-syphilis–anti-HCV coinfection were 30 per 100,000, 0%, 0%, and 0%, respectively [24]. The probability of coinfection varied across different populations. In contrast, the prevalence of dual HIV-HCV coinfection was 39.1% among people who

XSL•FO
RenderX

inject drugs in Vietnam, 8.5% among prison inmates in India, and 4% among drug users in the United States [25-27]. In Mexico, the national positivity rates for syphilis, HIV, and their dual coinfection among men who have sex with men were 15.2%, 10.2%, and 5.7%, respectively [28]. In the present study, the positivity rates for triple HIV-syphilis–anti-HCV coinfection among VCT clients at CDC-affiliated clinics were extremely low, with wide 95% Clopper-Pearson CIs, indicating substantial statistical imprecision. Therefore, the results should be interpreted with caution.

### Possible Explanations for Prevalence and Coinfection

The variation in the overall testing volume during the study period was significantly influenced by the COVID-19 pandemic. The peak testing volume observed in 2023 might be attributable to COVID-19 prevention and control restrictions implemented throughout 2022, which potentially biased the observed temporal trends in positivity rates for HIV and syphilis [29].

The increase in the number of VCT clients who engaged in male-male sexual behaviors at CDC-affiliated clinics in this study could be attributed to the integration of counseling and testing services for men who have sex with men provided by CBOs into the VCT information system in 2024. Although the number of men who have sex with men undergoing testing increased, the HIV positivity rates did not rise, which may be attributable to the generally stable HIV prevalence among key populations.

The rising trend on the syphilis epidemic may be associated with the economic prosperity of eastern China. The impact of HIV postexposure prophylaxis (PEP) and preexposure prophylaxis (PrEP) on syphilis infection warrants consideration. Recently, the coverage of PEP and PrEP services has expanded continuously. Currently, all 11 prefecture-level cities in Zhejiang Province have established 24-hour PEP clinics, and advancements in internet technology have provided robust support for PrEP service delivery [30]. However, evidence from available data is insufficient and warrants further research.

The generally low positivity rates for anti-HCV and concurrent HIV and anti-HCV infection could be attributed to the relatively small proportion of people who inject drugs among VCT clients at CDC-affiliated clinics, along with the notable effectiveness of harm reduction programs, such as clean needle exchange programs and methadone maintenance therapy in Zhejiang Province [31]. Conclusions regarding coinfection patterns should be interpreted cautiously and restricted solely to VCT attendees.

### Correlates of HIV, Syphilis, and Anti-HCV Positivity Among VCT Clients at CDC-Affiliated Clinics

In the present study, an inverse association was observed between educational background and the risk of HIV, syphilis, and anti-HCV positivity. The association between education and infectious disease outcomes has been extensively examined in prior research, with a consistent protective effect reported across most studies [32]. Individuals with higher levels of education exhibited greater health consciousness, more access to health information, and higher use of health services and resources, which may contribute to a reduced risk of infection with the aforementioned infectious diseases.

Compared with individuals who actively sought services at CDC-affiliated VCT clinics, those who received referral-based testing had a higher risk of positivity for HIV–anti-HCV coinfection. In contrast, individuals receiving counseling and testing through outreach services had a lower risk of positivity for HIV-syphilis coinfection but a higher risk of anti-HCV positivity. Individuals who voluntarily attended CDC-affiliated VCT clinics for testing generally exhibited stronger risk awareness and self-protection capabilities, as well as higher levels of awareness regarding condom use [33]. On the other hand, referred individuals typically had lower risk awareness than those who actively sought services yet still engaged in high-risk behaviors, and this led to a higher infection rate. Outreach services are generally targeted toward hard-to-reach populations, such as community-based drug abstainers and those under supervision in correctional facilities, such as compulsory drug detoxification centers. This may explain the relatively high HCV infection rate observed in this subgroup.

Male homosexual behavior and having HIV-positive intimate partners were associated with HIV infection among VCT clients at CDC-affiliated clinics in our province. As our province had low HIV prevalence, sentinel surveillance data revealed that the HIV positivity rate among this population reached 4%, making it the high-risk group with the highest infection rate in the province [34]. Spousal notification and testing constituted a core component of HIV prevention and control efforts in the province. The HIV positivity rate was as high as 30% among spouses, which was attributed to delayed diagnosis of index patients [35].

Our study showed that individuals with an HIV testing history had a higher risk of HIV, syphilis, and HCV infection. A history of HIV testing was associated with risky behaviors and psychological traits; for example, people with high health awareness and those engaging in more high-risk behaviors are more likely to undergo HIV testing [36]. Moreover, a high frequency of high-risk behaviors was a significant risk factor for these 3 diseases, which may explain this result.

### Programmatic Implications for VCT and Integrated Disease Control

The findings of this study yield several implications for intervention practices. First, testing for HIV, syphilis, and HCV in VCT clinics offers important data for epidemic surveillance. However, some VCT attendees at CDC clinics were not tested for syphilis and HCV, and anti-HCV–positive individuals failed to receive nucleic acid testing, which hinders epidemic monitoring. Screening strategies for syphilis and anti-HCV, as well as HCV nucleic acid testing, need to be improved. Second, this study found that VCT clients recruited through outreach and referral had higher positivity rates for HIV, syphilis, and anti-HCV compared with walk-in clients. Therefore, VCT clinics should scale up outreach and referral testing services. CBOs and high-risk behavior intervention teams, which have access to hard-to-reach high-risk populations, should be engaged to promote VCT services. Third, although the findings of this study cannot draw definitive conclusions, we still suggest delivering more targeted and individualized interventions during counseling sessions for the older adults, male participants, unmarried

XSL•FO
RenderX

individuals, people with low educational attainment, and populations identified via referral and outreach services, to reduce their risk of seroconversion.

### Limitations

There were many limitations in this study. First, follow-up nucleic acid testing results for individuals who screened positive for HCV were unavailable, which limited accurate estimation of the actual HCV infection rate among VCT clients at CDC-affiliated clinics. Second, from the perspective of factor exploration, this study was based on an analysis of existing data without a rigorous scientific theoretical hypothesis. This may have led to the omission of key confounding factors. Third, the participants were not recruited via random sampling, which limited the generalizability of the study findings to the general population or to all key populations. Fourth, testing services provided by VCT clinics are anonymous, so duplicate individual records may exist in theory. Although the large sample size can mitigate their impact on analytical results, we still recommend excluding duplicate cases in future studies. Finally, the MAR assumption could not be empirically verified, which was noted as a study limitation. Thus, future research with scientifically rigorous study designs is warranted, building on the key findings of the present study.

### Conclusions

From 2022 to 2024 in Zhejiang Province, the HIV and anti-HCV positivity rates among VCT clients at CDC-affiliated clinics declined, while the syphilis positivity rates increased. The coinfection positivity rates for these 3 infections remained at low levels. Individuals reporting homosexual behavior constituted a high-risk group for HIV yet exhibited a lower anti-HCV positivity rate. Among CDC-affiliated VCT clients, older age, lower educational attainment, and prior HIV testing history were associated with higher infection positivity rates, suggesting that these characteristics might help refine targeting of VCT and prevention efforts within this setting. It is suggested that VCT clinics enhance syphilis and HCV testing, expand outreach and referral services, and deliver targeted counseling and interventions for populations at high risk of infection.

## Acknowledgments

The authors acknowledge the contributions of the staff of Centers for Disease Control and Prevention–affiliated voluntary counseling and testing clinics across the province, as well as the personnel from community-based organizations who contributed to data collection.

The generative AI tool used in the manuscript was Doubao (version 2.69.9_mac; ByteDance Ltd), which was used for manuscript proofreading and editing.

## Funding

This research was supported by the Zhejiang Science and Technology Plan for Disease Prevention and Control (grants 2026JKZ009 and 2025JK154).

## Data Availability

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

## Authors' Contributions

JZ designed the study, performed the statistical analysis, and drafted the manuscript. LC performed the statistical analysis and reviewed and revised the manuscript. LH, TJ, HW, WC, and YY were responsible for on-site verification and data quality control. All authors read and approved the final manuscript.

## Abstract

**Background:** Widespread misinformation and low critical health literacy pose major barriers to public health worldwide. Rapid, scalable, and evidence-informed digital interventions are urgently needed to strengthen the public's ability to make informed health decisions.

**Objective:** Informed by critical health literacy frameworks, we developed and tested a brief, story-based critical thinking podcast, *Parents Making Informed Health Choices*, that was designed to improve critical health literacy and decision-making among US parents.

**Methods:** We conducted a 2-phase study. First, 5 parents participated in the user testing of the prototype podcast and provided qualitative feedback to refine content and delivery. The final podcast delivered 9 evidence-based practice principles through relatable scenarios about mental and physical health. In the second phase, we conducted a 2-arm randomized controlled trial (N=250) with a national online sample of US parents. Participants were randomly assigned to listen to either the critical thinking podcast (n=128, 51.2%) or a control podcast (n=122, 48.8%). There were no significant preintervention group differences except for age, which was controlled for in all analyses. Primary outcomes included critical thinking about health claims, intended health behaviors, attitudes toward evidence-based mental health practices, and treatment preferences.

**Results:** On average, parents were aged 35 (SD 7.8) years; 49% (121/247) were female, 75% (185/248) were White; and 60.0% (148/248) had a bachelor's degree or higher. Parents who listened to the critical thinking podcast demonstrated significantly improved critical thinking about health information compared to the control group (B=2.56; $P$<.001; $\Delta R^2$=0.06). They also reported stronger critical thinking–aligned intended behaviors (B=0.252; $P$=.001; $\Delta R^2$=0.015), and more evidence-informed treatment preferences (B=4.89; $P$=.038; $\Delta R^2$=0.02). The effect sizes were small to moderate across outcomes.

**Conclusions:** Findings suggest that a brief, story-based digital podcast can meaningfully improve critical thinking about health information, intended behaviors, and evidence-based practice attitudes. Podcasts represent a promising, low-cost, and scalable strategy for promoting critical health literacy and countering health misinformation in the general public.

## Introduction

### Background

Health misinformation is now widely recognized as a public health threat [1]. During the COVID-19 pandemic and beyond, inaccurate health claims about vaccines and treatments have spread rapidly across digital platforms, undermining public trust and distorting health-related decision-making. Parents, in particular, face a deluge of conflicting health messages as they seek information about their children's physical and mental health needs. However, few public health interventions directly aim to strengthen parents' ability to critically assess health claims and make evidence-informed choices. Furthermore, scalable, low-intensity interventions that leverage popular media formats, such as podcasts, represent an underexplored avenue for enhancing critical health literacy at the population level. Accordingly, we developed and tested the effectiveness of a brief, story-based podcast intervention aimed at improving critical health literacy among US parents.

Many individuals lack the critical thinking skills necessary to make empowered and well-informed health choices [2,3]. Low

XSL•FO
RenderX

critical thinking about health can lead to believing and acting on unreliable health information that is easily accessible by word of mouth, through mass media, and the internet [4-6]. Basing mental and physical health treatment decisions on unreliable information may lead to pursuing ineffective or potentially harmful services [7], delaying access to effective services (evidence-based practices [EBPs]), increasing risks, and wasting resources.

Unfortunately, few studies have focused on addressing the health-related critical thinking needs of the public, especially in the United States. Grounded in the Informed Health Choices Key Concepts framework, critical thinking about health extends beyond functional health literacy (ie, basic knowledge of health conditions and services) and involves applying EBP principles to access, understand, and evaluate sources of health information [8-10]. Studies across the world, even among high-income and highly educated populations, have found that the public engages in low levels of critical thinking about health [2,11-13].

Effective decision-making behavior in health care is complex, comprising not only critical thinking skills but also related attitudes and beliefs, among other characteristics and factors. Existing research has found that US adults and adolescents value scientific evidence when making health decisions; however, they have a limited understanding of what it means for practices to be evidence-based [14-16]. Additionally, US adults report that there are situations in which they would trust their doctor's opinion over scientific research [17]. Issues of public trust in medicine and medical research are particularly prominent in relation to vaccines [18]. Indeed, despite their demonstrated efficacy, safety, and benefits, antivaccination or vaccine hesitancy attitudes persist and have resulted in adverse public health consequences (eg, increase in outbreaks of diseases that were under control or eradicated, such as measles) [18,19]. As such, examining critical thinking about health alongside attitudinal factors such as vaccine hesitancy is an important next step toward deepening our understanding of public health literacy and health decision-making.

Considering the potential impact of increasing the public's ability to engage in critical thinking about health, it is crucial to develop and test brief, targeted, and scalable critical thinking interventions. This is especially important for parents, since they are responsible for health care decisions for both themselves and their children. Information and communication technologies play a crucial role in promoting critical health literacy by expanding access to information, fostering interactive learning environments, and enabling individuals to engage more actively with health content. Podcasts, in particular, offer a promising delivery method for addressing these challenges. They are widely accessible, cost-effective, and increasingly used for health communication and education [20-22]. As defined by the World Health Organization, digital health interventions are discrete uses of digital technologies, such as podcasts, to achieve health objectives [23]. Prior research and communication theory suggest that storytelling and narrative formats can improve engagement and promote behavior change, especially when combined with principles of EBP and tailored to target audiences [24]. However, few studies have tested the use of podcasts as a critical thinking intervention for health, and even fewer have done so using rigorous randomized designs.

Only one prior study has evaluated the effectiveness of such an intervention and focused on parents in Uganda [25]. Semakula et al [25] developed a 10-episode critical thinking podcast based on the needs of the Ugandan families. Via a randomized controlled trial (RCT) of 675 participants, the educational podcast was found to significantly improve parents' critical thinking compared to those who only listened to a public service announcement. Moreover, improvements in critical thinking were observed across varying levels of educational attainment, including those who had only completed elementary education. Unfortunately, this intervention has yet to be adapted for and tested in the United States, and it solely focused on physical health issues, without any mental health examples.

While educating the public is essential across all areas of health care, it is especially urgent in the context of mental health, where treatment decisions are often complex and nuanced. Public discourse in this area is frequently shaped by unscientific or pseudoscientific claims, which can contribute to misinformation and reduce public trust in evidence-based care. This environment poses a significant barrier to individuals' ability to make informed decisions and access appropriate mental health services [26-30]. Despite this, no existing critical health literacy intervention has specifically addressed decision-making in mental health care.

### This Study

The ability to critically think about health claims and treatment effectiveness enables the public to make well-informed health care decisions. By evaluating the effectiveness of treatments, the public can avoid potentially harmful or ineffective care and be empowered to take an active role in their health management. Thus, the primary aim of this study was to develop and test whether a brief critical thinking podcast increased critical thinking about health and related intended behaviors in comparison to an active control. The current intervention was adapted from the previously validated podcast used in Uganda [25] with cultural and contextual tailoring for a US-based audience. Additionally, because the original Ugandan podcast focused solely on physical health conditions, the current podcast expands its scope to include decision-making scenarios related to mental health. Given that this was the first evaluation of a critical health literacy podcast in the United States, the study also served as a proof-of-concept assessment to determine whether the approach would translate effectively in a different cultural and health communication context. A secondary aim was to examine the effects of the podcast on EBP attitudes, vaccine safety concerns, and mental health treatment preferences. We hypothesized that the critical thinking podcast would have a positive effect on all measured outcomes.

## Methods

### Design and Procedures

The study was conducted in the United States and included both community-based and online components. It consisted of two

XSL•FO
RenderX

phases: (1) podcast development and user testing, and (2) podcast evaluation through an online RCT.

Podcast development included reviewing the scripts and storyboards of the Ugandan podcast by Semakula et al [25], and determining the needed adaptations (eg, changing examples about malaria). Communication theory on learning through entertainment informed the podcast design to ensure that messaging was not merely didactic, and there was a sense of relatability in the storylines and characters [24]. The first author and undergraduate research assistants scanned US mass media websites, such as Health News Review, for examples of mental health care claims relevant to US parents. For example, one of the episodes covers a claim regarding vaccines causing autism. Once the podcast script was finalized, it was produced by the Orange Umbrella, a production company housed within the university's School of Communication.

We then conducted user testing where 5 parents from South Florida listened to the podcast prototype and provided feedback. A sample size of 5 is common in usability research where small samples are sufficient to identify most usability issues. For user testing, we recruited parents through the local chapter of the National Alliance on Mental Illness, advertisements in public community spaces, and Facebook posts. Eligible participants were aged at least 18 years, had at least 1 child aged less than 18 years, and were fluent in English. Participants were compensated with a US $15.00 gift card for their time and feedback. User-testing sessions lasted approximately 60 to 90 minutes, including 32 minutes of estimated individual podcast listening, a 20 to 30-minute semistructured interview, and a 5-minute online satisfaction survey. Their feedback was then reviewed and applied, and the podcast was finalized for testing through an online RCT. The podcast is available in SoundCloud [31].

A total of 250 parents participated in the RCT in May 2019 through Amazon Mechanical Turk (MTurk) [32,33]. A priori power analysis indicated that this sample size would provide adequate power to detect a large effect. As previously demonstrated by Jensen-Doss et al [33], MTurk is an appropriate space for recruiting parents online, especially for mental health care–related studies such as this one where capturing the perspectives of potential treatment seekers may be pertinent. The study was advertised to MTurk workers in the United States who had an MTurk approval rating of 98% or higher and were not participating in any other related study [3]. In the RCT, participants first provided consent and completed a baseline questionnaire of demographic and other characteristics. As in the original trial of the *Informed Health Choices* podcast by Semakula et al [25], outcome measures were completed after random assignment and after listening to the podcasts. Exposing participants to questionnaires prior to listening to the podcasts would have affected podcast listening, and it was expected that randomization would ensure that participants were equivalent at baseline (see the Randomization Success section). Following completion of baseline measures, participants were randomly assigned on a 1:1 ratio to either the critical thinking podcast or a control podcast. Participants in both conditions could not move on from the podcast listening page until 32 minutes (length of podcasts) had lapsed and they also could not fast forward. We also built in several "listening fidelity" checks (described in the Measures section). After they listened to the entire podcast, participants completed postintervention measures. Participants received a payment of US $7.25, in line with minimum wage at the time of the study. This study followed the CONSORT (Consolidated Standards of Reporting Trials) guidelines (Checklist 1).

## Podcast Intervention and Control Condition

The *Parents Making Informed Health Choices* podcast [31] consisted of nine 2 to 4-minute episodes, including an introduction episode and a conclusion episode. The entire podcast was 32 minutes long. The 7 main episodes covered 9 different EBP principles using medical and mental health conditions (eg, depression). Following the storylines developed for the Uganda *Informed Health Choices* podcast, the US podcast included 2 main characters who engaged in back-and-forth conversations while explaining and applying EBP principles to different medical and mental health conditions. Table 1 lists the EBP principles covered and provides examples of health care claims. The control podcast (a 33-minute-long mindfulness meditation) served as an inert condition that was similar in length to the critical thinking podcast, but included no content related to critical thinking.

XSL•FO
RenderX

**Table .** Evidence-based practice (EBP) principles [10] addressed in the *Parents Making Informed Health Choices* podcast. Examples are compared to those in the original *Informed Health Choices* podcast used in Uganda [25].

| EBP principle | US claim examples | Uganda claim examples |
|---|---|---|
| Treatments should be compared. | Elderberry is an effective treatment for child flu. | Quail eggs make you very strong. |
| Treatments should be compared fairly. | Cognitive-mental therapy for youth anxiety and depression works. | Group support is helpful for someone who is depressed. |
| Findings from small studies can be misleading. | We can know that vaccines cause autism based on information from one small study. | Washing hands with soap does not stop children from getting diarrhea. |
| Association is not the same as causation[a]. | Contraceptive pills cause women to gain weight[a]. | A lot of women gain weight when they take contraceptive pills. |
| Expert opinion is not always right[a]. | Contraceptive pills cause women to gain weight[a]. | Eating some hot pepper will heal ulcers. |
| Anecdotes are unreliable evidence. | Butter can heal burns. | Putting cooking oil on a burn will heal it. |
| Treatments might be harmful[a]. | An herbal treatment for ADHD[b] with no side effects exists[a]. | Quinine can cure malaria. It can also give you nausea and make you vomit. |
| Treatments have benefits and harms.[a] | Herbal treatment for ADHD with no side effects exists[a]. | Herbal medicines exist for malaria treatment that cure malaria and do not have any bad effects. |
| Common practice does not mean it is beneficial or safe. | Physical discipline is the best strategy for managing child behavior problems. | An herbal treatment called kyogero stops babies from getting infections. |

[a]Covered within the same episode of the *Parents Making Informed Health Choices Podcast*.

[b]ADHD: attention-deficit hyperactivity disorder.

## Measures

### *Demographics and Other Characteristics*

Participants' age, gender, ethnicity, educational attainment, employment status, podcast listening habits or consumption (listening time in min), and other characteristics data (eg, treatment-seeking history) were collected.

### *Critical Thinking About Health*

We assessed critical thinking about health using 18 items from the Claim Evaluation Tools, which consists of over 100 multiple choice questions that can be used with people aged 10 years and older [34,35]. We selected 18 questions that tapped into 9 different key concepts based on their cultural relevance to the United States and how well they performed in a validation study [34]. We also included 3 new questions that were worded exactly like Claim Evaluation Tools' questions but replaced physical health conditions with mental health conditions. The overall critical thinking score was the number of correct responses out of 21 items. The internal consistency of the final 21-item critical thinking measure was good ($\alpha$=.86).

### *Intended Behavior*

Intended behavior related to critical thinking was assessed through 3 items created and used by Semakula et al [25]. The questions asked about the likelihood that someone will (1) find out what a treatment claim is based on, (2) find out if a claim is based on a research study comparing the treatment to no treatment (a fair comparison), and (3) saying "yes" if asked to participate in a research study comparing 2 treatments for an illness they have. Response options were on a 4-point Likert scale from very unlikely to very likely, and also included an "I don't know" option.

### *Attitudes Toward EBPs in Mental Health*

The Consumer Attitudes Towards Evidence Based Services Scale (CAEBS) [36] consists of 29 items that load onto 4 factors: (1) beliefs regarding therapists' practices, (2) attitudes about mental health policy, (3) negative personal-level attitudes toward EBPs, and (4) negative societal-level attitudes towards EBPs. Items are rated on a 5-point scale from "strongly disagree" to "strongly agree." Internal consistencies in this sample were as follows: factor 1, $\alpha$=.77; factor 2, $\alpha$=.59; factor 3, $\alpha$=.88; and factor 4, $\alpha$=.73. To increase reliability, we removed item 13 from the factor 2 scale (new $\alpha$=.73), and item 24 from the factor 4 scale (new $\alpha$=.80).

### *Attitudes Regarding Empiricism in Mental Health Treatment*

We used 5 items created by Kirk et al [37] that assessed attitudes regarding empiricism in mental health treatment on a 5-point Likert scale, with higher scores indicating more agreement. The internal consistency of this 5-item scale in this sample was adequate ($\alpha$=.77).

### *Treatment Preferences*

We assessed treatment preferences using a measure developed by Kirk et al [37] that asked participants to rate how important various mental treatment components were to them by allocating 99 points across the following: (1) treatment being evidence-based, (2) therapeutic alliance, (3) therapist experience, (4) empathic qualities of the therapist, and (5) client speaking for the majority of sessions [37]. Participants were instructed that more points signify higher preference for that treatment component.

XSL•FO
RenderX

### *Vaccine Safety Concerns*

Following prior studies [38,39], we examined vaccine safety concerns through three items: (1) "vaccines are unsafe," (2) "vaccines have long-term negative side effects," and (3) "If I had another infant today, I do not want him/her to get all the recommended vaccinations." Participants rated these on a 5-point scale with higher scores indicating more negative vaccine attitudes. The internal consistency of this scale in this sample was $\alpha$=.93.

### *Podcast Listening Fidelity*

We assessed participant attention to the podcast through 7 questions about podcast content details that anyone who listened to the entire podcast should be able to answer, with specific questions for each study condition. Questions 1 to 6 were true or false, and question 7 required an open-ended response to a question about content at the end of the podcast. Responses to question 7 were assigned 0 to 2 points by the principal investigator; thus, participants could earn up to 8 points total.

### *Podcast Satisfaction*

Participants in both conditions also rated their satisfaction with the podcast through 5 items that asked about overall satisfaction, likelihood of recommending to others, and relevance.

### Ethical Considerations

All procedures were approved by the University of Miami Institutional Review Board (20180596). The submitted protocol document was the one submitted to the institutional review board and received approval. There were no deviations from the protocol. Participants provided informed consent electronically prior to participating in the study. Data were collected anonymously through secure online surveys (Qualtrics) and analyzed in deidentified form. All data were stored on password-protected, encrypted servers to ensure participant privacy and confidentiality. The 5 user-testing participants were compensated with a US $15.00 gift card for their time and feedback. RCT participants received a payment of US $7.25, in line with minimum wage.

### Analytic Plan

Analyses were run using SPSS (version 28; IBM Corp). Descriptive statistics examined participant demographics, podcast satisfaction, and measures of data quality. We used multiple measures of data quality, including length of study participation (anticipating it would take at least 60 minutes), attention check questions, and 2 questions measuring consistency in the report of demographic information (age and youngest child age) strategically placed at the beginning and at the end of the study. Analyses checking randomization success examined differences in demographic variables between the 2 study conditions. We tested hypotheses about podcast effects using multiple linear regression for continuous variables and binomial logistic regression for categorical variables. The Cohen *d* values of 0.20, 0.50, and 0.80 indicated small, medium, and large effects, respectively; and $R^2$ values of 0.01, 0.09, and 0.25 indicated small, medium, and large effects, respectively [40].

## Results

### Participants

Five parents participated in the user-testing phase of the study, and 250 parents participated in the online RCT. On average, parents in the RCT were aged 35 (SD 7.8) years with 49% (121/147) being female, 75% (185/248) being White, and 60.0% (148/248) having a bachelor's degree or higher. Table 2 provides additional sample characteristics.

## Analysis of Data Quality

Out of 250 participants, 6 (2.4%) completed the study under 42 minutes (70% of the projected completion time); 18 (7.2%) failed attention check questions or obtained a score of 4 or lower on the listening fidelity measure; and 25 (10%) provided inconsistent demographic data. Consistent with an intent-to-treat approach, all randomized participants who completed study procedures were included in the primary study analyses (Figure 1). For completeness, we report exploratory post hoc analyses excluding the 49 participants with data quality issues at the end of this section. Parents in the critical thinking podcast condition obtained an average score of 6.73 (SD 1.68; range 1 - 8) on the listening fidelity test and parents in the control condition earned an average score of 6.76 (SD 0.84; range 1 - 8).

**Figure 1.** CONSORT (Consolidated Standards of Reporting Trials) diagram of participant flow through the *Parents Making Informed Health Choices Podcast* randomized controlled trial. This figure depicts participant flow for main study analyses where all randomized participants were retained in accordance with an intent-to-treat approach; exploratory post hoc analyses excluding 49 participants with data quality issues (indicated in the allocation section of the figure) are reported separately.

### Randomization Success

There were no significant differences between the critical thinking podcast condition and control condition at preintervention based on gender ($\chi^2_1$=0.679; *P*=.41), education level ($\chi^2_1$=0.88; *P*=.35) annual household income ($t_{248}$=0.720; *P*=.47), podcast listening habits ($t_{248}$=–0.744; *P*=.46), and podcast listening fidelity scores ($t_{248}$=0.155; *P*=.88). However, the control group was significantly older, by 2 years ($t_{248}$=2.43; *P*=.02); therefore, we controlled for age in all analyses. Given some variability and to reduce the possibility that significant relationships were due to third variables, we also included education and listening fidelity as control variables in outcome analyses. Table 3 includes descriptive statistics for study measures, including means and SDs for this sample.

XSL•FO

### Effects on Critical Thinking

As hypothesized, parents who listened to the critical thinking podcast performed significantly better on the critical thinking measure than those who listened to the control podcast ($B$=2.56; $P$<.001), with a small-medium effect size ($\Delta R^2$=0.06). Table 4 presents all results from linear regression analyses.

**Table .** Results from linear regression analyses examining critical thinking podcast effect on critical thinking, intended behavior, attitudes, treatment preferences, and overall podcast satisfaction (control variables: age, education, and listening fidelity).

| Dependent variable | Critical thinking | | |
|---|---|---|---|
| | B | SE | β |
| Critical thinking | 2.56 | 0.515 | .237[a] |
| Intended behavior | | | |
| Find out what a claim was based on | 0.042 | 0.092 | .029 |
| Find out if a claim was based on a fair comparison study | 0.252 | 0.078 | .201[b] |
| How likely are you to participate in a fair comparison study | 0.109 | 0.116 | .063 |
| EBP[c] attitudes | | | |
| Beliefs Regarding Therapists' Practice | 0.073 | 0.093 | .050 |
| Attitudes About Mental Health Policy | 0.495 | 0.416 | .074 |
| Negative Personal-Level Attitudes towards EBPs | –1.96 | 0.893 | –.127[d] |
| Negative Societal-Level Attitudes towards EBPs | –0.160 | 0.446 | –.023 |
| Attitudes regarding empiricism | 0.156 | 0.080 | .124 |
| Vaccine safety concerns | –0.185 | 0.400 | –.026 |
| Treatment preferences | | | |
| Therapeutic alliance | –1.82 | 2.08 | –.056 |
| Scientific studies show therapy is highly effective | 4.89 | 2.34 | .131[d] |
| Therapist experience | –1.50 | 1.33 | –.071 |
| Empathic therapist | –1.59 | 1.64 | –.063 |
| Client speaking majority of session | 0.024 | 1.26 | .001 |
| Overall podcast satisfaction | –0.050 | 0.113 | –.028 |

[a]$P$<.001.

[b]$P$<.01.

[c]EBP: evidence-based practice.

[d]$P$<.05.

### Effects on Intended Behavior

Compared to control parents, parents in the critical thinking podcast condition reported a significantly higher likelihood of "finding out if a claim was based on a fair comparison study" in the future ($B$=0.252; $P$=<.001; $\Delta R^2$=.04). There were no significant differences between the conditions regarding the likelihood of engaging in the other 2 intended behaviors assessed: "finding out what a claim was based on," and "participating in fair comparison study."

### Effects on Attitudes

Between-group differences in EBP attitudes were examined across the 4 attitudes factors of the CAEBS. Parents in the critical thinking condition had lower scores on the negative personal-level attitudes towards EBPs scale ($B$=−1.96; $P$<.05; $\Delta R^2$=0.015). There were no significant differences between podcast groups in the 3 other CAEBS EBP attitudes scales, attitudes regarding empiricism in mental health, or vaccine safety concerns.

XSL•FO
RenderX

### Effects on Treatment Preferences

Parents who listened to the critical thinking podcast expressed a significantly higher preference for "receiving effective therapies backed by scientific studies" compared to the control group ($B$=4.89; $P$<.05; $\Delta R^2$=0.02). All other mental health treatment preferences did not vary significantly based on condition.

### Post Hoc Analyses Without Intent to Treat Sample

We also ran analyses excluding the 49 participants who failed data-quality checks. When we excluded these individuals in the comparison analysis of parents' critical thinking postintervention, we found that the magnitude of the intervention effect on critical thinking increased from 0.06 to 0.11 ($B$=0.525; $P$<.001). In regard to other outcomes, when we removed the intent to treat sample, we found that parents who listened to the critical thinking podcast reported significantly more positive attitudes regarding empiricism in mental health treatment ($B$=0.210; $P$<.05; $\Delta R^2$=0.03), and no longer found a significant difference between podcast groups in the negative personal-level attitudes towards EBPs scale.

## Discussion

### Principal Findings

To address the public health misinformation crisis at scale, we developed and tested the efficacy of a story-based, educational podcast—the *Parents Making Informed Health Choices Podcast*—a brief, scalable, low-intensity intervention designed to increase critical thinking about health among US parents. Through an online RCT, we found that listening to the podcast improved parent critical thinking and had an effect on intended behaviors, attitudes, and treatment preferences. To our knowledge, this is the first online RCT of a mass media, brief critical thinking intervention for a US audience.

A previous study's findings of low levels of critical thinking among US parents and young adult college students demonstrated a need for a scalable critical thinking intervention for the US public [3]. The impacts on critical thinking demonstrated in this study add to the growing body of empirical evidence demonstrating the efficacy of critical thinking learning resources designed for the lay public [41-43]. The critical thinking effects observed in this US sample are similar to those observed in the original Ugandan podcast, where they also found a significant difference in postintervention critical thinking performance favoring parents in the critical thinking condition [25].

Out of the 3 intended behaviors assessed, parents who listened to the critical thinking podcast were more likely to report intending to find out if a treatment claim is based on a fair comparison study with control parents, but contrary to the hypotheses, these 2 other intended behaviors were not significantly different between the 2 study conditions. A possible explanation for this may be that the podcast directly and repeatedly mentions "fair comparisons," whereas the other intended behaviors are less frequently mentioned. These findings also differ from the Ugandan podcast RCT, where they did not find any significant behavioral intention differences between study conditions.

In terms of attitudinal measures related to critical thinking about health, parents who listened to the critical thinking podcast had less negative personal-level attitudes toward EBPs (as measured by 1 of the 4 factors of CAEBS) [36], and reported a higher preference for receiving effective therapies backed by scientific studies. Contrary to expectations, conditions did not differ on any other EBP attitudes or vaccine safety concerns. Notably, this study was conducted prior to the COVID-19 pandemic; as such, public attitudes regarding vaccines may have changed.

Of the 4 CAEBS factors regarding consumer EBP attitudes (beliefs regarding therapists' practices, attitudes about mental health policy, negative personal-level attitudes toward EBPs, and negative societal-level attitudes towards EBPs), the personal-level attitudes toward EBP factor is most in line with the content of the critical thinking podcast, with items such as "I don't feel comfortable making treatment decisions." Nevertheless, the null findings regarding 3 out of the 4 CAEBS scales were surprising given the general similarity between the concepts covered in the critical thinking podcast and the factors assessed by the CAEBS [36]. Upon closer scrutiny of the CAEBS' scales and items, possible explanations become apparent. First, while the *Parents Making Informed Health Choices Podcast* centers on EBP principles and making them accessible to the lay public, it rarely mentions "evidence-based" terms because the focus is on teaching a skill rather than *telling* the audience they should seek out EBPs. On the other hand, the CAEBS frequently and explicitly mentions the term "evidence-based" and defines it in the instructions. Perhaps this suggests that evidence-based health care proponents and researchers have some middle ground to reach in regards to balancing efforts to teach *science and health literacy–based skills* (ie, critical thinking about health) and increasing consumer knowledge of *health care terms*. It would be interesting for future studies to examine whether explicitly and repeatedly mentioning EBPs in the podcast has a different effect on EBP attitudes as measured by the CAEBS. Another potential explanation for the null findings is that CAEBS items have a strong emphasis on society and policy themes, whereas the critical thinking podcast solely focused on individual actions around EBP principles.

It should be noted that the *Parents Making Informed Health Choices Podcast* achieved these effects through an online, one-time, brief, audio intervention whereas the original Ugandan podcast RCT used a lengthier podcast listening procedure. Thus, our choosing to prioritize ecological validity based on how the public interacts with health information on the internet did not diminish the intervention's effects. Notably, parents in this study were tested on their critical thinking abilities and other factors a few minutes after listening to the podcasts. As such, a follow-up study is necessary to examine long-term effects.

Future studies should also determine who is most likely to benefit from these critical thinking interventions. For example, including a sample with a broader range of levels of educational attainment could help determine if education is a moderator. Another important future direction for critical thinking research

XSL•FO
RenderX

is how to incorporate pragmatic tips on how parents can carry out critical thinking in conversations with health care providers, especially in situations where the evidence base may not be strong, but where a treatment is still recommended either because it is the only option or for other valid reasons. There are EBP principles that address these realities (eg, EBP principle "how certain is the evidence?") [44], and future intervention or podcast development should focus on creating additional short episodes that capture these EBP principles in decision-making (eg,[45].

Furthermore, critical thinking interventions could complement a shared-decision making framework [46,47] in that critical thinking interventions encourage patient activation. Thus, future studies might consider combining or embedding critical thinking interventions within shared decision-making frameworks. Indeed, although this is not directly communicated in the *Parents Making Informed Health Choices Podcast*, characters in the stories often do model appropriate interactions with health care providers; however, the storylines do not conclude in a shared decision about health care services.

### Limitations

As with any investigation, this study has several limitations that suggest additional directions for future research. First, although online-convenience samples of parents generally provide reliable data [33] and this study sample was relatively diverse, especially in regard to socioeconomic status, they may not always be representative of all US parents, especially of parents in low-resource, community settings. Thus, future studies should focus on testing the efficacy of the podcast with more representative samples of parents from community settings that could greatly benefit from interventions such as this one. Along those lines, the *Parents Making Informed Health Choices Podcast* is currently only available to English-speaking parents, creating a disparity for parents who speak other languages, especially predominantly Spanish-speaking parents, who make up the fastest growing linguistic population in the United States. Future efforts should focus on translating these materials and testing their efficacy in other languages, especially Spanish. Some of this work is already starting with children in Spain [48]. Second, we have found evidence of only the very short-term efficacy of the *Parents Making Informed Health Choices Podcast*. Therefore, an important future direction is to conduct a long-term follow-up assessment of critical thinking with parents who participated in this online RCT, especially given that a 1-year follow-up study on the effects of the Ugandan critical thinking podcast found a decline in critical thinking abilities [49]. Finally, all outcome variables were about parent attitudes and preferences regarding mental health services for themselves, but we did not specifically ask about their attitudes and preferences in regards to mental health services for their children, which may be an important addition to future studies.

### Conclusions

This pilot trial provided empirical evidence regarding the efficacy of a brief, story-based critical health literacy podcast for US parents—a population frequently targeted by health misinformation. We found that listening to a brief podcast significantly improved parents' critical thinking about health, as well as increased self-reported intended behavior, positive attitudes toward EBPs, and preference for EBPs. By delivering accessible, engaging content in a familiar digital format, podcasts may represent a scalable public health strategy to promote evidence-based decision-making and strengthen critical health literacy. Future research should examine long-term effects, implementation in diverse communities, and potential integration into broader digital health and health education ecosystems.

## Abstract

**Background:** Unlicensed medical practices (UMPs) pose a substantial threat to patient safety and public health, but their clandestine nature makes them difficult to monitor through conventional surveillance systems. Legal epidemiology offers a framework for using judicial data to study hidden health-related misconduct, and machine learning (ML) may help convert unstructured legal texts into analyzable public health information.

**Objective:** This study aimed to characterize prosecuted UMP cases in South Korea using a legal infoveillance framework and evaluate the utility of ML-assisted extraction from criminal court decisions for public health surveillance.

**Methods:** We conducted a retrospective observational study of 1532 criminal court decisions involving UMP-related convictions in South Korea between 2005 and 2023. Using an ML-assisted extraction pipeline with human-in-the-loop verification, we transformed unstructured judicial texts into structured legal and medical variables. Analyses were conducted at the case, charge, defendant category, and legal ruling levels. In addition to descriptive analyses, we performed exploratory inferential analyses to examine factors associated with legal rulings and professionals' involvement.

**Results:** Of 1718 charge entries, 987 (57.5%) were related to Article 5 of the Act on Special Measures for the Control of Public Health Crimes, and 731 (42.5%) were related to Article 27(1) of the Medical Service Act. Profit motive was coded in 91.6% (1404/1532) of the cases. At the legal ruling level (n=2004 entries), suspended sentences, meaning sentences whose execution was conditionally suspended under Korean criminal law, were the most common outcome (1261/2004, 62.9%), followed by fines (421/2004, 21%) and imprisonment without suspension (209/2004, 10.4%). Of 1716 defendant category entries, ordinary persons accounted for 1294 (75.4%), health care professionals accounted for 264 (15.4%), and health care providers accounted for 158 (9.2%). Physicians were the largest subgroup among health care professionals. In exploratory multinomial models, licensed personnel–only and mixed ordinary person and licensed personnel cases were more likely than ordinary person–only cases to result in fines or imprisonment without suspension rather than suspended sentences. Secondary exploratory analyses also suggested distinctive patterns of professional involvement and possible scope-of-practice or delegation-related boundary violations.

**Conclusions:** ML-assisted analysis of criminal court decisions can serve as a useful supplementary surveillance method for hidden UMPs. In South Korea, prosecuted UMPs were predominantly profit driven and involved both ordinary persons and licensed personnel. The findings support closer monitoring of scope-of-practice and delegation-related violations and demonstrate the value of judicial records as a source of public health intelligence.

## Introduction

The World Health Organization identifies unsafe care as a major global health challenge, with millions of patients harmed annually due to inadequate safety standards and unqualified practitioners [1]. One persistent but difficult-to-measure contributor is medical or quasi-medical practices by persons acting outside legally defined professional boundaries. Unlicensed medical practices (UMPs) include both practices performed by persons with no health-related license and practices performed by licensed personnel who exceed, improperly delegate, or otherwise violate their lawful scope of practice [2].

UMPs are difficult to study using conventional surveillance tools because they are inherently concealed. Administrative health data, claims systems, and routine public health reporting rarely capture such activity directly. In South Korea, as universal health coverage coexists with the strict licensing regime, UMPs may persist not because care is unavailable [3] but because commercially motivated noncompliance and legal ambiguity regarding the boundaries of "medical practice" create opportunities for underground or improperly delegated services [4].

In South Korea, the Medical Service Act strictly prohibits UMPs under Article 27(1) to protect patient safety [5]. Additionally, Article 5 of the Act on Special Measures for the Control of Public Health Crimes imposes severe penalties, including imprisonment, on nonprofessionals engaging in UMPs for profit [6]. However, the statutory provisions do not explicitly define "medical practice," leaving courts with wide discretion in interpreting the boundaries given potential risks to public health. Furthermore, these practices often lead to clinical negligence, compromising both patient safety and the integrity of the health care system. Therefore, establishing a stringent regulatory regime based on accurate situational awareness is crucial [7,8].

Despite its significant threat to public health, the inherently clandestine nature of UMPs makes them difficult to quantify [9]. Previous studies have been limited to regulatory reviews [10,11] or localized cross-sectional surveys [12], leaving a critical empirical gap regarding the actual prevalence and distinct characteristics of these offenses. Therefore, investigating the current status of UMPs using objective, large-scale data is essential to provide foundational evidence for regulatory policymaking.

South Korea provides a strategically informative setting for this approach because court decisions are highly digitized [13,14] and can be assembled at scale for computational analysis [15]. Recent work in legal natural language processing has made it increasingly feasible to extract structured variables from unstructured judicial text and analyze legal outcomes systematically [16,17]. Within the framework of legal epidemiology, which treats law and legal processes as measurable public health phenomena [18], we propose the term "legal infoveillance" to denote the systematic use of legal and judicial records as a source of surveillance for population health questions. This differs from conventional digital infoveillance, which relies primarily on internet-based or digitally generated information streams [19,20], because legal infoveillance relies on formal case records reflecting detected, investigated, prosecuted, and adjudicated events. Furthermore, while legal epidemiology examines the law as a factor in the distribution and prevention of disease and digital infoveillance monitors public health trends using internet-based behavioral data, our framework synthesizes and extends these domains. By integrating principles of legal epidemiology with recent advancements in artificial intelligence [20], we propose a scalable solution to this data bottleneck. Machine learning (ML) techniques can now process massive volumes of legal texts to predict outcomes and understand the factors influencing judicial decisions [16,17]. Applying these technologies to UMP precedents allows for a novel form of public health surveillance, turning retrospective legal data into actionable public health intelligence [18].

This study aimed to assess the status and characteristics of UMPs by analyzing a comprehensive dataset of criminal precedents using ML techniques. To our knowledge, this is the first study to use automated legal text analysis to generate evidence-based knowledge for global UMP policymaking and regulatory design.

## Methods

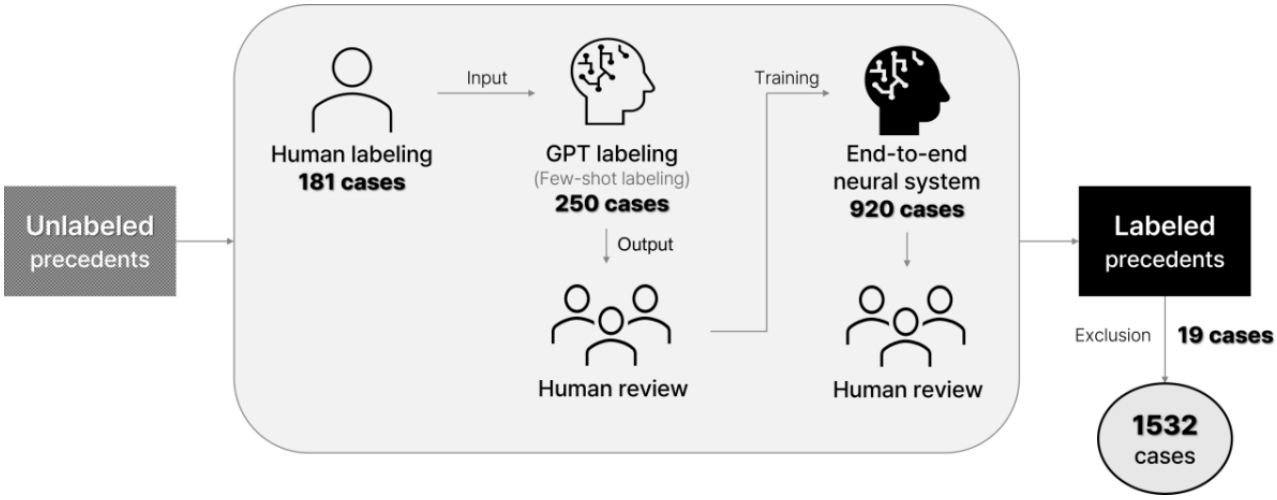
### Study Design and Data Collection

This study was a retrospective observational study of criminal court decisions involving UMP-related convictions in South Korea between 2005 and 2023. We identified closed criminal cases in which at least one defendant was convicted of an offense related to UMPs. The dataset was filtered from a comprehensive corpus of over 3 million court precedents collected by LBox, a legal technology company in South Korea [21]. We selected 2005 as the starting year because systemic indexing in the source corpus began in that year, allowing for consistent retrieval and longitudinal comparison across the study period [13,15]. This dataset serves as a proxy for the detected portion of UMPs, offering a rare window into the types of practices and defendants capture through regulatory oversight. This manuscript was reported with reference to the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) statement [22], and the completed checklist is provided in Multimedia Appendix 1.

### Data Processing

Processing raw legal data posed significant challenges because court decisions are often stored as unstructured images or PDFs. To address this, we used a specialized data processing pipeline [15]. First, a rule-based layout classifier distinguished text-only pages from those containing tables or figures. Then, texts were

XSL•FO
RenderX



extracted using LBox's custom rule-based parser for PDFs and an optical character recognition engine for image files [23]. Third, to extract variables from the unstructured text bundles, a custom-made parser based on bidirectional encoder representations from transformers [24] segmented the texts into functional components, such as facts, legal rulings, reasons for sentencing, and conclusions. This methodology aligns with emerging standards in legal text mining for public health, enabling the conversion of complex narrative data into structured epidemiological variables.

### ML-Assisted Extraction and Human Verification

We used an enhanced proprietary version of the end-to-end Information Extractor for Statistical Legal Analysis [25], an end-to-end neural system based on a domain-adapted mT5-Large architecture [26], for automated information extraction. The foundational model has been validated, achieving an average $F_1$-score of 93.1 across Korean legal information extraction tasks [25].

Given the high-stakes nature of legal and health data, we addressed the "black box" problem of artificial intelligence by implementing a rigorous human-in-the-loop validation process. Initially, 181 cases were labeled by the researchers to create the gold-standard set, which provided the few-shot examples for GPT-4 (OpenAI) [27] to generate labels for an additional 250 cases [28]. Second, these model-generated labels were thoroughly reviewed and corrected by 3 professional labelers, yielding a verified dataset of 631 cases. Third, this corrected dataset was used to fine-tune the Information Extractor for Statistical Legal Analysis–based system, which subsequently generated variable values autoregressively for the remaining cases. In total, 920 cases were labeled by the fine-tuned system and verified by the labelers. Cases involving complex compound charges (eg, UMPs combined with drug-related charges) were excluded (n=19) to ensure reliability. Finally, 1532 unique labeled cases were included in the final analysis (Figure 1).

**Figure 1.** Machine learning–assisted information extraction and human-in-the-loop labeling workflow. GPT: generative pretrained transformer.

### Analytic Units and Variable Definitions

As a single judicial decision could involve multiple charges, defendants, and legal rulings, counts across analytic levels were not directly comparable. Therefore, all percentages are reported with their explicit denominators. Analyses were conducted at 4 levels: cases (n=1532), charges (n=1718), defendants (n=1716), and legal rulings (n=2004).

Variables were defined through close collaboration between experts in computer science and medical law. For practitioner classification, we used 3 operational categories: health care professionals, health care providers, and ordinary persons. Health care professionals were defined as physicians, dentists, doctors of Korean medicine, midwives, and registered nurses under the Medical Service Act of South Korea [5]. Health care providers were defined as other licensed or certified health care–related personnel, such as nurse aides, medical technologists, and physical therapists. Finally, we defined ordinary persons as defendants without a health care–related professional license. Legal rulings were classified as imprisonment without suspension, fines, suspended sentences, suspension of imposition of sentence, acquittal, or other. Sentencing factors (eg, settlement with victims and self-reflection) were categorized according to the guidelines of the Sentencing Commission of South Korea [29].

### Data Analysis

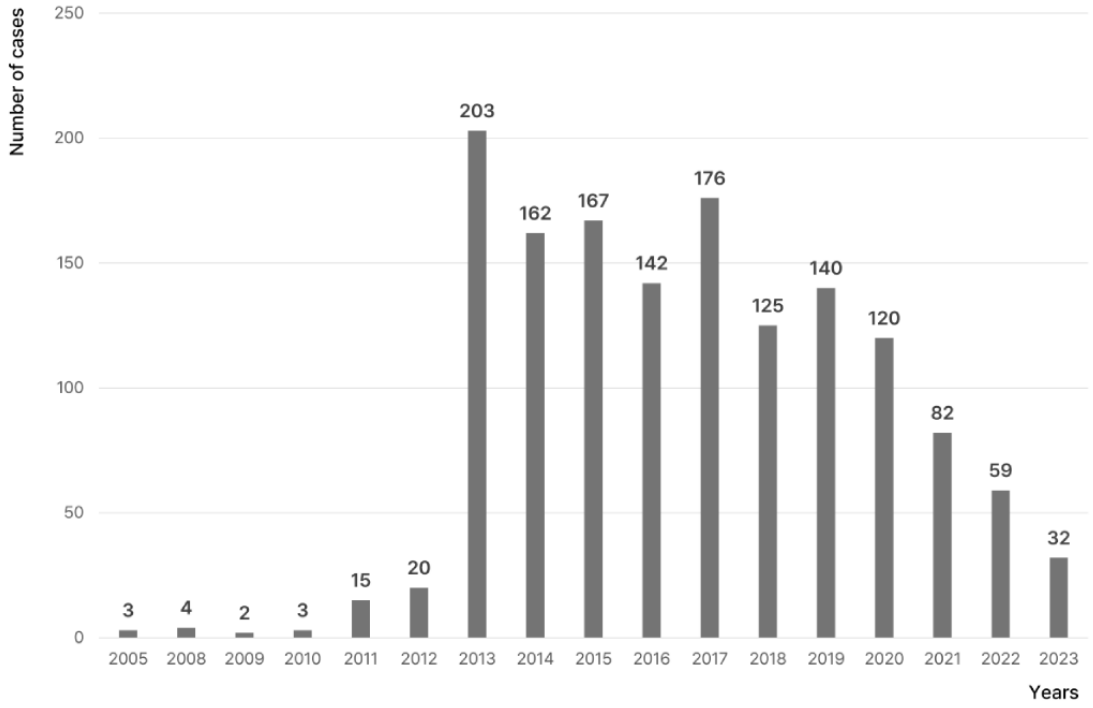
The variables were labeled and classified into legal and medical sections for each case. Before labeling the variables, ontologies were built for the individual sections, and a labeling page was set up using Label Studio (HumanSignal) [30]. To ensure the validity of the results, the researchers independently labeled the variables for each case (181 samples) and then cross-checked them. The section on legal facts and rulings was labeled by a PhD in Engineering at LBox (MC), which provides a cloud-based service to support the digitization of legal practices by processing court documents and records in South Korea [21]. A PhD in Medical Law and Ethics (MJK) verified the medical sections to ensure accuracy.

Statistical analyses were performed using SPSS (version 27.0; IBM Corp) and SAS (version 9.4; SAS Institute Inc). We first conducted descriptive analyses at the case, charge, defendant category, and ruling entry levels. We then examined annual case counts from 2005 to 2023 to visualize the temporal

XSL•FO
RenderX

distribution of UMP cases prosecuted. Because the dataset was conditioned on prosecuted cases with at least one UMP-related conviction, inferential analyses were framed as exploratory models of sentencing patterns among detected, prosecuted, and adjudicated cases rather than as estimates of underlying UMP prevalence, probability of offending, probability of conviction, or guilt. For the primary inferential analysis, we fit a multinomial logistic regression using the principal legal ruling recorded in each case as the dependent variable. Suspended sentence was used as the reference, and suspension of imposition of sentence, acquittal, and other rare outcomes were collapsed into a single "others" category due to small cell counts. Predictors included case composition (ordinary person only, licensed personnel only, mixed ordinary person and licensed personnel, or uncoded), involvement in the Act on Special Measures for the Control of Public Health Crimes charges, profit motive, and practice type. As secondary analyses, we fit logistic models of professionals' involvement among category-coded cases and of health care providers' coinvolvement among licensed personnel–involved cases as an exploratory proxy for delegation- or boundary-related scenarios.

### Ethical Considerations



The joint institutional review board designated by the Ministry of Health and Welfare of South Korea confirmed that the study protocol met the criteria for exemption from regular review because this research was based on literature that was publicly accessible by any individual and owing to the absence of direct or indirect involvement of human materials, animal experiments, or pathogens (P01-202406-01-025).

## Results

### Overview of UMP Cases

A total of 1532 criminal cases were analyzed. The annual distribution of these cases from 2005 to 2023 is illustrated in Figure 2, showing the longitudinal trends in UMP prosecutions. Annual case counts remained low until 2011, increased sharply from 2012, peaked at 203 cases in 2013, remained high until 2019, and steadily declined to 32 cases by 2023.

**Figure 2.** Annual distribution of 1532 prosecuted unlicensed medical practice cases identified from Korean criminal court decisions (2005-2023).

### Legal Characteristics and Rulings

All cases contained 1718 charge entries, of which 987 (57.5%) were related to violations of Article 5 of the Act on Special Measures for the Control of Public Health Crimes, whereas 731 (42.5%) were related to violations of Article 27(1) of the Medical Service Act. Profit motive was coded in 91.6% (1404/1532) of cases, indicating that the vast majority of prosecuted UMP cases were commercially motivated. At the legal ruling level (n=2004), suspended sentences were most common (1261/2004, 62.9%), followed by fines (421/2004, 21%), imprisonment without suspension (209/2004, 10.4%), and acquittal (57/2004, 2.8%). Analysis of sentencing factors revealed that payment or deposit for victims was recorded in 72.4% (63/87) of cases, settlements with victims were recorded in 75.4% (101/134) of cases, and self-reflection was recorded in 95.6% (586/613) of cases. Prior similar-offense counts were coded for 26.9% (412/1532) of cases, with a mean of 0.8 prior similar offenses per coded case (SD 1.2; range 0-12), and prior different-offense counts were coded for 11.3% (173/1532) of cases, with a mean of 0.3 prior different offenses per coded case (SD 0.6; range 0-5; Table 1).

**Table 1.** Legal characteristics and sentencing factors in prosecuted unlicensed medical practice cases identified from Korean criminal court decisions (2005-2023) in a retrospective observational study.

| Category and variable | Values |
|---|---|
| **Charges (n=1718), n (%)** | |
| Violation of Article 5 of the Act on Special Measures for the Control of Public Health Crimes | 987 (57.5) |
| Violation of Article 27(1) of the Medical Service Act | 731 (42.5) |
| **For-profit motive (n=1532), n (%)** | |
| Yes | 1404 (91.6) |
| No | 128 (8.4) |
| **Legal ruling (n=2004), n (%)** | |
| Suspended sentences | 1261 (62.9) |
| Fine | 421 (21) |
| Imprisonment without suspension | 209 (10.4) |
| Acquittal | 57 (2.8) |
| Suspension of imposition of sentence | 51 (2.5) |
| Others | 5 (0.2) |
| **Sentencing factors** | |
| **Payment or deposit for victims (n=87), n (%)** | |
| Done | 63 (72.4) |
| Not done | 24 (27.6) |
| **Settlement with victims (n=134), n (%)** | |
| Done | 101 (75.4) |
| Not done | 33 (24.6) |
| **Self-reflection (n=613), n (%)** | |
| Yes | 586 (95.6) |
| No | 27 (4.4) |
| **Criminal records, mean (SD; range)** | |
| Prior similar offenses per coded cases (n=412) | 0.8 (1.2; 0-12) |
| Prior different offenses per coded cases (n=173) | 0.3 (0.6; 0-5) |

## Medical Characteristics and Defendant Profiles

Defendant category coding was available for 97.8% (1499/1532) of cases, yielding 1716 defendant category entries as some cases involved more than one defendant category. Ordinary persons accounted for 75.4% (1294/1716); whereas health care professionals accounted for 15.4% (264/1716); and health care providers accounted for 9.2% (158/1716), including nurse aides, medical technologists, or physical therapists. Among health care professionals, physicians were the most frequent offenders (166/1716, 9.7%), followed by doctors of Korean medicine (41/1716, 2.4%) and dentists (35/1716, 2%). At the case level (n=1532), general UMP was the most common practice type (1056/1532, 68.9%), followed by unlicensed Korean medical practice (302/1532, 19.7%) and unlicensed dental practice (175/1532, 11.4%). Notably, one case was double coded for both general unlicensed medical and Korean medical practice (Table 2).

XSL•FO
RenderX

**Table 2.** Medical characteristics, defendant categories, and practice types in prosecuted unlicensed medical practice cases identified from Korean criminal court decisions (2005-2023) reported by analytic unit.

| Category and variable | Frequency, n (%) |
|---|---|
| **Defendant category (defendant entries; n=1716)** | |
| Ordinary person | 1294 (75.4) |
| Health care provider | 158 (9.2) |
| Health care professional | 264 (15.4) |
| Physician | 166 (9.7) |
| Doctor of Korean medicine | 41 (2.4) |
| Dentist | 35 (2) |
| Registered nurse | 22 (1.3) |
| **Type of practice (cases; n=1532)** | |
| Unlicensed medical practice[a] | 1056 (68.9) |
| Unlicensed Korean medical practice | 302 (19.7) |
| Unlicensed dental practice | 175 (11.4) |

[a]The general unlicensed medical practice category included tattoo-related cases when the conduct was adjudicated as unlicensed medical practice under Korean law; however, these cases were not analyzed as a separate practice type category in the revised analyses.

## Sanctions by Defendant Category

The distribution of legal rulings varied by defendant category. In the cross-tabulation of legal rulings and defendant categories among 1499 category-coded cases, suspended sentences (1129/1294, 87.2%) were the most frequently reported among ordinary person–involved cases. In contrast, fines were most frequently observed among physician-involved cases (130/166, 78.3%), followed by dentist-involved cases (26/35, 74.3%) and doctor of Korean medicine–involved cases (31/41, 75.6%; Table 3).

**Table 3.** Case-level multiple-response cross-tabulation of legal rulings and defendant categories in prosecuted unlicensed medical practice cases identified from Korean criminal court decisions (2005-2023)[a].

| Defendant category | Cases, n/N (%)[b] | Imprisonment without suspension, n/N (%)[c] | Fine, n/N (%)[c] | Suspended sentences, n/N (%)[c] | Suspension of imposition of sentence, n/N (%)[c] | Acquittal, n/N (%)[c] | Others, n/N (%)[c] |
|---|---|---|---|---|---|---|---|
| **Health care professionals** | | | | | | | |
| Physician | 166/1499 (11.1) | 36/166 (21.7) | 130/166 (78.3) | 90/166 (54.2) | 24/166 (14.5) | 17/166 (10.2) | 1/166 (0.6) |
| Dentist | 35/1499 (2.3) | 4/35 (11.4) | 26/35 (74.3) | 15/35 (42.9) | 2/35 (5.7) | 4/35 (11.4) | 0/35 (0) |
| Doctor of Korean medicine | 41/1499 (2.7) | 7/41 (17.1) | 31/41 (75.6) | 26/41 (63.4) | 6/41 (14.6) | 3/41 (7.3) | 0/41 (0) |
| Registered nurse | 22/1499 (1.5) | 4/22 (18.2) | 11/22 (50) | 9/22 (40.9) | 2/22 (9.1) | 5/22 (22.7) | 0/22 (0) |
| Health care providers | 158/1499 (10.5) | 31/158 (19.6) | 110/158 (69.6) | 99/158 (62.7) | 24/158 (15.2) | 14/158 (8.9) | 0/158(0) |
| Ordinary persons | 1294/1499 (86.3) | 167/1294 (12.9) | 249/1294 (19.2) | 1129/1294 (87.2) | 20/1294 (1.5) | 34/1294 (2.6) | 5/1294 (0.4) |
| Total | 1499/1499 (100) | 201/1499 (13.4) | 397/1499 (26.5) | 1232/1499 (82.2) | 49/1499 (3.3) | 53/1499 (3.5) | 5/1499 (0.3) |

[a]Because a single case could involve multiple defendant categories and multiple legal rulings, counts across rows are non–mutually exclusive; therefore, row percentages may add up to more than 100.

[b]The column shows the number and percentage of total analyzed cases (n=1499) that involved at least one defendant in the specified category.

[c]Values constitute the number and percentage of cases in each defendant category.

## Exploratory Inferential Analysis of Legal Rulings

To address the determinants of legal rulings, we fit an exploratory multinomial logistic regression model. Compared with ordinary person–only cases, licensed personnel–only cases were more likely to result in fines (adjusted relative risk ratio [aRRR] 2.13, 95% CI 1.36-3.32) and imprisonment without suspension rather than suspended sentences (aRRR 1.79, 95%

XSL•FO
RenderX

CI 1.02-3.16). Mixed ordinary person and licensed personnel cases showed even stronger associations with fines (aRRR 3.56, 95% CI 1.62-7.81) and imprisonment without suspension (aRRR 2.75, 95% CI 1.18-6.40). Act on Special Measures for the Control of Public Health Crimes–related cases were comparatively more likely to end in suspended sentences than in fines (aRRR 0.02, 95% CI 0.01-0.03) or imprisonment without suspension (aRRR 0.55, 95% CI 0.37-0.83; Table 4).

**Table 4.** Exploratory multinomial logistic regression of principal judicial outcomes among prosecuted unlicensed medical practice cases identified from Korean criminal court decisions (2005-2023; n=1532)[a].

| Predictor | Fine, aRRR[b] (95% CI)[c] | *P* value | Imprisonment without suspension, aRRR (95% CI)[c] | *P* value | Others, aRRR (95% CI)[c] | *P* value |
|---|---|---|---|---|---|---|
| Licensed personnel–only cases (vs ordinary person only) | 2.13 (1.36-3.32) | <.001 | 1.79 (1.02-3.16) | .04 | 5.14 (2.65-9.99) | <.001 |
| Mixed ordinary person and licensed personnel cases (vs ordinary person only) | 3.56 (1.62-7.81) | .002 | 2.75 (1.18-6.40) | .02 | 7.43 (2.73-20.21) | <.001 |
| Uncoded (vs ordinary person only) | 1.41 (0.53-3.78) | .50 | 0.74 (0.19-2.93) | .67 | 2.32 (0.59-9.07) | .23 |
| Act on Special Measures for the Control of Public Health Crimes–related charge involvement (vs not involved) | 0.02 (0.01-0.03) | <.001 | 0.55 (0.37-0.83) | .004 | 0.09 (0.04-0.18) | <.001 |
| Profit motive (vs no profit) | 0.98 (0.57-1.69) | .96 | 0.57 (0.28-1.13) | .11 | 0.66 (0.32-1.39) | .28 |
| Korean medical practice (vs general) | 0.86 (0.55-1.35) | .51 | 1.16 (0.77-1.74) | .49 | 0.93 (0.43-2.02) | .86 |
| Dental practice (vs general) | 0.58 (0.30-1.11) | .10 | 0.49 (0.26-0.92) | .03 | 0.29 (0.09-1.01) | .05 |

[a]As the dataset was restricted to detected, prosecuted, and adjudicated unlicensed medical practice cases with at least one conviction, the values estimate associations with ruling type within the prosecuted case set, not the underlying prevalence of unlicensed medical practices, probability of offending, probability of conviction, or guilt. The principal judicial outcome recorded for each case was used as the dependent variable.

[b]aRRR: adjusted relative risk ratio.

[c]The suspended-sentence category was the reference category.

### Secondary Exploratory Analyses of Professional-Related Case Patterns

Table 5 illustrates the secondary exploratory logistic model among 1499 category-coded cases. Professional involvement was less common in Act on Special Measures for the Control of Public Health Crimes–related cases (adjusted odds ratio [aOR] 0.10, 95% CI 0.06-0.14), profit-driven cases (aOR 0.47, 95% CI 0.28-0.77), and Korean medical practice cases (aOR 0.09, 95% CI 0.05-0.16).

In a further exploratory model restricted to 248 cases involving at least one health care professional, physician involvement, compared with involvement of other health care professionals, was associated with health care provider coinvolvement (aOR 4.67, 95% CI 2.40-9.10), a pattern consistent with possible delegation-related or boundary violation scenarios.

**Table 5.** Exploratory logistic regression of health care professional involvement among category-coded prosecuted unlicensed medical practice cases identified from Korean criminal court decisions (2005-2023; n=1499)[a].

| Predictor | aOR[b] (95% CI) | *P* value |
|---|---|---|
| Act on Special Measures for the Control of Public Health Crimes–related charge involvement (vs not involved) | 0.10 (0.06-0.14) | <.001 |
| Profit motive (vs no profit) | 0.47 (0.28-0.77) | .003 |
| Korean medical practice (vs general) | 0.09 (0.05-0.16) | <.001 |
| Dental practice (vs general) | 0.55 (0.33-0.93) | .03 |

[a]This model examined whether a case involved at least one health care professional.

[b]aOR: adjusted odds ratio.

## Discussion

### Principal Findings

This retrospective study used end-to-end neural systems to analyze 1532 criminal precedents and demonstrate the public health utility of legal infoveillance for prosecuted UMPs in South Korea. Three major findings emerged. First, commercially motivated offending predominated, with 91.6% (1404/1532) of cases coded as profit driven. Second, suspended sentences were the most common judicial outcome. Third, UMPs were not confined to ordinary persons without licenses; licensed health care professionals and providers were also substantially represented in the prosecuted case set. Taken together, these findings suggest that UMPs in South Korea should be understood not only as lay “quackery” but also as a problem of

XSL•FO
RenderX

regulatory boundary violation within and around formal health care settings.

Health care professionals, particularly physicians, constituted the largest subgroup among them, and fines were common among professional-involved cases. The exploratory inferential analyses further suggested that licensed personnel–only and mixed ordinary person and licensed personnel cases were more likely than ordinary person–only cases to result in fines or imprisonment without suspension rather than suspended sentences. Although judicial records cannot reveal underlying institutional arrangements with certainty, this pattern is consistent with broader concerns about scope-of-practice breaches and commercially driven delegation or task shifting [4,31,32]. In this context, the coinvolvement of physicians and health care providers should be interpreted cautiously as a signal of possible boundary violation scenarios rather than as direct proof of unlawful delegation.

Our findings also help explain why UMPs may persist even in a setting with universal health coverage. In South Korea, the persistence of prosecuted UMPs is unlikely to be explained solely by lack of access to formal care [3]. Rather, the concentration of profit-driven cases and the involvement of licensed actors suggest that legal ambiguity, commercial incentives, and inadequately deterred noncompliance may all contribute to the continuing presence of UMPs [4]. The predominance of suspended sentences and fines may further indicate that many courts viewed these offenses as serious but still compatible with conditional leniency, which may weaken deterrence when the underlying conduct is economically rewarding.

From a methodological standpoint, this study supports legal infoveillance as a supplementary surveillance approach for hidden health-related misconduct. Because UMPs are clandestine and rarely captured directly in routine public health or administrative datasets [19], digitized court decisions provide a rare observational window into detected, investigated, prosecuted, and adjudicated events [18,33]. The framework is potentially transferable to other jurisdictions, but its usefulness will depend on the degree of judicial digitization [14], public access to court records [13], and availability of natural language processing tools capable of handling jurisdiction-specific legal language [34].

The findings need to be carefully interpreted in light of several limitations. Most importantly, the dataset represents prosecuted cases rather than the true prevalence of UMPs. This creates selection and detection bias [33] and makes the observed patterns sensitive to enforcement practices, prosecutorial priorities, and reporting behavior [35]. Accordingly, the results describe the enforcement-visible portion of UMPs rather than the absolute population burden. Therefore, these models should be read only as exploratory descriptions of sentencing patterns among detected, prosecuted, and adjudicated cases; they do not estimate the underlying prevalence of UMPs, the probability that an individual will offend, or the probability that a reported or prosecuted case will result in conviction. Formal interannotator agreement metrics were not calculated, and some complex judicial features had to be simplified into structured variables. Nevertheless, this study narrows an important empirical gap by showing that large-scale legal text analysis can generate population-relevant evidence from otherwise difficult-to-study judicial corpora [24,36].

## Conclusions

This study demonstrates that ML-assisted analysis of criminal court precedents can serve as a useful supplementary method for monitoring hidden UMPs. In South Korea, prosecuted UMPs were predominantly profit driven and involved both ordinary persons and licensed personnel, with exploratory analyses suggesting distinct judicial outcome patterns when health care professionals were involved. These findings support stronger oversight of scope-of-practice and delegation-related violations and reinforce the value of judicial records as a practical source of public health intelligence. Future research should build on this descriptive foundation with richer inferential modeling, improved annotation reliability metrics, and cross-jurisdictional comparisons of how legal design and enforcement shape the detected profile of UMPs.

## Acknowledgments

First, the authors appreciate LBox for providing data and cooperating on this study. Second, the authors declare the use of generative artificial intelligence in the research and writing process. According to the Generative Artificial Intelligence Delegation Taxonomy (2025), proofreading and editing were delegated to Gemini 3 (Google) under full human supervision. Responsibility for the final manuscript lies entirely with the authors. Generative artificial intelligence tools are not listed as authors and do not bear responsibility for the final outcomes. This declaration is made under the collective responsibility of all authors.

## Abstract

**Background:** The National Diabetes Prevention Program (DPP) is an evidence-based intervention proven to delay or prevent progression to type 2 diabetes, yet most at-risk people do not enroll. In Hawai'i, Native Hawaiian and Other Pacific Islander (NHOPI) and Filipino adults experience disproportionately high rates of prediabetes and diabetes but have low DPP enrollment. From July to October 2024, the Hawai'i State Department of Health launched Beat Diabetes, a statewide media campaign encouraging DPP enrollment among at-risk adults, with a focus on NHOPI and Filipino communities.

**Objective:** This evaluation assessed whether campaign exposure was associated with self-reported likelihood of joining a DPP among Hawai'i adults at risk for diabetes, particularly NHOPI or Filipino adults.

**Methods:** A postcampaign cross-sectional online survey was conducted from October to December 2024, with Hawai'i residents aged 35-64 years who reported at least 1 diabetes risk factor. NHOPI or Filipino adults were oversampled to determine campaign effectiveness among the target audience. The survey measured self-reported likelihood of joining a lifestyle change program (main outcome), campaign recall (main exposure), demographic characteristics, diabetes risk factors, and beliefs that could affect DPP enrollment likelihood, including intrinsic motivation, perceived inevitability of developing diabetes, and perceived health benefits of DPP participation. Three general linear regression models examined the association between campaign exposure and DPP enrollment likelihood ratings, adjusted for demographic characteristics, diabetes risk factors, and belief variables. A sensitivity analysis among just those diagnosed with prediabetes was conducted.

**Results:** A total of 860 adults completed the survey, with 34.7% (298/860) and 12.2% (105/860) self-identifying as NHOPI and Filipino, respectively. In total, 40% (346/860) reported campaign exposure. Exposed individuals had higher mean DPP enrollment likelihood ratings and higher inevitability belief scores than those not exposed. A large proportion of exposed respondents reported that enrolling in a DPP would "improve their health a lot." No significant differences in campaign exposure were observed across ethnicities. All 3 regression models showed a significant positive association between campaign exposure and DPP enrollment likelihood ratings. In the final adjusted model controlling for all covariates, significant predictors included campaign exposure (β=.52, *P*<.001), male gender (β=.34, *P*=.01), residence outside Honolulu County (β=.31, *P*=.02), motivation index scores (β=.38, *P*<.001), inevitability belief (β=.20, *P*<.001), and the belief that DPP improves health "a little" (β=.76, *P*<.001) or "a lot" (β=1.63, *P*<.001). The sensitivity analysis among those diagnosed showed exposure was not associated with likelihood ratings (β=.30, *P*=.27).

**Conclusions:** Campaign exposure was associated with higher ratings of likelihood to join a DPP among at-risk adults with no prediabetes diagnosis. Perceived positive health impact of DPP participation was the strongest contributor to likelihood ratings. Campaigns aiming to increase awareness of DPP and intentions to join should promote DPP effectiveness and the urgency of preventative actions.

## Introduction

### Background

In the United States, approximately 97.6 million adults have prediabetes [1], placing more than one-third of the adult population at risk for developing type 2 diabetes. Although the statewide prevalence of diagnosed prediabetes in Hawai'i is lower than the national estimate (14.9% vs 38%) [1,2], disaggregated data reveal notable differences among racial and ethnic groups. Native Hawaiian (17.2%), Other Pacific Islander (16.9%), and Filipino (17.3%) adults have higher prevalence of diagnosed prediabetes than non-Hispanic White (9.0%) adults [2]. These groups, along with non–Hispanic Black and Hispanic adults, are recognized nationally as having elevated risk for type 2 diabetes [3].

Established risk factors for prediabetes and diabetes include being older than 40 years, having a family history of diabetes, having high blood pressure, physical inactivity, a history of gestational diabetes, and being overweight [4,5]. In 2021, the US Preventive Services Task Force lowered the recommended prediabetic screening age for adults who are overweight or obese from 40 to 35 years, citing these risk factors as the strongest predictors for progressing to diabetes [6]. Identifying individuals at high risk for prediabetes and intervening early is critical to preventing progression to type 2 diabetes.

The National Diabetes Prevention Program (DPP) is an evidence-based lifestyle intervention that can reduce the risk of progressing from prediabetes to type 2 diabetes by up to 58% [7]. Despite the success of the program, less than 1% of US adults with prediabetes enroll in the program [8]. Enrollment data show that certain groups such as Native Hawaiian and Other Pacific Islander (NHOPI) and Filipino adults are disproportionately affected by prediabetes [9] and yet enroll in DPPs at lower rates than Hispanic, non–Hispanic Black, and non–Hispanic White adults [8].

Multiple factors contribute to low enrollment. Extrinsic barriers include program cost, limited time to participate, long wait periods before enrollment, lack of online options, and competing health conditions [10-17]. Intrinsic barriers also play a role. Low autonomous motivation, defined as low internal drive to adopt healthier behaviors [18], and belief that diabetes is inevitable due to family history may reduce individuals' willingness to engage in prevention efforts [19,20]. Together, these barriers can hinder adults with prediabetes from taking steps to prevent disease progression.

### Campaign Development

In 2024, the Hawai'i State Department of Health (HDOH) conducted focus groups to better understand why adults diagnosed with prediabetes or at high risk for prediabetes do not engage in lifestyle changes and what messages might motivate enrollment in a DPP. Focus groups were segmented by the largest racial and ethnic groups in Hawai'i: Native Hawaiian, Other Pacific Islander, Filipino, and Other (White and Japanese) adults with focused recruitment of NHOPI or Filipino adults due to their high rates of prediabetes. Across groups, most participants reported that they did not have time to prioritize their health. Some participants felt little urgency to join a lifestyle change program, stating that they would be more likely to seek help only after receiving a diabetes diagnosis. Others were uncertain about how to start making a change but responded positively to messages that were direct and encouraging. Participants preferred campaign materials featuring people from diverse backgrounds, including NHOPI or Filipino adults.

Guided by these findings, the HDOH developed the Beat Diabetes media campaign to increase urgency around diabetes prevention and provide a clear call to action by joining DPP, a lifestyle change program. The campaign aimed to increase DPP enrollment overall, particularly for NHOPI or Filipino adults at risk for prediabetes and diabetes, by addressing intrinsic barriers such as low motivation and perceived inevitability of diabetes. The campaign consisted of 6 still advertisements and 1 video advertisement featuring NHOPI or Filipino adults delivering messages such as: "I'm not waiting. I'm preventing diabetes. Join the program." and "Tomorrow's a hard nope. I'm preventing diabetes today. Join the program." (Multimedia Appendix 1). Each advertisement contained a link to the landing page for the Beat Diabetes website, which provided more information about prediabetes, diabetes risk test, frequently asked questions, and information on how to enroll in a DPP [21]. The campaign ran from July to October 2024 across statewide television, radio, digital platforms, print outlets, and mall posters.

To evaluate the effect of the campaign on self-reported likelihood of joining a lifestyle change program, particularly among the campaign's target audience of NHOPI or Filipino adults at risk for diabetes, the HDOH collaborated with the Healthy Hawai'i Evaluation Team (HHET) to develop a postcampaign cross-sectional survey. A market research firm was contracted to administer the survey.

## Methods

### Study Design

This cross-sectional study followed the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) reporting guideline and checklist to draft this manuscript (Checklist 1) [22] and the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) statement to report on web-based surveys (Checklist 2) [23].

### Survey Development

The survey was developed by the HDOH and HHET teams, and programming of the screening and core survey questions was checked and revised by the market research firm. The online survey was pretested with 25 eligible respondents before fielding. It took approximately 10 - 12 minutes to complete and was composed of 7 screening questions and approximately 50

XSL•FO
RenderX

core questions in English. The survey could be viewed multiple ways: on a mobile phone showing 1 question per screen or on a desktop computer displaying multiple questions at once for a total of 24 screens.

### Participant Recruitment

Data collection occurred between October and December 2024. A convenience sample of adults aged 35 - 64 years was recruited from 3 proprietary statewide market research consumer panels. The market research firm emailed eligible panelists an invitation to complete a closed online survey via a secured survey link, following the conclusion of the Beat Diabetes campaign. Consumer panels were selected over other sampling methods as they are a more cost-effective method to evaluate health department media campaigns to provide timely feedback for campaign improvement [24]. Inclusion criteria included residency in Hawai'i for at least 6 months and a diagnosis of either prediabetes or borderline diabetes, or at least 1 recognized prediabetes risk factor as determined by a diabetes risk test. Individuals with a prior diabetes diagnosis were excluded, as they are ineligible for DPP enrollment and may instead join a diabetes self-management education and support program. A minimum of 700 responses were required, with a goal of 900 responses determined by the budget set aside for recruitment. NHOPI and Filipino adults were oversampled to ensure that they made up 50% of the end sample, a large enough sample size to examine campaign recall and effectiveness within the campaign's target audience.

### Ethical Considerations

This evaluation was reviewed by the HDOH Institutional Review Board, who confirmed it qualified as nonhuman subjects research under the revised Common Rule of 2018. Informed consent identified the purpose of the survey and who was conducting the investigation, identified the market research firm assisting with data collection, and gave details on the survey length and time, confidentiality and deidentification of data, and how participation was voluntary before eligible participants accessed the online survey. All survey responses were kept confidential on password-protected computers and deidentified prior to analysis. Incentives were provided by the marketing firm via each respondent's email address and ranged from points to gift cards valued at US $10, depending on the panel. The marketing firm retained email addresses in a separate working file used solely for incentive distribution, with no link to survey responses so that no personal identifier could be tracked.

### Survey Measures

The full postsurvey instrument is provided in Multimedia Appendix 2. Survey measures included the following:

1. DPP enrollment likelihood rating: The main evaluation outcome was participants' self-reported likelihood of joining a lifestyle change program. Participants were given a short description of such a program and asked, "How likely are you to consider joining a lifestyle change program such as *Beat Diabetes*?" Responses were recorded on a 7-point Likert scale ranging from 1 (*not at all likely*) to 7 (*very likely*). DPP enrollment likelihood ratings were treated as continuous in all analyses.
2. Campaign exposure: Campaign exposure was defined by self-reported recall of any of the campaign advertisements. Participants were shown 4 different still advertisements and 1 video advertisement and asked whether they had seen or heard each. Advertisements were rotated to reduce response bias. If participants had not seen or heard any of these advertisements, they were shown 2 additional still advertisements in a single question. Recall of any of the 7 advertisements was coded as exposure to the campaign.
3. Demographic characteristics: Participants reported their age, gender (woman and man), education, household income, and county of residence (Honolulu County and other counties). Health insurance status and type (private, Medicare, Medicaid, and TRICARE/other) were also collected. Participants reported the group that best represented their race or ethnicity. Race or ethnicity was coded into 3 categories: Filipino, NHOPI, and Other. Participants indicating Filipino alone or along with another race or ethnicity were categorized as Filipino. Participants reporting at least one of the following ethnicities alone or with any other race or ethnicity (ie, multiethnic participants)—Native Hawaiian or Part Hawaiian and Other Pacific Islander (including Samoan, Tongan, Guamanian or Chamorro, Fijian, and peoples of Micronesia and Melanesia)—were categorized as NHOPI. All other racial and ethnic groups were categorized as "Other."
4. Diabetes risk factors: Screening questions were used to identify diabetes risk factors, including self-perceived overweight status, physical inactivity (less than 3 times per week), hypertension diagnosis, and prediabetes diagnosis. Family history risk was determined by responses to "My family members or relatives have diabetes" in the screening question and "Does your family have a history of diabetes?" in the main survey. Gestational diabetes risk combined 2 items: "I have given birth to a baby that weighed more than 9 pounds" and "I had gestational diabetes in a past pregnancy." Only those indicating woman as gender were asked about gestational diabetes risk.
5. Motivation index score: Four items adapted from the Treatment Self-Regulation Questionnaire [18] assessed participants' autonomous motivation to prevent diabetes. Participants rated each statement on a 7-point scale from 1 (*not at all true*) to 7 (*very true*). Each statement started with, "The reason I would take steps to help prevent diabetes is that..." (1) "It is very important for being as healthy as possible," (2) "I personally believe it is the best thing for my health," (3) "I feel that I want to take responsibility for my own health," and (4) "It is consistent with my life goals." All items were treated as continuous, with interitem correlations ranging from 0.54 to 0.72. The 4 items were averaged to create a motivation index score for each participant. The scale demonstrated good reliability with a Cronbach α of 0.86 (95% CI 0.8 - 0.9).
6. Inevitability belief: Participants' perceptions of the inevitability of developing diabetes were measured using the statement, "It is only a matter of time before I get diabetes," rated on the same 7-point scale for the motivation items. Scores were treated as continuous.

XSL•FO
RenderX

7. Perceived DPP effectiveness: Participants' beliefs about the effectiveness of DPP were measured with the question, "If you joined a lifestyle program such as Beat Diabetes, do you think your health would...*decline*, *stay the same*, *improve a little*, or *improve a lot*." For analyses, *decline* and *stay the same* responses were combined to indicate negative beliefs about the effectiveness of DPP.

### Data Integrity

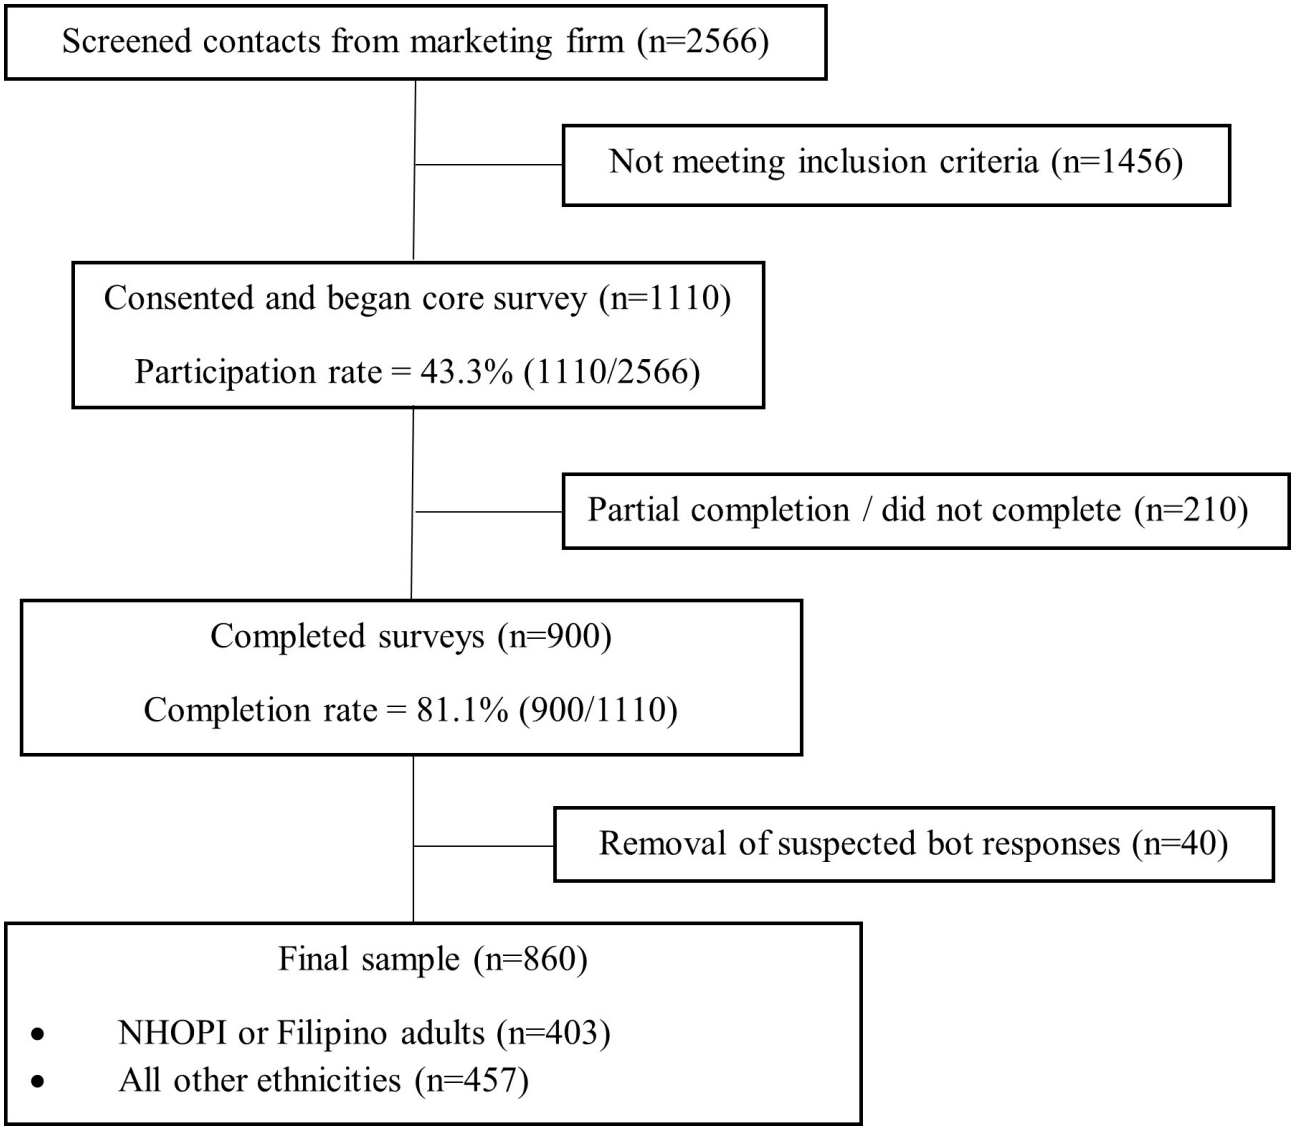
Data quality was continuously monitored throughout collection. Through the market research firm's data-cleaning protocols, surveys that took less than 5 minutes to complete were excluded from the completed surveys, as were those with duplicate IP addresses. Completeness of each survey was monitored by the market research firm and the number of completed surveys was reported in weekly field status updates alongside numbers of emailed contacts, those ineligible after screening, and surveys abandoned postscreening questions. Respondents were not able to review or change their answers once they submitted the survey. A final data cleaning was done to remove responses suspected to be bots due to open-ended responses that were nonsensical or inconsistent in their responses to multiple questions. The remaining responses were included in analysis.

### Data Analysis

Descriptive statistics were reported as frequencies and percentages for categorical variables and as means and standard deviations for continuous variables. Bivariate analyses were conducted to examine potential associations between campaign exposure, DPP enrollment likelihood ratings, and covariates using 2-sample *t* tests or chi-square tests, as appropriate. Missing data for gender and education were excluded from analysis.

Three general linear regression models were used to assess the association between campaign exposure and DPP enrollment likelihood ratings, controlling for covariates. Model 1 included demographic variables only, model 2 added diabetes risk factors to model 1, and model 3 further adjusted for motivation index score, inevitability belief, and perceived DPP effectiveness. Graphical tests were conducted to assess model assumptions. Because slight deviations from normality were observed, sensitivity analyses using ordered logistic regression (analyses not shown) were conducted to identify potential deviations from the general linear regression results. No significant deviations were detected and thus general linear regression models are presented. Multicollinearity among independent variables was evaluated using the variance inflation factor. Subgroup analyses were conducted to examine race in a disaggregated manner using model 3 stratified by race or ethnicity. A sensitivity analysis was also conducted using model 3 among participants diagnosed with prediabetes to evaluate consistency with the overall findings. All analyses were conducted using R (version 4.5.1; R Core Team). A *P* value less than .05 was considered statistically significant.

## Results



### Final Sample

A total of 2566 panel participants responded to the email invitation and were screened. Of these, 1456 were excluded for not meeting inclusion criteria and 210 were excluded for incomplete surveys, resulting in 900 completed surveys. An additional 40 responses were removed due to suspected bot activity, yielding a final analytic sample of 860 respondents (Figure 1).

XSL•FO
RenderX

**Figure 1.** Flow diagram of sample development for a cross-sectional study of associations between campaign exposure and ratings of likelihood to join a National Diabetes Prevention Program among adults at risk for diabetes. NHOPI: Native Hawaiian and Other Pacific Islander.

### Sample Characteristics

The mean age was 49.2 (SD 8.5 years), with 64.7% (556/860) identifying as women, reflecting an overrepresentation of women compared with the state's demographic composition [25]. Approximately half the sample, or 46.9% (403/860), self-identified as NHOPI or Filipino adults. Most participants reported a family history of diabetes (570/860, 66.3%) or perceived themselves as overweight (455/860, 52.9%). Despite all participants being classified as at risk based on screening criteria, only 22.7% (195/860) reported a prior diagnosis of prediabetes (Table 1).

[a]Row percentages are used to compare Exposed and Not exposed.

[b]Two-sample *t* test or chi-square test was used.

[c]Missing on gender and education were excluded from analyses.

[d]NHOPI: Native Hawaiian and Other Pacific Islander.

[e]HS: High school.

[f]DPP: National Diabetes Prevention Program.

## Sample Characteristics by Campaign Exposure

Table 1 also presents participant characteristics stratified by campaign exposure. Overall, 40.2% (346/860) of the sample reported exposure to the campaign. Among the 298 NHOPI or 105 Filipino participants, 123 (41.3%) and 34 (32.4%) reported being exposed to the campaign, respectively. Exposure to the campaign did not differ significantly across NHOPI, Filipino, and other racial or ethnic participant groups.

Significant differences between those exposed and not exposed to the campaign were observed by county of residence, specific diabetes risk factors, inevitability belief, and perceived DPP effectiveness. A smaller proportion of exposed participants resided in Honolulu County (239/631, 37.1%) compared with those not exposed (392/631, 62.1%; *P*=.02). Additionally, exposed participants were less likely to report a family history of diabetes (257/570, 45.1% vs 313/570, 54.9%; *P*<.001), perceive themselves as overweight (199/455, 45.1% vs 256/455, 56.3%; *P*=.03), or have been previously diagnosed with prediabetes (91/195, 46.7% vs 104/195, 53.3%; *P*=.04). Participants exposed to the campaign reported higher mean likelihood ratings for joining a DPP than those not exposed (mean 4.1, SD 2.0 vs mean 3.2, SD 1.8; *P*<.001) and had significantly higher mean scores for inevitability belief (mean 3.7, SD 2.2 vs mean 3.2, SD 2.0; *P*<.001). Fewer exposed participants believed that participation in a program such as Beat Diabetes would *improve* their health *a lot* (167/364, 42.3% vs 197/364, 63.6%; *P*=.04).

## Linear Regression Models on DPP Enrollment Likelihood Rating

Table 2 presents results from the 3 linear regression models. All models showed a significant positive effect of campaign exposure. In model 1, controlling for demographic characteristics, campaign exposure (β=.76, *P*<.001), age (β=−.02, *P*=.01), and insurance type (*P*=.02) were significantly associated with likelihood of joining a DPP.

[c]HS: high school.

[d]N/A: not applicable.

[e]DPP: National Diabetes Prevention Program.

Model 2 added diabetes risk factors. The association between campaign exposure and DPP enrollment likelihood ratings decreased slightly but remained significant (β=.67, *P*<.001). Significant predictors included male gender (β=.28, *P*=.049), family history of diabetes (β=.33, *P*=.02), self-perceived overweight status (β=.47, *P*=.001), physical inactivity (β=.28, *P*=.047), and prediabetes diagnosis (β=.37, *P*=.02). Age and insurance type were no longer significant. History of gestational diabetes and hypertension were not significantly associated with DPP enrollment likelihood ratings.

Model 3 further adjusted for intrinsic factors. Campaign exposure remained significant, albeit slightly reduced (β=.52, *P*<.001). Significant predictors included male gender (β=.33, *P*=.01), residence outside Honolulu County (β=.31, *P*=.02), motivation index (β=.38, *P*<.001), inevitability belief (β=.20, *P*<.001), and perceived effectiveness of DPP ("improve a little," β=.76; "improve a lot," β=1.63, *P*<.001). Diabetes risk factors were no longer significant.

No multicollinearity was detected (variance inflation factor <2). The variance explained by the models increased across model 1 to model 3 but remained low ($R^2$=0.08, 0.13, and 0.23, respectively). Graphical assessment of model assumptions indicated slight deviation from the normality assumption for model 1. Sensitivity analyses using ordered logistic regression showed similar results (not shown).

Table 3 presents the results of the subgroup analyses by race or ethnicity using model 3. Campaign exposure was positively associated with the outcome DPP enrollment likelihood ratings among NHOPI and other racial or ethnic groups, but the association did not reach statistical significance among Filipino adults. Notably, the estimated effect for the Filipino subgroup was larger in magnitude than those observed for NHOPI and other racial or ethnic groups and approached statistical significance. Across all subgroups, motivation index scores, inevitability belief, and perceived DPP effectiveness were consistently significant predictors.

[b]Ref: reference category.

[c]HS: high school.

[d]DPP: National Diabetes Prevention Program.

Table 4 presents the results of the sensitivity analysis restricted to participants with prediabetes to better assess the robustness of the main findings. In this restricted sample, campaign exposure was not significantly associated with the outcome, and the magnitude of the estimated effect was attenuated (β=.30, *P*=.27). However, several key predictors remained statistically significant, including male gender (β=.72, *P*=.02), motivation index (β=.39, *P*=.02), inevitability belief (β=.16, *P*=.03), and perceived effectiveness of DPP (“improve a little,” β=1.19; “improve a lot,” β=2.28, *P*<.001).

## Discussion

### Principal Findings

This evaluation found that exposure to the Beat Diabetes campaign was associated with higher ratings of likelihood to enroll in a DPP among those at risk for prediabetes, after adjusting for demographic and other relevant factors. However, the campaign was not significantly associated with likelihood ratings among those medically diagnosed with prediabetes in the sensitivity analysis, which highlights the limits of including people with any risk of prediabetes in the cross-sectional study, not just those at highest risk. Despite this limitation, these findings show that a campaign with clear, action-oriented messaging may serve as a useful public health approach for targeting the approximately 80% of people at risk for prediabetes but unaware of their status [26].

The campaign builds on prior HDOH efforts, including the Prevent Diabetes, Hawai'i campaign, which focused on raising awareness of prediabetes among Native Hawaiian and Filipino adults [27]. Beat Diabetes extended this work by targeting a broader group disproportionately affected by diabetes and by emphasizing an immediate behavioral step—enrolling in a DPP. Although the campaign was designed to resonate among NHOPI or Filipino adults by featuring only NHOPI or Filipino individuals in all 7 advertisements, these groups were not more likely to report exposure, and their DPP enrollment likelihood ratings did not differ significantly from all other groups. In the subgroup analysis stratified by race or ethnicity, campaign exposure was statistically significant for NHOPI and all other races or ethnicities, while it was close to significant for Filipino adults. However, only 34 Filipino adults recalled the campaign, so it is possible that with a larger sample size, their exposure to the campaign could result with statistical significance. Additionally, grouping diverse races or ethnicities may have masked some campaign effects. Furthermore, the "other" group represents a combination of the remaining races or ethnicities outside of NHOPI and Filipino adults, including races or ethnicities with both high and low risk of prediabetes, such as African American and White adults, respectively. Aggregating them into a single group was important to explore the campaign exposure and likelihood ratings among the target populations of NHOPI and Filipino adults. Larger studies that enable disaggregation by race or ethnicity are needed to determine whether tailored messaging resonates more effectively within these target populations.

The regression models highlight the complex relationship between diabetes risk awareness and likelihood to enroll in a DPP. In model 2, several diabetes risk factors (family history, overweight perception, physical activity, and prediabetes diagnosis) were associated with higher likelihood ratings. However, in model 3, these were no longer significantly associated with likelihood to enroll in DPP. All 3 intrinsic factors—motivation, inevitability belief, and belief in DPP effectiveness—remained significantly associated with DPP enrollment likelihood ratings. This aligns with previous research that shows how additional factors, such as motivational or cognitive supports, may be necessary to translate contemplation to action [12,28]. Furthermore, belief in DPP effectiveness emerged as one of the strongest drivers, surpassing even the impact of campaign exposure. Participants who believed that DPP would improve their health "a little" had DPP enrollment likelihood ratings 0.75 points higher, and those who believed that it would improve their health "a lot" had ratings 1.63 points higher, compared with those who believed that DPP would have a neutral or negative effect. These differences were larger than the effect of campaign exposure (0.52-point increase), underscoring that confidence in DPP's benefits strongly influences willingness to enroll. The sensitivity analysis of model 3 among those with a prediabetes diagnosis further supports this finding. It showed that the perception that DPP is effective was the most significant factor associated with likelihood to enroll in a DPP. In fact, among those with a prediabetes diagnosis who believed that DPP would improve their health "a lot" had a 2.28-point higher likelihood rating than those who thought that DPP would have no effect on their health and those who thought their health would decline. These findings are consistent with those of Joiner and colleagues [29], who reported that promoting the benefits of lifestyle interventions increased DPP enrollment among adults with prediabetes. Future campaigns may benefit from spotlighting participant success stories and emphasizing tangible health improvements associated with DPP participation.

Interestingly, in the main analysis and sensitivity analysis, inevitability belief scores were significantly associated with DPP enrollment likelihood ratings. Participants who believed that their diabetes progression was inevitable had higher DPP enrollment likelihood ratings. This finding was unexpected and counterintuitive based on findings by Ross et al [19], who interviewed a diverse set of British adults who were diagnosed with nondiabetic hyperglycemia and found that those who viewed diabetes progression as inevitable were less likely to pursue behavior change and questioned DPP's value. It is unclear whether differences in study design or confounding are the source of the diverging findings. Furthermore, with a cross-sectional study design, it is unknown whether being aware

XSL•FO
RenderX

of one's diabetes risk influences feelings of inevitability of diabetes progression or whether feelings of inevitability influence one's diabetes risk awareness. Both should be explored outside of this study design to fully understand whether a campaign can influence intention to enroll in DPP.

Individuals who identify as men reported higher DPP enrollment likelihood ratings, even in sensitivity analyses among those with diagnosed prediabetes. It is possible that men enrolled in the study just had higher baseline likelihood to enroll in DPP. It is also important to note that only 34.5% (293/860) of the sample identified as men, and of those men, only 42% (123/293) were exposed to the campaign. Given that men historically have had lower DPP participation rates [8], the association between gender and intention warrants future evaluation studies using more rigorous study designs and enrolling a higher portion of men, in particular, men of NHOPI or Filipino race or ethnicity, to explore whether media campaigns can be effective at changing intentions to enroll among men.

Despite these significant associations, the models' fit statistics were relatively low, indicating that additional unmeasured factors likely play a major role in shaping enrollment intentions. Extrinsic structural and logistical barriers, such as the time commitment required for DPP or caregiving conflicts, have been well documented as barriers to DPP participation [12,17] but were not captured in this evaluation. This evaluation shows that for population-based efforts to reach all people with prediabetes risk, a campaign to encourage enrollment in DPP is only one small piece of the puzzle. A multifaceted strategy that pairs motivational messaging (eg, highlighting program effectiveness and success stories) with practical supports (eg, flexible schedules, virtual delivery, and culturally tailored programming) may be necessary to convert intention into enrollment for those at risk for prediabetes and those with a prediabetes diagnosis. Together, these findings help clarify which types of messaging may be most effective in increasing interest in DPP and point to the importance of pairing motivational communication with practical supports to translate intention into action.

## Limitations

This evaluation has several limitations. First, the cross-sectional study design can show only associations between DPP enrollment likelihood ratings and advertisement recall and not definitive causal impacts of the campaign. Also, without baseline data, it is impossible to know whether the associations observed between campaign recall and likelihood ratings are true or due to confounding. Individuals who saw the campaign may simply have higher baseline intentions to join a lifestyle change program or may have been more likely to recall the advertisement due to their higher perceived personal risk of diabetes, or for reasons unrelated to the campaign. Despite the inherent limitations of a cross-sectional study design, they are the most cost-effective and feasible method of evaluating the real-world implementation of a health department media campaign [24]. Second, the sample was drawn from market research panels, which comprised both consumer data and participants with interest and time to participate in market research. Regardless of efforts by the market research firm to ensure a diverse database representative of the state's population and efforts to recruit participants from each county, the use of consumer panels limits the generalizability of the findings to the state's population. Third, although the survey incentive was of a nominal amount appropriate for a 10‐ to 12-minute survey, incentives can bias participation, encouraging more participation by those of lower rather than higher socioeconomic status or enticing participants to repeatedly complete a survey to receive multiple incentives. Although our sample included participants from a range of household incomes, over half of the sample (513/860, 59.6%) had household incomes lower than Hawai'i's median household income of US $100,745 [30], indicating the generalizability to the state's population is limited. Also, to avoid repeated participation, the market research firm used various data integrity checks, such as removing responses from duplicate IP addresses and removing responses that were completed too quickly. Fourth, because the purpose of the study was to evaluate a statewide media campaign aimed at reaching as many people at risk for developing diabetes as possible, the inclusion criterion was any individual with at least 1 recognized prediabetes risk factor. This resulted in a sample that included individuals with very low absolute risk of developing diabetes (eg, only being aged 40 years or older), which limits the generalizability of the data to only population-based strategies aiming to reach large segments of the population, not studies aiming to reach only those at highest risk of diabetes. Finally, the evaluation relied on self-reported likelihood to join a DPP rather than actual enrollment behavior. It is unclear whether higher DPP enrollment likelihood ratings will translate into real-world participation. During survey development, HHET looked for a psychometrically validated survey measure of campaign impact on likelihood to join a DPP, but none existed. The closest validated measure was an 11-item survey scale measuring autonomous and controlled motivation [18], which did not fully align with the campaign's goal of encouraging people to take urgent action. As a result, HHET developed a custom DPP enrollment likelihood question to measure intentions to change. However, because this measure is not psychometrically validated, its ability to accurately capture true likelihood to enroll is uncertain. Psychometric testing is warranted in the future to establish the validity of this item for measuring true likelihood to enroll in a DPP.

## Conclusions

The Beat Diabetes media campaign was designed to encourage people at risk for diabetes to take immediate action by joining a DPP. The campaign focused on NHOPI or Filipino adults who are disproportionately affected by prediabetes and diabetes in Hawai'i. However, the cross-sectional design of the study used a posttest survey that could observe associations only between campaign exposure and the likelihood or intent to join DPP. Results showed that NHOPI or Filipino adults did not report higher DPP enrollment likelihood ratings. Overall exposure was associated with higher likelihood ratings after controlling for multiple factors such as demographic characteristics, diabetes risk factors, and intrinsic motivations and beliefs. This association indicates that the campaign may be effective at encouraging people to consider joining a DPP. However, increasing one's likelihood is the first step in the pathway to

XSL•FO
RenderX

actual enrollment, and further evaluation is needed to determine whether media campaigns boost DPP enrollment and participation. Future campaigns aiming to boost DPP participation could be strengthened by promoting DPP effectiveness to increase DPP enrollment likelihood and emphasizing the urgency of taking preventive action at the prediabetes stage. More importantly, using motivational messaging alone is insufficient without addressing structural and logistical barriers to accessing DPPs.

## Acknowledgments

The authors would like to acknowledge Elia Titiimaea for his leadership as the diabetes project coordinator and his contributions to the development and launch of the Beat Diabetes campaign. The authors would like to thank all respondents who participated in the survey. They would also like to thank the National Diabetes Prevention Program providers who helped support campaign awareness. No artificial intelligence technologies were used to conduct this evaluation or the preparation of this manuscript. Finally, the authors would like to note that RMK was affiliated with the Healthy Hawai'i Evaluation Team at the University of Hawai'i at Mānoa at the time of data collection but is now currently affiliated with the Chronic Disease Prevention and Health Promotion Division at the Hawai'i State Department of Health.

## Funding

This evaluation study was funded by a contract to the University of Hawai'i's Healthy Hawai'i Evaluation Team from the Hawai'i State Department of Health's Chronic Disease Prevention and Health Promotion Division. Data collection for the evaluation was paid for using Hawai'i State Department of Health's general funds. Support for statistical analyses was partially given by PIKO (U54GM138062) from the National Institute of General Medical Sciences and Ola HAWAII (U54MD007601) from the National Institute on Minority Health and Health Disparities. The content is solely the responsibility of the authors and does not necessarily represent the official views of the funders.

## Data Availability

The data collected and analyzed during this study may be made available upon a reasonable request to the authors.

## Abstract

**Background:** Antimicrobial resistance (AMR) is a significant global health threat. Several public health campaigns aimed to raise AMR awareness and inspire related behavioral changes have been delivered in a time-specific, coordinated manner, while others have placed less emphasis on campaign timing. Social media platforms can be leveraged as key vehicles for delivering public health campaigns, particularly by collaborating with health content creators who serve as influential messengers. Increasingly, organizations such as the World Health Organization and TikTok have created health content creator networks; however, the impact of such networks in public health campaigns, especially when delivered in a coordinated, time-specific manner, remains uncertain.

**Objective:** This study aimed to investigate whether mobilizing an established health content creator network to create social media content on the topic of AMR, released in a coordinated, time-specific manner, can have an impact on audience engagement.

**Methods:** We conducted a longitudinal observational study evaluating the effect of a coordinated social media campaign ("Pulse") on YouTube, delivered by an established health content creator network during an international event on AMR. Members of the network prepared and coordinated the release of AMR-related videos. Engagement analytics were evaluated 6 months after release. The engagement with each campaign video was compared with that for a similar noncoordinated video and with the average engagement of the same creators.

**Results:** Around the day of the Pulse campaign on September 26, 2024, 18 campaign videos were released across 14 YouTube channels. Compared with paired videos, Pulse videos were not associated with higher view counts (incidence rate ratio [IRR] 0.98, 95% CI 0.44-2.13; *P*=.95) or like counts (IRR 1.10, 95% CI 0.48-2.41; *P*=.81) but were associated with significantly higher comment counts (IRR 2.99, 95% CI 1.02-8.52; *P*=.03). When compared with the creators' 12-month channel averages, campaign videos had a significantly higher comment count (IRR 15.5, 95% CI 5.5-24.0; *P*<.001) but no difference in view counts (IRR −82.0, 95% CI −190.3 to 58.5; *P*=.26) or like counts (IRR −0.50, 95% CI −6.3 to 10.5; *P*=.93).

**Conclusions:** Coordinating health content creators to release AMR-related videos on YouTube coinciding with an international AMR event increased audience interactivity but did not enhance reach. This study shows the need to better understand which AMR-specific content factors contribute toward greater traction and to assess audience needs among the wider public to discern how best to harness social media interventions as a tool to improve AMR-related outcomes.

## Introduction

Antimicrobial resistance (AMR) occurs when disease-causing microorganisms (including bacteria, viruses, fungi, and parasites) are no longer affected by antimicrobial agents [1]. In combating the rising threat of AMR, which is expected to result in 8-22 million deaths per year globally by 2050, the World Health Organization (WHO) has emphasized the importance of changing behaviors that contribute to AMR among both the public and health care professionals (HCPs) [2-4].

Global and regional AMR awareness campaigns have been designed to improve public awareness of AMR and inspire related behavioral changes [5]. A common mechanism for delivering such campaigns is through time-specific, coordinated

XSL•FO
RenderX

activities that can provide a surge of AMR coverage [6-8]. Such examples include the annual World AMR Awareness Week held in November, and beyond AMR, campaigns such as Mental Health Awareness Week, May Measuring Month (encouraging individuals to measure their blood pressure), and World Cancer Day (advocating for people-centered cancer care) [9-11]. Associated with specific health campaigns, organizations often release content packs or toolkits incorporating key campaign messaging and infographics that can be adopted and shared by individuals and organizations to amplify campaign objectives [12,13].

On the other hand, campaigns such as the United Kingdom Health Security Agency's "Keep Antibiotics Working" campaign are not designed to be released at a specific time but have nevertheless gathered significant traction and high campaign recognition, including through a social media video with more than 1 million views globally [14]. Other examples of non–time-specific campaigns include the US Food and Drug Administration's "Little Lungs," a digital campaign within which a video series delivering antismoking messaging has gathered more than 17 million views on the YouTube platform alone [15].

The past decade has seen great enthusiasm for leveraging the potential of social media as a key vehicle in driving and amplifying health campaigns [12]. Certain HCPs have generated a large network of followers through their active social media presence and have been referred to as "health content creators," "clinician content creators," or "health influencers" [16-19]. On the largest video-based social media platform, YouTube, a number of such individuals have gathered more subscribers (individuals who follow their channels and regularly watch their videos) than international and national medical organizations such as the WHO (approximately 874,000 subscribers) and the United States Centers for Disease Control and Prevention (approximately 637,000 subscribers) [20-22]. Increasingly, health organizations have sought to endorse their dedicated networks of health content creators who can serve as credible sources for broadcasting organization-specific health information and tackling misinformation [23]. An example of such a network is the WHO's network of more than 800 health content creators—WHO Fides [24]—who are mobilized periodically to create content on specific health-related topics and to elevate evidence-based content. Similarly, social media platforms such as TikTok have launched health content creator networks, uniting accredited clinicians to share their insights into trending health topics [25].

Nevertheless, it is unknown how much audience engagement a network of health content creators can generate when they act as messengers for health organizations in broadcasting organization-specific health information. Moreover, it remains uncertain whether delivering the campaign messaging in a time-specific, coordinated manner can generate greater audience traction than the sporadic release of content. Coordinated campaigns have the potential to enhance audience engagement—defined by the number of views, likes, comments, and shares—through repeated exposure, algorithmic amplification, and a sense of social momentum [26,27]. While such a strategy has not previously been explored, it may be a novel avenue for the impactful dissemination of public health information that policymakers and health professionals can use.

In this study, we aimed to answer the question "Can mobilizing an established health content creator network to create social media content on the topic of AMR, released in a coordinated, time-specific manner, have an impact on audience engagement?" Our hypothesis was that a coordinated mobilization of a health content creator network in creating AMR-related social media content can result in greater audience engagement.

## Methods

### Study Design

A longitudinal observational study was conducted to evaluate the impact on audience engagement, when coordinating a health content creator network to disseminate social media videos on the topic of AMR, coinciding with an international event on AMR. We named this coordinated release of social media content "Pulse."

We first established a health content creator network. A media pack (Multimedia Appendix 1) containing recommended AMR campaign messaging was developed and distributed to the network. Members were informed in advance to prepare AMR-related social media content in accordance with the media pack, to be released on YouTube, the largest video-based social media platform. A specific date was chosen for Pulse to take place, coinciding with a United Nations General Assembly (UNGA) high-level meeting on AMR [28].

The study was reported in accordance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) statement for cohort studies, given the prospective and observational nature of the study [29].

### Study Setting

We conducted the study online on the YouTube (Alphabet Inc) platform, as it is the largest video-based social media platform, and its associated work stream, YouTube Health, has dedicated its mission to delivering high-quality health information online [22]. Registered users of the platform can upload and openly share videos on their YouTube channels. Users can find videos of interest by entering key related terms or phrases into the dedicated YouTube search bar or through the platform's recommendations. In addition, users can save selected videos into a playlist that can be accessed later. Users can also subscribe to specific channels to receive regular updates. Each video has a unique code (video ID). Each playlist has an ID that is sourced from the web address (also known as URL).

Currently, there are 2 formats of videos on YouTube: traditional long-form videos that individuals browse on a YouTube web page and Shorts, defined as vertical videos that are less than 180 seconds in duration and are presented to users passively and sequentially, from which users can choose either to watch or to swipe away [30].

### Mobilization of a Health Content Creator Network to Release Time-Specific Social Media Video Content on AMR

An international network of health content creators, communications experts, and entertainment professionals was previously created through an in-person launch event on April 29, 2024, and social media platforms such as LinkedIn (Microsoft Corp) and X (X Corp). The network was called CHAIN (Content, Health, and AMR Innovation Network) [31]. The network aims to harness the power and global reach of video-based online content to drive the behavioral changes needed to tackle AMR [31].

A media pack was developed and approved by all researchers over a period of 2 months to coordinate the social media messaging during the Pulse. This media pack was released to CHAIN members immediately following its completion through email 1 month prior to the Pulse date. The media pack incorporated key messages from official sources such as the United Kingdom Health Security Agency and the WHO, explaining what AMR is and how members of the public could change their behaviors related to the development of AMR [32,33].

In addition to key messages, specific messages were created for key niches that the health content creators occupied, including women's health, children's health, pharmacists, ear, nose, and throat, dentistry, and medical myths. Creators were given the flexibility in the remaining aspects of video production, such as video format, narration, and imagery, to enable congruency of the content with their existing audience, while maintaining the diversity of content. The media pack is attached in Multimedia Appendix 1.

The Pulse took place on a date that coincided with the UNGA high-level meeting on AMR [28]. Given that this meeting was the principal official, health-focused event during the UNGA high-level meeting week, as well as the second UN high-level meeting on AMR since 2016, we anticipated a heightened global attention toward AMR [34].

### Evaluation of the Impact of the Coordinated Social Media Content Release on Audience Engagement

Six months after the Pulse day, we evaluated the audience engagement (views, likes, and comments) of the content released onto YouTube on the Pulse date using the publicly available engagement data. To discern whether coordinating the social media content had an impact on audience engagement, we undertook comparisons in 2 ways.

First, the engagement analytics of the Pulse videos were compared with those of a similar video that was sporadically released by the same health content creator. A variety of factors can contribute toward the level of engagement of a YouTube video, such as the video content, length of time since video release, thumbnail design and titles, and the channel's number of subscribers [35]. Choosing a video similar to the Pulse video from the same health content creator allowed for the control of confounding factors, such that a video released in a coordinated manner could be compared against a video released sporadically.

In addition, the engagement of the Pulse videos was compared with the creator's baseline average video engagement over a 12-month window around the Pulse date. This allowed for direct comparison of the engagement level of the Pulse videos with the average engagement level of the health content creator's channel, while minimizing time-related confounding factors.

### Data Collection

Following the date of the Pulse, 2 researchers (FC and JC) screened the YouTube channels hosted by members of the CHAIN for all videos released on the date of the Pulse, on the topic of AMR or relating to the appropriate use of antibiotics or other antimicrobial agents. Such videos were saved in a playlist on the YouTube platform. Videos released within 1 day of the Pulse day were also included.

For each Pulse video released by an individual health content creator, a paired video hosted on the same channel was selected by one researcher (FC) and verified by another researcher (KG). When selecting the videos, the following criteria were considered in terms of similarity, ordered by priority: video format (long-form vs Shorts), video topic, recency of release dates, video length, and video style. Given that it was unclear whether the video topic or recency of release can have a greater impact on the level of video engagement, a sensitivity analysis was conducted. An additional video was selected to pair with each Pulse video using slightly different prioritization criteria, in which recency was prioritized over video topic. The paired videos were collated into 2 other YouTube playlists, labeled "paired by topic" and "paired by recency."

We collected the engagement data of the Pulse videos at the 6-month point from the time of release to allow for the cumulative growth in video engagement to plateau. Therefore, for the paired videos, the researcher collected the engagement analytics at the time point closest to 6 months where possible, although there were variations in the dates of release (eg, some paired videos had been published for 3 years at the time of data collection). The exact dates of data collection for each video are shown in Multimedia Appendix 2.

The engagement analytics were extracted from publicly available YouTube data using YouTube Data application programming interface (API; version 3; Google LLC), which allowed the automated, scaled-up extraction of YouTube data. Specifically, an API key was created on the Google Cloud Platform (Alphabet Inc) and restricted to YouTube Data API [36]. For each playlist (Pulse video, paired by topic and by recency), the specific playlist ID was sourced from the URL of the YouTube playlist. The playlist ID and the API key were then entered into predetermined code using R software (version 4.4.2; R Foundation for Statistical Computing) on the RStudio platform (version 2026.01.0+392; Posit PBC) to extract the data [37,38]. The following data were extracted: YouTube video ID, video title, channel title, video publication date, video duration, video view count, like count, and comment count.

For each health content creator's videos and engagement data, the channel ID and the date range (a 12-month window around the Pulse date) were entered into the predetermined codes using Python (version 3.12; Python Software Foundation) on VSCode

XSL•FO
RenderX

platform (version 1.103; Microsoft Corp) [39,40]. The following data were collected on April 24, 2024: video ID, title, video publication date, views, likes, comments, and video duration.

### Ethical Considerations

Ethics approval for this study was not required as all collected data were publicly available. This was confirmed with the Imperial College London Research Governance and Integrity Team in accordance with local policies [41]. All data have been anonymized and deidentified.

Informed consent was not obtained because the study analyzed publicly accessible online content. In accordance with relevant ethical guidance for internet-based research, the study involved minimal risk and did not include any attempt to identify or contact individuals whose content was analyzed. Participant compensation was not applicable.

### Statistical Analysis

Summary statistics were calculated for the Pulse videos, including engagement data and video duration. Engagement outcomes (views, likes, and comments) were analyzed using a staged analytical approach. First, unadjusted comparisons were conducted between Pulse videos and noncoordinated videos paired by topic from the same health content creator. To assess for normality, differences in engagement were first computed within each pair, and the difference scores were assessed using the Shapiro-Wilk test [42]. For metrics for which the assumption of normality was met ($P>.05$), a paired 2-tailed $t$ test was performed [43]. For metrics that violated the normality assumption ($P\leq.05$), the Wilcoxon signed-rank test was used as a nonparametric alternative [44]. Results were presented as the Hodges-Lehmann median differences with 95% CIs [45]. Second, to account for residual confounding, adjusted analyses were conducted using negative binomial regression [46].

Engagement data were modeled as count outcomes, with Pulse status specified as the primary exposure. Models were adjusted a priori for video-level characteristics influencing engagement, including video format (Shorts vs long-form), video duration, and time since publication at the point of data extraction (expressed in months). To account for correlation of outcomes within creators, robust SEs clustered at the creator level were used. Results from regression analyses were presented as incidence rate ratios (IRRs) with 95% CIs. Statistical significance was set at $\alpha=.05$.

To evaluate how the Pulse videos compared with each creator's average performance, we calculated the median and IQR of engagement metrics (views, likes, and comments) for each creator's noncoordinated videos published within this 12-month interval. To assess normality, differences were calculated for each creator's Pulse video and median engagement of the baseline videos and were assessed using the Shapiro-Wilk test [42]. Given the anticipated highly skewed distribution of engagement metrics and the paired within-creator design, differences in views, likes, and comments between the Pulse videos and the median engagement values of the same creator were analyzed using the Wilcoxon signed-rank tests. In addition, the Pulse videos were compared with the mean performance of videos of the same format (long-form or Shorts) within the 12-month window around the coordinated release date, using the same method described. The Hodges-Lehmann median differences and 95% CIs were reported. Statistical significance was set at $\alpha=.05$.

Data collection and analysis were conducted in R software on the RStudio platform [37,38]. The following packages were used: *httr*, *httr2*, *jsonlite*, *here*, *dplyr*, *vosonSML*, *readxl*, *ggplot2*, *effsize*, *tidyverse*, *reshape2*, *MASS*, *sandwich*, *lmtest*, and *broom* [38,40,47-59].

## Results

### Overview

Around the Pulse date on September 26, 2024, the health content creator network released 18 videos from 14 YouTube channels hosted by members of the network. Six months after the Pulse, the audience engagement data for all 18 coordinated videos (V1-V18) were successfully collected, with no missing data. Overall, the coordinated videos gathered a total of 6153 views, 262 likes, and 76 comments. The campaign media pack and the complete video engagement datasets are available in Multimedia Appendices 1 and 2, respectively.

### Evaluating the Impact of a Coordinated Release on Video Engagement

#### *Comparison of the Pulse Videos With Paired Videos*

The chosen paired videos prioritizing topic choice (P1-P18) and recency (R1-R18) are shown in Multimedia Appendix 2. All engagement analytics were successfully collected with no missing data. The summary characteristics of the 3 video groups (Pulse, paired by topic, and paired by recency) are shown in Table 1 and Table S1 in Multimedia Appendix 3. Assessment of normality using the Shapiro-Wilk normality test is shown in Table S2 in Multimedia Appendix 3.

XSL•FO
RenderX

**Table .** Summary characteristics of the "Pulse" videos and the paired videos by the same health content creators[a].

| Engagement metrics | Pulse videos, median (IQR) | Paired by topic, median (IQR) | Hodges-Lehmann estimator, median difference (95% CI) | *P* value |
|---|---|---|---|---|
| View count | 123 (39-580) | 72 (36-367) | 58.5 (–31.5 to 237.0) | .15 |
| Like count | 10 (4-31) | 7 (2-12) | 8.0 (0.5-19.0) | .04 |
| Comment count | 2 (1-5) | 1 (0-2) | 2.0 (1.0-7.0) | .04 |
| Duration (s) | 95 (60-247) | 134 (59-238) | —[b] | — |
| Time since publication (mo) | 6 (6-6) | 6.5 (6-15) | — | — |

[a]The paired videos were chosen by prioritizing video topics. Paired differences in engagement (views, likes, and comments) were assessed using the Wilcoxon signed-rank test.

[b]Not applicable.

The differences in engagement between the video pairs were assessed using the Wilcoxon signed-rank test. When comparing the Pulse videos (V1-V18) with the videos paired by topic (P1-P18), no significant difference was found between the view counts (IRR 58.5, 95% CI –31.5 to 237.0; *P*=.15). However, the Pulse videos appeared to have significantly more like counts (IRR 8.0, 95% CI 0.5-19.0; *P*=.04) and comment counts (IRR 2.0, 95% CI 1.0-7.0; *P*=.04). Sensitivity analysis pairing videos by recency showed concordant findings (Table S1 in Multimedia Appendix 3).

After adjustment for confounding (Table 2), Pulse videos were not associated with higher view counts or like counts but were associated with significantly higher comment counts (IRR 2.99, 95% CI 1.02-8.52; *P*=.03). In sensitivity analyses pairing videos by recency rather than topic (Table S3 in Multimedia Appendix 3), effect estimates were directionally consistent, although associations were attenuated and no longer statistically significant.

**Table .** Adjusted association between "Pulse" videos and audience engagement[a].

| Association | Views | | Likes | | Comments | |
|---|---|---|---|---|---|---|
| | IRR[b] (95% CI) | *P* value | IRR (95% CI) | *P* value | IRR (95% CI) | *P* value |
| Pulse (vs noncoordinated) | 0.98 (0.44-2.13) | .95 | 1.10 (0.48-2.41) | .81 | 2.99 (1.02-8.52) | .03 |
| Shorts (vs long-form content) | 7.79 (2.98-20.49) | <.001 | 4.81 (1.97-11.93) | <.001 | 1.42 (0.45-4.53) | .51 |
| Video duration (per 60 s) | 1.06 (0.92-1.25) | .35 | 1.01 (0.88-1.20) | .82 | 1.00 (0.81-1.25) | .99 |
| Time since publication (per mo) | 1.03 (0.97-1.19) | .40 | 1.00 (0.93-1.07) | .93 | 1.00 (0.91-1.11) | .97 |

[a]Negative binomial regression models were used. Models were adjusted for video format, video duration, and time since publication. Robust SEs clustered at the creator level were used to account for within-creator correlation. Videos were paired based on topics.

[b]IRR: incidence rate ratio.

### *Comparison of the Pulse Video With the Creator's Average Level of Engagement*

The summary characteristics of all creators' baseline videos are shown in Multimedia Appendix 2. When comparing the Pulse videos with each creator's baseline performance, there was no significant difference in the number of views (IRR −82.0, 95% CI −190.3 to 58.5; *P*=.26) or like counts (IRR −0.50, 95% CI −6.3 to 10.5; *P*=.93). However, the Pulse videos had a significantly greater number of comments (IRR 15.5, 95% CI 5.5-24.0; *P*<.001; Table 3). When comparing the Pulse videos against creators' baseline videos of the same format, no significant differences were observed (Table S4 and S5 in Multimedia Appendix 3).

XSL•FO
RenderX

**Table .** "Pulse" videos compared with creator's baseline videos released over a 12-month window around the Pulse date[a].

| Engagement metrics | Hodges-Lehmann estimator, median difference (95% CI) | *P* value |
|---|---|---|
| View count | −82.0 (−190.3 to 58.5) | .26 |
| Like count | 0.50 (−6.3 to 10.5) | .93 |
| Comment count | 15.5 (5.5 to 24.0) | <.001 |

[a]Values are shown as Hodges-Lehmann median difference (95% CI). Paired differences in engagement (views, likes, and comments) were assessed using the Wilcoxon signed-rank test.

# Discussion

## Principal Findings

This study examined whether coordinating health content creators to release AMR-related videos simultaneously on YouTube, timed with an AMR-centered international event, could enhance audience engagement compared to sporadic, uncoordinated releases. The principal findings were that coordinating health content creators to release AMR-related videos on YouTube coinciding with an international event on AMR, defined as a Pulse, increased audience interactivity in terms of the number of comments but did not enhance overall reach compared with sporadic releases.

When comparing the Pulse videos with similar videos and baseline videos from the same health content creator, coordinated content gathered significantly greater comment counts. This suggests that coordinated campaigns may enhance interactive engagement among audiences, potentially through the perception of collective momentum or amplified algorithmic exposure. However, the lack of a significant difference in view counts and like counts after adjustment between coordinated and sporadic videos suggests that coordination alone may not be sufficient to drive greater overall reach.

It is noteworthy that Shorts, compared with long-form videos, have been found to be significantly associated with greater engagement in terms of views and likes ($P$<.001). While YouTube has traditionally been the main hub for long-form video content, the introduction of YouTube Shorts has transformed how individuals consume social media content. The audience tends to spend more time watching shorter videos, which provides them with bite-sized content, while long-form videos have seen a significant decrease in engagement [60].

Several possible explanations exist for the principal findings. First, although coordination can enhance visibility within a narrow window, it does not necessarily equate to broader audience interest or long-term viewership. Second, the relatively small size of the coordinated cohort (18 videos across 14 channels) may not have generated the critical mass required to trigger meaningful algorithmic amplification. Third, the media pack was developed based on accuracy of messaging rather than the enhancement of audience engagement. Currently, there remains a lack of research on how to design video content, particularly AMR-specific content, to improve audience engagement.

From a campaign design perspective, these findings suggest that while coordination can enhance engagement quality and audience interactivity (as seen in likes and comments), it may not inherently improve reach. Therefore, coordinated campaigns may be best seen as complementary tools within a broader health communication strategy rather than as standalone solutions.

Previous HCP-led social media campaigns have mostly aimed at HCPs, focusing on advocacy for particular specialties such as surgery, radiology, and nursing [61-64]. The remaining HCP-led social media campaigns took place during the COVID-19 pandemic, relating to vaccination and travel restrictions [64-66]. No studies have evaluated the impact of collaborating with HCPs in delivering time-coordinated social media campaigns relating to other global health challenges outside the COVID-19 pandemic period. To our knowledge, this study is the first evaluation of the impact of collaboration with health content creators during an international public health campaign. Our findings provide important insights into the dynamics of health communication on social media platforms and the potential role of health content creator networks in supporting public health campaigns [67,68].

## Limitations

Several limitations should be acknowledged. The sample size of creators and videos was relatively small, limiting statistical power and generalizability. The observational design precludes causal inference. While we matched video pairs based on format, topic, and recency, not all engagement data were collected at the 6-month point from their time of release. Some creators posted relatively infrequently, such that their most recent video was posted 24 months ago. Although we welcomed creators internationally, most participating health content creators were based in the United Kingdom, meaning that the health challenge of AMR was competing with other country-specific challenges. Moreover, engagement metrics such as views, likes, and comments do not necessarily reflect a deeper impact on audience such as changes in knowledge, changes in attitudes, or AMR-related behavioral changes, which were not explored in this study.

## Opportunities for Future Work

Future work should explore how to optimize coordinated health campaigns on social media platforms to support health policymakers in designing more effective public health strategies. This may include testing different messaging styles, content formats, and durations of such coordinated activity. Second, it will be valuable to assess the impact of such campaigns on AMR-related outcomes such as individual knowledge, attitudes, and behavioral intentions, which can be collected from YouTube through qualitative analysis of the

XSL•FO
RenderX

audience comments, as well as through embedded survey methodologies as part of the campaign content. Finally, the study calls for the need to better understand which AMR-specific content factors contribute toward greater audience traction and for assessment of audience needs among the wider public, to discern how best to harness social media interventions as a tool to improve AMR-related outcomes, including inspiring behavioral changes.

### Conclusions

This study highlights both the potential and the limitations of using social media to engage the public on AMR. While campaigns led by health content creators increased audience interactivity, they did not substantially improve overall reach, reflecting the broader challenge of promoting AMR-related content in crowded social media environments. These findings highlight the need to understand the nuances behind audience behavior, preferences, and engagement dynamics within social media platforms, such that the content can objectively influence knowledge, attitudes, and behaviors. Importantly, our results underscore the need for innovative evaluation methods that capture the real-world impact of social media campaigns on AMR-related outcomes. By integrating content strategy with behavioral insights, future campaigns could more effectively leverage digital platforms to support antimicrobial stewardship and inform policy on health communication in the social media era.

## Acknowledgments

The authors declare the use of generative artificial intelligence (GenAI) in the research and writing process. According to the GenAI Delegation Taxonomy (2025), the following tasks were delegated to GenAI tools under full human supervision: code generation and code optimization. The GenAI tool used was ChatGPT (version 4.5; OpenAI). Responsibility for the final manuscript lies entirely with the authors. The GenAI tools are not listed as authors and do not bear responsibility for the final outcomes.

## Abstract

**Background:** Vaccine hesitancy has increased in recent decades internationally, which sets up a critical barrier to the rapid deployment of novel vaccines against infection with SARS-CoV-2.

**Objective:** This study used a quasi-experimental design to evaluate the cost-effectiveness of a social media intervention to reduce COVID-19 vaccine hesitancy implemented in Nigeria in 2022.

**Methods:** The intervention targeted health care providers and adults from the general population who were users of a specific social media platform. We used published estimates from a quasi-experimental evaluation of the campaign's effectiveness compared to the status quo across 6 intervention states and 31 comparison states over a 10-month period. We estimated the cost-effectiveness of the campaign in terms of cost (2022 US dollars) per person vaccinated using a decision tree analysis and probabilistic sensitivity analysis.

**Results:** On the basis of the quasi-experimental trial, the campaign led to a crude 6.4–percentage point increase (219/692, 31.6% vs 117/463, 25.3%; *P*=.045) in vaccination rates and an adjusted 7.8–percentage point increase (95% CI 1.68-14.2; *P*=.02) controlling for age group, gender, educational level, religion, and occupation among the 20% (1933/9607) of the overall sample who were unvaccinated and in the persuadable middle. Scaled to the overall population, the campaign led to a 1.57–percentage point (95% CI 0.337-2.87; *P*=.02) increase in the proportion of those vaccinated against COVID-19 among those reached by the social media campaign. The social media campaign resulted in 58.3 million impressions and 1.87 million people reached for a total societal cost of US $1.15 million, or US $0.61 per person reached. This resulted in an incremental cost-effectiveness ratio of US $54.70 (95% uncertainty interval US $20.90-$163) per person vaccinated.

**Conclusions:** A social media–based campaign to address COVID-19 vaccine hesitancy in 6 states in Nigeria resulted in an increase in vaccination rates. The cost-effectiveness of the campaign compared to no campaign is comparable to that of other campaigns promoting COVID-19 vaccine uptake. The cost per person vaccinated due to the social media campaign was 1% to 8% of the estimated cost per life year saved by vaccination against COVID-19 in low- and middle-income countries. Investing in social media campaigns would likely be a cost-effective approach to increase vaccine uptake and save lives.

## Introduction

The COVID-19 pandemic led to the death of 15 to 20 million people worldwide up to 2021 [1,2]. In response to this threat, governments and private companies demonstrated high capacity for innovation; the rapid development and testing of multiple effective vaccines stands out as a critical success [3]. The pandemic also highlighted ongoing systemic failures in global and national public health systems, including limited capacity for surveillance, communication, and distribution of preventive materials and services [4]. These failures exacerbated existing health inequities within and between countries.

The potential impact of the successful development, manufacture, and distribution of effective vaccines was not fully realized due to the public health system's inability to communicate the safety and benefit of the new vaccines in the context of widespread mis- and disinformation about the pandemic and the public health response. Building on well-established antivaccine movements, COVID-19 vaccine hesitancy emerged as a major barrier to the control of the pandemic [5]. By November 2023, a total of 80% of people living in high-income countries had received at least one dose of a COVID-19 vaccine compared to 33% of people living in low-income countries [6]. In the years before the COVID-19 pandemic, researchers were evaluating the potential use of social media communication campaigns to address vaccine misinformation and increase vaccine uptake. Previous vaccine promotion campaigns addressing vaccine hesitancy have mostly targeted a narrow set of vaccines (eg, influenza and human papillomavirus in high-income countries and diphtheria, tetanus, pertussis, and polio in middle- and low-income countries) [7]. Reviews of health promotion campaigns covering communicable and noncommunicable diseases on social media have found limited or mixed evidence of reported or observed behavior changes (ie, high engagement) and more reports of interaction with posts or changes in knowledge and attitudes (ie, low to medium engagement) [8,9].

With this promising but mixed and limited research base, and accompanied by calls for development of theoretically based and practice-based social marketing strategies [10], funders and public health organizations rapidly implemented social media campaigns to promote COVID-19 vaccine uptake. Initial evaluations of efforts to promote COVID-19 vaccination or other disease control behaviors through social media campaigns have been positive but with low to moderate effects, leading the public health community to consider whether and how to invest in a sustainable public health social media communication infrastructure [11-14]. Social media campaigns have the potential to reach targeted audiences with tailored messages in ways that may improve both impact and efficiency compared to mass media campaigns [15].

We evaluated the cost-effectiveness of a targeted social media campaign to promote vaccination against COVID-19 among health care providers and other adults in their social environment in Nigeria in 2022. By May 2022, after recording 250,000 COVID-19 cases, Nigeria had received enough COVID-19 vaccines to cover 25% of the population and had administered the first dose to 13% and the second dose to 8% of the population [16]. High levels of vaccine acceptance (76%) in late 2020 were being reported to be much lower as more data were published in 2021 (40%-60%) [16,17]. The World Bank, which classifies Nigeria as a lower-middle–income country, reported that 38% of the Nigerian population accessed the internet in 2022 [18]. A rapid rise in the use of social media in Nigeria and its complex role in the response to COVID-19 had been reported by the time the social media campaign in this paper had been implemented [19].

In this analysis, we aimed to evaluate the cost of implementing a social influencer–based social media campaign and estimate the value of the campaign in terms of cost per person vaccinated, which can be compared to other campaigns targeting vaccine uptake.

## Methods

### Overview

The prospective economic analysis plan was included in the overall analysis plan submitted to the funder and has not been published elsewhere. This project followed the guidelines of the Second Panel on Cost-Effectiveness in Health and Medicine and the reporting guidelines from the Consolidated Health Economic Evaluation Reporting Standards checklist [20,21]. The data used in the model synthesis were collected from 2021 to 2022. The analysis was completed in 2023.

### Intervention Description

This cost-effectiveness analysis is based on the implementation and quasi-experimental evaluation of a 10-month social media campaign promoting vaccination against COVID-19 in Nigeria among health care workers and those in their social networks in 2022 [22]. The campaign was designed and implemented by a team of designers and local organizations and delivered through Facebook and Instagram. The campaign included provaccination social norms and vaccine hesitancy reduction messages delivered by social influencers (eg, local celebrities, health care providers, and religious and business leaders). The campaign theory of change was based on the theory of diffusion of innovations; social norms theory; and the motivation, opportunity, and ability framework [23-25].

### Study Population and Setting

The intervention was implemented in 6 states in Nigeria (Anambra, Bauchi, Lagos, Niger, Rivers, and Sokoto), with participants in the control condition recruited from the Federal Capital Territory and all other states. Participants were eligible if they were aged ≥18 years, had a Facebook account registered in Nigeria and received recruitment advertising in their live feed promoting a study on COVID-19 vaccination, had not been previously vaccinated against COVID-19, and were defined as members of the "persuadable middle" [22]. Those who

XSL•FO
RenderX

responded "Definitely" or "Definitely not" to the question "Would you take a COVID-19 vaccine that is approved for use in Nigeria if offered to you?" were excluded based on not being in the persuadable middle. While people in low- and middle-income countries (LMICs) generally have higher vaccine acceptance than those in high-income countries. Nigeria faced vaccine availability and other challenges that may have impacted vaccine hesitancy differently than in higher-income settings, including perceptions that safety and efficacy had not been adequately evaluated in that setting [26-28].

### Cost Evaluation

We used the standard microcosting approach, for which we evaluated all component costs of the intervention instead of using a global project budget. Microcosting includes 3 main steps: identification, measurement, and valuation. To identify the resources used, we prospectively developed a detailed description of the intervention activities and identified necessary resources for each activity. Resources were measured and valued using actual reported expenditures from implementing partners and reported or estimated opportunity costs for the nonbudgeted time from implementing partners, influencer organizations, and participants. Direct costs were all reported in US dollars by the implementing partners and were adjusted for inflation to 2022 US dollars. Opportunity costs accrued in Nigeria were estimated in 2022 Nigerian naira. Nigerian currency was converted to purchasing power parities, with total costs reported in 2022 purchasing power parities, which is equivalent to 2022 US dollars. Costs were converted in 2023. As we did not assess health or economic benefits of vaccination, we did not include opportunity costs of individuals or direct health care sector costs for receipt of the vaccine.

### Intervention Reach

The intervention included 245 distinct advertising campaigns implemented on the Facebook social media platform, which means that the campaigns may have included distinct creative content or audience-targeting and promotion methods and their unique individual reach could not be combined with that of other campaigns. For each of these campaigns, the platform reported the total number of unique individuals receiving campaign messages (reach), the total impressions (ie, the number of times the campaign message was displayed on the target audience member's screen), and a range of engagement metrics for each of these campaigns. Because we did not have access to the total number of unique individuals reached across all campaigns, we estimated reach based on the largest reported reach across all campaigns. Due to a lack of data on the degree of overlap within a targeted campaign, we based our reach estimate on a conservative assumption that there was complete audience overlap across campaigns.

### Cost-Effectiveness Analysis

We used a societal and payer perspective, which captured both the budgetary costs of implementing a similar campaign in the future and the opportunity costs of implementing partners and individuals engaging with campaign messages. The comparator was the status quo (ie, the current state of affairs in the absence of this intervention), which was chosen based on the intervention design and effect estimate. The time horizon for this study was 1 year to capture planning and implementation; we did not have the capacity to model longer-term health and cost effects following a change in vaccination rates. We did not discount costs or benefits over the 1-year time horizon.

### Outcome Measurement

The primary outcome for this study was vaccination against COVID-19. The incremental effect of exposure to the advertising campaign was estimated from a survey of 10,965 participants who were users of the Facebook social media platform. Of the initial 10,965 participants screened for eligibility, 6198 (56.5%) were excluded as already vaccinated, 1476 (13.5%) were excluded for not being in the persuadable middle, 675 (6.2%) were excluded for missing baseline data, 648 (5.9%) were excluded for not meeting the age criteria, and 35 (0.3%) were excluded for having a duplicate ID. The remaining 17.6% (1933/10,965) of the participants were enrolled in the study. Surveys were fielded to the same cohort, with baseline data collection taking place during the period from December 1 to 31, 2021; first follow-up data collection taking place during the period from March 1, 2022, to April 30, 2022; and second follow-up data collection taking place during the period from October 1 to 4, 2022. Of the 1933 participants enrolled in the study, 1155 (59.8%) completed the first follow-up, and 462 (23.9%) completed the second follow-up. Exposure was based on state of residence, with the intervention implemented in 6 states (Anambra, Bauchi, Lagos, Niger, Rivers, and Sokoto) and control participants recruited from all other states in Nigeria.

Participants were recruited through a social media–based research platform called Virtual Lab. Recruitment was stratified by whether participants were health care providers, with the goal of recruiting 50% of the sample from the health care provider community. COVID-19 vaccination uptake was measured through a single question: "Have you received a COVID-19 vaccine?" Participants could respond as follows: "Yes, a single-dose vaccine"; "Yes, the first dose of a two-dose regimen"; "Yes, both doses of a two-dose regimen"; and "No." Due to changes in the types of vaccines available, as well as recommendations for boosters, we collapsed the outcome into a binary "vaccinated or not vaccinated" outcome.

The effect of the intervention was estimated using a linear regression model predicting vaccination status at the midpoint and final survey. The primary independent variable in each model was exposure to the intervention. Adjusted models included the following control variables: age group, gender, educational level, religion, and occupation. We used clustered SEs to account for nesting within state of residence. Additional details on the evaluation of the intervention on vaccine uptake are reported elsewhere [22].

For the purposes of this cost-effectiveness analysis, we estimated the reach of the campaign in the intervention states based on the impressions reported by the Facebook social media platform. Impressions are defined as an individual user's exposure to specific content on the platform that may or may not result in active engagement, such as liking, commenting, or following the account that disseminated or originated the content [29].

XSL•FO
RenderX

Impressions have been shown to account for most of the information exposure on social media, have low correlation with active engagement or "expression," and be independently correlated with user-reported influence of a given information source [29].

### Uncertainty Analyses

We conducted a probabilistic sensitivity analysis by sampling from the distributions of all parameters with measured uncertainty (Table 1). We included the following scenario analysis: instead of using the effect estimate from the first follow-up from the original outcome study [22], we used the effect estimate from the second follow-up period from the same study. We did not evaluate the heterogeneity of the intervention effect or distributional effects of the intervention. Decision tree models and the probabilistic sensitivity analysis were conducted using TreeAge Pro (R2.0; TreeAge Software, LLC).

**Table 1.** Summary of inputs for the cost-effectiveness analysis of the COVID-19 vaccine promotion social media campaign in Nigeria in 2022.

| Variable | Source | Point estimate (95% uncertainty interval) | Distribution (parameters) |
|---|---|---|---|
| Target population already vaccinated at the start of the campaign (%) | Quasi-experimental trial data [22] | 64.5 (63.5 to 65.5) | Binomial ($p^a$=0.645, $n^a$=9607) |
| Persuadable middle population among those unvaccinated (%) | Quasi-experimental trial data [22] | 56.7 (55.1 to 58.3) | Binomial (p=0.567, n=3409) |
| Percentage point increase in vaccination status due to treatment among the persuadable middle | Quasi-experimental trial data [22] | 7.8 (1.68 to 14.2) | Normal (mean 0.078, SD 0.032) |
| Campaign reach | Meta advertiser platform | 1,870,000 | —[b] |
| Average engagement time per media impression (s) | Publisher analysis [30] | 1.7 | — |
| Total campaign impressions | Meta advertiser platform | 58,300,000 | — |
| Total cost (US $) | Campaign microcosting | 1,150,000 | — |
| Cost per person reached (US $) | Calculation | 0.613 | — |
| **Sensitivity and scenario analyses** | | | |
| Scenario 1: percentage point increase in vaccination status due to treatment among the persuadable middle using the second follow-up | Quasi-experimental trial data [22] | 11.0 (−0.00337 to 0.225) | Normal (mean 0.110, SD 0.058) |

[a]Parameters of each named distribution, where p denotes the probability and n denotes the number of trials.

[b]Not applicable.

### Ethical Considerations

All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional or national research committee and with the 1964 Declaration of Helsinki and its later amendments or comparable ethical standards. This evaluation was approved by the George Washington University Institutional Review Board (NCR213708), as well as by the National Health Research Ethics Committee in Nigeria (NHREC/01/01/2007-04/10/2021). No identifiable data were used in this study. All participants provided informed consent to participate in the study following the institutional review board–approved protocol. Participants were compensated with 400 naira (approximately US $1) for completion of the 40-item survey implemented through the Facebook Messenger chat function.

## Results

The intervention generated 58,255,000 total impressions across 245 distinct advertising campaigns, which, on the Meta platform (the company that owns Facebook), included one or more sets of individual advertisements. Distinct campaigns were run to allow the intervention to best measure and optimize performance against advertising objectives. The mean reach (unique individuals generating one or more impressions) per campaign was 100,000 (SD 176,000; range 1000-1,873,000). On the basis of an assumption that there was complete overlap across distinct advertising campaigns, the intervention reached 1,873,000 unique individuals.

We summarize intervention costs by activity category in Table 2. Due to the use of marketing labor in the United States and the United Kingdom as well as dollar-denominated contracts with partners in Nigeria, the payer costs accounted for 93% of the total societal costs even though the paid hours to implement the project constituted 14% of the total person-time included in the societal perspective.

XSL•FO
RenderX

**Table 2.** Cost of the COVID-19 vaccine promotion social media campaign by activity in Nigeria in 2022.[a]

| | Payer perspective (US $) | Societal perspective (US $) |
|---|---|---|
| Government liaison | 73,400 | 73,400 |
| Monitoring and evaluation | 98,300 | 98,300 |
| Campaign development | 360,000 | 360,000 |
| Advertising expenditure | 102,000 | 102,000 |
| Advertising campaign implementation | 134,000 | 134,000 |
| Stakeholder management | 293,000 | 293,000 |
| Participant engagement with advertising | —[b] | 77,700 |
| Influencer campaign implementation | — | 7520 |
| Total | 1,060,000 | 1,150,000 |

[a]Costs may not add up due to rounding.

[b]There are no participant opportunity costs included in the payer perspective.

Across both the control and intervention samples (excluding those who were ineligible based on age, duplicate ID, and missing baseline data), 64.5% (6198/9607) of the participants were already vaccinated at baseline. The vaccination rate among this sample of Facebook users was substantially higher than the 13% single-dose uptake reported at a similar point in the rollout (eg, May 2022) [16]. Of the 3409 participants screened in the study who were not vaccinated and were otherwise eligible, 1933 (56.7%) were considered to be in the persuadable middle and were enrolled in the study. In a previous study, we estimated that the intervention led to a 7.8–percentage point increase (95% CI 1.68-14.2) in vaccine uptake controlling for demographic variables among those in the persuadable middle.

In the primary analysis, we estimated that the incremental cost of the intervention per person reached was US $0.63 and the incremental percentage point increase in vaccination prevalence was 0.0157 (95% uncertainty interval [UI] 0.00337-0.0287). This resulted in an incremental cost-effectiveness ratio of US $54.70 (95% UI US $20.90-$163), which means that it cost US $54.70 more than the status quo (ie, the current state of affairs without the intervention) for every additional vaccination.

In scenario analysis 1, we used the effect estimate from the second follow-up of the same study as the primary analysis. In this scenario, the larger percentage point increase in vaccinations per person (0.0221 vs 0.0157) than in the no-intervention condition reduced the incremental cost-effectiveness ratio almost by half (US $29.60, 95% UI negative to US $180; Table 3). The UI includes 0 due to the smaller sample at the second follow-up and resulting marginally significant coefficient reported in the evaluation study. We found that using this estimate resulted in 3% of all model iterations having a negative effect.

**Table 3.** Cost-effectiveness results of the COVID-19 vaccine promotion social media campaign in Nigeria in 2022.

| | Mean (95% uncertainty interval) |
|---|---|
| Incremental cost per person reached (US $) | 0.613 (0.613 to 0.613) |
| Incremental increase in COVID-19 vaccinations per person exposed to the campaign | 0.0157 (0.00337 to 0.0287) |
| Incremental cost-effectiveness ratio (US $ per vaccination) | 54.70 (20.90 to 163) |
| Scenario 1: incremental COVID-19 vaccination per person | 0.0221 (−0.000649 to 0.0452)[a] |
| Scenario 1: incremental cost-effectiveness ratio (US $ per vaccination) | 29.60 (negative to 180)[b] |

[a]For scenario 1, we used an alternative estimate of the effectiveness of the intervention from the second follow-up period of the same intervention used for the primary analysis.

[b]A total of 3% of the model iterations were negative.

# Discussion

## Principal Findings

In this cost-effectiveness analysis of a social media campaign promoting vaccination against COVID-19 among health care workers and adults in their social environment in Nigeria in 2022, we found that the intervention increased vaccination rates among the target audience at a cost in line with similar efforts in the field.

Incremental cost-effectiveness estimates of media campaigns promoting vaccine uptake vary substantially. On the basis of an analysis of attitude changes as a result of social media campaigns run by 174 public health organizations during the COVID-19 pandemic and another study linking attitudes to vaccination outcomes, Athey et al [31] estimated that the campaigns cost US $5.68 per person vaccinated. The study by Athey et al [31] only incorporated the cost of advertising, which accounted for only 12% of the total costs of running and participating in the campaign in our study. This suggests that

XSL•FO
RenderX

our estimate of US $54.70 is likely consistent with that of the analysis by Athey et al [31] (which estimated that it would cost US $48 per person vaccinated assuming a similar cost structure) and highlights the importance of incorporating as many relevant costs as feasible when presenting the cost-effectiveness of social media campaigns.

Because there is no willingness-to-pay threshold for the cost of an incremental person vaccinated, it may be useful to integrate the findings of this study with those of others that have measured the cost per year of life saved (YLS) or cost per disability-adjusted or quality-adjusted life year. A study estimating health benefits and donor costs of increase in COVID-19 vaccination rates in 91 LMICs found that spending on vaccination would cost between US $670 per YLS and US $7820 per YLS depending on the level of vaccination achieved [32]. The authors noted that the cost per YLS for COVID-19 vaccination was similar to the cost for antiretroviral therapy for HIV under the President's Emergency Plan for AIDS Relief, which they estimated at US $4310 per YLS using the total budget and life years saved from the President's Emergency Plan for AIDS Relief 2004 to 2013 [31]. The cost per person vaccinated in this study (US $54.70) was between 1% and 8% of the estimated cost per YLS by vaccination against COVID-19 in the 91 LMICs in the aforementioned study [32]. To further contextualize the value of the social media campaign evaluated in this study, vaccination against COVID-19 in LMICs was estimated to prevent 20.39 deaths per 10,000 people vaccinated; each death from COVID-19 was separately estimated to lead to 16 years of life lost [33,34]. This means that, for each person vaccinated, there was an average of 0.0326 (20.39 × 16/10,000) years of life lost prevented. On the basis of the estimates of the variable cost of vaccination delivery after rollout of a national campaign (US $10 for the vaccine and US $2.46 for delivery) and the cost of promotion obtained from this study (US $54.70), the marginal cost for each vaccination delivered would be US $67.16, leading to an estimate of US $2060 per year of life lost averted. The value of rapidly disseminating science-based vaccine promotion in terms of within-country health benefits likely underestimates the benefits of responding to shared global vulnerabilities with shared investments in mutually beneficial solutions such as vaccination. Baker et al [35] highlight this need for rapid collaboration as they paint an alarming picture of our new era of globally shared infectious disease risk caused by the confluence of climate change, urbanization, migration, travel, and intensifying trade of plants and animals.

Much of the work to prepare and launch this specific campaign to increase COVID-19 vaccine uptake could support other public health communications campaigns in Nigeria and potentially other countries. Moving the intervention to scale, such as all 37 states instead of the 6 in the intervention arm of this study, would spread fixed costs across a much larger population and reduce the cost per person vaccinated substantially. Goulbourne and Yanovitzky [36] argue that the COVID-19 pandemic clarified the role of health communication infrastructure as a social determinant of health and that public health organizations will need to invest in hyperlocal health communication capacity across populations to address health inequities. They suggest that training and providing ongoing technical support to trusted intermediaries is one approach to providing hyperlocal health communication at scale. The intervention evaluated in this study did implement the COVID-19 vaccine promotion social media campaign through 12 local health organizations and 10 other local influencers. The involvement of local influencers to shape and deliver health messages was considered an essential component of the campaign. This approach could limit the degree to which the intervention could be scaled at a lower marginal cost.

A primary limitation of this cost-effectiveness analysis is that we were not able to obtain a specific estimate of the total unique individuals reached by the intervention on the Meta platform. To be conservative, we estimated a total intervention reach of 1.87 million unique users based on the reach of the largest single campaign and not the 24.5 million reached if we summed the reported reach estimates for all campaigns. Our estimated US $0.61 per person reached by the campaign would instead be US $0.05, shifting the cost per vaccination from US $54.70 to US $2.98. This order of magnitude difference in the cost-effectiveness of the intervention emphasizes the importance of understanding how social media reach metrics are reported and how studies estimating the same cost-effectiveness outcomes (eg, cost per person vaccinated against COVID-19) are using these metrics. The lack of comparability across studies may be further compounded when studies only use active engagement or expression as a measure of campaign reach [29].

The extent of competing social media and other communication campaigns promoting vaccination against COVID-19, as well as the high levels of mis- and disinformation about the pandemic and the vaccines on the same social media platforms, created another limitation. The incremental effect of the intervention campaigns on the message environment was lower than it would have been in a nonpandemic context. We were not able to assess any competing or synergistic effects of the campaign due to variation in individual or community media environments, nor were we able to evaluate how the campaign interacted with other public health campaigns on the same platform or across channels. Extrapolation of findings from this study period to future pandemics may be limited by the rapidly changing nature of the social media landscape, including as it relates to platform responsibility to address public health misinformation. The recent divergence in the degree of regulatory control over content moderation between the European Union's Digital Services Act requirement that platforms address the systemic risks posed by misinformation and American jurisprudence's strengthening of free speech protections of content moderation means that mostly American corporations will potentially pursue jurisdictionally fragmented approaches to misinformation during the next pandemic [37].

We used a self-reported measure of vaccination, which could potentially overestimate the effect of the intervention. Stephenson et al [38] reported that, among a sample of approximately 2000 patients with both self-reported and recorded COVID-19 vaccination status in a hospital setting, the self-reported and recorded vaccination status matched for 95% of the participants. While we used existing studies on the cost-effectiveness of vaccination in similar settings [32], we did not directly estimate how the campaign affected health

XSL•FO
RenderX

outcomes, which may vary based on, among other factors, the vaccination level in the community, underlying demography and health status of the population, type of vaccine used, and health care system cost and effectiveness. Incorporating these factors within evaluation of new health communication and other strategies is likely infeasible for most interventions but could be accomplished by partnering with modeling groups that do address these factors or through sustained support of modeling consortia that could share modeling capacity more rapidly during future pandemics [39].

### Conclusions

We found that a local influencer–based social media campaign implemented in 6 states in Nigeria during the COVID-19 pandemic increased COVID-19 vaccination rates among those exposed to the campaign. The campaign demonstrated comparable cost-effectiveness to that of other COVID-19 vaccination campaigns when accounting for differences in cost data included across studies. When combined with existing estimates of the effect of vaccination against COVID-19 on mortality and years of life lost per death due to COVID-19, this intervention achieved a lower cost per year of life lost averted (US $2060) than debated but recognized thresholds of 3 times the national gross domestic product per year of life lost averted [40]. Boosting the reach of vaccination efforts through influencer-based social media campaigns such as the one implemented in this study is likely to be a cost-effective approach to save lives.

## Acknowledgments

The social media campaign evaluated in this study was led by M+C Saatchi, UpSwell, and a consortium of Nigerian organizations that published the social media content with approval from the Nigerian government. The authors thank these organizations for their collaboration.

## Funding

This study was funded by the Bill & Melinda Gates Foundation (INV-033413).

## Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

## Abstract

**Background:** Physical inactivity and sedentary behavior are important modifiable risk factors for noncommunicable diseases. High prevalences of physical inactivity among children and adolescents continue to represent a significant public health challenge globally, with approximately two-thirds of children worldwide not achieving the recommended daily amount of physical activity (PA). Countries in the Middle East exhibit some of the highest levels of physical inactivity and sedentary behavior, which contribute to the increasing rates of obesity among children and adolescents.

**Objective:** This study aims to provide a comparative synthesis of PA indicators among children and adolescents in Lebanon, Qatar, and the United Arab Emirates (UAE) based on the Active Healthy Kids Global Alliance (AHKGA) PA Report Cards and further compare the findings with regional and global trends.

**Methods:** Data were synthesized from previous AHKGA PA Report Cards published by researchers from Lebanon, Qatar, the UAE in the years 2016 (Global Matrix 2.0; 1998 - 2014 data), 2018 (Global Matrix 3.0; 2016 - 2017 data) and 2022 (Global Matrix 4.0; 2017 - 2022 data). We evaluated 10 key PA indicators across these countries to identify trends and gaps in PA levels among children and adolescents. These findings were further compared with regional and global data gathered and published in previous iterations of the AHKGA Global Matrix.

**Results:** Based on data collected between 1998 and 2022, less than one-third (15% - 33%) of children and adolescents in Lebanon, Qatar, and the UAE achieved the recommended daily average of 60 minutes of moderate- to vigorous-intensity PA. Additionally, more than one-half (45% - 74%) of children and adolescents exceeded the recommended limit of 2 hours of recreational screen time per day. Overall, boys were more physically active than girls; however, PA levels declined with increasing age. Other behavioral indicators such as participation in organized sports and active transportation revealed insufficient PA levels. The results were slightly better for sources of influence indicators especially with the opportunities provided by schools and governments. Compared with global estimates, PA levels in the Middle Eastern countries were similar to the averages observed

XSL•FO
RenderX

across Asian countries participating in the AHKGA; however, they were generally lower than PA levels in other regions of the world.

**Conclusions:** Data from a 25-year period show consistently low levels of PA and high levels of sedentary behavior among children and adolescents from these 3 Arab Middle Eastern countries. Despite governmental investments in implementation of PA initiatives, there seems to be a lag in eliciting increases in PA at the population level. Evidence points to a critical need for behavioral and lifestyle modifications among children and adolescents. These concerns are exacerbated by a lack of national surveillance systems and evidence-based policy interventions to improve PA levels.

## Introduction

### Background and Rationale

Physical activity (PA) is an important factor for preventing and managing noncommunicable diseases, as well as enhancing mental health, quality of life, and overall well-being [1]. The high prevalence of physical inactivity among children and adolescents continues to represent a global health challenge, with approximately two-thirds of children worldwide failing to achieve the minimum recommended level of daily PA (ie, at least an average of 60 minutes of moderate- to vigorous-intensity PA [MVPA]) [2]. Moreover, countries in the Middle East report some of the highest levels of physical inactivity and sedentary behavior [3,4]. This trend is further reflected in the increasing rates of obesity among children, adolescents, and adults in the region [5]. Given that physical inactivity is an independent risk factor for various chronic diseases, PA surveillance and intervention should be a top priority for public health agencies, policymakers, and governments [6,7].

In 2005, a team of Canadian researchers developed a Report Card that provided a comprehensive assessment of PA among Canadian children and adolescents, with the aim of identifying areas of concern and advocating for action to improve their PA levels [8,9]. The Report Card included indicators related to PA in different domains, and each indicator was assigned a letter grade (A to F) based on the best available evidence, with "A" representing the highest level of achievement and "F" representing the lowest. For 20 years, Active Healthy Kids Canada and ParticipACTION have worked to inspire the country to engage all children and adolescents in PA, and the Canadian Report Card was released annually between 2005 and 2016 and periodically thereafter.

Building on the success of the Canadian model, the Active Healthy Kids Report Card initiative expanded globally to an international project encompassing 15 countries producing PA Report Cards as part of the Global Matrix 1.0 in 2014 [10]. Since then, the project has continued to grow and include more countries from all regions (Global Matrix 2.0, 2016, 38 countries [11]; Global Matrix 3.0, 2018, 49 countries [12]; Global Matrix 4.0, 2022, 57 countries [13]). The Active Healthy Kids Global Alliance (AHKGA) leads the Global Matrix initiative and has made significant efforts to gather evidence-based data on PA indicators among children and adolescents worldwide [14,15]. As a result, the individual country Report Cards have formed a source of consolidated research knowledge on PA, with contributions to academia, research, education, health, policy, and related fields [16,17]. The primary goal of the AHKGA "Global Matrix" initiative is to raise awareness, develop capacity, and exchange knowledge and strategies, as well as expand PA surveillance of children and adolescents aged 5 years through 17 years across different jurisdictions, countries, and continents. The initiative follows a systematic assessment process; it involves reviewing key indicators and influencing factors using a predefined methodology and grading rubric. This process, steered by the AHKGA, is conducted periodically (every 2 years to 4 years). The AHKGA Global Matrix is currently the only worldwide initiative that comprehensively assesses PA among children and adolescents, covering a diverse range of indicators. This study presents the first comparative synthesis across participating Arab Middle Eastern AHKGA countries.

Data gathered from various participating countries over the past decade (ie, Global Matrix 2.0, 3.0, and 4.0) have consistently indicated low levels of PA across most domains [18]. Without significant changes in behaviors and lifestyles, current and future generations may face increased risks of noncommunicable diseases as they transition into adulthood [3]. In Asia, the number of countries taking part in the AHKGA initiative has increased over the years (9 in Global Matrix 2.0, 12 in Global Matrix 3.0, and 16 in Global Matrix 4.0), demonstrating the region's enthusiasm for the promotion of PA. However, the overall PA levels have been relatively low throughout the years in most Asian countries [19,20]. As such, gaining additional insights on the region's PA landscape is important for shaping targeted interventions and informing policy decisions to enhance PA levels and outcomes among children and adolescents. Cross-country analysis of data gathered by the AHKGA can help identify trends and influencing factors specific to the region, as well as reveal gaps in existing surveillance systems [21]. Within the Middle East region, participation in the AHKGA initiative has so far been limited to a few countries, with Lebanon, Qatar, and the United Arab Emirates (UAE) being the only Arab nations that have independently developed Report Cards.

### Objectives

This study aimed to synthesize and compare evidence from the PA Report Cards developed by these Arab Middle Eastern countries. Our study specifically focused on Arab nations, with the objective of evaluating trends and identifying gaps in PA

XSL•FO
RenderX

indicators among children and adolescents in countries with similar cultural backgrounds but different socioeconomic and political climates. It also examined the relationships between socioeconomic and geographic factors and the levels of PA, thereby enabling a comparison of findings with those of other regions and global averages.

## Methods

### Study Design

We used a harmonized comparative approach to evaluate PA indicators among children and adolescents across 3 Arab countries in the Middle East region (Lebanon, Qatar, UAE) using previous PA Report Card outcomes published as part of the AHKGA Global Matrix initiative. We further compared these results with regional and global findings.

### Variables

We evaluated 10 key indicators of PA related to children's and adolescents' behaviors, fitness, and sources of influence in this study. The indicators, as defined by the AHKGA, included (1) Overall Physical Activity, (2) Organized Sport and Physical Activity, (3) Active Play, (4) Active Transportation, (5) Physical Fitness (added in Global Matrix 3.0 onward), (6) Sedentary Behavior, (7) Family and Peers, (8) School, (9) Community and Environment, and (10) Government.

### Data Sources

The AHKGA Report Card archives were checked for all Arab Middle Eastern countries that were involved in any Global Matrix initiative (1.0 to 4.0). Relevant publications outlining the results of each of the published Report Cards were identified by collaborating authors who were involved in the original projects. This study included data from the Report Cards published in Global Matrix 2.0 2016 (data from 1998 - 2014) [22,23], Global Matrix 3.0 2018 (data from 2016 - 2017) [24-26], and Global Matrix 4.0 2022 (data from 2017 - 2022) [27,28] by Lebanon, Qatar, and the UAE. Participation among these countries varied across the years; the UAE participated in 3 iterations of the Global Matrix (2.0 to 4.0), Qatar participated in Global Matrix 2.0 and 3.0, and Lebanon participated in Global Matrix 3.0 and 4.0. A total of 7 PA Report Cards were identified, and the results were evaluated in our study.

During the development of the Report Cards for each respective iteration (2016, 2018, 2022), teams from each country systematically gathered the most valid and reliable evidence and relevant data from the given time periods (ie, Global Matrix 2.0 data from pre-2016, Global Matrix 3.0 data from 2016 - 2017, and Global Matrix 4.0 data from 2017 - 2022). The countries' Report Card teams included researchers, clinicians, and policymakers from universities, educational authorities, public health departments, and government health authorities from each country. Data sources included local, national, and international studies; national surveys; and official reports. Data were then synthesized by Report Card teams, and a consensus was established regarding the grading of each indicator. The grading was based on specific benchmarks, with the assigned grades corresponding to the proportion of children who achieved the benchmark (Table 1). Grading in the 2016 Report Cards was as follows: A=81% to 100%; B=61% to 80%; C=41% to 60%; D=21% to 40%; F=0% to 20%; INC =incomplete data. However, from 2018 onward, each grade band was further subdivided (Table 2). Report Card grades for each country, including rationale and references, were audited and reviewed by the AHKGA prior to final approval and release.

XSL•FO
RenderX

**Table .** Indicators and benchmarks used to guide the Report Card grading for Global Matrix 2.0 in 2016 (data from 1998 - 2014), Global Matrix 3.0 in 2018 (data from 2016 - 2017), and Global Matrix 4.0 in 2022 (data from 2017 - 2022).

| Indicator | Benchmark |
|---|---|
| Overall Physical Activity | • % of children and adolescents who meet the Global Recommendations on Physical Activity for Health, which recommend that children and adolescents accumulate at least 60 minutes of moderate- to vigorous-intensity PA[a] per day on average<br>• % of children and adolescents meeting the guidelines on at least 4 days a week (when an average cannot be estimated) |
| Organized Sport and Physical Activity | • % of children and adolescents who participate in organized sport or PA programs |
| Active Play | • % of children and adolescents who engage in unstructured or unorganized active play at any intensity for more than 2 hours a day<br>• % of children and adolescents who report being outdoors for more than 2 hours a day |
| Active Transportation | • % of children and adolescents who use active transportation to get to and from places (eg, school, park, mall, friend's house) |
| Sedentary Behavior | • % of children and adolescents who meet the Canadian Sedentary Behavior Guidelines for 5- to 17-year-olds, which is no more than 2 hours of recreational screen time per day |
| Physical Fitness | • Average percentile achieved on certain physical fitness indicators based on the normative values published by Tomkinson et al [29] |
| Family and Peers | • % of family members (eg, parents, guardians) who facilitate PA and sport opportunities for their children (eg, volunteering, coaching, driving, paying for membership fees and equipment)<br>• % of parents who meet the Global Recommendations on PA for Health, which recommend that adults accumulate at least 150 minutes of moderate-intensity aerobic PA throughout the week or do at least 75 minutes of vigorous-intensity aerobic PA throughout the week or an equivalent combination of moderate- and vigorous-intensity PA<br>• % of family members (eg, parents, guardians) who are physically active with their kids<br>• % of children and adolescents with friends and peers who encourage and support them to be physically active<br>• % of children and adolescents who encourage and support their friends and peers to be physically active |
| School | • % of schools with active school policies (eg, daily PE[b], daily PA, recess, "everyone plays" approach, bike racks at school, traffic calming on school property, outdoor time)<br>• % of schools where the majority (≥80%) of students are taught by a PE specialist<br>• % of schools where the majority (≥80%) of students are offered the mandated amount of PE (for the given state, territory, region, or country)<br>• % of schools that offer PA opportunities (excluding PE) to the majority (>80%) of their students<br>• % of parents who report their children and adolescents have access to PA opportunities at school in addition to PE classes<br>• % of schools with students who have regular access to facilities and equipment that support PA (eg, gymnasium, outdoor playgrounds, sporting fields, multipurpose space for PA, equipment in good condition) |

XSL•FO
RenderX

| Indicator | Benchmark |
|---|---|
| Community and Environment | • % of children or parents who perceive their community or municipality is doing a good job at promoting PA (eg, variety, location, cost, quality).<br>• % of communities or municipalities that report they have policies promoting PA<br>• % of communities or municipalities that report they have infrastructure (eg, sidewalks, trails, paths, bike lanes) specifically geared toward promoting PA<br>• % of children or parents who report having facilities, programs, parks, and playgrounds available to them in their community<br>• % of children or parents who report living in a safe neighborhood where they can be physically active<br>• % of children or parents who report having well-maintained facilities, parks, and playgrounds in their community that are safe to use |
| Government | • Evidence of leadership and commitment in providing PA opportunities for all children and adolescents<br>• Allocated funds and resources for the implementation of PA promotion strategies and initiatives for all children and adolescents<br>• Demonstrated progress through the key stages of public policy making (ie, policy agenda, policy formation, policy implementation, policy evaluation, and decisions about the future) |

[a]PA: physical activity.

[b]PE: physical education.

**Table .** Report Card grading rubric used in the Global Matrix 2.0[a] in 2016 (data from 1998 - 2014), Global Matrix 3.0 in 2018 (data from 2016 - 2017), and Global Matrix 4.0 in 2022 (data from 2017 - 2022).

| Grade | Interpretation |
|---|---|
| A+ | 94% - 100% |
| A | 87% - 93% (We are succeeding with a large majority of children and adolescents.) |
| A– | 80% - 86% |
| B+ | 74% - 79% |
| B | 67% - 73% (We are succeeding with well over half of children and adolescents.) |
| B– | 60% - 66% |
| C+ | 54% - 59% |
| C | 47% - 53% (We are succeeding with about half of children and adolescents.) |
| C– | 40% - 46% |
| D+ | 34% - 39% |
| D | 27% - 33% (We are succeeding with less than half but some children and adolescents.) |
| D– | 20% - 26% |
| F | <20% (We are succeeding with very few children and adolescents.) |
| INC[b] | Incomplete—insufficient or inadequate information to assign a grade |

[a]Grading in the 2016 Report Cards was as follows: A=81%-100%; B=61%-80%; C=41%-60%; D=21%-40%; F=0%-20%.

[b]INC: incomplete data.

In this study, we incorporated references to the published results of the Report Cards from each country over the years [22-28]. We also relied on the interpretations made by the Report Card teams to generate a comprehensive table with the assigned grades and percentages based on the previous publications. In certain instances, we cited additional sources that did not play a direct role in determining the indicator's grade at the time that the Report Card was issued (eg, governmental policies, future plans, and suggested strategies for improvement); however, they remain relevant to the context of the grading. This approach

XSL•FO
RenderX

helped us provide thorough interpretations while ensuring that the grading process was based on information from the published Report Cards. Additionally, the most recent Report Cards (2022) included the top 3 priorities for improving 10 key PA indicators, as identified by Report Card teams in each country. Building on these priorities, we provided key applicable recommendations for the indicators to support the improvement of PA within the 3 Arab Middle Eastern countries.

Sociodemographic characteristics of the countries were obtained from the latest (2023 and 2024) Human Development Reports issued by the United Nations and the World Bank [30,31], including the Human Development Index (HDI), gross domestic product (GDP) per capita, Gender Inequality Index, Gini Index, expenditure on health, life expectancy at birth, mean years of schooling, total population, population density, urban population, and average mean temperature [32]. They were used to assess and interpret grade variations between these countries and in relation to other regions of the world.

### Ethical Considerations

This study used secondary data from published papers and did not require institutional review board review as the data were publicly available. Specifically, data were collected from Global Matrix and Report Card papers published in the Journal of Physical Activity and Health [11-13] as well as the AHKGA website [14] for Global Matrix 2.0, 3.0, and 4.0. This article presents a comparative secondary data analysis of the aforementioned publications for the 3 participating countries. As such, no ethical approval was required for conducting the study. The referenced publications included data from local, national, and international studies; national surveys; and official reports. References to these data sources can be found in the relevant original Report Card publications as cited in the Methods section [22-28]. Further information about the process of Report Card development in each participating country can be found in the original Global Report Card publications [11-13].

## Results

### Overview

To contextualize the findings across these Arab Middle Eastern countries, sociodemographic and economic characteristics were first examined (Table 3). Qatar (0.886) and the UAE (0.940) had very high (≥0.800) HDIs [30,33]; Lebanon (0.752) had a high (0.700 - 0.799) HDI [30,34]. As of the year 2024, the UAE had the largest population among the 3 countries, with approximately 11 million residents, and the lowest population density (142 people/km$^2$ of land area) and urban population percentage (88%). Public health expenditure as a percentage of GDP was the highest in Lebanon (5.74%) and the lowest in Qatar (2.18%). Life expectancy at birth ranged from 77.8 years in Lebanon to 82.9 years in the UAE. The lowest Gini Index (least income inequality) was observed in the UAE (26.4), and the highest (greatest income inequality) was in Qatar (35.1) [31].

**Table .** Sociodemographic characteristics of the 3 participating Arab Middle Eastern countries from the most recent available data.

| Sociodemographic variable | Country | | |
|---|---|---|---|
| | Lebanon | Qatar | UAE[a] |
| Human Development Index | 0.752 | 0.886 | 0.940 |
| GDP[b] per capita (US $) | 3477.70 | 127,711.10 | 49,377.60 |
| Gender Inequality Index | 0.036 | 0.195 | 0.040 |
| Gini Index | 31.8 | 35.1 | 26.4 |
| Expenditure on health (% of GDP) | 5.74 | 2.18 | 4.68 |
| Life expectancy at birth (years), mean | 77.8 | 82.4 | 82.9 |
| Schooling duration (years), mean | 10.4 | 10.8 | 13.0 |
| Population (millions), n | 5.8 | 2.9 | 10.9 |
| Population density (people/km$^2$) | 562 | 231 | 142 |
| Urban population, % | 90 | 99 | 88 |
| Temperature (°C), mean | 16.0 | 28.3 | 28.9 |

[a]UAE: United Arab Emirates.

[b]GDP: gross domestic product.

In total, 37 letter grades (37/66, 56%) and 29 incomplete (INC) grades (29/66, 44%) were assigned across all 7 Report Cards (Table 4). The indicator with the highest grade was Government (average of B+), and the indicator with the lowest grade was Overall Physical Activity (average of D/F). Active Play, Physical Fitness, and Community and Environment were marked INC throughout all Report Cards. The grades are explained in the following sections, except for indicators with INC grades, which are not included in the rest of the Results section.

XSL•FO

[a]GM: Global Matrix.

[b]Minus sign in the 2016 Report Card grading scheme indicates variations in subgroups based on age, gender, nationality, socioeconomic status, and geographic location.

[c]INC: incomplete.

[d]Percentages may not correspond to final grades, as final grades were determined by expert consensus.

[e]Not applicable: The Physical Fitness indicator was added in Global Matrix 3.0 onward.

Additionally, during each iteration of the Global Matrix (2016, 2018, 2022), participating countries had the choice to include supplementary indicators in their respective Report Cards, as deemed beneficial to enhance the value of their results. Due to this, some variations in the indicators were observed across the different countries and Report Cards. For example, Qatar's Report Card team decided not to evaluate Active Transportation and considered it "Not Applicable" due to road safety issues and the prevalence of high temperatures during much of the year. Instead, they included Obesity and Dietary Habits as additional indicators in their 2016 Report Card. Likewise, Lebanon included Weight Status in addition to the common indicators in their 2018 Report Card and Sleep and Body Mass Index in their 2022 Report Card.

## Overall Physical Activity

Across all 3 countries, the proportions of children and adolescents meeting the recommended PA levels (ie, minimum of 60 minutes of MVPA per day on average) varied from 15% to 33%, with the average grades ranging from F to D. In the UAE, data from 1998 to 2021 showed that most children and adolescents (72% - 84%) were physically inactive. The first UAE Report Card (2016), which was based on the largest amount of data collected (1998 - 2014), revealed 17% to 28% of children and adolescents achieved the recommended daily PA, with a noticeable difference between boys (23% - 24%) and girls (13% - 16%). The World Health Organization (WHO) Global School-based Health Survey (GSHS) [35] and other studies with smaller sample sizes were used to inform this indicator, resulting in a split grade of D−/F−, with the minus sign indicating variations in subgroups. Overall Physical Activity remained low in subsequent UAE Report Cards, with only 16% of children and adolescents (21% of boys; 11% of girls) in 2018 and 19% of children and adolescents (27% of boys; 8% of girls) in 2022 accumulating sufficient PA. Likewise, in Qatar, only 15% of children and adolescents (30% of boys; 10% of girls) met the recommended daily PA as reported in their first and most comprehensive Report Card issued in 2016. There was a notable increase in the following Qatar Report Card (2018), with PA levels ranging between 25% and 39% among children and adolescents. The final average grade assigned to Overall Physical Activity in the 2018 Report Card by Qatar was D (32%). The Lebanese Report Cards for 2018 and 2022 reported comparable results, with average grades of D (33%) and D− (21%) assigned in those respective years. Like Qatar and the UAE, their evaluation primarily relied on the WHO GSHS data using self-report PA estimates. Boys had higher levels of PA (29%) than girls (14%), and students attending private schools (23%) appeared to be more active than students in public schools (17%) in Lebanon. In all 3 countries, the Overall Physical Activity estimates were mostly derived from

XSL•FO
RenderX

self-reported questionnaires, while device-based (accelerometer) assessments were limited.

### Organized Sport and Physical Activity

In Lebanon, the proportion of children and adolescents participating in events or competitions administered by the Ministry of Youth and Sports was extremely low, leading to an F grade (5%) in 2018. This may be due to a lack of public sport infrastructure and investment in community-level sport programs. Their subsequent Report Card (2022) graded this indicator INC. In Qatar and the UAE, governmental support and investment in infrastructure were and continue to be higher than in Lebanon. In 2016, Qatar's GSHS national survey found that approximately 30% of children and adolescents regularly participated in at least one organized sport annually. Qatar also held a National Sports Day and had several initiatives aimed at promoting sport participation, which contributed to a grade D in this area. This grade improved to D+ in 2018, when nearly 48% of children and adolescents participated in organized sports. Additionally, 58% of boys and 42% of girls in Qatar were registered with sport clubs. The UAE marked this indicator as INC throughout all Report Cards.

### Active Transportation

Of the 3 included countries, Lebanon reported the highest active transportation use (26% - 37%; grade D). The proportion remained similar (37%), but the grade increased from D (2018) to D+ in 2022. Additionally, sex-based differences were observed (42% of boys and 32% of girls) in the 2017 GSHS national survey results. The UAE's evaluation of Active Transportation in 2016 was derived from 2005 and 2010 GSHS national reports, when data showed that 19% to 21% of adolescents walked or cycled to school at least once during the week (grade F−/D−). The minus sign added to the grade in the 2016 Report Card was due to sex-based differences (29% of boys and 16% of girls in 2005; 29% of boys and 15% of girls in 2010). No data were available for the following (2018) UAE Report Card; however, the 2022 UAE Report Card used data from an online survey run by the Knowledge and Human Development Authority in Dubai. The survey of 33,784 parents indicated that only 5% of children and adolescents in Dubai used active transportation modes to travel to and from school (4.8% walked; 0.2% cycled) [27]. Based on these findings, the indicator received an F in 2022. Qatar did not include Active Transportation in their Report Cards, as they considered it to be not applicable for assessment in their country due to road safety issues and the predominantly hot climate.

### Sedentary Behavior

All 3 countries have faced ongoing challenges in reducing sedentary behavior. The UAE Report Card showed 62% (2005) and 49% (2010) of children achieving the recommended Canadian Sedentary Behavior Guidelines of screen time exposure (ie, no more than 2 hours of recreational screen time per day), with variations according to age and sex. The indicator was assigned a C− in the UAE in the first two Report Cards (2016 and 2018), with the minus sign indicating variations in subgroups in 2016. The numbers declined over time to 40% in 2018 (C–) and only 26% in 2022 (D−). In Qatar, the 2016 Report Card showed that less than one-third of children and adolescents met the recommended daily recreational screen time, which corresponded to a D grade. These figures improved slightly to 35% for children and 45% for adolescents (D+) in 2018. Qatar did not participate in the 2022 Report Card; therefore, updated data were unavailable. The 2018 Lebanese Report Card showed that approximately 40% of children and 52% of adolescents met the screen time recommendations, resulting in an average grade of C− (46%). Similar findings were reported in 2022, with 55% of adolescents meeting the recommendations.

### School

In the UAE, due to limited access to national data on school distribution, the benchmark used for this indicator varied between (1) the proportion of children and adolescents attending ≥3 physical education (PE) classes per week (approximately 150 minutes) and (2) the proportion of schools where the majority (≥80%) of students were taught by PE specialists. In 2016 and 2018, the UAE reported that slightly more than one-quarter (26% - 28%) of adolescents adhered to the mandated PE requirements and that participation decreased as age increased. The 2022 Report Card reflected updated figures, with an A− grade; however, this grade was based solely on data confirming that all children and adolescents in Dubai received PE classes taught by specialists. The minus sign in the 2022 Report Card was added to acknowledge the difference in the frequency of weekly PE classes across various schools. Although several components of the UAE schools (such as all PE teachers holding bachelor's degrees in PE and the adequate availability of PA facilities) would typically warrant a high grade for this indicator, only 79% of children reported receiving more than 100 minutes of PE classes per week. In Qatar, School was marked INC in 2016 due to insufficient data. In 2018, it was graded C, indicating that 67% of children participated in PE classes and 61% of schools offered support for PA programs or initiatives such as "Qatar Active Schools" and "Health Promoting Schools." It is worth noting here that, at the time, many PE teachers in Qatar were not classified as specialists. Therefore, schools in these circumstances would not have been counted, even if their PE classes were delivered adequately. In Lebanon, School was graded D in 2018 (22%) and 2022 (32%). In both instances, the results were based on self-reported participation of school students in the number of weekly PE classes. Additionally, there was a notable sex discrepancy observed, with 28% of boys participating in PE classes compared with only 18% of girls.

### Family and Peers

This indicator relied on data showing the influence of family members and peers in encouraging or limiting PA opportunities and participation among children and adolescents. Based on parental PA levels in the UAE, the Family and Peers indicator was assigned C− (62%) in 2016 and D− (20% - 26%) in 2022. In the 2016 Qatar Report Card, it was graded D based on the overall prevalence of physical inactivity, suboptimal dietary habits, and a high rate of obesity among the population. Lebanon did not have any data to inform this indicator; hence, it was marked INC.

XSL•FO
RenderX

### Government

This indicator was evaluated based on any evidence of governmental support in promoting and providing PA opportunities for children and adolescents through policy, legislation, or regulation. All 3 countries relied mainly on unpublished data to grade this indicator. Qatar assigned its highest grade to the Government indicator in both 2016 (B) and 2018 (B+). Similarly, in the UAE, the indicator was graded B+ across all 3 Report Cards. However, Lebanon's grades were C+ in 2018 and D in 2022.

## Discussion

### Summary of Main Findings

This study addressed an important research gap by offering the first regional comparative synthesis of PA indicators in 3 Arab Middle Eastern countries with shared cultural and climatic contexts. It provides insights into a critical public health concern based on 25 years of data (1998 - 2022). The findings revealed that less than one-third (15% - 33%) of children and adolescents participated in the recommended daily amount of PA (ie, an average of 60 minutes of moderate- to vigorous-intensity PA). Moreover, a large proportion (45% - 74%) exhibited high levels of sedentary behavior (ie, ≥2 hours of recreational screen time per day). Qatar and the UAE had comparable trends due to their similar demographics, geographic location, climate, and cultural characteristics. Compared with global estimates, PA levels in the 3 Arab Middle Eastern countries were close to those observed across other Asian countries participating in the AHKGA; however, they were generally lower than PA levels in other regions of the world.

### Interpretations, Implications, and Comparisons With Existing Literature

#### *Human Development Index*

Countries worldwide are classified by their level of development using the HDI, which measures a country's success in 3 key dimensions: life expectancy, education levels, and the standard of living as measured by income per capita [30]. Global analysis of PA levels by HDI showed that countries with high and very high HDI generally had lower grades in behavioral indicators (ie, Overall Physical Activity, Organized Sports, Active Play, Active Transportation, and Sedentary Behavior) but higher grades in sources of influence indicators (ie, School, Family and Peers, Community and Environment, and Government) [36]. This pattern of lower PA and higher HDI was evident in most indicators (except for the Government indicator) across the 3 Middle Eastern countries included in our study.

On a global scale, the overall PA grades for countries with very high (≥0.800) HDI approximated a C, with the behavioral indicators near D and the source of influence indicators around B [33]. The UAE and Qatar grades were not far from the global averages of PA among other very high HDI countries participating in the Global Matrix initiative. Similarly, Lebanon's grades were consistent with other participating countries classified as having a high HDI (eg, Thailand, China, Bulgaria, and several nations in South America), with most results predominantly around a grade of D [34].

#### *Behavioral Indicators*

The latest global insights from the Global Matrix 4.0 (2022) revealed an Overall Physical Activity average of D (27% - 33%) based on data gathered from 57 countries [13]. A study evaluating further temporal trends of Asian countries from Global Matrices 2.0 - 4.0 showed consistently lower grades for Overall Physical Activity, with an average grade of D− (20% - 26%) across the years [20]. Countries in the Middle East have had similar and sometimes lower results (F to D) than regional (Asian) averages; however, the grades vary across the specific indicators.

The assigned grades for Sedentary Behavior across the 3 participating Arab Middle Eastern countries ranged between D− and C−, which is in line with the global findings observed over the past decade [37]. This was expected given the advancement in technologies and the widespread use of digital media. Moreover, the Organized Sport and Physical Activity indicator was marked INC in nearly all Asian countries (including Lebanon and the UAE) in Global Matrix 4.0 [13]. Considering its role in the overall health and PA of children and adolescents, it is important to incorporate organized activities into PA questionnaires with further specification of the type, intensity, frequency, and duration of each activity.

Active Play, known for its numerous health benefits in children and adolescents, remains one of the least researched and documented areas of PA [38]. This indicator is a critical component of children's and adolescents' physical, social, and cognitive well-being; however, it often goes unrecorded due to its unstructured nature [39]. In the most recent global reports (Global Matrix 4.0, 2022), Active Play was the indicator with the most INC grades (27/57, 47% INC; 30/57, 53% graded) [13]. Moreover, the average grades differed across countries participating in the Global Matrix in relation to the HDI; low-medium HDI countries scored around a C+, while high HDI countries scored around a D− [13]. This highlights the impact of the modern world regarding replacing unstructured PA with sedentary behavior. Country-specific barriers and enablers to assessing this indicator are worth exploring to better understand children's total PA and design interventions that promote healthy, playful, and active lifestyles.

Low levels of Active Transportation in the 3 Middle Eastern countries may be partially explained by the transport infrastructure and urban design. None of the 3 countries have sufficient walking or cycling lanes dedicated to traveling long distances between residential communities and schools. Most cycling and pedestrian tracks are primarily designed for recreational use, rather than serving as active transportation routes. The region's hot climate also adds to the barriers of outdoor PA in general, especially in Qatar and the UAE where temperatures can peak at 40.0 °C to 45.0 °C [32]. In Lebanon, the weather throughout the academic year is generally moderate (mean temperature 16.0 °C) [32], facilitating better conditions for active transportation. Additionally, the noticeable difference in Active Transportation between boys and girls may be due to cultural factors, such as the acceptability of female adolescents

XSL•FO
RenderX

walking and cycling to and from school or other places. A study conducted in the Middle East and North Africa region identified a number of barriers and facilitators to PA among different subgroups of the population [40]. The most common barriers among children and adolescents were being female, older age, lack of time, and obesity. Other less common barriers included high screen time, inadequate school PE programs, lack of sports facilities, peer support, sleep, and dietary habits [40].

These findings highlight the relationship between different behavioral indicators and their joint effect on achieving optimal daily PA. Therefore, in order to improve PA levels among children and adolescents (girls and boys), the first step would be to develop and implement a systematic tool for the assessment of PA across different domains [41-43].

### *Physical Fitness Indicator*

The dearth of data on physical fitness levels presents a critical public health concern, as it is an indicator that offers important insights into the overall health of children and adolescents and reveals early risk factors for chronic diseases that can develop later in life [44,45]. Routine evaluation and monitoring of physical fitness can also serve as a baseline national indicator of the efficacy of PA policies, educational interventions, and environmental support for promoting active lifestyles among children and adolescents. Since its introduction in the Global Matrix 3.0 (2018), Physical Fitness has been reported as INC in over one-half of the participating countries. Most grades for this indicator were assigned to countries classified as having high or very high HDIs, with a global average of C− [12,13].

Within the Middle East, Qatar has exhibited preliminary progress, where the Ministry of Education and Higher Education initiated a "Physical Fitness Evaluation for Public School Students" and published their report for the 2019 - 2020 academic year online [46]. The results included 104,191 students (50% Qatari nationals) who were evaluated for cardiorespiratory fitness, strength endurance, flexibility, speed, and consistency. Based on these findings, normative values were established for each fitness component. Qatar did not participate in the latest Global Matrix; therefore, these data were not included previous Report Cards and will likely be included in future ones.

### *Sources of Influence Indicators*

Globally, countries with very high HDIs typically scored the highest in the School indicator [36]. The most common grades assigned to this indicator among the 3 Arab Middle Eastern countries were D− and D, which are lower than the Asian and global averages (C+). It is worth noting that the School grades were partially affected by the variations in benchmarks used for grading throughout the Global Matrix iterations. Hence, it is difficult to directly compare this indicator across countries, regionally and globally. Having said that, many countries in Asia are still not performing well with school-related PA [19,20]. Although PE is mandated in most school curricula, the duration or frequency of classes does not always provide adequate amounts of PA to meet international guidelines. Additionally, the heavy focus on academic grades and achievements often causes students to neglect PE and overlook the importance of sports [20]. Given the benefits of PA to the overall well-being and academic performance of children and adolescents, it is essential for schools to place greater importance on PE classes and other sports within their curricula.

The influence of Families and Peers is multidimensional and demands extensive research for better understanding and assessment across regions and cultures [47]. Globally, this indicator had great variations (from INC to F to A+), with Asian countries globally scoring an average of C− [13,20]. Despite the recognized importance of social influences, the available data on this indicator remain limited and mostly incomplete in the 3 Arab Middle Eastern countries, mainly due to a lack of valid assessment tools. Community and Environment is another indicator that strongly influences children's and adolescents' engagement in PA and is assessed based on various factors such as local policies, infrastructure, the perception of safety, and access to green and blue spaces. Globally, the grades for this indicator varied between very high HDI countries (B) versus low, medium, and high HDI countries (C−) [36]. Further variations were observed across different regions such as Africa (D+), Asia-Pacific (C), Europe (B−), and the Anglosphere (B−) [13]. In Lebanon, Qatar, and the UAE, this indicator was marked INC across all Report Cards. This is due to a lack of consistent monitoring in these countries, which highlights a critical gap in understanding how the built and social environments support or hinder active lifestyles. To standardize the evaluation of these indicators, it is necessary to conduct periodic public household surveys aimed at assessing social and environmental factors related to PA. Addressing this gap is essential for informing urban planning and public health interventions and policies [48].

Finally, the government plays an important role in facilitating PA opportunities. In the UAE, the data suggested strong governmental support and leadership in promoting PA through national strategies, policies, and local initiatives. The "National Sports Strategy 2031" [49] aims to increase sports participation to 71% of the UAE population by enhancing access to both community-level and competitive sports. Further evidence included the "National Policy for Promoting Healthy Lifestyles" [50], "National Strategy for Wellbeing 2031" [51], and "Masar Project" [52]. Likewise, Qatar's highest grades were assigned to the Government indicator in both Report Cards, reflecting the country's commitment to supporting PA in the population. Some of Qatar's strategies that prioritized PA for children and adolescents included the "Qatar National Sports Day" [53], "Qatar National Physical Activity Guidelines" [54], and "National Health Strategy 2018-2022" [55]. Additionally, the WHO-Qatar partnership (2021 - 2024) on the FIFA (Fédération Internationale de Football Association) World Cup and health legacy played a significant role in advancing PA through global awareness campaigns [56]. Lebanon's results for the Government indicator reflected moderate efforts from both governmental and nongovernmental stakeholders, based on data from the 2018 Report Card [26]. Although existing policies focus on enhancing PA in schools, the implementation and coverage remained limited, and there was no indication of sustainable funding, evaluation, or national legislation mandating these efforts. As a result, Government grades declined in the latest Report Card (2022) for Lebanon. To maximize the benefits of these governmental initiatives and

XSL•FO
RenderX

programs, it is essential for all 3 countries to prioritize public education on the importance of PA across different domains.

## Report Card Team Recommendations for Improvement of Physical Activity Levels in the Region

In Global Matrix 3.0 (2018), Report Card members provided their top 3 priorities to improve the 10 common PA indicators in their respective countries. Based on these, we developed recommendations that are relevant to all 3 countries and the broader Middle East region for improving PA levels among children and adolescents.

### *Overall Physical Activity*

We recommend developing and implementing PA surveillance programs using nationally representative samples, with the aim of measuring subjective and objective estimates of PA across different domains.

### *Organized Sport and Physical Activity*

Our recommendations include improving access to affordable, well-structured organized sports within schools and communities; establishing talent identification programs and athlete development pathways that increase mass participation at the grass-roots level; and promoting PA participation among girls and children and adolescents with disabilities or chronic conditions.

### *Active Play*

For this PA domain, we recommend the integration of active play into urban planning by creating safe, accessible, and culturally appropriate play environments and the development of relevant surveillance tools.

### *Active Transportation*

Accelerating the development of safe and accessible infrastructures (eg, walking, running, and cycling path networks) within communities and cities could promote active transportation.

### *Physical Fitness*

We recommend developing and implementing nationwide standardized physical fitness tests and monitoring programs in school curricula, paired with targeted interventions to improve fitness and physical performance levels.

### *Sedentary Behavior*

Integration of regular active breaks in school lessons can interrupt long periods of sedentary behavior, and implementation of awareness campaigns could promote reductions in nonessential screen time.

### *School*

We recommend the development of physical literacy among students and maximizing the time spent in MVPA (minimum of 150 minutes per week during school time across all schools and grades) while offering fun, enjoyable, and skill-developing activities for both boys and girls.

### *Family and Peers*

Establishment of family-centered community PA initiatives and peer-led activity clubs in collaboration with municipalities and sports clubs are recommendations in this area.

### *Community and Environment*

Our recommendations include continued development and maintenance of accessible green and blue active spaces (ie, parks and beaches) for all children and adults to interact socially as well as the development and implementation of related surveillance systems.

### *Government*

Establishment of national multisectoral PA monitoring and accountability frameworks could support the implementation of health policies, PA guidelines, and school-based PA programs.

## Strengths and Limitations

To the best of our knowledge, this is the first study to synthesize and compare trends in PA indicators among children and adolescents in all Arab Middle Eastern countries participating in the AHKGA. The results were further compared with regional and global trends, offering valuable insights for policymakers. The study also highlighted major research and surveillance gaps and provided recommendations for the various PA indicators. Despite PA being an emerging area of research within the region, teams of PA researchers in each country retrieved and synthesized multiple data sources to grade several PA indicators over a 25-year period. When evaluating these grades and comparing between countries, we identified differences in data sources (ie, PA assessment was not harmonized across and within countries). This was carefully considered when comparing results and drawing conclusions.

The main limitation of this study was the lack of high-quality data for the majority of PA indicators (7/10, 70%) and the complete absence of data sources for the remaining 3 indicators (ie, Active Play, Physical Fitness, and Community and Environment). Specifically, there was a dearth of studies collecting accelerometer-derived objective estimates of PA using nationally representative samples. Certain indicators (eg, School, Family and Peers) were difficult to compare across the countries due to variations in the benchmarks used for grading. These challenges further point to the gaps in PA research within the region and the critical need for standardized and comprehensive PA surveillance studies.

## Conclusions

Children and adolescents in Lebanon, Qatar, and the UAE had low PA levels overall coupled with high levels of sedentary behavior. These results were consistent with regional findings and global trends. Overall, there was a dearth of data from representative samples in all 3 countries. There were significant gaps in specific indicators such as Active Play, Physical Fitness, and Community and Environment. Addressing the current challenges requires a thoughtful approach that considers the unique context of each country and promotes equitable access to opportunities for active living across the lifespan. There is a clear need for a standardized and comprehensive PA surveillance

XSL•FO
RenderX

strategy that assesses both self-report and objective estimates of PA among children and their parents. School remains an important opportunistic arena for increasing PA levels. Enhancing the quantity and quality of PE programs and extracurricular sports would maximize the proportion of children and adolescents receiving the health benefits of regular PA. Stakeholder collaboration is essential for developing evidence-informed, locally relevant plans that address the current implementation gap between policy and practice. Specifically, this requires educational authorities, municipalities, environmental agencies, and sports councils to implement a harmonized approach to providing PA opportunities for all children and adolescents.

## Acknowledgments

The authors would like to acknowledge the Active Healthy Kids Global Alliance (AHKGA) for organizing and leading the international initiative, developing the Physical Activity Report Card methodology, and standardizing the benchmarks and grading rubrics. We are also thankful to Report Card team members from Lebanon, Qatar and the United Arab Emirates (UAE) for all their dedicated hard work.

Responsibility for the final manuscript lies entirely with the authors. Generative artificial intelligence tools are not listed as authors and do not bear responsibility for the final outcomes. Declaration submitted by all authors of the manuscript (AB, LM, MJL, AMA, PAN, SS, ASA, JN, SA, MST, TL).

## Funding

No external financial support nor grants were received from any public, commercial, or not-for-profit entities for the research, authorship, or publication of this study. All authors are salaried staff of their respective institutions. The authors would like to thank Mohammed Bin Rashid University of Medicine and Health Sciences for payment of the article processing fee.

## Data Availability

All data reported and analyzed in this study were obtained from published sources and publicly available datasets as cited in the reference list.

## Abstract

**Background:** Future health professionals are expected to recommend vaccines, communicate with patients about vaccine safety, and support clinical trial literacy and recruitment during public health emergencies. However, their own willingness to participate in vaccine trials, and the barriers that shape that willingness, remain incompletely characterized across Europe.

**Objective:** This study aimed to assess willingness to participate in future vaccine trials among European students in health-related disciplines and to describe their perceived barriers, motivations, vaccine attitudes, and preferred sources of health information.

**Methods:** We conducted an open, multilingual, cross-sectional web survey within the VACCELERATE network from June to November 2023. National coordinators distributed the survey through institutional mailing lists, student associations, and program channels in participating European countries. Eligible participants were students aged 18 years or older enrolled in medicine, dentistry, nursing, pharmacy, psychology, biomedical sciences, physiotherapy, occupational therapy, or other health-related

XSL•FO
RenderX

programs. The questionnaire assessed demographic characteristics, primary sources of health information, vaccine attitudes, willingness to participate in future vaccine trials, barriers among unwilling or unsure respondents, and motivations for participation. Analyses were descriptive, and denominators varied by item because nonmandatory questions could be skipped.

**Results:** Of 1381 eligible respondents, 1192 (86.3%) answered the primary willingness question: 32.9% (n=392) were willing to participate in a future vaccine trial, 38.8% (n=463) were unsure, and 28.3% (n=337) were unwilling. Among the 769 respondents who were unwilling or unsure and selected barriers, the most frequent concerns were potential side effects (n=574, 74.6%) and not wanting to be a "test subject" (n=276, 35.9%). Among 1289 respondents included in the motivation analysis, commonly selected motivators included knowing the risks and side effects involved (n=575, 44.6%), becoming part of the solution to an important health problem (n=584, 45.3%), and knowing that personal safety would be protected (n=500, 38.8%).

**Conclusions:** In this multicountry European sample of health professional students, only one-third reported willingness to participate in future vaccine trials, while the largest group was unsure. The findings suggest that trial-readiness initiatives for future health professionals should prioritize transparent communication about safety monitoring, risks and side effects, participant protections, and the practical conduct of vaccine trials. Because recruitment used an open convenience approach, the results should be interpreted as exploratory and hypothesis generating rather than representative of all European health professional students.

## Introduction

The COVID-19 pandemic demonstrated that vaccine development alone is insufficient for an effective public health response. Vaccine confidence, transparent communication, and public willingness to participate in vaccine research are also essential components of epidemic and pandemic preparedness [1-4]. In this context, health care professionals (HCPs) occupy a central position because they translate scientific evidence into patient-facing recommendations and often serve as trusted sources of vaccine information.

Health professional students are a particularly relevant group for vaccine research readiness. Although they are not the only potential clinical-trial participants, they are future clinicians, pharmacists, dentists, nurses, psychologists, biomedical scientists, physiotherapists, and allied health professionals who may later recommend vaccines, counsel vaccine-hesitant patients, explain clinical-trial safeguards, and support recruitment to ethically conducted studies. Previous studies among health care students and young adults suggest that vaccine attitudes and willingness to participate in trials are shaped by knowledge, trust, perceived safety, prior vaccination behavior, and information sources [1,2,5-8]. Understanding this group can therefore inform both curriculum development and future trial-engagement strategies.

In Europe, VACCELERATE was established in 2021 to strengthen coordination and infrastructure for vaccine trials and to support preparedness beyond the acute COVID-19 pandemic emergency [4,9-16]. A research-ready workforce requires not only technical capacity but also future HCPs who understand vaccine-trial design, participant protections, safety oversight, and the ethical basis of voluntary participation.

Against this background, this VACCELERATE survey aimed to assess willingness among students in health-related disciplines across multiple European countries to participate in future vaccine trials. Secondary aims were to describe barriers among students who were unsure or unwilling, motivations among potential participants, vaccine attitudes, and preferred sources of health information. COVID-19 pandemic–specific willingness, pandemic-related attitude change, previous trial participation, and subgroup analyses were treated as secondary descriptive context and are reported mainly in the supplementary material.

## Methods

### Study Design and Reporting Guidelines

We conducted an open, multilingual, cross-sectional web survey between June and November 2023 among university students enrolled in health-related disciplines in participating European countries. The study is reported in accordance with relevant elements of the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) checklist for web-based surveys and the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidance for cross-sectional studies [17,18].

### Questionnaire Development

The questionnaire was developed specifically for the VACCELERATE survey to address the study objectives and included sections on demographics, health and COVID-19 vaccination status, previous clinical-trial participation, willingness to participate in COVID-19 and non–COVID-19 vaccine trials, perceived barriers and motivations, willingness to participate in nonvaccine clinical trials, and sources of health information. The questionnaire was piloted for clarity before dissemination but was not designed or validated as a psychometric instrument. The full English-language questionnaire is provided in Multimedia Appendix 1.

### Participants and Eligibility

Eligible participants were students aged 18 years or older who were enrolled in medicine, dentistry, nursing or midwifery,

XSL•FO
RenderX

pharmacy, psychology, biomedical sciences, physiotherapy, occupational therapy, or other health-related programs at participating institutions. Dentistry students were included because dental professionals contribute to prevention-oriented health counseling. The survey landing page described the study aims, voluntary nature of participation, data use, anonymity, and confidentiality. Proceeding beyond the landing page constituted electronic informed consent. Respondents could skip nonmandatory items and withdraw before submission.

### Survey Administration and Data Handling

The survey was open and hosted in Google Forms. No IP addresses, cookies, or direct identifiers were collected. Duplicate submissions were discouraged in the instructions and screened through time-stamp patterns and implausible repeated entries; no duplicates were flagged for exclusion. Not all items were mandatory, and item-level denominators therefore varied across analyses. The multiselect barrier and motivation items instructed respondents to select up to 3 options; however, the form did not technically enforce this limit. Responses exceeding 3 selections were excluded from the corresponding item-level analyses and this is acknowledged as a limitation. Data were exported to CSV and stored on secure institutional drives in accordance with applicable General Data Protection Regulation (GDPR) requirements.

### Outcomes and Variables

The primary outcome was self-reported willingness to participate in a future vaccine trial, assessed using the questionnaire item asking whether respondents would be interested in enrolling in a vaccine trial unrelated to COVID-19 pandemic (eg, for another infectious disease such as malaria, tuberculosis, or human papillomavirus). Responses were categorized as willing, unsure, or unwilling. Secondary outcomes included barriers among respondents who were unsure or unwilling, motivations for vaccine-trial participation, primary sources of health information, general vaccine attitudes, COVID-19 vaccine attitudes, previous participation in trials, and willingness to participate in COVID-19 vaccine and nonvaccine clinical trials. Health information sources were included because they may identify channels through which future trial-literacy interventions could be delivered; the questionnaire did not include formal coursework or curriculum as a separate option, which is noted as a limitation.

### Statistical Analysis

Categorical variables were summarized using frequencies and percentages. For each questionnaire item, percentages were calculated using the number of respondents who answered that specific item as the denominator. Because not all questionnaire items were mandatory, denominators varied between analyses.

The primary willingness outcome was presented using 3 response categories: willing, unsure, and unwilling. Respondents who selected “unsure” or “unwilling” were considered together only for the descriptive presentation of reported barriers.

Subgroup analyses by discipline, medical training stage, country of birth, and country of training region were descriptive. Missing responses were handled using item-level available-case analysis. Analyses were conducted using R (version 4.x; R Foundation for Statistical Computing) and Stata (version 17; StataCorp).

### Ethical Considerations

The study questionnaire received initial approval from the Cyprus National Bioethics Committee (EEBK ΕΠ 2021.01.118). The approval documentation was shared with participating countries, and additional local ethics approvals were obtained where required. Before accessing the questionnaire, potential participants were presented with an electronic study-information page describing the purpose of the study, eligibility criteria, voluntary nature of participation, intended use of the data, anonymity, confidentiality, and the right to withdraw before submitting the questionnaire. Participants were required to confirm their consent electronically before proceeding to the survey.

No names, IP addresses, cookies, or other direct personal identifiers were collected. Survey data were stored on secure institutional drives in accordance with applicable data protection requirements, including the GDPR. No financial compensation or other incentives were provided to participants.

### Missing and Item-Level Data

Not all participants answered all questions; therefore, denominators are reported separately for each item. Stratified analyses were descriptive and included discipline (medicine vs other health-related disciplines), medical training stage (preclinical medical students: years 1 - 3, clinical medical students: years 4 - 6), country of birth (European Union vs non–European Union), and country of training (northern European Union vs southern European Union). Participants reporting training in 2 countries contemporaneously (n=4) were excluded from the country of training analysis. Switzerland (n=1) and Norway (n=2) were also excluded from this stratification because they are not European Union member states. For vaccine-attitude items, “very positive” and “positive” were combined as “positive,” whereas “neutral,” “negative,” and “very negative” were combined as “neutral or negative.” For COVID-19 vaccine attitude, “very positive” and “positive” were combined as “positive,” whereas “neutral negative” and “very negative” were combined as “neutral or negative” to preserve cell sizes and improve interpretability. For self-reported health, the original response options were “very good,” “good,” “fair poor,” and “very poor.” For descriptive analysis, “very good” and “good” were combined as “good,” whereas “fair poor” and “very poor” were combined as “fair or poor.”

### Sample Size, Response Rate, Dissemination, and Recruitment

No formal a priori sample size calculation was performed because recruitment was based on a feasible, time-limited VACCELERATE network survey. The central study team prepared a standard survey invitation containing a brief description of the study, the eligibility criteria, and an open hyperlink to the online questionnaire. The invitation and survey link were circulated through the VACCELERATE network to national coordinators in participating European countries.

XSL•FO
RenderX

National coordinators facilitated dissemination within their respective countries through participating universities and other health professional training institutions. At the institutional level, the invitation was distributed through available institutional mailing lists, program- or course-level communication channels, student associations, and relevant student networks. Local institutional collaborators and, where applicable, student representatives supported the redistribution of the invitation to students enrolled in eligible health-related programs.

Recruitment followed a nonprobability convenience sampling approach. Participation was voluntary, and no financial or other incentives were provided. Because the questionnaire was accessed through an open link that could be redistributed within institutional and student networks, no centralized sampling frame was available. Therefore, the number of students who received or viewed the invitation could not be determined, and a formal response rate could not be calculated.

For the primary willingness item, 1192 respondents provided an answer. At this denominator, a proportion near 50% would have an approximate 95% precision of +2.8 to –2.8 percentage points, and the observed willing proportion of 32.9% would have an approximate precision of +2.7 to –2.7 percentage points. These calculations describe statistical precision only and do not overcome the potential selection bias inherent to convenience sampling.

## Results

### Participant Flow

A total of 1410 students submitted the online questionnaire. Twenty-six respondents were excluded because they did not meet eligibility prerequisites recorded in the screening questions, and 3 were excluded because they were no longer students. The final analytic sample therefore included 1381 eligible respondents. Because the survey was distributed through an open link, the denominator of all students who received or viewed the invitation could not be established.

### Country of Residence and Residential Setting

Respondents most resided in Germany (384/1381, 27.8%), Italy (189/1381, 13.7%), Cyprus (172/1381, 12.5%), the Czech Republic (170/1381, 12.3%), Sweden (167/1381, 12.1%), and Austria (108/1381, 7.8%).

Among respondents who reported a residential setting, 72.6% (1000/1378) lived in urban areas, 15.5% (214/1378) in semiurban areas, and 12% (164/1378) in rural areas (Table S1 in Multimedia Appendix 2). These results describe the responding sample and should not be interpreted as a representative distribution of European health professional students.

### Age, Gender, Health Status, Discipline, and Year of Training

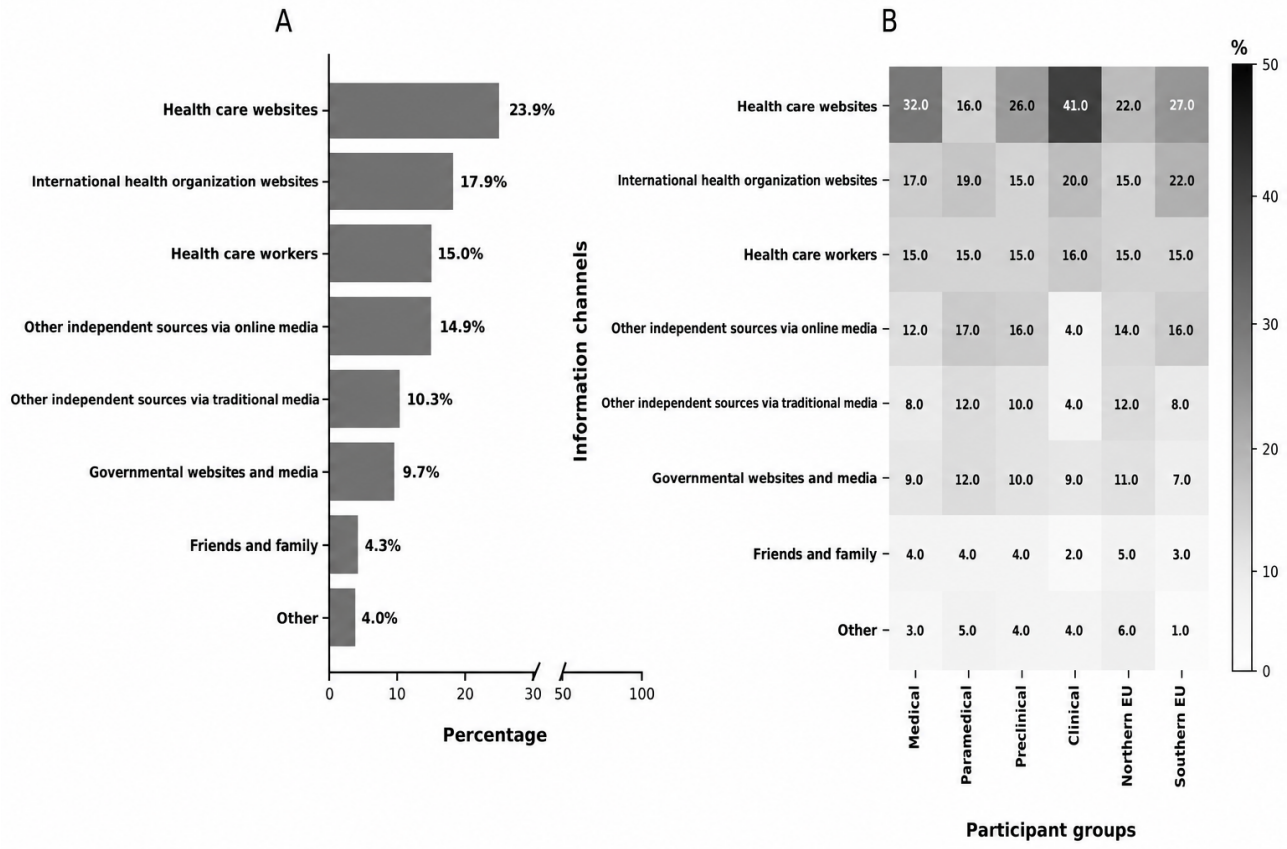
Among the 1373 respondents who reported age, most were aged 18 to 24 years (n=987, 71.9%), followed by 25 to 34 years (n=331, 24.1%), 35 to 64 years (n=54, 3.9%), and 65 years or older (n=1, 0.1%). The single respondent aged 65 years or older was retained because student status and eligibility were confirmed through the survey responses. Among 1379 respondents who reported gender, 68.8% (n=949) were female, 29.7% (n=409) were male, 0.8% (n=11) identified as nonbinary or other, and 0.7% (n=10) preferred not to disclose. Most respondents were medical students (920/1305, 70.5%), the remaining respondents were enrolled in nursing or midwifery, psychology, pharmacy, dentistry, biomedical sciences, physiotherapy, or occupational therapy (Table 1).

XSL•FO
RenderX

**Table .** Demographic characteristics, self-reported health status, discipline, and year of training among eligible respondents in a cross-sectional VACCELERATE web survey of European students in health-related disciplines (June-November 2023).

| Demographics | Participants, n (%) |
|---|---|
| Age group (n=1373; years) | |
| 18 to 24 | 987 (71.9) |
| 25 to 34 | 331 (24.1) |
| 35 to 64 | 54 (3.9) |
| >65 | 1 (0.1) |
| Gender (n=1379) | |
| Female | 949 (68.8) |
| Male | 409 (29.7) |
| Nonbinary or other | 11 (0.8) |
| Prefer not to say | 10 (0.7) |
| Health status (n=1380) | |
| Good | 1323 (95.9) |
| Fair or poor | 57 (4.1) |
| School of training (n=1305) | |
| Medicine | 920 (70.5) |
| Nursing (midwives) | 153 (11.7) |
| Psychology | 49 (3.8) |
| Pharmacy | 47 (3.6) |
| Dentistry | 46 (3.5) |
| Health sciences (biomedical sciences) | 41 (3.1) |
| Physiotherapy | 29 (2.2) |
| Occupational therapy | 20 (1.5) |
| Year of training (n=1318) | |
| First | 338 (25.6) |
| Second | 313 (23.7) |
| Third | 238 (18.1) |
| Fourth | 170 (12.9) |
| Fifth | 162 (12.3) |
| Sixth | 97 (7.4) |

Most respondents reported having good health (1323/1380, 95.9%), while only a few (57/1380, 4.1%) reported having fair or poor health. The largest discipline groups after medicine were nursing or midwifery (153/1305, 11.7%) and psychology (49/1305, 3.8%). Regarding year of training, the largest proportions were first-year students (338/1318, 25.6%) and second-year students (313/1318, 23.7%).

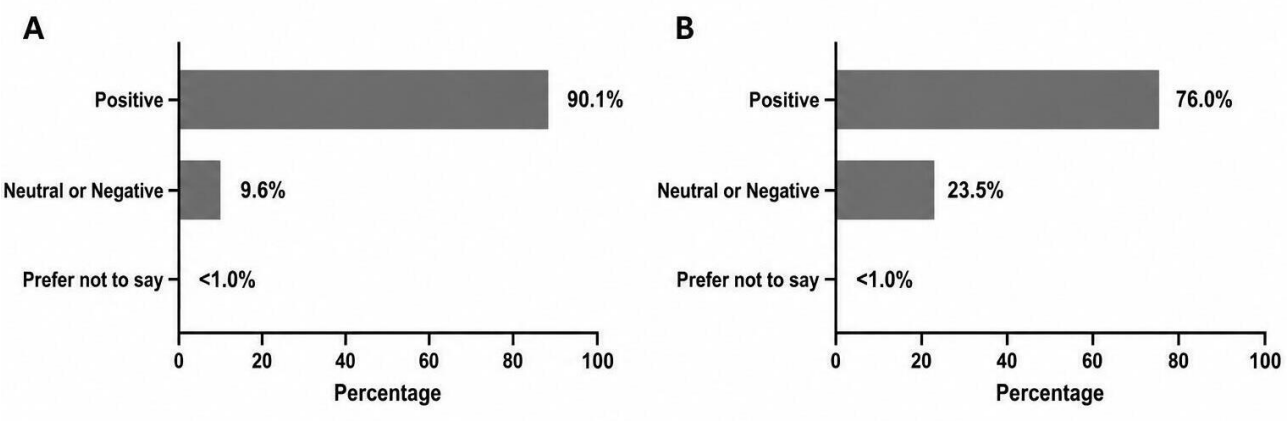


## Primary Sources of Health Information

Health information sources were included to identify potential channels for future trial-literacy interventions. Among 942 respondents, the most commonly reported primary sources were health care websites, such as Mayo Clinic, Medscape, or WebMD (n=225, 23.9%); international health organization websites (n=169, 17.9%); health care providers, such as physicians or nurses (n=141, 15%); and independent online media sources, such as blogs or social media pages, groups, or accounts (n=140, 14.9%; Figure 1A). Traditional media refers to television, radio, and newspapers. The questionnaire did not offer coursework or curriculum as a separate response option, which limits interpretation among students in health-related disciplines.

XSL•FO
RenderX

**Figure 1.** Primary sources of health information reported by respondents in a cross-sectional VACCELERATE web survey of European students in health-related disciplines, June-November 2023: (A) overall responses among students who answered the item (n=942); (B) descriptive heat map by subgroup (medical students, n=523; other health-related disciplines, n=345; preclinical medical students, n=317; clinical medical students, n=161; northern European Union (EU) training, n=533; southern EU training, n=396). Traditional media refers to television, radio, and newspapers.



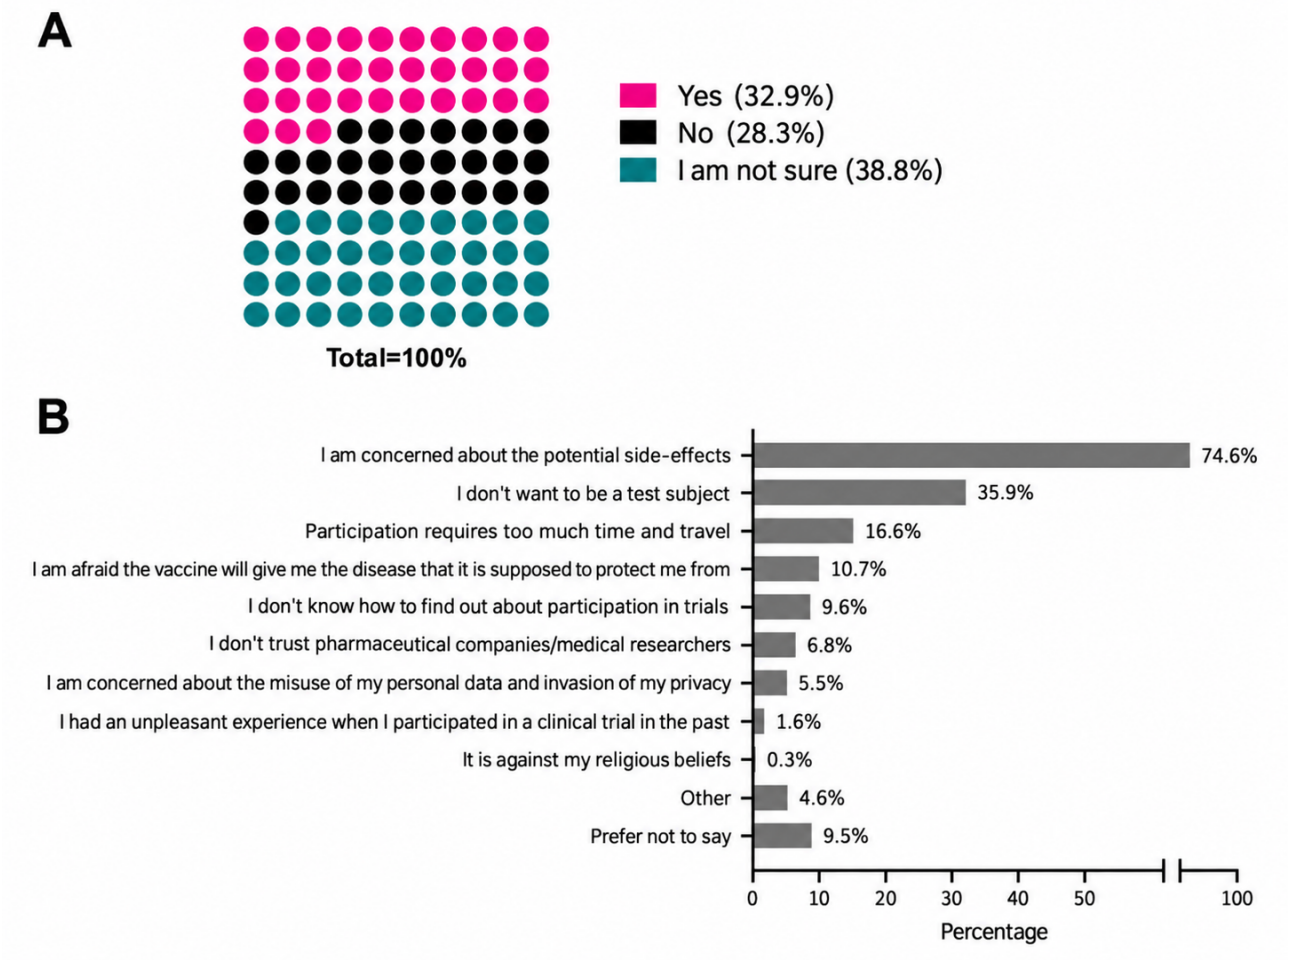
Descriptive stratification by discipline, medical training stage, and country of training is shown in Figure 1B. The heat map is descriptive and was not designed for formal pairwise statistical comparisons across groups.

## General and COVID-19 Vaccine Attitudes

Overall, 90.1% of respondents reported a positive attitude toward vaccination in general, whereas 9.6% reported a neutral or negative attitude. For COVID-19 vaccination, 76% reported a positive attitude, 23.5% reported a neutral or negative attitude, and fewer than 1% preferred not to say (Figure 2).

Detailed subgroup analyses of vaccine attitudes by discipline, medical training stage, country of birth can be found in Multimedia Appendix 2 (Figures S1-S3) to keep the main text focused on the primary study objectives. COVID-19 pandemic–specific attitude-change results and previous trial participation results can be found in Multimedia Appendix 2 (Figures S4-S6), as secondary descriptive context.

**Figure 2.** Attitudes toward (A) vaccination in general and (B) COVID-19 vaccination among respondents in a cross-sectional VACCELERATE web survey of European students in health-related disciplines, June-November 2023.



XSL•FO
RenderX

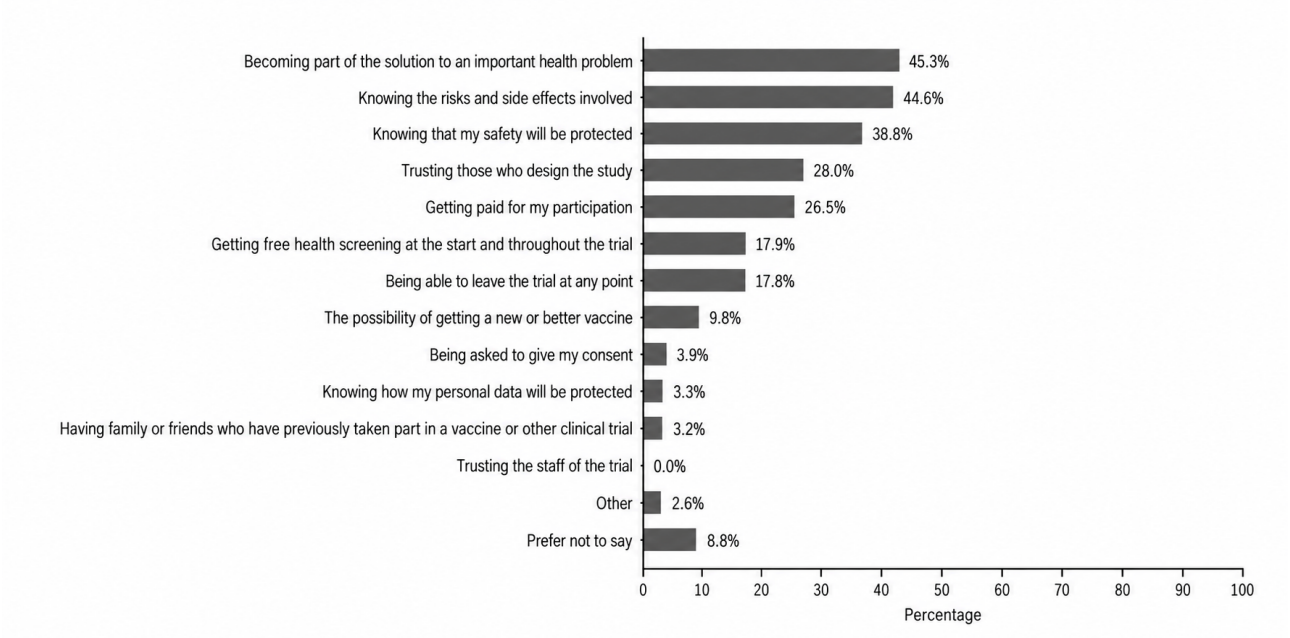
### Willingness to Participate in Future Vaccine Trials

Among 1192 respondents who answered the primary willingness question, the most common response was "I am not sure" (n=463, 38.8%), followed by "yes" (n=392, 32.9%), and "no" (n=337, 28.3%; Figure 3A).

**Figure 3.** Willingness to participate in future vaccine trials and barriers among unwilling or unsure respondents in a cross-sectional VACCELERATE web survey of European students in health-related disciplines (June-November 2023): (A) primary willingness outcome among respondents who answered the item (n=1192) and (B) barriers among respondents who answered "no" or "I am not sure" and selected up to 3 barriers (n=769). Percentages in panel B use respondents, not selections, as the denominator and should not be summed.

Respondents who answered "no" or "I am not sure" were asked to select up to 3 barriers. Among 769 respondents included in this item-level analysis, the most frequently selected barriers were concern about potential side effects (n=574, 74.6%), not wanting to be a "test subject" (n=276, 35.9%), participation requiring too much time or travel (n=128, 16.6%), concern that the vaccine could cause the disease it is intended to prevent (n=82, 10.7%), and not knowing how to find trial-participation opportunities (n=74, 9.6%; Figure 3B). Because the survey form did not technically enforce the 3-option limit, 6 responses exceeding 3 selections were excluded from this analysis.

Subgroup analyses of willingness to participate in COVID-19 vaccine, other infectious-agent vaccine, and nonvaccine trials are presented in Figure S7 in Multimedia Appendix 2, rather than in the main text.



### Motivations to Participate in Future Vaccine Trials

Respondents could select up to 3 motivators for enrolling in a non–COVID-19 vaccine trial. Of 1378 responses received, 89 exceeded the selection limit and were excluded, leaving 1289 respondents in the item-level analysis. The most commonly selected motivators were knowing the risks and side effects involved (n=575, 44.6%), becoming part of the solution to an important health problem (n=584, 45.3%), knowing that personal safety would be protected (n=500, 38.8%), trusting those who designed the study (n=361, 28%), and receiving compensation for participation (n=341, 26.5%; Figure 4).

XSL•FO
RenderX

**Figure 4.** Motivations for potential participation in a future non–COVID-19 vaccine trial among respondents in a cross-sectional VACCELERATE web survey of European students in health-related disciplines (June-November 2023). Respondents could select up to 3 options; percentages use the number of respondents included in the item-level analysis (n=1289) as the denominator and should not be summed.

## Discussion

### Main Findings

This multicountry VACCELERATE survey found that willingness to participate in future vaccine trials among students in health-related disciplines was mixed: approximately one-third were willing, more than one-third were unsure, and more than one-quarter were unwilling. The predominance of an "unsure" group is important because it identifies a potentially reachable population for trial-literacy education, transparent communication about participant protections, and practical information about how vaccine trials are conducted.

The main barriers reported by unsure or unwilling respondents were concern about side effects and reluctance to be a "test subject." These findings are notable because they arose in a population that is already training for health-related professions and reported generally favorable vaccine attitudes. They suggest that positive attitudes toward vaccination do not automatically translate into willingness to participate in vaccine trials. Educational approaches for future HCPs should therefore distinguish vaccine confidence from clinical-trial literacy, including safety monitoring, ethics review, informed consent, data protection, and the right to withdraw.

Motivators for potential participation also point toward modifiable recruitment and education targets. Respondents emphasized knowing the risks and side effects involved, knowing that their safety would be protected, and contributing to the solution of an important health problem. Recruitment materials and curricula that address both altruistic and self-protective motivations may therefore be more effective than messages focused only on public benefit.

These results align with prior studies showing that vaccine attitudes and trial willingness among students and health care workers are influenced by trust, safety concerns, knowledge, and information sources [1-3,5-8]. The present survey extends this literature by focusing on a multicountry European sample of future HCPs within a vaccine-trial preparedness network. Because students will later serve as patient counselors, role models, and sources of health information, their understanding of vaccine research may influence both future patient communication and trial recruitment.

The practical implication is that pandemic preparedness should include trial-literacy training for future HCPs, not only vaccine-knowledge training. Such training could address how trials are reviewed, how risks are monitored, how adverse events are managed, how personal data are protected, and how participants can find legitimate opportunities to enroll.

### Limitations

Several limitations should be considered. The survey used an open convenience sampling approach through the VACCELERATE national coordinators and institutional and student networks, so the number of students who received or viewed the invitation could not be determined, and a response rate could not be calculated. The sample should not be interpreted as representative of all European students in health-related disciplines. Selection bias is likely because students with stronger vaccine interest, stronger research interest, or greater trust in institutions may have been more likely to respond.

The data are self-reported and cross-sectional, which precludes causal inference. The questionnaire was developed for this VACCELERATE survey and piloted for clarity but was not a fully validated psychometric instrument. Some response categories were collapsed to improve interpretability and cell sizes, which may reduce granularity. The multiselect barrier and motivation items did not technically enforce the 3-option limit at data entry, leading to post hoc exclusion of responses

XSL•FO
RenderX

exceeding the limit. In addition, the survey did not include coursework or curriculum as a specific health information source, and the June to November 2023 recruitment window provides a time-specific postpandemic snapshot rather than a current longitudinal assessment.

The barrier categories of "concern about potential side effects" and "not wanting to be a test subject" may overlap conceptually, and the present survey cannot determine whether they reflect distinct concerns or a shared underlying perception of risk. Qualitative follow-up through interviews or focus groups would be valuable to understand these concerns in greater depth and to design more precise educational interventions.

### Conclusions

This VACCELERATE survey suggests that many European students in health-related disciplines hold positive vaccine attitudes but remain uncertain about personal participation in future vaccine trials. Addressing concerns about side effects, participant protections, trial oversight, and practical trial logistics may help strengthen clinical-trial literacy among future HCPs and support a more research-ready health care workforce.

### Acknowledgments

The authors thank Marianna Michalettou, Maria Fyrilla, Antonis Pikoulos, Anna Kritharidou, and Georgia Barbagianni for their voluntary logistical assistance with survey dissemination and local coordination support. These contributors did not participate in study conception, data analysis, interpretation, manuscript drafting, or final approval of the manuscript and therefore did not meet authorship criteria.

The authors declare the use of generative AI (GenAI) in the research and writing process. According to the Generative AI Delegation Taxonomy (2025), the following tasks were delegated to GenAI tools under full human supervision: evaluation of the novelty of the research and identification of gaps, proofreading and editing, translation, and reformatting. The GenAI tool used was ChatGPT (OpenAI). Responsibility for the final manuscript lies entirely with the authors. GenAI tools are not listed as authors and do not bear responsibility for the final outcomes.

### Funding

This research was funded by the European Union's Horizon 2020 research and innovation program (grant agreement 101037867, VACCELERATE).

### Data Availability

Aggregate data relevant to the research are included in the manuscript and supplementary materials. Additional deidentified data may be available from the corresponding author upon reasonable request and subject to applicable ethics, privacy, and consortium requirements.

### Conflicts of Interest

All authors, excluding OAC, have no competing interests as defined, or other interests that might be perceived to influence the results and/or discussion reported in this paper. All the authors excluding OAC have no relevant financial or nonfinancial interests to disclose. OAC reports grants or contracts from BMBF, Cidara, DZIF, EU-DG RTD, F2G, Gilead, MedPace, MSD, Mundipharma, Octapharma, Pfizer, and Scynexis; consulting fees from AbbVie, AiCuris, Basilea, Biocon, Boston Strategic Partners, Cidara, Seqirus, Gilead, GSK, IQVIA, Janssen, Matinas, MedPace, Menarini, Molecular Partners, MSG-ERC, Mundipharma, Noxxon, Octapharma, Pardes, Partner Therapeutics, Pfizer, PSI, Scynexis, Seres, Shionogi, and The Prime Meridian Group; speaker and lecture honoraria from Abbott, AbbVie, Akademie für Infektionsmedizin, Al-Jazeera Pharmaceuticals and Hikma, amedes, AstraZeneca, Deutscher Ärzteverlag, Gilead, GSK, Grupo Biotoscana, United Medical, Knight, Ipsen Pharma, Medscape, WebMD, MedUpdate, MSD, Moderna, Mundipharma, Noscendo, Paul-Martini-Stiftung, Pfizer, Sandoz, Seqirus, Shionogi, streamedup!, Touch Independent, and Vitis; payment for expert testimony from Cidara; and participation in a DRC, DSMB, or advisory board for Cidara, IQVIA, Janssen, MedPace, PSI, Pulmocide, and Vedanta Biosciences.

## Abstract

**Background:** Nonalcoholic fatty liver disease (NAFLD) is a global public health challenge, yet its relationship between occupational noise exposure and perceived noise impact remains unclear.

**Objective:** We characterized maritime noise exposure patterns and examined the associations of noise exposure, perceived noise impact, and BMI with NAFLD among seafarers.

**Methods:** A population-based survey was conducted from March to May 2024 through the China Shipowners' Association. Participants completed a structured online questionnaire. Noise exposure was assessed via self-report, and NAFLD presence was determined by self-reported physician diagnoses based on the 2018 updated NAFLD guidelines.

**Results:** A total of 8143 male seafarers was included, with an overall NAFLD prevalence of 18.5% (n=1503). The prevalence was significantly higher among seafarers with a BMI of 24.0 kg/m² or above (25.9%, n=1261), chronic noise exposure (19.4%, n=1293), and higher perceived noise impact (slightly: 16.9%, n=589; moderate: 19.1%, n=359; significant: 22.5%, n=511). Among seafarers with a BMI of 24.0 kg/m² or above, chronic noise exposure and higher perceived noise impact were significantly associated with an elevated risk of NAFLD. After full adjustment, the combined association of chronic noise exposure and higher perceived noise impact remained significantly associated with increased NAFLD risk, with consistent patterns observed across both workplace and rest area settings. A significant interaction was also observed between rest-area noise exposure and perceived noise impact in this BMI subgroup.

**Conclusions:** Noise exposure, perceived noise impact, and BMI were significantly associated with NAFLD among seafarers. These findings highlight the importance of optimizing occupational health benefits, especially among those with metabolic disorders.

noise exposure; perceived noise impact; nonalcoholic fatty liver disease; NAFLD; seafarers; occupational health; BMI

## Introduction

Nonalcoholic fatty liver disease (NAFLD) has emerged as a critical global public health challenge among chronic noncommunicable diseases [1]. Over the past decades, its worldwide prevalence has risen dramatically, from 25.5% before 2005 to 37.8% after 2016 [2]; in China, the prevalence has also increased significantly, climbing from 23.8% in the early 2000s to 32.9% in 2018 [3]. NAFLD encompasses a spectrum of liver conditions, progressing from simple hepatic steatosis to steatohepatitis, which may gradually develop into fibrosis and ultimately advance to cirrhosis or hepatocellular carcinoma [4]. Furthermore, NAFLD is associated with various extrahepatic complications, including cardiovascular diseases, type 2 diabetes, and chronic kidney disease [5]. Its pathogenesis involves multiple factors, such as genetic, nutritional, and

XSL•FO
RenderX

environmental determinants [6], with chronic noise exposure and its related psychological impacts emerging as a potential environmental trigger that has received insufficient attention.

Chronic noise exposure is known to significantly elevate cortisol levels and contribute to obesity-related metabolic disorders [7,8]—2 key risk factors for NAFLD. Animal experiments demonstrate that 3 months of chronic low-intensity noise exposure exacerbates NAFLD in high-fat diet–fed mice by activating the hypothalamic-pituitary-adrenal (HPA) axis [9]. Additionally, noise may indirectly promote hepatic lipid accumulation by disrupting circadian sleep rhythms [10]. This evidence is particularly relevant to seafarers, a globally neglected occupational group who experience unavoidable noise exposure during voyages alongside a high metabolic burden. The maritime settings are plagued by noise pollution from propulsion systems, power plants, and structural vibrations aboard vessels [11], and seafarers are continuously exposed to excessive noise during voyages, as both working places and living quarters are confined to ships. Notably, obesity-related metabolic disorders are already a major health burden among seafarers [12], further highlighting their vulnerability to NAFLD.

However, few studies have explored the unique exposures among seafarers that are associated with NAFLD. Most studies on NAFLD focus on traditional metabolic factors (eg, BMI, diet), which are typically derived from the general population, while 2 important factors—chronic noise exposure and perceived noise impact—remain understudied in the context of NAFLD. Crucially, emerging evidence indicates that perceived noise and its perceived impact, as the key sources of psychological distress, may independently amplify some disease risks [13-15]. However, such effects have been predominantly documented in mental health outcomes, with no exploration of their potential link to NAFLD.

Therefore, even studies investigating the association between noise exposure, perceived noise impact, and NAFLD remain scarce in the general population, let alone in occupational groups such as seafarers. To the best of our knowledge, no comprehensive epidemiological studies have systematically evaluated the prevalence of NAFLD or its association with noise exposure or perceived noise impact specifically among seafarers. Given the potential progression of NAFLD to liver fibrosis, it poses long-term health and occupational risks for seafarers, and seafarer health directly impacts workforce efficiency and maritime safety, as poor health may impair job performance and increase accident risks [16]. Since NAFLD is reversible, investigating its disease burden among seafarers and analyzing the impacts of noise exposure, noise sensitivity, and metabolic disorder are essential for targeted prevention strategies.

Against this backdrop, we conducted a large-scale cross-sectional study with three primary objectives: (1) to estimate the prevalence of NAFLD among seafarers; (2) to characterize the unique noise exposure patterns in maritime environments; and (3) to examine the association of noise exposure, perceived noise impact, and BMI on NAFLD. This study may yield evidence not only for the specific prevention and treatment of NAFLD but also for an evidence base to inform ship design and health management strategies.

# Methods

## Study Design and Participants

This cross-sectional study is the baseline survey of the Seafarers Health Cohort of China, which is an ongoing large-scale health surveillance cohort aiming to promote physical and mental health among seafarers in China.

Participants were recruited from March to May 2024 in collaboration with the China Shipowners' Association (CSA). As a national authoritative maritime industry organization, the CSA consists of nearly 400 domestic and international member entities, including shipowners, shipping operators, vessel managers, as well as shipping insurance, financial institutions, maritime research institutes, and universities. Its member enterprises account for more than 85% of China's national maritime transport capacity. This membership system encompasses both national leading shipping conglomerates and numerous local professional maritime service institutions.

Considering seafarers' frequent cross-regional mobility and irregular work schedules, all recruitment and data collection procedures were conducted online using a structured electronic questionnaire hosted on the Wenjuanxing survey platform [17]. This allowed participants to complete the survey either on board or on shore leave, without geographical constraints. A standardized, multistage recruitment procedure was followed across all participating institutions. The research team developed a unified study protocol and the electronic questionnaire. The questionnaire link and recruitment notice were distributed by the CSA through its official communication channels to the designated contacts at each participating enterprise. The coordinators were then responsible for forwarding the survey invitation to all active seafarers within their respective companies. The recruitment strategy covered all occupational ranks and departments, with no artificial screening or selective exclusion. All eligible seafarers accessed the survey voluntarily and completed it independently, free from managerial supervision or external interference. Participants were informed of their right to decline or withdraw from the survey at any time.

Several exclusion criteria were applied to the final analytical sample. Participants with preexisting hepatic conditions were excluded, including viral hepatitis (hepatitis B, C, etc), drug-induced liver injury, autoimmune liver diseases, and inherited metabolic liver disorders. Female seafarers accounted for merely 0.85% (n=70) of the original sample and were excluded from formal analyses due to extremely limited sample size. The characteristic comparisons between excluded female seafarers and included male seafarers are presented in Table S2 (Multimedia Appendix 1). Additionally, participants with missing BMI records were also excluded (Figure S1 in Multimedia Appendix 1).

## Ethical Considerations

This study was approved by the Institutional Review Board of Ruijin Hospital (approval number: 2023248). Written informed consent was obtained from all study participants before enrollment. Prior to data analyses, complete anonymization of all study datasets was performed to protect participants' privacy

XSL•FO
RenderX

and maintain information confidentiality. No financial remuneration was offered to participants for their involvement in this research. In addition, none of the images and figures in the manuscript and supplementary materials contains any information that could identify individual participants.

## Measurement

### *Noise Exposure*

Noise exposure among seafarers was assessed using a self-designed 4-item scale, developed based on previous studies and expert consultations [15,18]. The first question assessed whether seafarers had chronic noise exposure, such as crew working in the engine department. The second and third questions required seafarers to rate the noise levels in their working environment and rest area, respectively, using the 4-point Likert scale: quiet, moderate, noisy, and very noisy. For subsequent analyses, to avoid sparse strata with insufficient sample sizes, we combined quiet with moderate and noisy with very noisy, yielding 2 categories: quiet or moderate and rather noisy. Finally, the fourth item evaluated the perceived impact of noise exposure on rest and sleep during the voyage, also scored on a 4-point Likert scale: no effect, slight, moderate, and significant.

### *BMI Category*

The BMI was calculated by dividing weight in kilograms by the square of height in meters [BMI = weight (kg)/height (m) [2]. In accordance with the Chinese health industry standard *Criteria for weight classification of adults* (WS/T 428 - 2013), all participants were stratified into 2 subgroups: normal weight (BMI <24.0 kg/m²) and overweight or obese group (BMI ≥24.0 kg/m²) [19].

### *Measurement of Covariates*

Covariates in this study included demographic features, lifestyle, occupational characteristics, and comorbidity. Demographic variables included age, ethnicity (Han vs ethnic minority), household registration type (Hukou; rural vs urban), marital status (unmarried, married, or others), and education level (bachelor's degree or higher vs below). Lifestyle variables covered smoking status (never, previous, or current), alcohol drinking frequency, physical activity habits both onshore and offshore, dietary patterns, and sleep duration. Alcohol drinking behavior was evaluated based on drinking frequency in the past month, categorized as 4 or more times/week, 1 - 3 times/week, 1 - 2 times/month, and less than 1 time/month. Participants who reported drinking alcohol 4 or more times/week were defined as frequent drinkers. In addition, daily ethanol intake (grams) was further calculated for each participant using the formula: Alcohol intake (g) = consumed volume (mL) × ethanol concentration (%) × 0.79 (density conversion coefficient of ethanol). Dietary patterns were constructed based on 3 items: frequency of breakfast consumption, regularity of meal times, and balance of meat-to-vegetable intake in daily meals. A "healthy diet" was defined as meeting all 3 of the following criteria: consuming breakfast 5 or more times per week, having meals at regular times 5 or more times per week, and maintaining a balanced mix of meat and vegetables in the daily diet. Occupational characteristics included years of service in the current position, months per shipboard duty tour, daily working hours on broad, number of job position changes, shift work status (yes vs no; for those who worked shifts, periods were categorized as 4:00 AM-8:00 AM or 4:00 PM-8:00 PM, 8:00 AM-12:00 PM or 8:00 PM-12:00 AM, 12:00 AM-4:00 AM or 12:00 PM-4:00 PM, and others), and monthly income (>8000 vs ≤8000 yuan [CNY ¥1=US $0.149 as of September 9, 2026]). Comorbidities included hypertension, dyslipidemia, and diabetes mellitus/impaired glucose tolerance (DM/IGT).

### *Assessment of Outcome*

NAFLD status was ascertained using self-reported physician-diagnosed fatty liver disease data obtained from the study questionnaire, which allowed assessment of the disease burden among maritime occupational workers. In accordance with the *2018 updated guidelines for NAFLD prevention and management* [20], individuals with excessive alcohol consumption (defined as ≥30 g/day for men) were excluded from the NAFLD case definition. Those with a positive fatty liver diagnosis and alcohol intake below this threshold were classified as having NAFLD.

## Statistical Analysis

Descriptive characteristics of seafarers were described as mean (SD) or median (IQR) for continuous variables and numbers and percentages for categorical variables. The Student *t* test and Kruskal-Wallis tests were used for continuous variables, and $\chi^2$ test was used for categorical variables in comparing characteristics differences between the groups, as appropriate. Harman's single-factor test incorporating all 123 questionnaire items was conducted to assess common method bias. The first factor accounted for 19.94% of the total variance, which fell below the 40% threshold, indicating that common method bias was unlikely to be a major concern (Table S1 in Multimedia Appendix 1).

The prevalence of NAFLD was estimated across strata by demographic characteristics, lifestyle factors, occupational characteristics, comorbidity, noise exposure, as well as perceived impact of noise. To explore the associations of noise exposure and perceived noise impact with NAFLD, we performed a series of age-adjusted and fully adjusted logistic regression, calculating odds ratios (ORs) and 95% CIs. Next, we estimated the prevalence, ORs, and 95% CIs of NAFLD stratified by noise exposure and BMI, as well as by perceived noise impact and BMI. In addition, we explored the combined associations of noise exposure and perceived noise impact with NAFLD and further examined these combined associations stratified by noise levels at different locations (workplace and rest areas). Multiplicative interactions between noise exposure, location-specific noise levels, and perceived noise impact were tested by including product terms in the regression models, and the corresponding interaction *P* values were calculated. All models were adjusted for age, educational level, marital status, household registration, smoking status, physical activity, dietary habits, shift work, monthly income, sleep duration, hypertension, dyslipidemia, DM/IGT, and BMI as a continuous variable.

To assess the robustness of our findings, we conducted sensitivity analyses excluding participants with hearing loss

XSL•FO
RenderX

and reestimated both the independent and combined associations. All analyses were performed using Stata (Stata Corporation). A 2-tailed *P* value of <.05 was considered to be statistically significant.

## Results

### Characteristics of Chinese Seafarers

A total of 8143 male seafarers were included in the final analysis, with a median age of 39 (IQR 33 - 49) years. Over half (n=4868, 59.8%) of the participants had a BMI of 24.0 $kg/m^2$ or above. The demographic characteristics of the study population are presented in Table 1. Compared with those without NAFLD, individuals with NAFLD tended to be older and more likely to be married, and had higher proportions of smoking, frequent alcohol consumption, and lack of regular exercise. They also tended to have shorter sleep duration. Participants with NAFLD also had significantly higher prevalence of hypertension, dyslipidemia, and DM/IGT (all *P*<.001). Notably, the proportions of overweight or obesity, exposure to chronic workplace noise, and high perceived noise impact were significantly higher among individuals with NAFLD. The distributions of various noise exposure types and perceived noise impact are illustrated in Figures S2 to S4 (Multimedia Appendix 1).

## The Prevalence and Associated Factors of NAFLD Among Seafarers

### *Overall Prevalence and Multivariate Regression Analysis*

The overall prevalence of NAFLD is 18.5% (1503/8143). Table 2 presents the prevalence and associated factors of NAFLD among seafarers. Overall, the prevalence of NAFLD was significantly higher among seafarers with a BMI 24.0 kg/m² or above (25.9%, 1261/4868 vs 7.2%, 236/3275), chronic noise exposure (19.4%, 1293/6670 vs 13.8%, 204/1473), higher perceived noise impact (slightly: 16.9%, 589/3490; moderate: 19.1%, 359/1879; significant: 22.5%, 511/2273 vs no effect: 7.6%, 38/501), hypertension (42.5%, 352/828 vs 15.7%, 1151/7315), dyslipidemia (53.3%, 152/285 vs 17.2%, 1351/7858), and DM/IGT (48.7%, 108/222 vs. 17.6%, 1395/7921; all *P*<.001). Additionally, participants with NAFLD were more likely to be older, urban residents, highly educated, former smokers, and those with higher income and shorter sleep duration (Table 2).

[f]Not applicable. The corresponding variables were not included in the multivariable regression model.

[g]This variable only describes shift workers and was therefore excluded from the final multivariate regression model.

[h]DM/IGT: diabetes mellitus/impaired glucose tolerance.

The increased risk of NAFLD was associated with a BMI of 24.0 kg/m² or above (adjusted odds ratio [aOR] 4.12, 95% CI 3.53 - 4.80), chronic noise exposure (aOR 1.22, 95% CI 1.03 - 1.46), higher perceived noise impact (reference: no effect; slightly: aOR 2.15, 95% CI 1.49 - 3.12; moderate: aOR 2.31, 95% CI 1.58 - 3.38; significant: aOR 2.20, 95% CI 1.51 - 3.21), age of 50 years or above (reference: age <30 years; aOR 1.25, 95% CI 1.39 - 3.46), urban residency (aOR 1.37, 95% CI 1.20 - 1.58), former smoker (aOR 1.18, 95% CI 1.02 - 1.36), one position change (aOR 1.40, 95% CI 1.12 - 1.75), shorter sleep duration (reference: >7 h; 6-7 h: aOR 1.39, 95% CI 1.17 - 1.66; 5 - 6 h: aOR 1.73, 95% CI 1.46 - 2.06;<5 hours: aOR 1.72, 95% CI 1.27 - 2.33), hypertension (aOR 2.17, 95% CI 1.82 - 2.58), dyslipidemia (aOR 3.45, 95% CI 2.63 - 4.52), and DM/IGT (aOR 3.50, 95% CI 2.58 - 4.75). Conversely, frequent exercise (reference: no regular exercise routine; exercise at home: aOR 0.73, 95% CI 0.63 - 0.85; exercise at home and on board: aOR 0.65, 95% CI 0.52 - 0.80) and a healthy diet (aOR 0.83, 95% CI 0.69 - 0.99) were associated with lower risk of NAFLD.

### *Associations of Noise Exposure and Perceived Noise Impact With NAFLD Across BMI Categories*

Across all noise exposure and perceived impact levels, seafarers with a BMI of 24.0 kg/m² or above had a significantly higher prevalence of NAFLD (all *P*<.001; Figure 1A and B).

XSL•FO
RenderX

**Figure 1.** Prevalence and associations of nonalcoholic fatty liver disease (NAFLD) with chronic noise exposure and perceived noise impact stratified by BMI category. (A) and (B) show the prevalence of NAFLD across chronic noise exposure status and perceived noise impact, respectively, stratified by BMI category groups. Bars represent the prevalence (with 95% CIs) of NAFLD. *P* values for trend in (A) and (B) were calculated for both BMI categories, but only the statistically significant values were presented. Forest plots (C) and (D) illustrate the associations of chronic noise exposure and perceived noise impact, respectively, with NAFLD by BMI category. Different colors represent different BMI groups. All multivariate regression models were adjusted for age, household registration, marital status, education, smoking status, physical activity, dietary habits, shift work, monthly income, sleep duration, hypertension, dyslipidemia, diabetes mellitus or impaired glucose tolerance, and BMI (continuous variable). aOR: adjusted odds ratio.

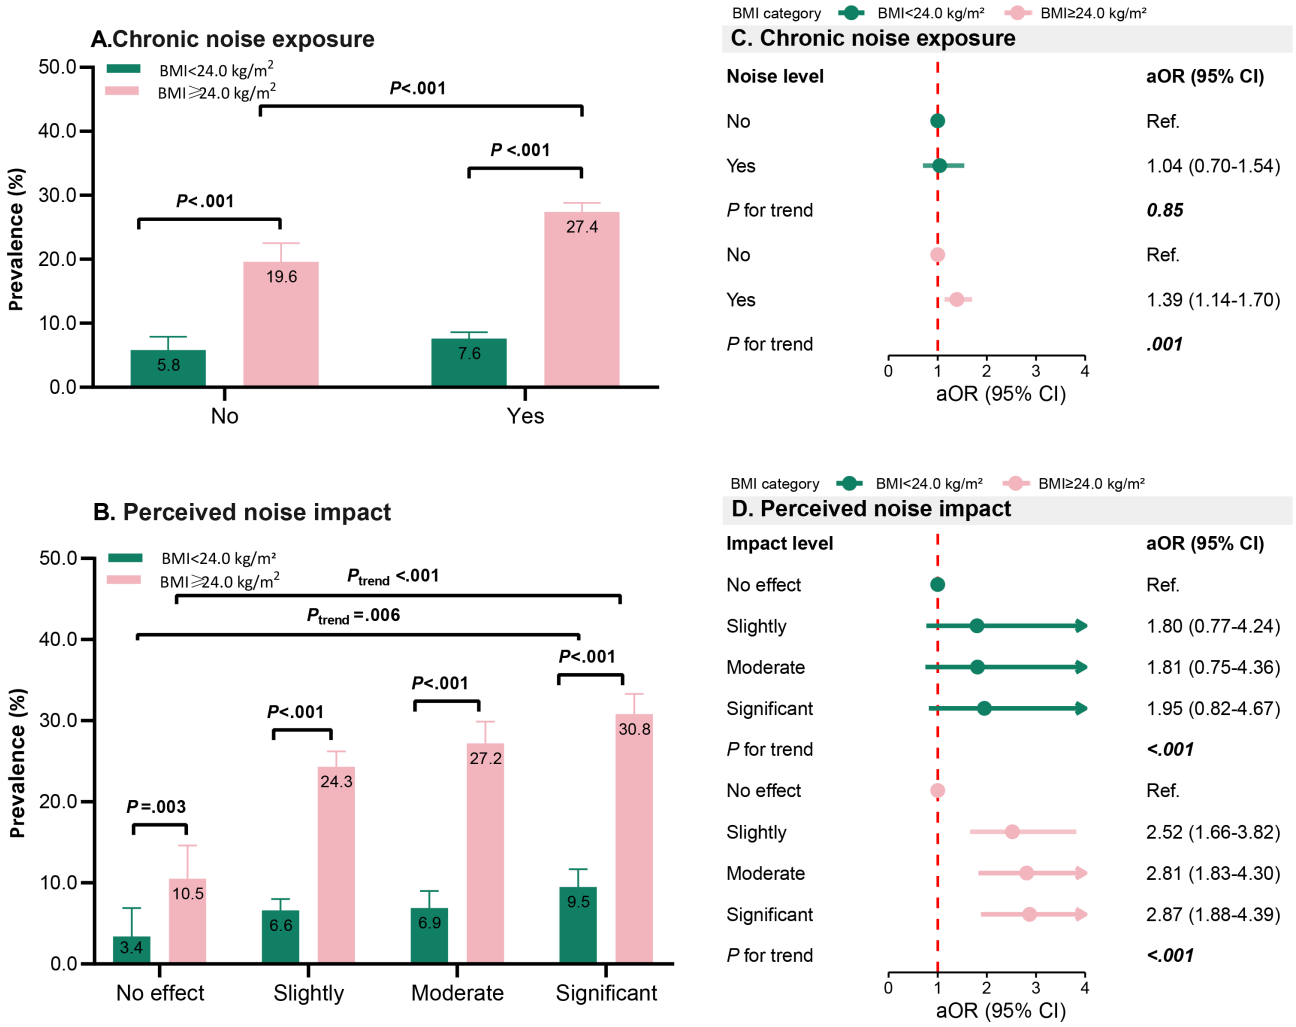

Figure 1A shows the NAFLD prevalence by chronic noise exposure and BMI group. Among the BMI ≥24.0 kg/m² group, those with chronic noise exposure showed a significantly higher prevalence of NAFLD (*P*<.001). However, among the BMI<24.0 kg/m² group, no significant difference in NAFLD prevalence was observed between the noise-exposed and nonexposed groups. Multivariate logistic regression further showed that chronic noise exposure was significantly associated with higher risk of NAFLD in this subgroup (aOR 1.39, 95% CI 1.14 - 1.70; Figure 1C). Additionally, NAFLD prevalence rose alongside higher noise exposure in workplace and resting environments, yet no significant association was observed in multivariate regression analyses (Figure S5 in Multimedia Appendix 1).

Figure 1B also shows an uptrend in NAFLD prevalence as perceived noise impact increased in both BMI groups ($P_{trend}$=.006 for BMI <24.0 kg/m², and $P_{trend}$<.001 for BMI ≥24.0 kg/m²). When perceived noise impact was included as a categorical variable in the model, it was significantly associated with higher risk of NAFLD among the group of BMI ≥24.0 kg/m² (reference: no effect; slightly: aOR 2.52, 95% CI 1.66 - 3.82; moderate: aOR 2.81, 95% CI 1.83 - 4.30; significant: aOR 2.87 95% CI 1.88 - 4.39; Figure 1D). Results stratified by BMI into the normal weight, overweight, and obese subgroups are also presented in Table S3 (Multimedia Appendix 1), which were consistent with the above findings. Significant positive associations with NAFLD were observed only in the overweight and obese subgroups for both chronic noise exposure and perceived noise impact.

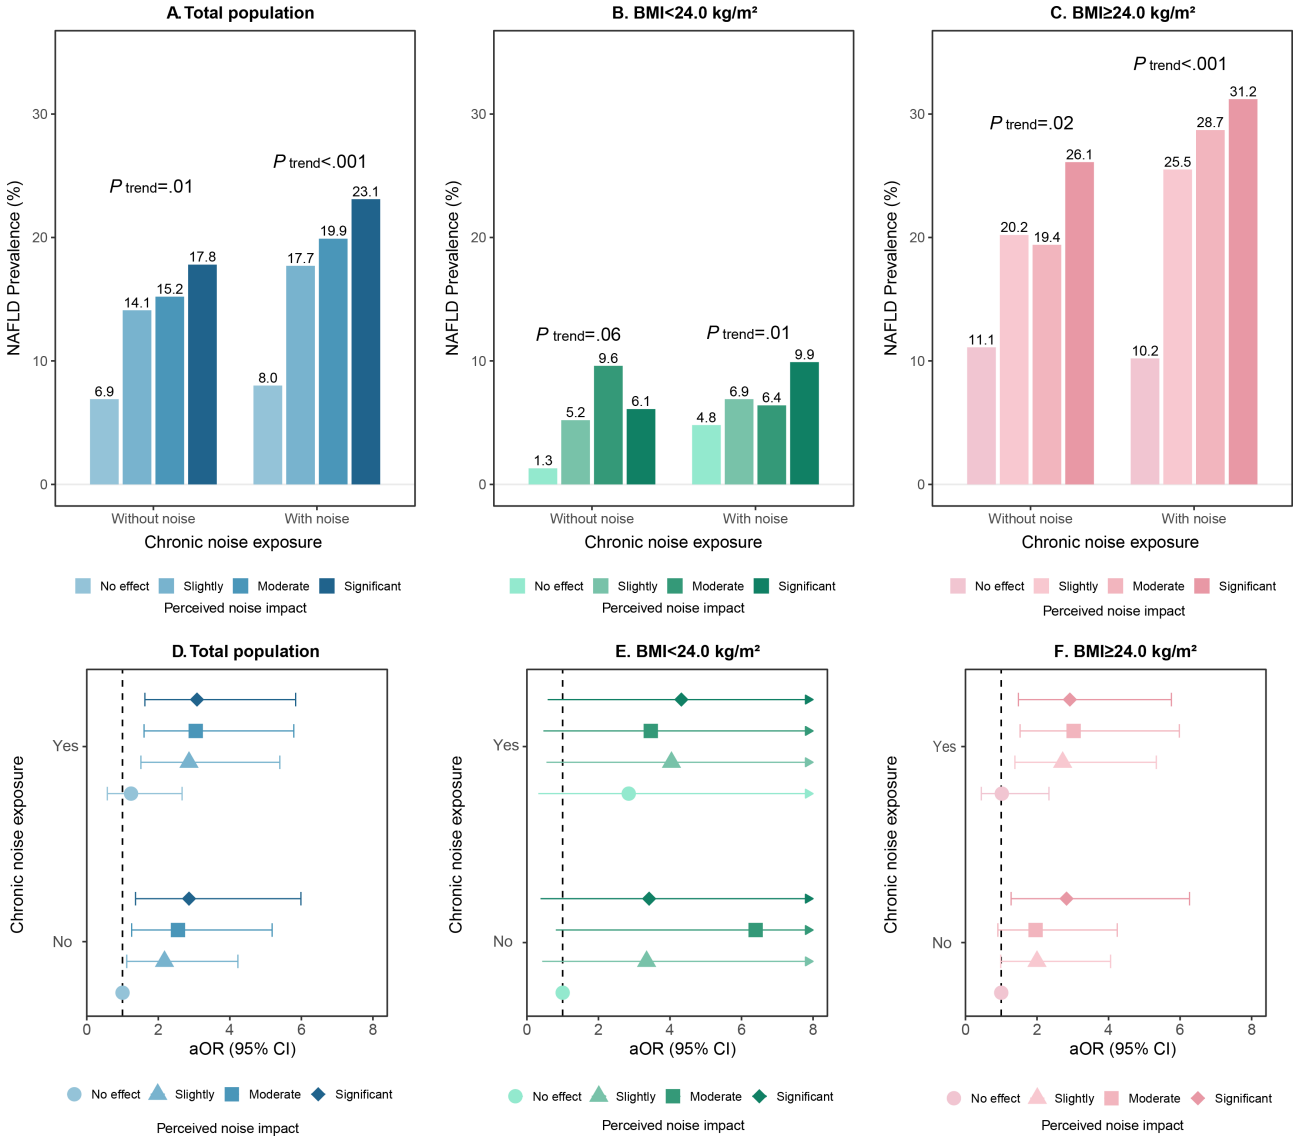
### *Combined Associations of Chronic Noise Exposure and Perceived Noise Impact With NAFLD*

Figure 2A-C illustrates the trends in NAFLD prevalence across combined subgroups of noise exposure and perceived noise impact in the total population, individuals with a BMI of less than 24.0 kg/m², and individuals with a BMI of 24.0 kg/m² or above, respectively. After full adjustment, among participants with a BMI of less than 24.0 kg/m², none of the subgroups combining noise exposure and elevated perceived noise impact exhibited a significantly elevated NAFLD risk compared with the reference group (no noise exposure and no perceived noise impact; Figure 2E). In contrast, among participants with a BMI

XSL•FO
RenderX

of 24.0 kg/m² or above, chronic noise exposure combined with elevated perceived noise impact was significantly associated with higher risk of NAFLD (slightly: aOR 2.72, 95% CI 1.38 - 5.34; moderate: aOR 3.02, 95% CI 1.53 - 5.98; significant: aOR 2.92, 95% CI 1.49 - 5.76). Notably, even in the absence of noise exposure, the highest level of perceived noise impact alone remained significantly associated with increased risk of NAFLD (aOR 2.83, 95% CI 1.27 - 6.26; Figure 2F).

**Figure 2.** The combined association of chronic noise exposure and perceived noise impact with nonalcoholic fatty liver disease (NAFLD) in total and by BMI category. Panels (A), (B), and (C) show the prevalence of NAFLD stratified by chronic noise exposure and perceived noise impact for all participants and by BMI subgroups, respectively. Forest plots (D), (E), and (F) illustrate the combined association of chronic noise exposure and perceived noise impact with NAFLD for all participants and by BMI category, respectively. All multivariate regression models were adjusted for age, household registration, marital status, education, smoking status, physical activity, dietary habits, shift work, monthly income, sleep duration, hypertension, dyslipidemia, diabetes mellitus or impaired glucose tolerance, and BMI (continuous variable). aOR: adjusted odds ratio.



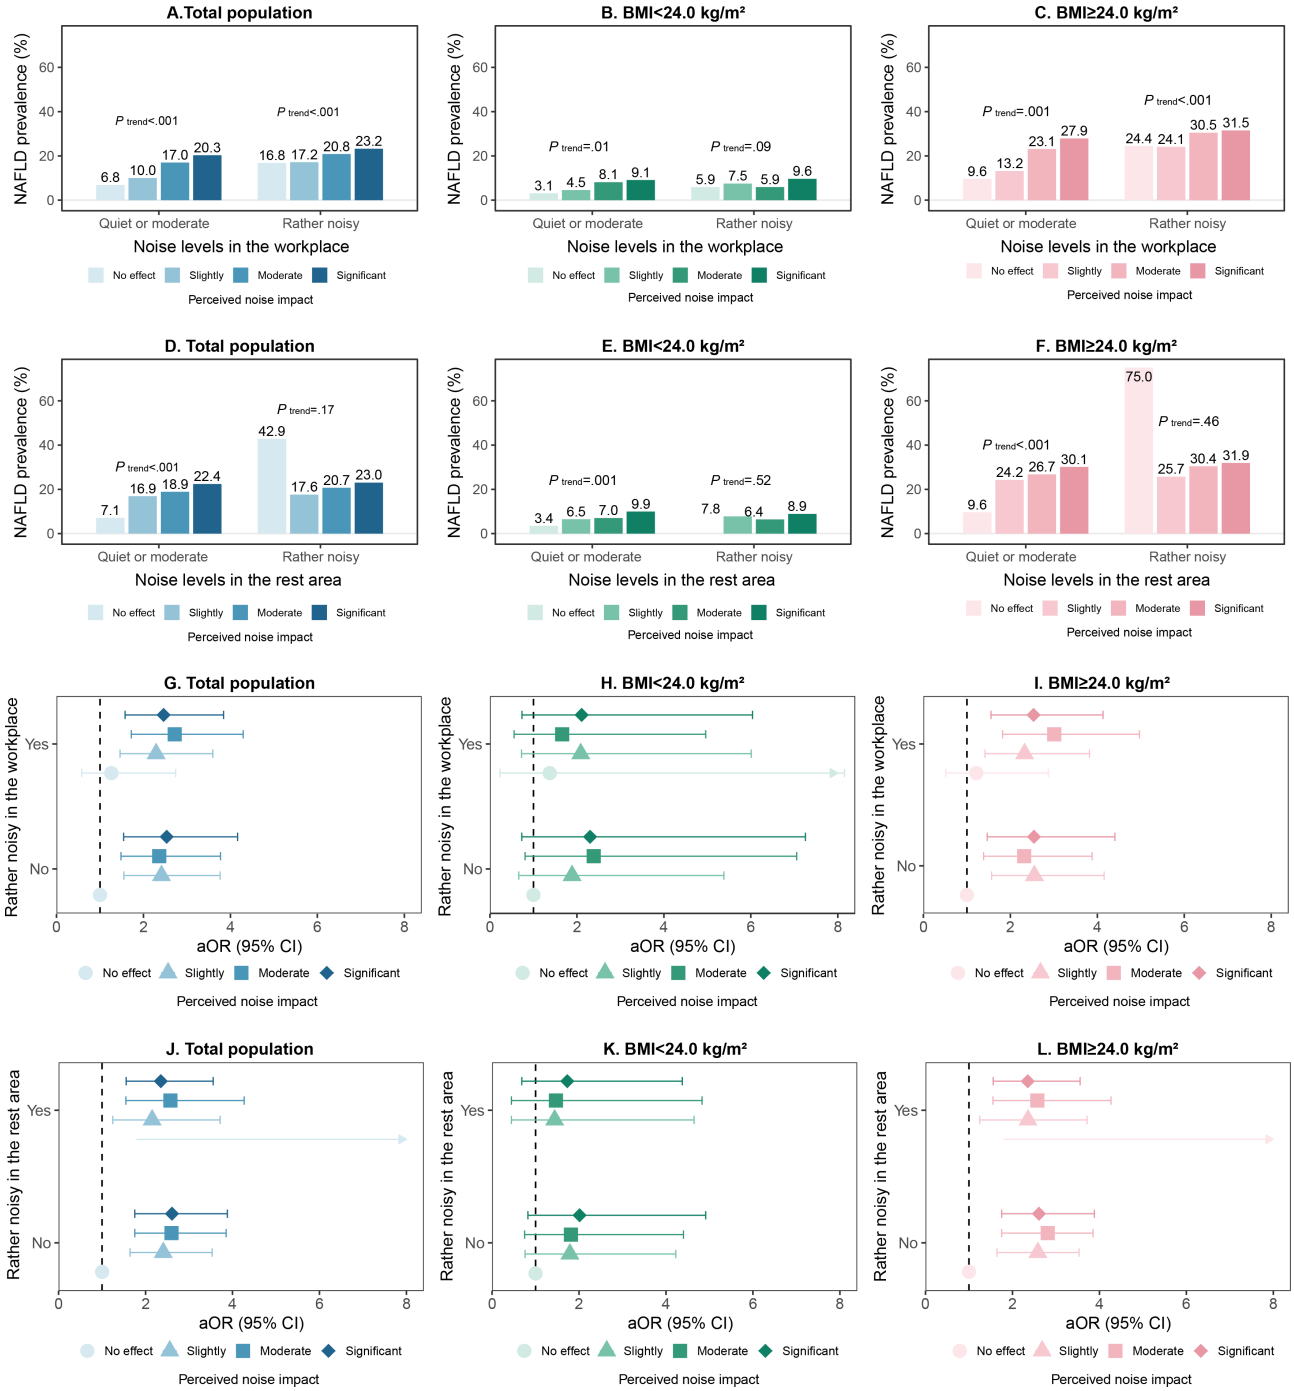


Figure 3 presents the NAFLD prevalence and the combined associations of workplace or resting-area noise levels and perceived noise impact with NAFLD. Among participants with a BMI of less than 24.0 kg/m², the results remained consistent with our previous observations (Figure 3H,K). However, in the BMI ≥24.0 kg/m² group, elevated perceived noise impact was significantly associated with higher risk of NAFLD, regardless of environmental noise levels in work or rest settings (Figure 3I,L).

XSL•FO
RenderX

**Figure 3.** The combined association of noise levels at different places and perceived noise impact with nonalcoholic fatty liver disease (NAFLD) in total and by BMI category. Panels (A), (B), and (C) show the prevalence of NAFLD stratified by noise levels in the workplace and perceived noise impact for all participants and by BMI subgroups, respectively. Panels (D), (E), and (F) show the prevalence of NAFLD stratified by noise levels in the rest area and perceived noise impact for all participants and by BMI subgroups, respectively. Forest plots (G), (H), and (I) illustrate the combined association of noise levels in the workplace and perceived noise impact with NAFLD for all participants and by BMI category, respectively. Forest plots (J), (K), and (L) illustrate the combined association of noise levels in the rest area and perceived noise impact with NAFLD for all participants and by BMI category, respectively. All multivariate regression models were adjusted for age, household registration, marital status, education, smoking status, physical activity, dietary habits, shift work, monthly income, sleep duration, hypertension, dyslipidemia, diabetes mellitus or impaired glucose tolerance, and BMI (continuous variable). aOR: adjusted odds ratio.

## *Interactive Effect of Noise Exposure and Perceived Noise Impact on NAFLD by BMI*

Interactive analysis of noise exposure and perceived noise impact could be seen in Table S4 (Multimedia Appendix 1). Among individuals with a BMI of 24.0 kg/m² or above, a significant multiplicative interaction between resting-area noise and perceived noise impact was observed (all $P$<.05). Specifically, the positive association between perceived noise impact and NAFLD was significant only in quiet or moderately noisy resting environments ($P_{trend}$<.001), but not under noisy conditions. Moreover, this positive association was consistently observed across all workplace noise levels and chronic noise exposure statuses, regardless of whether perceived noise impact

XSL•FO
RenderX

was modeled as a categorical or continuous variable (Table S4 in Multimedia Appendix 1).

### Sensitivity Analysis

To examine the robustness of our findings, we performed sensitivity analysis by excluding participants with self-reported hearing loss. The associations of chronic noise exposure and perceived noise impact with NAFLD across BMI strata (Tables S5-S6 in Multimedia Appendix 1) remained materially unchanged, confirming the stability of our results.

## Discussion

### Key Findings

This is the first large-scale study to estimate the prevalence of NAFLD and its associations with noise exposure, perceived noise impact, and BMI among seafarers. It not only fills a critical gap in maritime occupational noise-related metabolic health research, but also highlights an urgent need for targeted NAFLD prevention strategies to mitigate liver damage in 2.03 million Chinese seafarers and global seafarers more broadly [21]. The overall prevalence of NAFLD among 8143 Chinese seafarers was 18.5% (n=1503), with higher prevalence observed in those with a BMI of 24.0 kg/m² or above, chronic noise exposure, and higher perceived noise impact (Textbox 1). The combined association of chronic noise exposure and perceived noise impact with NAFLD was only observed among individuals with a BMI of 24.0 kg/m² or above. Furthermore, a significant interaction between resting-area noise levels and perceived noise impact in relation to NAFLD was identified specifically in the overweight and obese subgroup.

**Textbox 1.** Key messages.

- We assessed the association of chronic noise exposure, perceived noise exposure, and metabolic status on nonalcoholic fatty liver disease (NAFLD) in seafarers, a crucial occupational group.
- We found evidence that chronic noise exposure, higher perceived noise impact, and their interaction were significantly associated with NAFLD only among seafarers with a BMI higher than 24.0 kg/m$^2$.
- Our findings provide novel insights into the potential mechanisms underlying the roles of chronic noise exposure and psychological factors in the development and progression of NAFLD, particularly among individuals with metabolic disorders.

### Comparison With Previous Studies

The prevalence of NAFLD in this study was significantly lower than that reported in the general Chinese population in 2 previous studies (36.7% and 23.6%) [22,23]. This difference is partly attributable to the predominantly manual labor roles of seafarers, which result in higher levels of habitual physical activity compared to the largely sedentary general population. Additionally, the occupational demands of seafaring impose higher physical fitness requirements, necessitating preemployment medical screening. This selection process likely contributes to a "healthy worker effect," leading to a higher baseline level of health within this occupational group. As seafaring is a strenuous occupation with rigorous physical fitness criteria, only physically qualified individuals can sustain active sea service, rendering currently employed seafarers generally healthier than the general population. Additionally, NAFLD prevalence increases progressively with age. While our study population was predominantly composed of young and middle-aged seafarers, with individuals aged 55 years or above accounting for merely 6.9% (n=563) of the total sample. This relatively young age distribution may further partially explain the lower NAFLD prevalence observed in the present seafarer population.

Previous studies have confirmed that overweight and obesity act as the core pathological basis of NAFLD through triggering insulin resistance and ectopic fat deposition [24,25]. While our study suggests that the noise exposure may synergistically exacerbate NAFLD pathogenesis alongside obesity-related metabolic disorders. As obesity inherently disrupts insulin sensitivity and promotes ectopic lipid accumulation, concurrent noise exposure might amplify hepatic lipid metabolic disturbances via the HPA axis. This pathway elevates circulating cortisol and stimulates sympathetic nerve activity, jointly accelerating the progression of NAFLD [26].

Several studies have reported associations between occupational noise exposure and lipid metabolic disorders, yet direct evidence linking noise exposure to NAFLD, and its combined effects with obesity, remains limited. Studies based on Chinese public institutions and corporate workers, as well as the general US population, have documented a significant association between noise exposure and elevated BMI [27,28]. A previous study involving 4672 male automotive manufacturing workers reported that individuals with cumulative noise exposure of 95 dB(A) or above had a 39% increased risk of NAFLD [29]. Chronic noise exposure may activate the HPA axis, resulting in elevated glucocorticoid levels [8]. Glucocorticoids in turn promote hepatic lipid accumulation by stimulating adipose tissue lipolysis and hepatic de novo lipogenesis, while simultaneously reducing hepatic fatty acid β-oxidation [30], thereby favoring the development of NAFLD.

Interestingly, we observed that higher perceived noise impact was significantly associated with a higher prevalence of NAFLD. Perceived noise impact can be conceptualized as a phenotypic expression of psychological stress in response to environmental noise. It arises from the combined influence of noise stimuli and personal traits and is positively associated with noise sensitivity [31,32]. The positive relationship between perceived noise impact and NAFLD might also be mediated by the chronic HPA axis stress pathway. Long-term perceived noise disturbance may elicit negative emotions and psychological annoyance, thereby activating the HPA axis and promoting excessive cortisol secretion. Previous acoustic research has shown that individuals with high perceived noise exposure report significantly higher levels of negative emotions and

XSL•FO
RenderX

remain in a sustained stress state [31], which provides theoretical support for the mechanistic hypothesis of this study. However, given the cross-sectional design of this study, the observed association between perceived noise impact and NAFLD cannot rule out reverse causality; that is, individuals with preexisting NAFLD may be more vulnerable to perceived noise disturbance. To date, some studies have reported a positive association between NAFLD and anxiety, and further targeted research on this topic is warranted.

This study is also the first to investigate the combined associations of chronic noise exposure and perceived noise impact with NAFLD. We found that NAFLD risk was significantly elevated among individuals who reported higher perceived noise impact in relatively quiet environments, or who had both chronic noise exposure and perceived noise impact. This suggests that perceived noise impact may operate independently of noise exposure. Accordingly, environmental noise reduction alone is insufficient to protect this population; psychological stress alleviation and acoustic environment optimization are also needed. Notably, perceived noise impact was significantly associated with higher risk of NAFLD regardless of whether the workplace or living quarters were reported as noisy, underscoring its importance as a psychological stress indicator. In resting areas, even when perceived noise impact was rated as "no effect," NAFLD risk remained significantly elevated, possibly because metabolic regulation is more vulnerable during rest periods, and residential noise may still disturb metabolic homeostasis with little subjective awareness. Furthermore, a significant multiplicative interaction between noise exposure and perceived noise impact in resting areas suggests that noise-related psychological stress is a key driver of NAFLD.

These associations were observed exclusively among overweight or obese individuals, indicating that this population is more vulnerable to noise-induced stress, which may disrupt hepatic lipid metabolism through chronic stress pathways. Notably, clinical research further supports this biological rationale: body fat distribution and cortisol clearance jointly modulate the association between NAFLD and insulin sensitivity, and higher cortisol clearance is independently associated with reduced insulin sensitivity regardless of BMI [33].

Given that noise-induced psychological stress contributes to metabolic dysfunction, lifestyle interventions that relieve stress and improve metabolism may mitigate NAFLD risk. Currently, physical activities, such as yoga and mindfulness meditation, not only exert positive effects on mood regulation but also contribute to the improvement of inflammation and metabolic status [34,35]. Consistent with this, our study found that regular physical activity and a healthy diet were both significantly associated with a lower prevalence of NAFLD. All the above findings confirm that a healthy lifestyle may effectively improve health simultaneously through multiple pathways.

## Practical Implications for Maritime Occupational Health

This study highlighted the importance of corresponding public health interventions for seafarers. The onboard acoustic environment can be improved by renovating living quarters, reducing mechanical equipment noise, and developing and deploying advanced noise-protection equipment for seafarers. Beyond physical noise control, targeted support for crew members is also critical, such as reasonable shift planning to secure adequate rest and avoid cumulative noise-triggered psychological stress, psychological counseling services, and regular recreational activities. Shipping companies should also establish integrated occupational health management systems featuring routine health education, specialized physical examinations, and personalized intervention programs to sustain seafarers' physical and mental health.

## Limitations

Several limitations should be considered when interpreting the findings of this study. First, noise exposure was assessed via self-reported measures rather than objective personal dosimetry. While self-reported noise exposure assessment is a practical approach for large-scale epidemiological surveys and has been shown to correlate reasonably well with objective instrumental measurements in previous validation studies, it does not allow for precise quantification of the actual decibel levels experienced by individual seafarers. Second, detailed data on the use of hearing protection devices (HPDs) were not collected. The use of HPDs could attenuate the actual noise exposure intensity and thus may influence the observed effect estimates. Nevertheless, self-perceived noise exposure—even with HPD use—may still reflect the actual exposure level in the current occupational setting and may capture the association with the outcome of interest [36]. However, the absence of both objective dosimetry and HPD usage data in the present study limits our ability to directly compare our findings with quantitative exposure-response relationships reported in the literature. Future investigations incorporating objective noise dosimetry and detailed HPD usage records are needed to more precisely describe the association between occupational noise exposure and NAFLD among seafarers. Third, as seafarers self-reported their fatty liver findings from routine check-ups, which may introduce information bias. Participants might underreport fatty liver due to poor memory or stigma, or alternatively over-attribute liver abnormalities to occupational stress. Although multivariate adjustment for highly comorbid metabolic disorders was performed, it cannot correct for recall errors directly. However, the questionnaire did not explicitly implicate a causal link between noise exposure and liver disease, reducing the likelihood of systematic overreporting driven by participant expectations. We additionally conducted a sensitivity analysis excluding participants with self-reported hearing loss—a subgroup potentially more attentive to noise-related health effects—and found that the ORs, effect directions, and statistical significance of the noise-NAFLD associations were consistent with the primary analysis, suggesting that reporting bias did not materially alter our main findings. Nevertheless, in the absence of objective clinical gold-standard verification or individual-level Kappa concordance tests against medical records, residual recall bias cannot be entirely ruled out. Fourth, the nature of the cross-sectional study design limits its capacity to establish causality. In addition, the sample only comprises Chinese male seafarers. Female participants only accounted for only 0.85% (n=70) of the original sample, consistent with the

XSL•FO
RenderX

1% share of female maritime workers reported in the 2024 survey by the International Maritime Organization and the Women's International Shipping & Trading Association [37]. Therefore, the results cannot be generalized to female seafarers. Finally, the generalizability of our findings to other populations or occupational settings should be interpreted with caution, as offshore working conditions and living environments differ substantially from land-based jobs.

## Conclusions

In conclusion, this study suggests that chronic noise exposure and perceived noise impact are significantly associated with elevated NAFLD risk among seafarers, particularly individuals with a BMI higher than 24.0 kg/m$^2$. The combined associations of chronic noise exposure and perceived noise impact highlight the potential role of environmental and psychological factors in NAFLD. Longitudinal studies are warranted to confirm these associations.

## Abstract

**Background:** Digital surveillance systems are increasingly recognized as essential tools for enhancing early outbreak detection, reporting, and response, especially in low-resource settings. The COVID-19 pandemic unveiled the critical role of digital health surveillance systems in timely detection, monitoring, and responses to public health threats. However, successful implementation depends on public awareness, acceptance, and willingness to participate. Limited evidence exists on how the public perceives and interacts with digital surveillance in Malawi.

**Objective:** The aim of the study was to assess the awareness, attitudes, and practices of adult Malawians toward digital surveillance during pandemics and epidemics.

**Methods:** A cross-sectional quantitative study design was used. Data were collected in 10 selected districts (Chitipa, Mzimba South, Kasungu, Lilongwe, Salima, Balaka, Thyolo, Phalombe, Blantyre, and Chikwawa) of Malawi that had high and low levels of cholera and COVID-19 disease burden. The survey recruited 1174 participants who were 18 years or older at the time of data collection. Descriptive statistics were computed using R statistical software. Ethical approval was obtained from the National Health Sciences Research Committee prior to data collection.

**Results:** A total of 1174 participants were surveyed, 65% (n=768) were female, and the mean age was 36.9 (SD 14.26) years. Only 59% (n=697) demonstrated awareness of digital surveillance systems, though 51% (n=603) had smartphones and 41% (n=477) used mobile phones. A positive attitude was observed in 89% (n=1044) of respondents, with most believing digital reporting could improve outbreak control, and 80% (n=939) were confident in privacy and data security. Practices related to digital reporting were low, with only 18% (n=211) having ever reported health symptoms through any digital platform.

**Conclusions:** Enhancing digital health surveillance literacy, promoting inclusivity, and ensuring accountability will improve readiness for future pandemics through digital surveillance systems. Hence, there is a need for nationwide community sensitization programs to raise awareness about the benefits of digital health surveillance.

digital surveillance; public health; awareness; attitudes; pandemic preparedness; COVID-19; cholera

## Introduction

Digital surveillance, defined as the use of digital tools and platforms for real-time disease detection, reporting, and response, has become increasingly important to global health systems. In 2019, the world faced a deadly COVID-19 pandemic. The disease claimed approximately 4 million lives worldwide [1-3]. The rapid spread of the disease necessitated that surveillance activities adapt quickly to provide decision-makers with real-time data for decision-making. During the COVID-19 pandemic, various digital tools were used for public health surveillance. A total of 90 countries reported having used at least one digital technology for public health surveillance [4]. The COVID-19 pandemic highlighted the

XSL•FO
RenderX

importance of timely surveillance systems capable of monitoring outbreaks and enabling rapid public health action [4]. Low- and middle-income countries, such as Malawi, stand to benefit significantly from digital surveillance due to persistent constraints in traditional surveillance systems, including delayed reporting, low coverage, and limited capacity.

With the rapid expansion of mobile penetration, digital health tools have emerged as feasible, scalable solutions. Malawi has seen notable increases in mobile ownership, use of mobile money, and expansion of digital health programs. However, technology adoption is influenced by public awareness, trust, and willingness to engage. For instance, 1 study found that the mobile contact tracing app (MCTA) was the most significant predictor of an individual's willingness to adopt such technologies/tools and resistance to their use. Moreover, the study found that barriers to taking action positively influenced resistance, whereas personal norms negatively influenced resistance to the use of MCTA [5].

Beyond awareness and attitude, public health specialists and policymakers need to understand the levels of acceptability. Donelle et al [6] noted several factors attributing to low acceptability of digital health surveillance, deterring individuals from using technologies, including issues with limited mobile phone battery life, limited access to technology including smartphones and inadequate internet connection, users' concerns around data privacy and security, and lack of trust.

In a multicountry study, Altmann et al [7] looked at the acceptability of app-based contact tracing for COVID-19. The study aimed to investigate the user acceptability of a contact tracing app (CTA) in 5 countries hit by the pandemic: France, Germany, Italy, the United Kingdom, and the United States. The study measured intentions to use CTAs across 2 different installation regimes (voluntary vs automatic installation by mobile phone providers). The findings showed that the app was widely supported under both regimes. However, issues of cybersecurity and privacy and a lack of trust in the government and other relevant officials were the main barriers to adopting CTAs.

Zetterholm et al [8], in their study on public acceptance of digital CTAs during COVID-19, found that, as much as acceptance varied from country to country, what was common and key was that there was lower acceptance of the CTAs among mistrusting people. This is consistent with a study on public attitudes toward digital health surveillance by Nurgalieva et al [9]. Additionally, there were disparities among people who were socially disadvantaged and people with low technical skills in lower acceptance of the CTAs.

Wnuk et al [10] conducted a study on the acceptance of COVID-19 tracking technologies: the role of perceived threats, lack of control, and ideological beliefs. The study aimed to examine if the perceived threat and lack of control during a pandemic, as well as stable ideological views, predicted the acceptance of surveillance technologies. The study's results also showed that, despite having a smaller predictive value, there was a significant positive relationship between the perceived threat and lack of control and the acceptance of surveillance technologies.

Furthermore, during a participatory survey to evaluate the functionality and acceptability of the classical swine fever surveillance system in wild boars in Germany, the study highlighted the importance of considering actors who provide data on system acceptability as a key attribute when selecting surveillance strategies to ensure effective field implementation and continuous system improvement [11]. Digital technologies support real-time data collection, analysis, presentation, and dissemination [8,12,13], thereby enabling timely decision-making during disease outbreaks. Digital surveillance tools are therefore essential to ensure efficient data flow across all levels of the public health response.

Digital surveillance solutions in Malawi are implemented mainly using the One Health Surveillance Platform (OHSP) and District Health Information System (DHIS2). In 2022, the ministry deployed a WhatsApp COVID-19 chatbot to the general public to increase access to health services related to COVID-19. The health services that were available on the chatbot were COVID-19 surveillance, including self-reporting, as well as providing COVID-19 vaccination information and reminders for the second dose depending on the type of vaccine. Digital health surveillance has proven to be effective in infectious disease, epidemic, and pandemic prevention and control despite being new in the public health field. Several global studies have shown gaps in public awareness, attitudes, and acceptability toward digital health surveillance, and Malawi is no exception.

Despite the potential benefits, limited research has been conducted in Malawi to understand public perceptions and behaviors toward digital surveillance. Understanding community awareness, attitudes, and practices (AAPs) is critical to designing systems that are accepted, trusted, and culturally appropriate. This study, therefore, examined the AAPs of Malawians regarding digital surveillance for infectious disease detection and reporting.

## Methods

### Design

This study used a cross-sectional survey design and was conducted in 10 districts of Malawi.

### Population and Setting

The study included adults aged 18 years and older residing in sampled households within the selected enumeration areas (EAs; Table 1). Eligible participants included permanent residents able to speak the study's supported languages (English, Chichewa, or Tumbuka). Nonresidential individuals were excluded.

| Southern | | |
| Balaka | 12 | 11 |
| Blantyre | 12 | 11 |
| Chikwawa | 12 | 11 |
| Phalombe | 12 | 11 |
| Thyolo | 12 | 11 |

[a]EA: enumeration area.

## Sample Size Determination

Sample size was estimated separately for each of Malawi's 3 administrative regions (Northern, Central, and Southern—hereafter "regions"), which together comprise the country's districts and served as the primary sampling strata for this study. For each region, the standard formula for estimating a single population proportion was used, applying a 95% confidence level, a 5% margin of error, and an assumed design effect of 1 in the following equation:

$$n = \frac{Z^2 p(1-p)}{d^2}$$

where n is the sample size per region; *Z* of 1.96, corresponding to a 95% confidence level; *P* is the estimated proportion of the population with a positive attitude toward digital health surveillance (assumed to be 0.5 to maximize sample size in the absence of prior local data); and *d* is the margin of error, set at 0.05.

This yielded a minimum required sample size of 385 respondents per region. To account for an anticipated nonresponse rate of 10%, this was adjusted upward to 428 respondents per region. Across the 3 regions, this gave a combined target of 1284 respondents (428×3). For operational feasibility, this target was rounded up and evenly distributed as 1320 households—corresponding to 12 EAs per district and 11 households per EA across the 10 purposively selected districts (see the *Sampling Procedure* section and Table 1). During household listing, 1290 of these households were confirmed to contain an eligible adult (aged ≥18 y) and were invited to participate; of these, 1174 respondents completed the survey, giving a response rate of 91% (see the *Results* section).

## Sampling Procedure

A 4-stage sampling approach was used within the 3 regions of Malawi: the Northern, Central, and Southern regions.

### *Stage 1 (District Selection)*

Within each region, districts were purposively selected based on combined COVID-19 and cholera disease burden (Table 1). A combined burden score of 3.66 or higher was classified as high burden and below 3.66 as low burden. A total of 10 districts were selected: 5 with high disease burden (Mzimba South, Salima, Balaka, Lilongwe, and Blantyre) and 5 with low disease burden (Phalombe, Kasungu, Chikwawa, Thyolo, and Chitipa), distributed across the 3 regions as follows: in the northern region 2 districts were selected, in the central region 3 districts were selected, and in the southern region 5 districts were selected.

### *Stage 2 (EA Selection)*

Within each selected district, 12 EAs were randomly sampled using probability-proportional-to-size sampling, favoring EAs with a higher number of households, giving 120 EAs in total (12×10 districts). The sampling frame used to select EAs was the 2018 Malawi Population and Housing Census EA frame. An EA was defined as the smallest demarcated geographical statistical unit, comprising a group of adjacent households that may form part of a village, a whole village or several villages, estates, trading or mission centers, or part of an urban area; this typically comprises approximately 250 to 300 households.

### *Stage 3 (Household Selection)*

Within each selected EA, a full listing of households was conducted by the research team prior to selection. From this listing, 11 households per EA were then selected using systematic random sampling, calculated as the sampling interval (total listed households in the EA ÷ 11) with a random starting point drawn between 1 and the sampling interval. This gave a target of 132 households per district (12 EAs×11 households) and 1320 households in total across the 10 districts, consistent with Table 1. During listing and selection, 1290 of these households were confirmed to have at least one eligible resident and were retained as the invited sample.

XSL•FO
RenderX

### *Stage 4 (Respondent Selection)*

Within each selected household, the household head or any other eligible adult (aged ≥18 y) present at the time of the visit was interviewed. If more than one eligible adult was present in a household, the person representing the head of the house was chosen as the respondent.

### Data Collection

Data were collected electronically using a structured questionnaire deployed on Open Data Kit (ODK) and Kobo Collector and were secured using a protected system. The questionnaire collected demographic variables and AAP measures related to digital health surveillance during pandemics. Face-to-face interviews were conducted by trained research assistants using tablets and lasted approximately 20 to 30 minutes.

### Measurements

Awareness of digital health surveillance was defined as whether respondents had previously heard of, or been exposed to, any digital health surveillance tool (eg, the WhatsApp COVID-19 chatbot, SMS-based reporting, or similar platforms), independent of how well they understood its function. It was categorized by binary responses to each awareness item (yes="1" and no="0"), and respondents affirming more than 50% of the awareness items were classified as "aware"; those affirming 50% or fewer were classified as "not aware." Attitude toward digital health surveillance was defined as the usefulness, trustworthiness, and willingness to engage with digital health surveillance systems. Scoring was done using a Likert scale ("strongly disagree" to "strongly agree") and a score above 50 means positive attitude and a lower score means negative attitude. Practice toward digital health surveillance referred to the actual use of mobile phones or digital platforms by respondents to report illness and receive health information. It was binomially coded as (yes="1" and no="0") and classified as good practice with an affirmative response and bad practice otherwise.

### Data Analysis

The data were analyzed in R software version 4.4.2 (R Foundation for Statistical Computing). Descriptive statistics were used to summarize demographics using frequencies and percentages. Bivariate analyses were conducted to assess the association between sociodemographic variables and variables of interest (ownership of phone, ownership of smartphone, awareness, practice, and attitudes toward digital health surveillance tools) using Fisher exact test and the chi-square test.

### Ethical Considerations

The study was conducted after getting ethical approval from the National Health Sciences Research Committee (NHSRC; protocol number 25/05/4681), and a support letter was sought from the Secretary of Health. The district councils and the District Health Management teams were shared with the support letter from the ministry and the ethical approval certificate. The local chiefs whose community members were potential study participants were informed of the pending study in their jurisdiction. The study was carried out in compliance with local and international guidelines, codes, and statutes.

Confidentiality was strictly maintained throughout the study. Personal information, such as name, residence, or identifying markers, was not collected. Results were presented in aggregated form to ensure participants' privacy. The data were stored on a password-protected hard drive, with access restricted to the principal investigator and coinvestigators. Participation in the study was voluntary, and participants were not penalized if they chose not to participate. Informed consent was obtained before participation, with participants either signing or placing their thumbprint on the consent form.

Participants were not paid for participating in the study. However, MWK 10,000 (at the exchange rate of MWK 1=US $0.00058 as of October 12, 2026) was given as compensation for derailing them from their responsibilities.

## Results

A total of 1290 eligible participants were invited to participate in the study. Of these 1174 responded to the questions, resulting in a response rate of 91%.

### Participant Characteristics

A total of 1174 participants were enrolled in the study. The majority were female (n=768, 65%) participants with a mean age of 36.9 (SD 14.26) years. Most respondents had attained primary education. Over half (n=661, 56%) of respondents lived in rural areas and were evenly distributed across 10 districts. Phone ownership was high (n=922, 79%), with 51% (n=603) owning smartphones. Awareness of digital health surveillance tools was reported by 59% (n=697), even though half of the respondents indicated that they were unfamiliar with digital health tools, while 74.7% (n=877) had received health information via phone, and 58% (n=683) had heard of campaigns promoting digital reporting. Only 41% (n=487) had used a phone or app to report or receive health information. However, out of the total respondents, 76% (n=889) never reported illness using electronic tools specifically. SMS (n=464, 40%) and phone calls (n=375, 32%) were the most preferred reporting methods, and 92% (n=1077) believed digital health surveillance works well. Despite positive perceptions, only 18% (n=211) had reported health information digitally in the past year (Table S3 in Multimedia Appendix 1).

### Awareness of Digital Health Surveillance

The study revealed that 59% (n=697) of respondents were aware of digital health surveillance systems (Table 2). Awareness differed significantly by education and district ($P$<.001). Regarding education, 44% (309/697) had primary education and 5% (35/697) had no formal education; regarding district of residence, in Balaka, Salima, and Chitipa, around 14% were aware of digital surveillance systems, while in Chikwawa, 5% were aware of digital surveillance systems.

## Sources of Digital Health Surveillance Information

The main sources through which respondents accessed digital health surveillance information were the Ministry of Health (MoH) through SMS, with 59% (n=687) among female participants (*P*=.006; Table S4 in Multimedia Appendix 1). The sources and channels of use for receiving health information were commonly SMS from MoH (34.4%; Figure 1). Other sources, such as health workers, social media, friends and family, and community meetings, were reported less frequently.

XSL•FO
RenderX

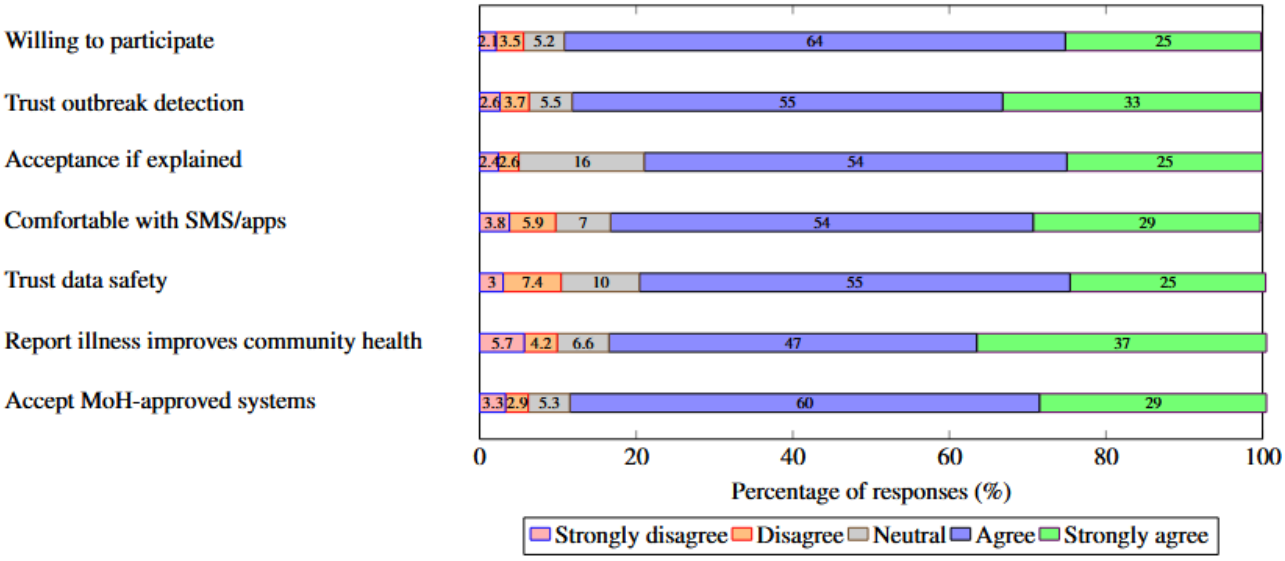
**Figure 1.** Source and channel used for receiving information on digital health. (A) Awareness sources of digital health surveillance and (B) channel of receiving health information. PPT: Pandemic Preparedness Toolkit. Source: PPT digital acceptability survey.

## Receive Health Information via Phone During the COVID-19 Pandemic or the 2022-2024 Cholera Outbreak in Malawi

The majority of participants (n=877, 75%) received COVID-19 and cholera information via phone. Receipt of information differed significantly by sex, age, education, and district ($P$<.05). By sex, female participants (64%) received information via phone. By age group, 66% (18‐39 y) received health information via phone. On education, those with primary education (43%) had received the information. Regarding the districts of Salima and Thyolo, 12% each received the information via phone (Table S5 in Multimedia Appendix 1).

## Outbreak Digital Reporting Awareness Campaigns

Out of the total sample of 1174 respondents, 683 reported awareness of digital reporting of outbreaks. Awareness was associated with the level of education ($P$=.03). Respondents with primary education (n=310, 45%) were aware of digital reporting. The district of residence was also associated with awareness ($P$<.001). Awareness was higher in Salima, Balaka, Chitipa, Kasungu, and Lilongwe. On the other hand, awareness was lower in Blantyre, Chikwawa, and Thyolo (Table S6 in Multimedia Appendix 1).



## Attitude Toward Digital Health Surveillance Tools

Most respondents (n=1044, 89%) expressed willingness to accept a digital system if approved by the MoH, and 84% agreed that using phones to report illness could improve community health. Confidence in data security was also high (80%). About 83% felt comfortable reporting symptoms through SMS or apps, while 79% agreed that people could accept digital tools once properly explained (Figure 2).

XSL•FO
RenderX

**Figure 2.** Attitudes toward digital health surveillance tools. MoH: Ministry of Health; PPT: Pandemic Preparedness Toolkit. Source: PPT digital acceptability survey.

## Belief and Comfort in Phone-Based Illness Reporting

More than half (n=232, 54%) of rural residents and 46% (n=197) of urban residents strongly agreed that using phones to report illness can improve health care in their communities (*P*=.04). Across districts, Thyolo (15%) recorded the highest level of strong agreement, while Mzimba South (6%) recorded the lowest (Table S7 in Multimedia Appendix 1). Regarding comfort in reporting health symptoms via SMS or mobile apps, participants residing in Chitipa (16%) recorded the highest level of comfort, while Lilongwe recorded the lowest (5%; *P*<.05; Table S8 in Multimedia Appendix 1).

## Public Practices of Using Digital Health Surveillance Tools

### *Use of Phone or Mobile App to Receive and Report Health Information*

A significantly higher proportion of female (n=297, 61%) than male (n=190, 39%) reported using mobile phones or apps for health purposes (*P*=.007). Younger respondents (18 - 39 y) showed the highest usage (n=315, 65%), while usage dropped sharply among those aged 60 years or older (n=30, 6.2%; *P*=.003). Digital health tool use increased with education. Only 3.5% (n=17) of respondents with no formal education used them, compared to 11% (n=53) among those with tertiary education (*P*<.001). Significant variation was observed across districts (*P*=.001). For example, Chitipa (n=72, 15%) had the highest usage, while Chikwawa (n=27, 5.5%) had the lowest (Table S9 in Multimedia Appendix 1).

### *Methods Preferred for Reporting Symptoms or Receiving Alerts*

The preferred method of reporting was through SMS. By age, SMS preference was highest among respondents aged 18 to 39 years (n=320, 69%) and lowest among those aged 60 years and older (n=22, 4.7%) with *P*<.001. By location, the highest preference was among those in rural areas (n=259, 56%) compared with urban areas (n=205, 44%) with *P*<.001. At the district level, Salima (n=80, 17%) recorded the highest SMS reporting preference, while Kasungu (n=27, 5.8%) had the lowest (*P*<.001; Table S10 in Multimedia Appendix 1).

## Digital Health Tools Used in the Past 12 Months for Reporting Health-Related Information

By sex, out of the respondents who used the digital health tools, 57% (n=119) were female while 43% (n=89) were male (*P*=.06). By location, for those who had used the digital tools, 64% (n=134) were from rural areas while 36% (n=74) were from urban areas (*P*=.009). Another statistical significance was observed at the district level, where, out of those who used, the highest were from Balaka (n=35, 17%) and the lowest from Chikwawa (n=8, 3.8%; *P*<.001; Tables 2 and 3).

[a]Pearson chi-square test.

### Frequency of Phone Use for Health Services

In general, the frequency was low with 691 participants reported never using their phones for health services. Significant observations were noted in use by sex, location, and district. Among those who reported weekly use, 61% (n=40) were female and 39% (n=26) were male (*P*=.003). By location, among those who reported weekly, 55% (n=36) were from rural areas and 45% (n=30) from urban areas (*P*=.045). Finally, by district of residence, the highest was in Balaka (n=14, 21%; *P*<.001) and the lowest was in Lilongwe (n=2, 3%; *P*<.001; Table S11 in Multimedia Appendix 1)

## Discussion

### Principal Findings

This study set out to assess public AAPs toward digital health surveillance among adults in 10 Malawian districts selected for contrasting COVID-19 and cholera disease burdens. Three findings stand out. First, basic mobile phone ownership was high (n=922, 79%) even though smartphone ownership was more modest (n=603, 51%), suggesting that SMS-based and feature-phone–compatible surveillance tools are likely to reach more of the population than smartphone-dependent applications in the near term. Second, awareness (n=697, 59%) and attitudes (n=1044, 89% positive) toward digital health surveillance were considerably more favorable than actual practice, with only 18% (n=208) of respondents having ever used a digital platform to report a health symptom—a pattern consistent with the

XSL•FO
RenderX

well-documented "intention-behavior gap" seen in digital health adoption elsewhere. Third, confidence in data privacy and security was notably high (n=939, 80%)—a result that runs counter to much of the literature on digital surveillance acceptance cited in the *Introduction* section. Together, these findings suggest that the primary barrier to digital health surveillance uptake in this setting is not attitudinal resistance but a combination of limited exposure/awareness and limited translation of positive attitudes into actual use.

The survey found high levels of basic phone ownership compared to lower smartphone ownership, indicating widespread and increased access to digital devices, including phones, in Malawi, aligning with regional estimates showing extensive mobile phone penetration across sub-Saharan Africa, though smartphone adoption remains uneven due to cost and infrastructure barriers [14]. Evidence from other African contexts also shows that SMS-based health interventions remain effective where smartphone penetration is limited [15,16]. Therefore, Malawi's high basic phone ownership presents a strong foundation for digital health surveillance using simple platforms like SMS.

Awareness of digital health surveillance in this study was moderately high and varied across levels of education and district of residence among the study participants. High awareness among secondary education participants is consistent with previous studies showing that educational attainment is a strong predictor of digital health literacy and adoption [17]. On the other hand, awareness differences across districts also suggest the influence of geographical inequalities, including digital infrastructure, network coverage, and exposure to health campaigns. Similar disparities have been documented in other low-resource settings, where rural populations often have limited digital exposure [18]. The preference for SMS communication from the MoH reinforces the credibility of official health communication channels, consistent with findings that trusted sources enhance uptake of health technologies [19].

This study revealed moderate familiarity with digital health surveillance, particularly among older and less educated participants. This is a result of the user interface, which requires orientation and background awareness. A previous study attributed the actual use of digital tools to familiarity, as individuals who are more confident with technology are more likely to engage with digital health programs [20].

In the current study, the lower usage of phones to report illness in the last 12 months and moderately low use of mobile phones or apps to receive health-related information or report are consistent with research indicating that while digital readiness may exist, actual behaviors often lag due to a lack of awareness and digital skills, as well as technological barriers and trust concerns [21]. Practice was associated with sex, age, education, and district of residence.

There were positive attitudes toward the use of digital health tools for public surveillance in this study, and confidence in data privacy and security was particularly high (80%). This finding is notable because it diverges from much of the international literature reviewed in the *Introduction* section, where concerns about data privacy, cybersecurity, and government trust were consistently reported as the primary barriers to accepting digital contact-tracing and surveillance tools [6-10]. Similarly, high acceptance has been reported with digital health platforms perceived as trustworthy [22], suggesting that trust itself, once present, is a strong enabler. Several explanations may account for this divergence. First, the wording of the survey item asked about general confidence in privacy and data security rather than probing specific concerns (eg, government access to data, third-party data sharing, or reidentification risk); more specific questions may have revealed lower confidence, and social desirability bias may also have inflated affirmative responses given that data were collected by research assistants face-to-face rather than anonymously. Second, this may reflect a genuine contextual difference: unlike the high-income settings where much of the comparator literature originates [6,7,12,13], most respondents in this study had limited prior exposure to digital surveillance tools (only 59% were aware of them), and lower familiarity with a technology's actual data flows may translate into fewer specific privacy concerns rather than genuinely stronger trust. Third, high baseline trust in the MoH as a source of health information in this sample, reflected in the preference for SMS communication from the MoH noted above, may extend to trust in how MoH-linked platforms would handle personal data. Distinguishing between these explanations—genuine contextual trust, limited familiarity, or measurement artifact—would be a valuable direction for future qualitative or mixed methods research in this setting [22].

Comparing these findings with the wider literature highlights both convergence and divergence with other settings. Consistent with studies from France [1] and a multicountry comparison including developing-nation contexts [5], positive attitudes toward digital surveillance tools were common in this study despite low actual usage—suggesting that the attitude-practice gap identified here is not unique to Malawi but a recurring pattern across settings with differing income levels and digital infrastructure. However, this study's high reported trust in data privacy and security contrasts with the consistently trust-limited findings from France, Germany, Italy, the United Kingdom, the United States [7], Poland [10], and cross-national comparisons [9], where privacy and government-trust concerns were the dominant barriers to acceptance. This divergence may reflect structural differences between Malawi and these comparator settings: lower prior exposure to large-scale digital surveillance programs (and, correspondingly, less public debate about their risks), a still-developing formal data protection regulatory environment, and a health system in which the MoH remains a comparatively high-trust institution relative to the government generally. Where similar AAP-type surveys have been conducted in other African or low-income and middle-income country settings, findings on awareness and practice gaps broadly align with this study [5,6], reinforcing that limited exposure—rather than resistance—is likely the primary barrier to digital health surveillance uptake across comparable settings, though direct like-for-like comparisons remain scarce and represent a gap in the literature that this study helps to address.

XSL•FO
RenderX

## Limitations

This study has several limitations. First, data were self-reported, which may introduce recall bias, particularly for questions asking respondents to recall past exposure to health information or campaigns. Second, selecting one eligible adult per sampled household may have introduced selection bias if household composition (eg, presence of a working-age adult during daytime visits) systematically differed by district or region. Third, the cross-sectional design limits the ability to establish causal or temporal relationships between sociodemographic characteristics and awareness, attitudes, or practices; associations reported here should be interpreted as descriptive rather than explanatory. Fourth, the 10 study districts were purposively selected based on disease burden rather than randomly sampled from all districts nationally, which limits the generalizability of these findings to Malawi as a whole; districts not represented in this sample may differ in ways that affect AAPs. Fifth, the sample size calculation assumed a design effect of 1 (ie, no clustering effect) in the absence of a locally derived estimate; because the sampling design was in fact multistage and clustered by EA, this assumption likely understates the true variance of the estimates, and CIs reported in this study should be interpreted with some caution. Finally, the survey item on confidence in data privacy and security asked a general question rather than probing specific concerns, and face-to-face data collection may have introduced social desirability bias on this and other sensitive items.

## Implications

These findings carry several implications for the design and rollout of digital health surveillance in Malawi. First, on the district-level analyses: awareness and practice varied meaningfully by district of residence, independent of the high/low disease-burden classification used for site selection. This suggests that district-level factors other than disease burden alone, such as network coverage, prior exposure to health campaigns, or local trust in health authorities, shape uptake, and that a uniform national rollout strategy may be less effective than one that allows district health offices some flexibility to adapt communication and channel choice (eg, SMS vs community radio vs in-person outreach) to local conditions. Further research directly modeling which district-level factors predict awareness and practice would help translate this into specific, targeted measures. Second, on appropriateness given current phone ownership: with 79% basic phone ownership but only 51% smartphone ownership, and just 41% having ever used a phone or app for health reporting or information, digital health surveillance strategies in Malawi should be designed around basic-phone-compatible channels (SMS, USSD [Unstructured Supplementary Service Data], and voice) as the primary access route, with smartphone-based apps treated as a supplementary rather than primary channel for the foreseeable future. Population groups most at risk of exclusion under a smartphone-first approach include older adults, those with lower educational attainment, and residents of rural or low-coverage districts, all groups in which this study found lower awareness. Mitigation strategies could include maintaining nondigital reporting channels in parallel (eg, community health workers and radio call-in lines) during any transition period, subsidizing or distributing basic phones through existing community health structures, and prioritizing SMS/USSD-based tools in the districts and demographic groups identified here as having the lowest current awareness. Digital surveillance strategies must therefore remain inclusive through both basic mobile phones and smartphone-based applications, supported by targeted communication strategies for individuals with lower education levels and older adults, if these systems are to achieve equitable population coverage rather than reinforcing existing digital divides.

## Conclusions

This study explored the acceptability of digital health surveillance among the Malawian population during public health emergencies, including the COVID-19 pandemic. Public acceptability of digital health surveillance systems is not solely determined by technological availability but is deeply rooted in ethical, social, and contextual considerations. In this study, there was high awareness, acceptability, and willingness to participate in various digital health surveillance tools. However, the usage and practices of digital health surveillance tools were low. The level of participation was influenced by the levels of trust in health authorities (mainly the MoH), data protection assurances, and perceived personal and community benefits. Therefore, strengthening digital health literacy, ensuring clear policies on data privacy, and demonstrating tangible public benefits may improve the acceptability and use of digital health surveillance tools in Malawi, as well as strengthen Malawi's capacity for effective, sustainable, technology-driven pandemic responses.

## Acknowledgments

The research team extends its sincere appreciation to all individuals and institutions that contributed to the successful completion of this study. The authors express gratitude to the Ministry of Health for the leadership, guidance, and support throughout the study. The authors thank Welcome Trust, Luke International, National Statistical Office, and Public Health Institute of Malawi for providing technical and logistical support. The authors also acknowledge contributions of the research assistants and data collectors for their dedication and professionalism in conducting field work under challenging circumstances. Finally, but not least, the authors would like to thank the respondents for providing responses that have informed the analysis and production of this report. No generative AI tools were used in the preparation of the manuscript.

## Funding

The study was funded by Wellcome (grant number 226596/Z/22/Z).

## Abstract

**Background:** In the Inner Mongolia Autonomous Region, men who have sex with men (MSM) have become a high-risk group for HIV transmission due to their complex, secretive sexual relationships, posing challenges to HIV-1 prevention.

**Objective:** We analyzed factors associated with molecular transmission clustering and pretreatment drug resistance (PDR) among newly reported HIV-1–infected MSM in Baotou, China, and to provide locally relevant evidence for targeted public health interventions.

**Methods:** We conducted a subgroup cross-sectional molecular epidemiological analysis of all newly reported HIV-1 cases attributed to homosexual transmission in Baotou between January 2022 and December 2024. The sample comprised 213 treatment-naïve MSM, from whom plasma samples were obtained. A 1.3-kb fragment of the HIV-1 pol gene was amplified and sequenced using next-generation sequencing. Inclusion criteria were a newly reported HIV-1 infection, no antiretroviral therapy at the time of this writing, and self-reported same-sex sexual behavior. Primary outcomes were clustering in a genetic distance–based molecular transmission network and the presence of PDR according to the Stanford HIV Drug Resistance Database.

**Results:** In total, 176 pol gene sequences were successfully obtained, with circulating recombinant form (CRF)–07_BC being the most prevalent subtype, accounting for 56.82% of the total sequences. The molecular transmission network was constructed using a pairwise genetic distance of 1.30%, with 52 of 176 (29.55%) sequences forming 19 clusters within the network. The network exhibited significant assortative mixing by age (ra=0.41; *P*=.001), marital status (ra=0.408; *P*=.002), and educational attainment (ra=0.385; *P*=.001), rather than random mixing. Multivariate logistic regression analysis revealed that CRF07_BC subtype–infected individuals had a significantly higher risk of clustering (AOR 4.98; 95% CI 1.92 - 12.94; *P*<.01). Compared to never-married individuals, divorced or widowed individuals were less likely to have clustered cases (AOR 0.27; 95% CI 0.08 - 0.92; *P*<.05). The prevalence of PDR was 6.57% (n=14). Nonnucleoside reverse transcriptase inhibitor resistance was the most common (n=8, 3.76%), followed by protease inhibitor resistance (n=5, 2.35%), and nucleoside reverse transcriptase inhibitor resistance (n=3, 1.14%). Drug-resistant strains were more frequently detected among individuals infected with the CRF07_BC subtype ($\chi^2_8$=90.44; *P*<.001).

**Conclusions:** Unlike previous studies primarily focused on high-burden southeastern coastal regions of China, we investigated the molecular transmission characteristics of HIV-1 among MSM in the Inner Mongolia Autonomous Region. Our findings demonstrate that transmission clustering and drug resistance patterns previously observed are also present in northern border areas. This study integrated HIV-1 molecular transmission network analysis with next-generation sequencing technologies to identify key populations involved in local HIV transmission, thereby supporting targeted public health interventions. In addition, surveillance of PDR among high-risk populations may facilitate the development of evidence-based antiretroviral treatment strategies and improve the efficient allocation of limited health care resources.

## Introduction

AIDS is a chronic infectious disease caused by HIV. AIDS continues to pose substantial challenges to public health, demographic stability, and socioeconomic development worldwide. The US Centers for Disease Control and Prevention (CDC) reports that in 2023, over 80% of those diagnosed with HIV were men, with 66% of those cases linked to men who have sex with men (MSM) [1]. A nationwide study showed that in some regions of China, 21.4%-23.4% of new AIDS cases were related to HIV transmission among MSM [2,3]. The HIV-1 prevalence rate among MSM in China rose from 5.7% in 2010 to 23.0% in 2019 [4]. As a relatively small group with complex social relationships, some MSM may simultaneously engage in both receptive and insertive sexual behavior, which accelerates HIV transmission. Therefore, given the critical role that MSM play in HIV-1 prevention and management efforts, studying their molecular epidemiological characteristics is of vital importance.

Due to underreporting in MSM, the actual proportion of infections transmitted through MSM may be underestimated. Socioepidemiological investigations can provide some information on HIV-1 transmission patterns, but the secrecy of MSM sexual behaviors limits the reliability of the information obtained on HIV transmission [5]. Interventions targeting individual high-risk behaviors have had limited effectiveness in eliminating HIV/AIDS. Consequently, research focus has shifted to the role of networks in HIV transmission, including sexual transmission networks, social networks, and molecular transmission networks [6]. With continuous advances in genomic sequencing technologies and the ongoing accumulation of data on HIV drug resistance, researchers have increasingly focused on molecular transmission networks constructed from viral sequence data. These networks offer unique advantages. They can trace viral transmission pathways and identify clusters of drug-resistant strains, pinpoint risk factors for HIV transmission, and reveal potential transmission routes within transmission chains, thereby facilitating targeted interventions. The use of molecular transmission networks to identify clusters of high-risk individuals supplements the incomplete information obtained solely through studying social and sexual behavior patterns among people living with HIV [7,8]. By using these insights, public health measures can more effectively curb viral transmission and reduce infection rates [9-11].

Antiretroviral therapy (ART) remains the best treatment option for HIV/AIDS [12]. It effectively suppresses viral replication, reduces mortality, and improves patients' quality of life [13,14]. With the expansion of ART coverage, most patients achieve viral suppression and maintain a certain level of immune function following antiviral treatment. However, with the widespread use of antiviral drugs, the virus continues to undergo genetic mutations under selective pressure, leading to reduced drug sensitivity and the development of drug resistance, which in turn results in treatment failure. Some drug-resistant mutant strains may spread from treatment-failed patients to untreated individuals, and certain mutant strains with transmission advantages may spread widely in the population, leading to increased proportions of transmission-associated drug resistance and pretreatment drug resistance (PDR) [15-17]. PDR refers to drug resistance detected in individuals with no prior history of ART exposure. PDR may reduce the efficacy of ART, increase mortality, and lead to secondary transmission of HIV [16,18]. Therefore, assessing PDR levels helps to better understand the current status of HIV-1 drug resistance in specific regions and provides a foundation for formulating alternative treatment strategies.

In China, individual ART regimens are primarily determined by national standard first-line and second-line treatment strategies [19], and people living with HIV should initiate antiviral treatment as early as possible, within 30 days of diagnosis. Typically, individual HIV genotypic resistance testing is required before starting ART. Failure to identify drug-resistant strains in a timely manner may facilitate onward viral transmission. Since 2011, the prevalence of PDR in China has shown an upward trend [20]. Data from a multicenter observational study indicate that the overall prevalence of PDR in China was 7.40% in 2022 [19]. Previous studies have shown that while several common mutations account for the transmission of most subtypes and cases of high-level resistance, the prevalence of PDR among HIV-1-infected MSM varies geographically. For example, the prevalence of PDR was 12.72% in Guiyang [21], and in Chongqing it was 5.60% [22].

Inner Mongolia Autonomous Region is located in the northern frontier of China, and Baotou is situated in the central-western part of the region. Between 2022 and 2024, 99.36% of newly reported cases in Baotou were sexually transmitted infections, with MSM accounting for 65.14% of these cases. Although homosexual transmission is predominant in the city, research on the transmission patterns among MSM remains limited. Therefore, the primary objectives of this study were (1) to characterize the HIV-1 molecular transmission network and identify factors associated with phylogenetic clustering among newly reported MSM in Baotou; (2) to assess the prevalence and patterns of PDR in this population; and (3) to provide locally relevant evidence for targeted public health interventions. An analysis of representative cities is not only crucial for refining and evaluating the effectiveness of HIV-1 prevention and control strategies in the Inner Mongolia Autonomous Region but also provides valuable insights for other cities. This approach facilitates a deeper understanding of HIV-1 transmission risks at the local level and enables the rational distribution of limited public health resources to achieve targeted interventions against HIV/AIDS.

## Methods

### Study Design

This study is a subgroup analysis derived from a broader HIV-1 molecular surveillance project conducted in Baotou, Inner Mongolia Autonomous Region, between January 2022 and

XSL•FO
RenderX

December 2024 [23]. This subgroup analysis was preplanned to address the research questions specific to the MSM population, which accounts for the highest proportion of newly reported HIV-1 cases in the region.

### Inclusion and Exclusion Criteria

Inclusion criteria were (1) newly reported HIV-1 infection, (2) no prior exposure to ART, and (3) men who self-reported having sex with men. Exclusion criteria were (1) individuals with a prior history of ART exposure, (2) individuals who declined to provide written informed consent or who withdrew consent during the study period, and (3) cases where plasma samples were insufficient in volume (<200 µL).

### Participant Characteristics

A total of 213 ART-naïve MSM were enrolled in this study. Their median age was 33 (IQR 26 - 45) years. Additional demographic and clinical characteristics of the 176 participants with successfully sequenced samples are summarized in Table 1.

[a]Other includes CRF67_01B subtype (n=3), CRF59_01B subtype (n=1), CRF08_BC subtype (n=1) and unique recombination form (n=4).

[b]Corrected chi-square test was used for reporting year and Fisher exact probability method was used for the remaining variables.

[c]CRF: circulating recombinant form.

[d]CD4+: cluster of differentiation 4.

### Sampling Procedure

From January 2022 to December 2024, all newly reported cases of HIV-1 infection among MSM in Baotou were continuously recruited through the local CDC. Blood samples were collected after confirmation of infection and prior to initiation of ART. Plasma samples were separated and stored at −80 °C immediately after collection. This continuous enrollment approach resulted in a sampling coverage rate of 91.42% (n=213) for all newly reported MSM in the city during the study period.

### Sample Size Determination

The sample size was determined by the total number of eligible newly diagnosed HIV-1 cases among MSM in Baotou during the study period.

### Measures and Covariates

Demographic variables were obtained from the National Center for AIDS/Sexually Transmitted Disease Control and Prevention (NCAIDS) information system and included age, ethnicity, marital status, educational level, and registered residence. Clinical variables included cluster of differentiation 4 (CD4+) T cell count at diagnosis. HIV-1 sequence analysis was used to determine viral subtype, identify molecular transmission clustering status (clustered or nonclustered based on genetic distance thresholds), and detect PDR-associated mutations.

### Data Collection and Sources of Secondary Data

Demographic and epidemiological data were obtained from the NCAIDS information system. Laboratory data, including HIV-1 pol gene sequences, were generated using the Illumina next-generation sequencing (NGS) platform.

### HIV-1 Nucleic Acid Extraction, Polymerase Chain Reaction Amplification, and Sequencing

Viral DNA/RNA was extracted using the TGuide S96 Magnetic Bead Method Viral DNA/RNA Extraction Kit (GDP804; TIANGEN Biotech [Beijing] Co, Ltd) according to the manufacturer's instructions. To study the HIV-1 pol gene region, particularly the first 226 codons within the protease (PR) and reverse transcriptase (RT) regions, triple fragment analysis was performed using one-step RT-polymerase chain reaction (PCR; Takara; RR055A) and nested PCR (Takara; RR901A). Amplification primers and conditions have been previously reported [24]. Electrophoresis (1% agarose gel) confirmed amplicons from PCR-positive specimens. The library was constructed using segmented labeled amplicons, labeled with unique barcode sequences, and mixed according to the results of DNA quantification to ensure that the DNA input of individual samples was ≥50 ng and the total library amount was ≥150 ng. The prepared libraries were sent to the sequencing company to be analyzed by second-generation sequencing using the Illumina High-Throughput Sequencing Platform after passing the quality test by connecting the P5/P7 sequencing connectors at both ends of the DNA fragments.

### Sequence Processing and HIV-1 Subtyping

The second-generation sequencing data in FASTA format provided by the sequencing company were preprocessed under a Linux environment by Mothur software (Patrick D Schloss) for quality control to remove low-quality sequences and mixed sequences. Batch processing in Mothur was performed to generate consensus sequences using a quality-score cutoff of 20. Quality control was performed by the HIV database, excluding sequences with >5% mixed bases and those containing stop codons [25]. The obtained sequence fragments were calibrated and assembled using Sequencer (v5.4.5; GeneCodes). After preliminary processing, the sequences were manually aligned and edited in BioEdit (v7.7.1; Tom Hall, Ibis Biosciences) and compared with reference sequences in the HIV database at Los Alamos National Laboratory. Phylogenetic analysis was subsequently performed in MEGA (v6.0; Koichiro Tamura, Glen Stecher, Daniel Peterson, Alan Filipski, and Sudhir Kumar) using the neighbor-joining method. For circulating recombinant form (CRF), clustering analysis was first conducted with established international reference strains, and additional validation was performed using the COMET (Daniel Struck) online tool [26]. Sequences not clustered with known reference strains were classified as unique recombination forms (URFs) and further analyzed for recombination patterns using the RIP (Siepel AC, Halpern AL, Macken C, Korber BT) [27] and jpHMM (Anne-Kathrin Schultz) [28] online tools.

### HIV Molecular Transmission Network Analysis

To analyze the characteristics of HIV-1 transmission among MSM in Baotou, a molecular network was constructed using collected pol gene sequence data. First, pairwise genetic distances between aligned sequences were calculated using HyPhy (v2.2.4; Sergei L Kosakovsky Pond). Nodes were connected when the pairwise genetic distance between their corresponding sequences fell below the predefined threshold. To more reliably identify infected individuals with potential transmission links within the molecular network, an optimal threshold was selected by maximizing the number of clusters, thereby avoiding network fragmentation or excessive merging. Consequently, sequence pairs with genetic distances <1.30% were used to construct the molecular transmission network. Finally, the network was visualized using Cytoscape (v3.5.1; Cytoscape Consortium). The assortativity coefficient (ra) is an important measure of network assortativity, with values ranging from −1 to 1 [29]. A value close to 1 indicates that the network exhibits high assortativity, meaning similar nodes are more likely to connect with each other. A value close to −1 indicates that the network exhibits high disassortativity, meaning nodes of different types are more likely to connect with each other. A value close to 0 indicates that the network connections are random.

XSL•FO
RenderX

### Drug Resistance Analysis

According to the National Technical Specifications for AIDS Testing, as outlined by the Chinese Center for Disease Control and Prevention, the sequenced data were forwarded to the HIV Drug Resistance Database of Stanford University [30]. Specifically, the HIV database program's sequence analysis online feature was used to assess the genotypic drug resistance mutations and resistance levels in HIV-1-infected MSM. The clinical significance of drug resistance, encompassing protease inhibitors (PIs), nucleoside reverse transcriptase inhibitors (NRTIs), and nonnucleoside reverse transcriptase inhibitors (NNRTIs), is categorized into 5 distinct levels for each antiretroviral medication: susceptible, possible resistance, low resistance, moderate resistance, and high resistance. Any level of resistance, from low to high, is deemed resistant. The prevalence of drug resistance is calculated as the proportion of individuals with infections resistant to 3 drugs among all newly reported HIV-1 infections.

### Statement on Missing Data

Of the 213 enrolled participants, plasma amplification and sequencing were successful in 176 (82.6%). The 37 cases with missing sequence data did not differ significantly from those with available sequences in terms of age, marital status, education, or baseline CD4+ lymphocyte count (all $P>.05$). For all 176 participants with sequence data, no values were missing for the primary outcomes (clustering and PDR), demographic variables, or covariates. The small proportion of missing sequences was handled by complete-case analysis for the molecular network and logistic regression and by using the total enrolled sample as the denominator for PDR prevalence to provide a conservative estimate.

### Ethical Considerations

The study was approved by the Biomedical Ethics Review Committee of Inner Mongolia Center for Disease Control and Prevention (approval number 202411282). All procedures were conducted in accordance with the Declaration of Helsinki. Written informed consent was obtained from every participant prior to blood sample collection. The consent form explicitly stated that the specimen and associated clinical data would be used for HIV molecular epidemiology research, including genetic sequencing and drug resistance analysis. All study data were deidentified. During sequencing and data analysis, participants were identified solely by unique study codes; personal identifiers were removed before data analysis. Only authorized research team members had access to the key data. No financial compensation was provided to participants, as sample and data collection were carried out as part of routine public health surveillance and clinical care, with no additional study-specific procedures beyond standard post-diagnosis evaluation. No images, photographs, or any other materials that could reveal the identity of individual participants are included in this manuscript or its supplementary files.

### Statistical Analysis

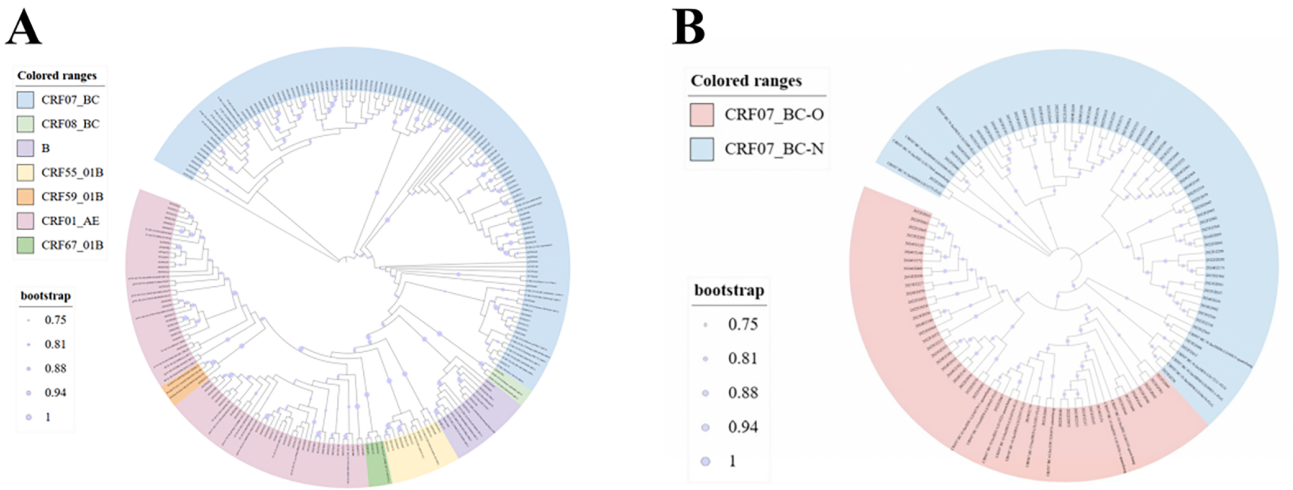
Demographic and baseline characteristics were summarized according to variable type. Categorical variables were expressed as frequencies and percentages, while continuous variables were assessed for normality and presented as medians with IQRs, as appropriate. To identify factors associated with clustering within the molecular transmission network, univariate logistic regression analysis was first performed to examine the association between each independent variable and the outcome variable (clustered vs nonclustered). To control for potential confounding effects, all factors found to be statistically significant ($P<.05$) in the initial univariate analysis were included in a multivariate logistic regression model. A stepwise selection approach was used to construct the final model, retaining only those variables that remained statistically significant ($P<.05$) after controlling for all other factors. Odds ratios (OR) and their corresponding 95% CIs were calculated to estimate the strength of associations. This modeling strategy was chosen because the outcome variable (molecular clustering) was binary, and logistic regression is the appropriate method for identifying independent predictors of binary outcomes in cross-sectional epidemiological data. Network assortativity was assessed using the assortativity coefficient (ra), which measures the tendency of nodes with similar attributes to connect with one another. The coefficient ranges from −1 (disassortative) to 1 (assortative). All data analyses were performed using SPSS (version 25; IBM Corp) software, and figures were generated using GraphPad Prism (version 8; GraphPad Software LLC) and R (version 4.4.2; R Foundation for Statistical Computing) software.

## Results

### Demographic Characteristics of the Study Population

This study involved gathering samples from 213 newly diagnosed HIV-1 cases among MSM, achieving a high sampling rate of 91.42% (n=213). Among newly reported cases, HIV-1 infections accounted for 32.86% (n=70) in 2022, 36.62% (n=78) in 2023, and 30.52% (n=65) in 2024. Of these, we successfully sequenced and analyzed 82.62% (n=176) of the samples. A total of 63 sequences were obtained in 2022, 64 in 2023, and 49 in 2024. As shown in Table 1, among the sequenced participants, the majority were 30 - 50 years old (n=91, 51.70%). About 66.48% (n=117) were never-married individuals, and 79.55% (n=140) had at least a senior middle school education. CRF07_BC (n=100, 56.82%) was the most common subtype, followed by CRF01_AE (n=51, 28.98%), CRF55_01B (n=10, 5.68%), B (n=6, 3.41%), and other (n=9, 5.11%).

### Subtype Distribution Characteristics



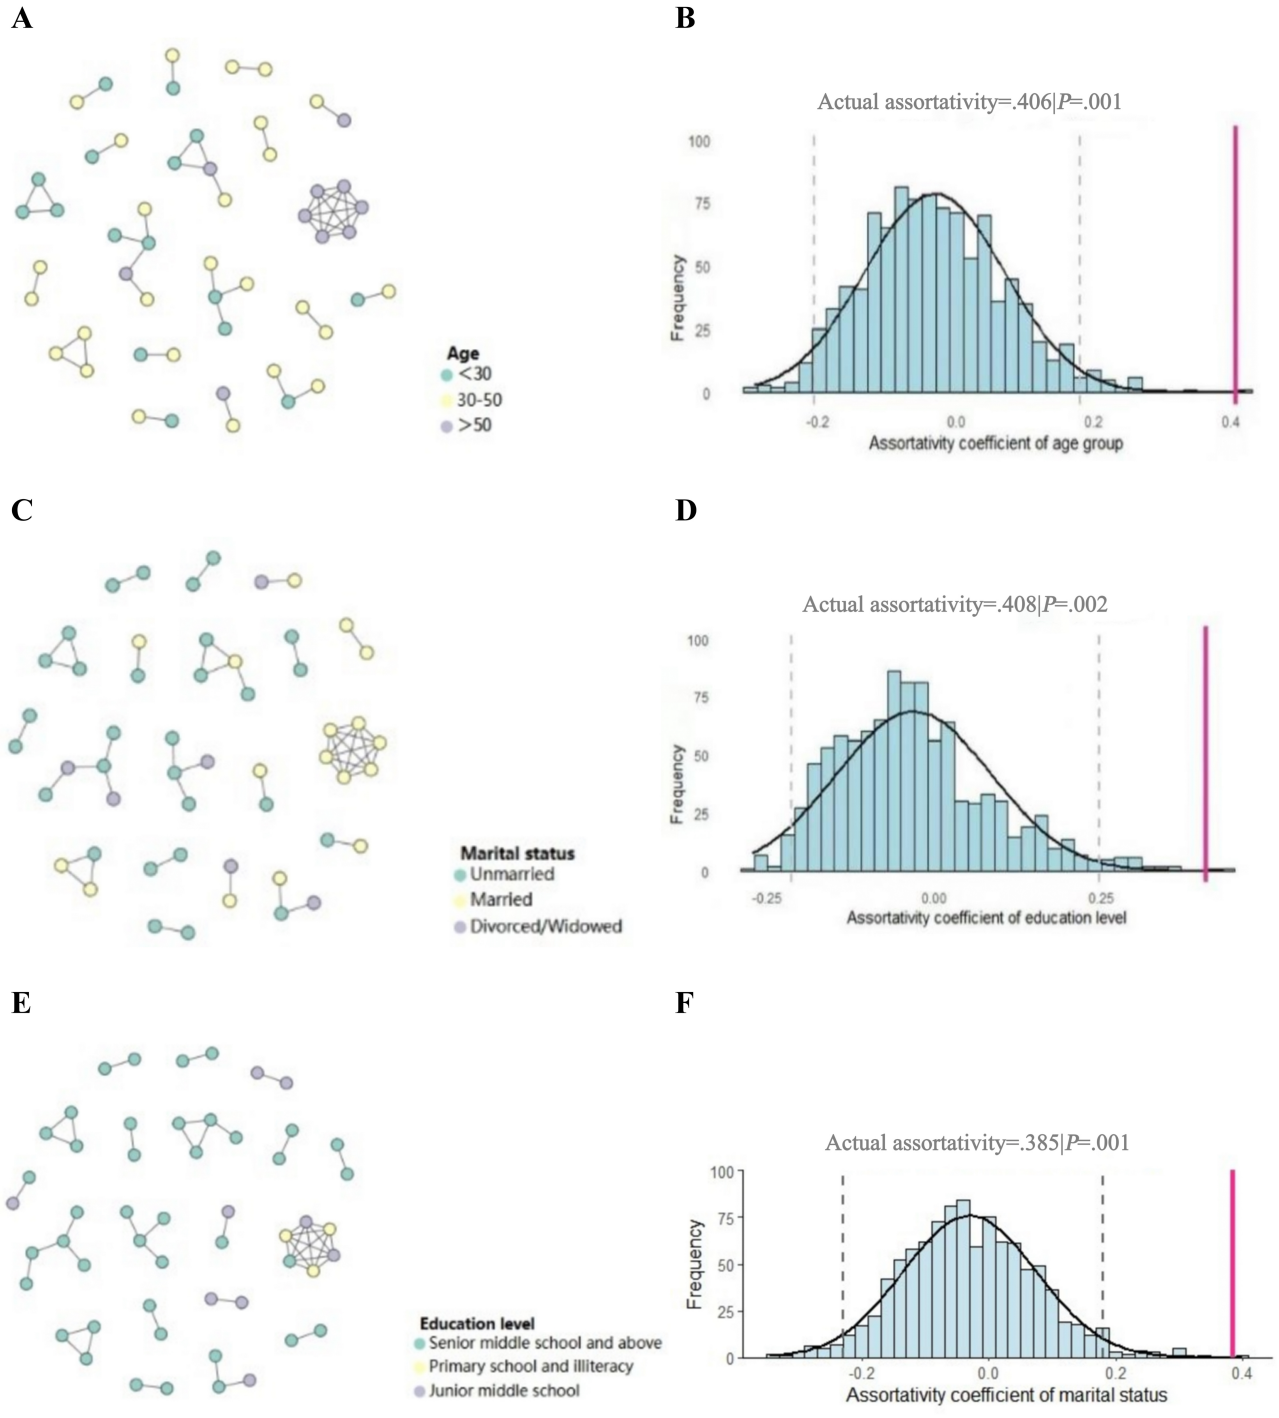
The MSM population newly reported with HIV-1 infection over the past 3 years includes 7 subtypes and 4 URFs. The subtypes in this region are primarily composed of CRF07_BC (n=100, 56.82%) and CRF01_AE (n=51, 28.98%), followed by CRF55_01B (n=10, 5.68%), B (n=6, 3.41%), and others (n=9, 5.11%), including CRF67_01B (n=3, 33.33%), CRF59_01B (n=1, 11.11%), CRF08_BC (n=1, 11.11%), and URF (n=4, 44.44%; Figure 1). The CRF07_BC-N subclusters dominate in these current circulating strains (Figure 1B). Among never-married individuals under the age of 50 with a high school education or higher, CRF07_BC is a common subtype. In analyzing the demographic characteristics of HIV-1 infection among MSM, no significant association among infection report

XSL•FO
RenderX

year, personal age, race, education level, marital status, or registration location and viral infection was found ($P$>.05). There were significant differences in the genotypic composition of HIV-1 MSM infections across different CD4+ T lymphocyte counts ($P$<.05).

(B) Shows the phylogenetic tree of CRF07_BC. Different colors represent different subclusters. CRF: circulating recombinant form.

## Molecular Transmission Network Analysis



The number of clusters and the number of nodes included in the network were calculated separately for genetic distances ranging from 0.10% to 2%. The molecular transmission network was constructed using a genetic distance threshold of 1.30%, which yielded the largest number of clusters. Among the 176 pol gene sequences, 52 sequences (29.55%) were included as nodes in the network using a genetic distance threshold of 0.013, distributed across 19 clusters. Cluster sizes ranged from 2 to 6 nodes, 12 out of 19 clusters consisted of only 2 nodes connected by a homosexual transmission link, and 7 out of 19 clusters (36.84%) had 2 or more links. The largest cluster contained 6 nodes (11.54%) and 15 edges (32.61%). The median pairwise genetic distance was 0.0070 (IQR 0.0030 - 0.0103). Node degrees ranged from 1 to 5, with most nodes in the network having a degree of 1. Among these 19 clusters, CRF07_BC accounted for 73.68% (n=14), CRF01_AE for 15.79% (n=3), and CRF55_01B for 10.53% (n=2). In addition, we identified 2 small drug resistance clusters in the network, both belonging to the CRF07_BC subtype. The key drug resistance mutations identified in the 2 clusters were Q58E and K103N, respectively.

Then, this study analyzed the assortative coefficients of demographic characteristics to better reflect assortative mixing within molecular transmission networks. The results indicate that the network exhibited significant assortative mixing by age (ra=0.41; $P$=.001), marital status (ra=0.408; $P$=.002), and educational attainment (ra=0.385; $P$=.001), rather than random mixing (Figures 2A-2F). Therefore, we analyzed the connection strength for these 3 demographic characteristics (Figures 3A-3C). The visualization results show that, regarding age, the connection strength was highest among older individuals (>50 years; n=14, 31.11%). The connection strength was higher among married individuals (n=17, 37.78%). Nodes with a senior high school education and above were more likely to establish connections (n=26, 57.78%).

XSL•FO
RenderX

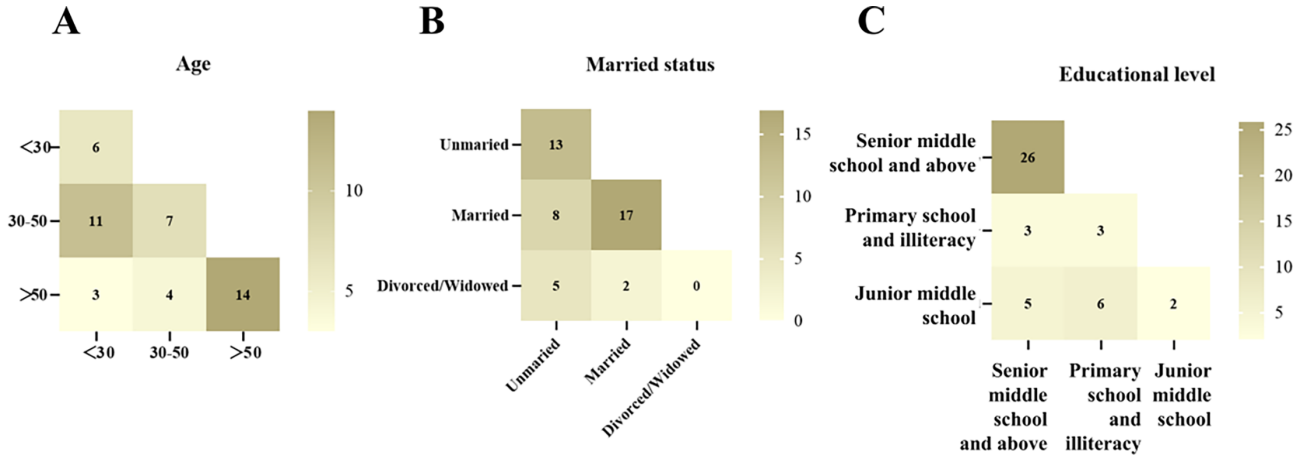


**Figure 2.** Assortativity within the HIV-1 molecular transmission network. (A) Clusters of HIV-1 molecules coded by age group. (B) Assortativity analyzed by age group. (C) Clusters of HIV-1 molecules coded by marital status group. (D) Assortativity analyzed by marital status group. (E) Clusters of HIV-1 molecules coded by education level. (F) Assortativity analyzed by education level. The gray dashed line represents the 5% significance level. Pink vertical lines represent the actual assortativity. A value close to 1 indicates that the network exhibits high assortativity, meaning similar nodes are more likely to connect with each other.

## Factors Associated With Clustering

Results from multivariate logistic regression indicated that, among MSM, marital status and subtype were most strongly associated with clusters of infections (Table 2). Compared with CRF01_AE, CRF07_BC was more likely to be associated with clusters of infections (OR 4.98; 95% CI 1.92 - 12.94). Furthermore, compared with never-married individuals, those who were divorced or widowed were less likely to experience clustering (OR 0.27, 95% CI 0.08 - 0.92). Other factors, such as age, year of reporting, educational level, ethnicity, pretreatment CD4+ T cell count, presence of PDR, and region of registration, were not associated with clustering (Table 2).

### Drug Resistance in HIV‐1‐Infected MSM

The prevalence of PDR increased from 4.29% (n=3) in 2022 to 9.23% (n=6) in 2024. The overall prevalence of PDR in the HIV-1-infected MSM population was 6.57% (n=14). A chi-square test for trend revealed a significant increasing trend in PDR prevalence over the 3-year period ($\chi^2_1$=17.885; *P*<.001), showing an increasing trend in PDR. NNRTI resistance was the most common (n=8, 3.76%), followed by PI resistance (n=5, 2.35%), and NRTI resistance (n=3, 1.14%).

For HIV-1-infected MSM in Baotou, NNRTIs were associated with the most common resistance mutations, with the K103N mutation (n=5, 2.35%) being the most frequent, followed by L100I (n=2, 0.94%). For NRTIs resistance, the most frequently detected mutation was D67N/del (n=2, 0.94%), while for PIs resistance, Q58E (n=3, 1.41%) was the most common mutation.

As shown in Table 3, mutations associated with NNRTIs primarily result in moderate/high resistance to doravirine (DOR), efavirenz (EFV), etravirine (ETR), nevirapine (NVP), and rilpivirine (RPV), with 5 cases exhibiting high resistance to EFV and 7 cases exhibiting high resistance to NVP. Mutations associated with PIs primarily result in low resistance to nelfinavir (NFV) and tipranavir boosted with ritonavir (TPV/r). Mutations associated with NRTIs primarily result in moderate resistance to abacavir (ABC), zidovudine (AZT), lamivudine (3TC), emtricitabine (FTC), and tenofovir disoproxil fumarate (TDF), and high resistance to stavudine (D4T) and didanosine (DDI). In addition, this study used chi-square tests to assess the association between subtypes and the presence of resistance. Significant differences were observed, with resistance more likely to be found in the CRF07_BC subtype ($\chi^2_8$=90.44; *P*<.001).

# Discussion

## Principal Findings

China's economic development is characterized by substantial regional disparities. Western regions are geographically vast, relatively underdeveloped economically, and feature widely dispersed populations, which pose considerable challenges for disease prevention and control. Targeted interventions based on HIV-1 molecular transmission networks have been widely implemented in economically developed regions and have demonstrated promising effectiveness in HIV prevention and control. Meanwhile, with the continuous advancement of NGS technologies, these approaches have also been increasingly applied to HIV drug resistance surveillance, thereby providing improved guidance for ART.

XSL•FO
RenderX

The Inner Mongolia Autonomous Region, located in northern China's border area, remains relatively underdeveloped economically and has limited experience in the application of novel HIV prevention technologies and methodologies. Therefore, this study selected Baotou, Inner Mongolia, as the study site and applied HIV-1 molecular transmission network analysis combined with NGS technology to investigate transmission clustering and pretreatment drug resistance among local HIV-infected individuals. With a sampling rate exceeding 90%, the study is representative of this population. The findings are expected to provide more precise and efficient strategies for HIV prevention and control in Baotou and potentially across the entire Inner Mongolia Autonomous Region.

Demographic analysis indicates that HIV-1-infected MSM in Baotou tend to be younger, never-married, and better educated. Similar results have been reported in other studies on MSM populations [31,32]. Previous studies have shown that young MSM in the Inner Mongolia Autonomous Region have a high level of HIV/AIDS knowledge. However, the proportion of commercial sex has increased annually, and the rate of consistent condom use remains low, resulting in a disconnect between knowledge and behavior. This may explain the relatively high infection rate among young MSM in the region [33]. For MSM engaging in unprotected receptive anal sex, interventions that reduce infection risk are critical. Therefore, this group should be a priority for prevention and control efforts, with screening expanded to include both infected individuals and their sexual partners.

Among HIV-1-infected MSM in Baotou, the predominant subtypes are CRF07_BC and CRF01_AE. Phylogenetic analysis indicates that the CRF07_BC-N subclusters are the dominant epidemiological cluster. CRF07_BC-N subclusters originated in Yunnan Province and are primarily transmitted among MSM [34]. Compared with the CRF07_BC-O subclusters, CRF07_BC-N subclusters exhibit higher network density, interprovincial transmission rates, and interregional transmission rates [35]. The results of this study further indicate that this lineage may have undergone large-scale interprovincial and intraprovincial transmission across China. Therefore, strengthening the diagnosis and surveillance of HIV-1-infected MSM is crucial for controlling the spread of CRF07_BC. With the increase in homosexual transmission, CRF01_AE has become one of the predominant strains among MSM [36,37]. In Hebei Province [38] and Heilongjiang Province [39], which border the Inner Mongolia Autonomous Region, the proportion of CRF01_AE among MSM is the highest, indicating that the predominant circulating subtypes among MSM exhibit regional characteristics. Recent studies have identified novel recombinant strains (CRF01_AE/CRF07_BC) among MSM in Beijing [40]. The high frequency of recombination between these 2 subtypes underscores the importance of closely monitoring viral transmission and evolution in high-risk areas and populations. Therefore, continuous surveillance of HIV-1 subtype diversity and transmission dynamics is essential for effective epidemic control.

Molecular network analysis has revealed the transmission patterns of HIV-1 among MSM. Compared to individuals infected with the CRF01_AE strain, those infected with the CRF07_BC strain showed a stronger association with clustered HIV-1 transmission within the network. These findings are consistent with those observed in Chongqing [41] and Guangxi [42]. Pathogenic studies of the CRF07_BC strain indicate a relatively low baseline viral load. A 7-amino acid deletion (Δ7) in the p6gag region impairs viral maturation and release, leading to reduced replicative capacity [43]. Because of its transmission advantages, CRF07_BC may continue to play an important role in HIV transmission among MSM populations in China [44]. Compared with MSM who have never been married, divorced, or widowed, MSM are associated with a lower risk of forming transmission clusters. MSM who have never been married are typically younger and may engage in high-risk sexual behavior, such as frequently changing sexual partners and having unprotected sex. A greater number of sexual partners may increase opportunities for HIV transmission, which in turn may facilitate viral clustering and spread [44]. Although this group has a relatively high level of education, previous studies have shown that there is a discrepancy between their knowledge of HIV/AIDS and their actual behavior in the Inner Mongolia Autonomous Region [33]. Our findings merely indicate that, among HIV-1-infected individuals in Baotou, divorced or widowed MSM are less strongly associated with viral clustering and transmission compared to MSM who have never been married. To confirm these results, further validation through expanded sampling and epidemiological investigations is required.

In this study, the assortative coefficients for age group, marital status, and educational level were statistically significant. HIV-1-infected individuals within the same age group, marital status, and educational level tended to cluster within the network. The connection patterns indicated that older individuals, married individuals, and those with higher educational levels were more likely to connect with similar nodes within the network. Analyzing the assortative characteristics of nodes within a network can rapidly identify key nodes [45]. Therefore, during epidemic surveillance, it is necessary to integrate network indicators with molecular transmission networks to provide critical information on priority populations for population-based epidemic prevention and control, formulate interventions targeting HIV transmission hotspots, and use public health resources more efficiently to achieve precise HIV prevention and control [46].

This study assessed the prevalence of PDR and the presence of drug resistance mutations (DRMs) among MSM in Baotou over the past 3 years. The local PDR rate in Baotou was 6.57%, slightly lower than the national average (7.4% in 2022) [47]. This difference may be attributed to the more stable demographic structure of the MSM population in Baotou, which reduces the likelihood of cross-regional transmission of drug-resistant strains. Despite being slightly below the national average, the local PDR rate still exceeds the World Health Organization (WHO) warning threshold of 5%. This study observed the highest frequency of DRMs among NNRTIs, followed by NRTIs, with resistance of the CRF07_BC subtype being the predominant type. This is consistent with findings reported in certain cities [19,21]. This finding may be associated with the relatively low genetic barrier of NNRTIs and the

XSL•FO
RenderX

widespread use of first-line treatment regimens [48-50]. High levels of resistance were primarily observed for drugs such as EFV, NVP, and D4T, highlighting the potential impact of long-term use of the same antiviral treatment regimen and urging the exploration of effective alternative regimens [51,52]. The PDR rate for NNRTIs was 3.76%, higher than that for NRTIs and PIs. Studies indicate that the increase in PDR prevalence is primarily driven by NNRTI resistance [53]. Additionally, it is worth noting that the proportion of dual resistance to NRTIs and NNRTIs among individuals with drug resistance is 14.29%, which limits the options for second-line treatment regimens. This suggests that resistance testing should be conducted on patients with virological failure before considering second-line treatment regimens.

Then this study analyzed the distribution of DRMs. First, the most commonly detected NNRTI-associated resistance mutation is K103N. Multiple studies have demonstrated that K103 is the most common DRM site for NNRTIs used as first-line antiviral drugs, and this mutation is closely associated with resistance to EFV and NVP, and it is also commonly found in CRF07_BC [54-57]. Our research results also prove this point. Therefore, particular vigilance is required for the K103N mutation. The next most common DRM is L100I, which can lead to moderate to high resistance to NVP, RPV, and DPV. We found that several drug-resistant individuals exhibited varying levels of resistance to DOR. A Dutch study demonstrated that DOR holds promise for more effective and cost-effective treatment for patients living with HIV [58], but the results indicate that close monitoring will still be necessary when using DOR in the future.

Our research team recently published a comprehensive analysis of sexually acquired HIV-1 cases in Baotou, which identified older heterosexual men as key drivers of local transmission networks [23]. The present study is a logical extension of that work, specifically designed to conduct an in-depth, dedicated molecular investigation of the MSM population—the group accounting for the highest proportion of newly reported HIV-1 cases in Inner Mongolia. While the two studies share the same geographical setting and methodological framework, they address fundamentally distinct research questions and target populations, and are therefore complementary rather than redundant. This study demonstrates that MSM remain the core population sustaining the epidemic and require dedicated, population-specific attention. Together, these two studies provide a more complete picture of the HIV-1 epidemic in Baotou, with the current manuscript filling a critical gap by delivering the granular, population-specific data necessary for designing targeted interventions for MSM in Inner Mongolia.

## Limitations

This study has certain limitations. First, a portion of the samples was collected during the COVID-19 pandemic, and changes in epidemic prevention measures and health care–seeking behaviors may have resulted in incomplete sampling. Some transmission chains may not have been effectively identified because infected individuals failed to seek medical care, undergo testing, or be included in the surveillance system in a timely manner. This resulted in an incomplete description of the local HIV transmission network and may have underestimated the size of certain transmission clusters. Future studies could incorporate samples and data from multiple time periods to validate these results and reduce the impact of sampling bias on the identification of transmission chains. Second, the proportion of potentially nondisclosed MSM (pnMSM) in the sample may have been underestimated, and reporting bias may have existed during epidemiological data collection, which could introduce bias in cluster analysis and pre-treatment resistance rates. Future studies should include pnMSM to reduce potential reporting bias. Finally, testing for integrase strand transfer inhibitors (INSTI)–associated resistance has not yet been included. Although the reported rate of INSTI-associated resistance is currently low, the potential risk of resistance cannot be ignored given the expanding use of these drugs. Future studies will focus on conducting resistance analyses for these drugs.

## Conclusion

Unlike previous studies that primarily focused on high-burden southeastern and coastal regions of China, this study addresses an important geographical gap by investigating HIV-1 molecular transmission clusters and pretreatment drug resistance among MSM in Baotou, a major city in northern China.

This study is distinguished by its use of NGS technology to provide a comprehensive characterization of the local HIV epidemic by integrating molecular transmission network analysis, assortative mixing analysis, and pretreatment drug resistance surveillance. These findings demonstrate that the high clustering of CRF07_BC and the predominance of NNRTI resistance are not confined to coastal regions with severe HIV epidemics but are also present in northern border regions characterized by different demographic and behavioral patterns.

These results highlight the importance of incorporating molecular network surveillance into routine HIV monitoring systems to identify high-risk transmission clusters and support precision public health interventions. In particular, younger, unmarried, and highly educated MSM exhibited a greater likelihood of being HIV-1-infected and should therefore be prioritized for targeted prevention strategies. Furthermore, surveillance of pretreatment drug resistance may facilitate the optimization of region-specific first-line antiretroviral regimens and improve the efficient allocation of limited health care resources.

In the Inner Mongolia Autonomous Region, the geographically dispersed population and relatively limited health care resources have hindered the widespread implementation of advanced HIV surveillance technologies and targeted intervention strategies. These findings may provide important evidence for molecular surveillance-based HIV prevention strategies in other resource-limited border regions of China.

## Acknowledgments

The authors would like to express their sincere gratitude to the study participants for their invaluable support. The authors also thank the dedicated staff at the clinical sites and the Inner Mongolia Autonomous Region Center for Disease Control and Prevention for their assistance in gathering blood samples and data.

## Generative AI Use

The authors declare the use of generative AI (GenAI) in the research and writing process. According to the GAIDeT (Generative AI Delegation) taxonomy (2025), the following tasks were delegated to GenAI tools under full human supervision:

- Translation

The GenAI tool used was: Grammarly.

Responsibility for the final manuscript lies entirely with the authors.

GenAI tools are not listed as authors and do not bear responsibility for the final outcomes.

## Funding

This work was supported by the National Key Research and Development Program of China under Grant numbers (grant 2022YFC2304903), the National Natural Science Foundation of China under Grant number (grant 82173583), and the Natural Science Foundation of the Inner Mongolia Autonomous Region of China (grant 2025MS08104). The funders had no role in the study design, data collection, analysis, data interpretation, manuscript writing, or the decision to submit the paper for publication.

## Data Availability

The data presented in this study are not publicly available due to privacy and ethical restrictions related to the sensitive nature of the information.

## Authors' Contributions

# Social Determinants of Health Associated With Unhealthy Weight Management Behaviors Among Emerging Adult Women: Nationwide Cross-Sectional Study

## Abstract

**Background:** Unhealthy weight management behaviors (UWMBs) have become increasingly common among emerging adult women, yet prior research has largely focused on psychological or perceptual correlates in isolation. In appearance-oriented contexts, structural influences, including social norms, may co-occur with individual characteristics to shape these behaviors. The social determinants of health (SDOH) framework offers a useful lens for examining UWMBs by jointly considering structural and intermediary determinants.

**Objective:** This study aimed to identify key SDOH associated with engagement in UWMBs among emerging adult women in South Korea by examining structural and intermediary determinants within a single adjusted model.

**Methods:** A nationwide cross-sectional survey was conducted among women aged 19 to 25 years using stratified sampling with quota allocation based on residential area and employment status. The final analytic sample included 1594 participants. UWMBs were assessed using a 9-item checklist; reporting at least 1 behavior in the past year was classified as UWMB engagement. Structural determinants included social norms, social influence, and socioeconomic position. Intermediary determinants included perceived body shape, body weight misperception, weight disparity, weight self-stigma, media health literacy, social network support, and BMI. Multivariable logistic regression analyses were performed to identify factors associated with UWMBs.

**Results:** Overall, 88% (1404/1594) of participants reported at least 1 UWMB in the past year, and 71.4% (n=1002) engaged in 2 or more UWMBs. Compared with women without UWMBs, those engaging in UWMBs reported stronger weight-related social norms, greater social influence, more distorted perceptions of body image, higher weight self-stigma, and greater media health literacy and social network support. In the multivariable model, UWMB engagement was significantly associated with perceived body shape (average vs thin: OR 2.41, 95% CI 1.52-3.83; *P*<.001; obese vs thin: OR 2.33, 95% CI 1.13-4.79; *P*=.02), descriptive norms (OR 1.38, 95% CI 1.19-1.61; *P*<.001), thin-ideal internalization (OR 1.32, 95% CI 1.01-1.71; *P*=.04), BMI (OR 1.10, 95% CI 1.01-1.19; *P*=.04), and educational attainment (in college vs high school or less; OR 1.69, 95% CI 1.09-2.62; *P*=.02; college or higher vs high school or less; OR 1.81, 95% CI 1.13-2.91; *P*=.01), with perceived body shape showing the largest odds ratios.

**Conclusions:** UWMBs are widely practiced among emerging adult women and are associated with both intermediary body image–related factors and broader sociocultural norms when considered simultaneously. These findings underscore the need for interventions that address appearance-related norms, particularly those disseminated through social media environments, rather than approaches focused solely on individual determinants. Future research should clarify the mechanisms linking structural and individual determinants to inform culturally relevant prevention strategies.

**KEYWORDS**

unhealthy weight management behaviors; social determinants of health; emerging adults; body image; social norms; South Korea

## Introduction

Heightened societal attention to appearance and weight stigma has intensified demand for weight loss [1], and unhealthy weight management behaviors (UWMBs) are increasingly adopted by emerging adult women [2]. These behaviors are associated with multiple adverse health outcomes, particularly eating disorders and psychological distress [3]. Social media and the growing availability of weight loss medications have further reinforced

XSL•FO
RenderX

expectations of rapid and effortless weight reduction [4,5]. In the United States, more than half of emerging adult women have reported at least 1 UWMB, and more than 20% have engaged in extreme methods such as diet pills, self-induced vomiting, or the use of diuretics and laxatives [2]. As women at this life stage remain highly sensitive to appearance-related judgments [6] and prone to self-criticism [7], this pattern may extend beyond the United States and reflect a broader global trend. Similar concerns have also been reported in Asian [8] and European [9] populations. Moreover, longitudinal evidence indicates that UWMBs tend to emerge during emerging adulthood and may persist over time [2,8]. Therefore, identifying factors associated with UWMBs specific to emerging adult women is essential.

Distorted body image has been consistently identified as a key factor associated with UWMBs [10]. In particular, multiple forms of perceptual inaccuracy—such as heightened distortion in perceived body shape, discrepancies between actual and ideal body weight, and body dissatisfaction—are strongly associated with the adoption of unhealthy practices. These risks are particularly pronounced when thinness is internalized as the desirable body ideal. Various interventions targeting perceptual components of body image, including cognitive dissonance-based programs [11], self-compassion training [12], and media or health literacy education [13], have been developed to address this issue. However, such approaches largely remain centered on reshaping individual cognitions or attitudes and offer limited sustainability or responsiveness to broader sociocultural and structural forces that shape body image norms.

Beyond individual perceptions, social norms provide a structural context that reinforces weight concerns. Social norms refer to collectively shared expectations regarding acceptable or desirable body shapes within a given sociocultural environment. According to the tripartite influence model [14], family, peers, and media function as primary channels through which these appearance-related expectations are transmitted to individuals. This transmission operates through social influence, which encompasses the process by which socially shared norms are perceived as external pressure to conform to dominant body ideals and subsequently internalized as personal standards. With repeated exposure to such influences, body dissatisfaction and weight-related self-stigma intensify, and individuals' body ideals progressively converge with prevailing sociocultural standards [15]. In South Korea, where thinness is culturally valued as a symbol of self-discipline and aesthetic capital [16], the prevalence of underweight remains high despite rising UWMBs [8], a pattern that may reflect the influence of social factors, particularly those conveyed through appearance-ideal content on social media [17]. Accordingly, media literacy, which enables critical evaluation of media messages, may serve as a potential protective factor [13].

Nevertheless, most prior research has examined factors associated with UWMBs in isolation, focusing on psychological or perceptual aspects such as body image, while broader structural determinants have received comparatively little attention. This fragmented perspective overlooks how social context and individual cognition interact to shape behavioral risk. To address this limitation, this study adopts the World Health Organization's (WHO) social determinants of health (SDOH) framework [18], situating health behaviors within the interplay between structural determinants (eg, socioeconomic status [SES], social norms, and social influence) and intermediary determinants (eg, BMI, body image, and health literacy). Through this approach, the study aimed to identify SDOH empirically associated with UWMBs within the sociocultural context of emerging adult women.

## Methods

### Study Design

This cross-sectional study used primary data collected through a nationwide survey of emerging adult women aged 19 to 25 years in South Korea, referred to as the STOP 2025 survey. This age range reflects the conventional definition of emerging adulthood [19], excluding people aged 18 years, who are minors under Korean law. The study adhered to the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines for cross-sectional studies.

### Study Setting and Participants

The survey was conducted via an online panel managed by a professional survey research agency and drawn from the subscriber base of a major South Korean telecommunications provider. This panel included approximately 90,000 registered women aged 19 to 25 years, representing approximately 4.9% of the national female population in this age group. This limited coverage reflects the panel's restriction to subscribers of a single telecommunications provider who had also enrolled as survey panelists.

Eligible participants were emerging adult women who could read and understand Korean and who provided informed consent prior to participation. Exclusion criteria, assessed via self-report at the online screening stage, included (1) severe cognitive impairment or communication difficulties, (2) current pharmacological treatment for a diagnosed eating disorder, or (3) medically supervised weight loss treatment for a chronic condition.

Stratified sampling with quota allocation was applied based on residential area (metropolitan vs nonmetropolitan) and employment status (employed vs nonemployed) to obtain a demographically diverse sample of women aged 19 to 25 years. Quota targets for these strata were set based on population statistics from Statistics Korea [20], approximating the actual distribution of women aged 19 to 25 years in South Korea (approximately equal proportions for both residential area and employment status).

The minimum required sample size was calculated using the Cochran formula for a single population proportion, assuming a prevalence of 30% [21], a 95% confidence level, and a 5% margin of error, yielding an initial estimate of 323 participants. We assumed that individuals within the same quota stratum might share lifestyle-related characteristics relevant to UWMBs (eg, consumption patterns and environmental exposure), potentially resulting in within-stratum correlation; accordingly, each quota stratum was conservatively treated as a cluster for the sample size calculation. In the absence of Korea-specific

XSL•FO
RenderX

intraclass correlation coefficient (ICC) estimates for UWMBs, we applied an ICC of 0.039 [22] and a cluster size (m) of 100 (consistent with the Korea National Health and Nutrition Examination Survey [KNHANES] sampling convention), yielding a design effect of 4.861 and a required analytic sample size of approximately 1569. To allow for potential dropouts and exclusions, 1600 participants were recruited, allocated equally across the 4 resulting strata (400 participants per stratum), of whom 1594 were included in the final analysis. Six participants were excluded due to an outlier BMI value or logically inconsistent responses to the weight management behavior items.

## Measurements

### *Dependent Variable*

UWMBs were assessed using a 9-item checklist adapted from Neumark-Sztainer et al [23]. Participants were asked, "During the past year, have you done any of the following to lose or maintain your weight?" Responses were recorded as yes or no for each of the following behaviors: (1) fasted, (2) ate very little food, (3) used food substitutes (eg, powders or diet drinks), (4) skipped meals, (5) smoked more cigarettes, (6) took diet pills (prescribed pills or diet-related health supplements), (7) induced vomiting, (8) used laxatives, and (9) used diuretics. Participants reporting at least 1 of these 9 behaviors were classified as having engaged in UWMBs.

### *Independent Variables*

#### Structural Determinants

##### *Social Norms*

Two types of norms were assessed: descriptive norms (perceived prevalence of weight control behaviors among others) and injunctive norms (perceived expectations to engage in such behaviors). Both were adapted from Paek and Hove [24], with higher scores indicating stronger perceived norms. The norms are described as follows:

- Descriptive norms were measured with 2 items asking, "How many of the following people do you think are trying to stay thin or lose weight?" Responses were provided for (1) close friends and (2) same-age peers on a 6-point scale (1="none" to 6="80% or more"). The mean score across the 2 items was calculated (Cronbach α=0.813).
- Injunctive norms were measured with 3 items asking, "To what extent do the following people expect you to stay thin or lose weight?" Participants rated (1) close friends, (2) parents, and (3) significant others on a 5-point scale (1="not at all" to 5="very much"). The mean score across the 3 items was computed (Cronbach α=0.863).

##### *Social Influence*

Social influence, consisting of the internalization of appearance ideals and perceived appearance-related social pressure, was measured using the Korean version of the Sociocultural Attitudes Toward Appearance Questionnaire-4-Revised (SATAQ-4R) [25]. The instrument includes 31 items rated on a 5-point Likert scale (1="strongly disagree" to 5="strongly agree"), comprising 7 subscales assessing the internalization of thinness or low body fat, muscularity, and general attractiveness, as well as perceived pressure from family, peers, significant others, and media. Reverse-coded items were recoded prior to analysis. Higher scores on each subscale indicated stronger internalization or greater perceived pressure to conform to sociocultural appearance ideals. Cronbach α values ranged from 0.818 to 0.950 across subscales.

##### *Socioeconomic Position*

Socioeconomic variables included educational attainment, employment status, monthly income, marital status, household composition, residential area, and primary activity area. Subjective social status (SSS) was measured using the youth version of the MacArthur Scale of Subjective Social Status [26], with scores ranging from 1 (lowest) to 10 (highest).

#### Intermediary Determinants

##### *Perceived Body Shape*

Perceived body shape was assessed using a single item from the KNHANES [21]: "What do you think about your body shape?" Responses were rated on a 5-point scale (1="very thin" to 5="very obese") and were recoded into 3 categories by merging each extreme category with the adjacent category: thin (very thin and slightly thin), average, and obese (slightly obese and very obese).

##### *Body Weight Misperception*

Body weight misperception was defined as the discrepancy between actual BMI and perceived weight status. BMI was calculated from self-reported height and weight and classified according to Korean adult standards [27]: underweight (BMI <18.5 kg/m$^2$), normal (BMI 18.5-22.9 kg/m$^2$), and overweight (BMI ≥23.0 kg/m$^2$). Perceived weight status was assessed using a single item [28]: "What do you think about your weight?" Responses were rated on a 5-point scale (1="very underweight" to 5="very overweight") and were recoded into 3 categories corresponding to the BMI classifications described above. Body weight misperception was classified as accurate estimation (perceived weight category matching the BMI category), underestimation (overweight perceived as normal or underweight; normal weight perceived as underweight), and overestimation (underweight perceived as normal or overweight; normal weight perceived as overweight) [28].

##### *Weight Disparity*

Weight disparity was calculated as the ratio of desired weight to actual weight, expressed as a percentage. It was categorized into 3 groups: <100% (desired weight lower than actual weight), 100% (desired weight equal to actual weight), and >100% (desired weight higher than actual weight) [29].

##### *Weight Self-Stigma*

Weight self-stigma was measured using the Korean version of the Weight Self-Stigma Questionnaire (WSSQ) [30]. The 12 items were rated on a 5-point Likert scale (1="completely disagree" to 5="completely agree"), with higher scores indicating stronger internalized weight stigma (Cronbach α=0.914).

XSL•FO
RenderX

### *Media Health Literacy*

Media health literacy was measured using a modified Korean version of the eHealth Literacy Scale (eHEALS) [31]. The 8 items were rated on a 5-point Likert scale (1="strongly disagree" to 5="strongly agree"), with higher scores reflecting a greater ability to find, evaluate, and use online health information (Cronbach α=0.914).

### *Social Network Support*

Social network support was assessed using a modified Korean version of the Social Support for Exercise scale [32]. Although the cited scale's items assessed perceived social support for exercise from family and friends, item wording in this study was modified to refer to support for weight control from people encountered on social media. The 6 items were rated on a 4-point Likert scale (1="strongly disagree" to 4="strongly agree"), with higher scores reflecting greater perceived support from social media–based networks for weight control (Cronbach α=0.943).

## Data Collection

Data were collected via an online self-administered questionnaire distributed by a professional survey agency over a 1-week period in January 2025. The research team provided the agency with the study information sheet, consent form, and questionnaire. Responses within each stratum were automatically closed to further submissions once the predefined quota was reached.

Survey invitations were sent to the provider's nationwide panel via SMS and pop-up notifications. Participants accessed the questionnaire only after reviewing the online consent form and selecting "Agree." Those selecting "Disagree" were automatically exited from the survey. Eligible respondents proceeded to a screening page, and only those meeting the inclusion criteria and none of the exclusion criteria completed the survey. Survey completion required approximately 30 minutes. All data were anonymized and deidentified by the survey agency prior to transfer to the research team.

## Statistical Analysis

Prior to analysis, the anonymized dataset was screened for normality assumptions, outliers, and missing data. Categorical variables were dummy coded, and negatively worded items were reverse scored. Descriptive statistics (means, SDs, frequencies, and percentages) were computed to summarize participants' sociodemographic characteristics and the prevalence of UWMBs. No poststratification weighting was applied in the analysis. Group differences between women with and without UWMBs were first examined using independent *t* tests and chi-square tests, based on variables selected according to the SDOH framework. Subsequently, a multivariable logistic regression analysis was conducted by entering variables that were selected a priori based on the SDOH framework and that showed significant associations in bivariate analyses. Odds ratios (ORs) and 95% CIs were estimated from the multivariable logistic regression model. Multicollinearity among predictors in the multivariable model was assessed using variance inflation factors (VIFs). Model fit was evaluated using the Hosmer-Lemeshow goodness-of-fit test and Nagelkerke $R^2$. Statistical significance was set at $P<.05$ (2-tailed). All analyses were performed using SPSS (version 29.0; IBM Corp).

## Ethical Considerations

This study was approved by the Institutional Review Board of Yonsei University Health System (4-2024-1456). A waiver of written consent was granted because the survey was conducted online through a professional research agency. Before participation, all respondents were presented with an online consent form describing the study purpose, procedures, confidentiality, and voluntary participation, including the right to withdraw at any time. Minimal personal information (sex, age, and residential area) was collected to verify eligibility and monitor quota compliance across strata. All responses were anonymized before being provided to the research team, and the survey agency permanently deleted all identifiable data after data delivery. Participants received a mobile gift voucher provided by the survey panel provider upon completion of the questionnaire. All procedures performed in this study were conducted in accordance with the ethical standards of the institutional review board and the Declaration of Helsinki and its later amendments.

# Results

## Participant Characteristics

The mean age of participants was 22.96 (SD 1.85) years. Most participants were currently enrolled in college (729/1594, 45.7%) or had graduated from college (n=539, 33.8%), and approximately half (n=796, 49.9%) were employed. The average SSS score was 5.26 (SD 1.64). The majority were unmarried (n=1537, 96.4%), and about one-quarter lived alone (n=402, 25.2%; Table 1).

[a]This table presents the socioeconomic position component of the structural determinants within the social determinants of health framework.

[b]1 KRW=US $0.00075, as of October 28, 2026.

## Prevalence and Patterns of UWMBs

Among all participants (N=1594), 1404 (88%) reported engaging in at least 1 UWMB during the past year. The most frequently reported UWMB methods were eating very little food (n=1277, 80.1%) and skipping meals (n=720, 45.2%), followed by taking diet pills (n=545, 34.2%), using food substitutes (n=518, 32.5%), fasting (n=250, 15.7%), smoking more cigarettes (n=162, 10.2%), self-induced vomiting (n=90, 5.6%), laxative use (n=26, 1.6%), and diuretic use (n=23, 1.4%). Multiple UWMB methods were common: 1002 (71.4%) participants who engaged in UWMBs reported using 2 or more methods, whereas 402 (28.6%) reported using only 1 method.

XSL•FO
RenderX

### Group Differences by UWMB Status

As shown in Table 1, engagement in UWMBs differed significantly according to educational attainment, employment status, monthly income, and marital status. No significant differences were observed in age, SSS, household composition, or residential or primary activity area.

As shown in Table 2, significant differences between the UWMB and non-UWMB groups were observed in descriptive and injunctive norms and in sociocultural influences related to appearance, including internalization of appearance ideals and perceived appearance-related pressures. The groups also differed significantly in weight self-stigma, media health literacy, social network support, and BMI. Significant group differences were additionally found in perceived body shape and weight disparity, with a higher proportion of participants in the UWMB group reporting desired weights lower than their actual weights and perceiving themselves as obese. In contrast, body weight misperception did not differ significantly between the groups.

[a]This table presents the social norms and social influence components of structural determinants within the SDOH framework, together with intermediary determinants.

## Factors Associated With UWMBs

Perceiving oneself as having an average or obese body shape, higher educational attainment, stronger descriptive norms, greater internalization of thinness or low body fat ideals, greater social network support, and higher BMI were significantly associated with increased odds of engaging in UWMBs (Table 3). No other factors remained significant after adjustment. VIF for all predictors in the multivariable model ranged from 1.03 to 4.26, indicating no substantial multicollinearity.

[b]Not applicable.

Participants who perceived themselves as having an average body shape showed the highest odds of UWMB engagement (OR 2.41, 95% CI 1.52-3.83), followed by those who perceived themselves as obese (OR 2.33, 95% CI 1.13-4.79), compared with those who perceived themselves as thin. Educational attainment showed a positive gradient: college students (OR 1.69, 95% CI 1.09-2.62) and college graduates (OR 1.81, 95% CI 1.13-2.91) had higher odds of engaging in UWMBs than high school graduates. Stronger descriptive norms (OR 1.38, 95% CI 1.19-1.61) and greater internalization of thinness or low body fat ideals (OR 1.32, 95% CI 1.01-1.71) were also significantly associated with UWMBs. Greater social network support (OR 1.29, 95% CI 1.01-1.63) and higher BMI (OR 1.10, 95% CI 1.01-1.19) were also positively associated with UWMB engagement.

## Discussion

### Key Findings

This study demonstrated that UWMBs were highly prevalent among emerging adult women in South Korea, underscoring their importance as a public health concern. Within the SDOH framework, this study found that perceived body shape emerged as the factor most strongly associated with UWMB engagement among emerging adult women in South Korea, supporting the existing body of knowledge. Notably, this study further highlights the influence of structural determinants—including descriptive norms and internalization of thin or low body fat ideals—on UWMBs. These findings extend prior research that has primarily emphasized individual psychological and perceptual correlates [10,15,16] by demonstrating that both intermediary and structural determinants remain salient when considered simultaneously. Therefore, UWMBs should be understood not as matters of personal choice but as behaviors embedded within social and structural environments, highlighting the need for structural approaches aimed at shifting sociocultural norms, alongside individual-level efforts.

The prevalence of UWMBs in this study (88%) was substantially higher than the 30% estimate in national statistics [21] and exceeded the international estimates reported in prior research (approximately 50%-60%) [2,23]. In this study, diet pills were operationalized to include weight loss supplements, consistent with a common definition of the term; however, as it is unclear whether diet pills were defined similarly in other studies, comparisons of prevalence estimates across studies should be made with caution. A persistent upward trend in behaviors such as meal skipping and diet pill use has also been observed in Korea over the past decade [8], suggesting a genuine increase in these behaviors over time within this population. Moreover, Korean women frequently attempt weight loss [33] and often engage in unhealthy methods [8], even when they have relatively low BMI or do not perceive themselves as overweight. Comparable patterns have been reported in other Asian countries, where young women show consistently high levels of weight loss attempts across the entire BMI distribution, substantially exceeding those observed in European, Mediterranean, and American populations [34]. Longitudinal studies from the United States have shown a marked increase in extreme weight control behaviors—a subset of the behaviors encompassed by UWMBs—from adolescence to adulthood [2], suggesting that similar upward trends may be occurring elsewhere. Taken together, these findings suggest that UWMBs may be increasingly normalized within the sociocultural context examined in this study, shaped by everyday appearance-based comparison in digital media [4], self-discipline–oriented views of weight control [16], and widely shared thinness norms [15]. Therefore, efforts to reduce or prevent UWMBs require careful consideration of both individual and structural contexts that may encourage emerging adult women to engage in these risky behaviors.

This study reaffirms prior evidence that distorted body image is a salient correlate of UWMBs [10], with perceived body shape emerging as the factor most strongly associated with UWMB engagement. Notably, even women who perceived themselves as having an “average” body shape showed an elevated likelihood of engaging in UWMBs. Previous studies have documented substantial discrepancies between objectively measured BMI and perceived body shape, even among individuals within the normal weight range, with some tending to perceive their body size as larger than it actually is [35]. Such perceptual discrepancies suggest that UWMBs may be more closely related to subjective, visually oriented standards of body evaluation than to objective weight status. This interpretation is consistent with contemporary shifts in body perception, particularly in the context of the expanding use of social media, where body evaluation increasingly relies on visual self-presentation and the perceived gaze of others rather than on measurable indicators such as BMI [36]. Overall, these findings indicate that perceived body shape reflects a socially mediated aspect of body image and call for more multidimensional approaches to its measurement. Unlike previous studies [10], weight disparity and body weight misperception were not significantly associated with UWMB engagement in the present study. Given the heterogeneity of body image indicators currently used in research, future assessment models should incorporate cognitive, emotional, perceptual, and sociocultural dimensions rather than relying on a single index or construct.

The specific role of social media in shaping perceived body shape remains exploratory, as social media use and appearance-related online behaviors were not directly assessed in this study. The perceived gaze of others may nonetheless be interpreted through the lens of objectification theory [37], which posits that women come to adopt an observer’s perspective on their bodies. This phenomenon has been consistently documented in social media–based appearance comparison research [4,36]. In the social media context, this has been conceptualized as appearance-related social media consciousness (ASMC), which shows substantial associations with body surveillance, body shame, and appearance comparison [38] and remains associated with disordered eating among emerging adults even after controlling for general social media use [39]. Other evidence suggests that exposure to appearance-ideal

XSL•FO
RenderX

content, rather than social media use itself, is more strongly linked to body dissatisfaction [17]. Future research should clarify which of these mechanisms best accounts for the present findings.

The tripartite influence model [14] helps clarify why descriptive norms and internalization of thin or low body fat ideals emerged as significant structural factors associated with UWMBs in this study. Even though perceived pressures from peers, family, or media were not independently significant, repeated exposure to others' weight control behaviors may normalize such practices and encourage similar engagement [40]; higher levels of social network support for weight control may likewise reflect embeddedness in appearance-oriented social environments in which dieting and weight control behaviors are more visible and socially reinforced, thereby amplifying descriptive norms. As these norms become more pervasive, appearance-related standards may be internalized as personal expectations even in the absence of explicit pressure. These mechanisms underscore the need for interventions that address both individual self-perception and the broader sociocultural norms that shape and reinforce it.

Unlike the SDOH perspective [18] and prior evidence suggesting that individuals with lower SES are more vulnerable to unhealthy behaviors [41], prior research indicates that women with higher SES tend to monitor their weight more strictly and attempt weight loss more frequently [42], and that even among underweight women, those with higher income levels report more frequent weight loss attempts [33]. In our study, monthly income, employment status, and marital status were associated with UWMB engagement in bivariate analyses, but only higher educational attainment remained significantly associated with greater odds of engaging in UWMBs after multivariable adjustment. These patterns imply that appearance-oriented cultural contexts [16] may create heightened vulnerability among women with higher educational attainment. Although higher educational attainment is associated with greater awareness of weight-related health information [43], which would generally be expected to reduce risky behaviors, media health literacy—the construct measured in this study—was higher among women engaging in UWMBs in the bivariate analysis but lost significance after adjustment. This pattern may reflect more active health information-seeking related to weight control, and may also indicate that eHEALS, as a unidimensional scale [31], does not capture the capacity to critically resist appearance-related media ideals. Future research should therefore operationalize SES in a manner that reflects the developmental characteristics of emerging adult women to further investigate these associations.

### Limitations and Future Directions

UWMBs were assessed using a self-reported behavioral checklist rather than a validated psychometric instrument and were operationalized as a broad binary outcome encompassing 9 behaviors of markedly different severities. This approach may have introduced measurement error and may have contributed in part to the high prevalence observed in this study. Given the resulting imbalance in the outcome distribution, the ORs are more appropriately interpreted as indicators of the direction and relative magnitude of associations rather than as precise estimates of relative risk. Similarly, the measure of social network support for weight control was modified from an existing exercise-related scale, and its validity for this purpose has not been established beyond internal consistency.

Separately, the survey response rate could not be obtained from the survey agency, which further limits the ability to assess nonresponse or self-selection bias in this online panel. Although quota targets were set to approximate the national population distribution [20], the panel was restricted to subscribers of a single telecommunications provider, and no poststratification weighting was applied. The sample should therefore not be assumed to be representative of the general population of South Korean emerging adult women.

A cross-sectional design precludes causal or directional inference, and because associations are situated within specific sociocultural and media environments, the generalizability of the findings to other populations, cultural contexts, or genders remains uncertain. Social media use and appearance-related online exposure were not directly measured, despite their plausible role in shaping UWMB engagement. In this context, although prior research has repeatedly validated pathways linking body image, body dissatisfaction, and disordered eating [4,44], such analyses have rarely been extended to UWMBs. To rigorously examine how these mechanisms operate within sociocultural contexts, future research should use structural modeling approaches, including mediation and moderation analyses.

Beyond theoretical refinement and in line with public health implications, future research should also focus on developing intervention strategies that mitigate the sociocultural norms constructed around the visible body. Social norm–based approaches have shown some promise in shaping health-related behaviors by altering perceived norms and collective expectations [45]. Likewise, media-based public campaigns that shift the focus from appearance to functionality or strength have demonstrated limited yet encouraging effects in improving body image outcomes [46]. Such interventions may gradually contribute to redefining appearance-centered values and promoting more inclusive, health-oriented social norms.

## Conclusions

This study demonstrates that UWMBs are highly prevalent among emerging adult women in South Korea and are shaped by both individual and structural determinants. UWMB engagement was associated not only with subjective body evaluation—particularly perceived body shape and BMI—but also with pervasive appearance-oriented social norms and the internalization of thin ideals. These cross-sectional findings suggest that UWMBs may not be effectively addressed through individual-level approaches alone, underscoring the potential need for interventions that target sociocultural norms while supporting healthier self-perceptions and more realistic body evaluations. Future research should clarify the pathways through which structural and individual determinants jointly relate to UWMBs using longitudinal designs and mediation analyses to inform culturally relevant prevention and intervention strategies. In addition, social media–based initiatives promoting diverse

XSL•FO
RenderX

and health-oriented body ideals may represent an important strategy for reducing the social normalization of UWMBs.

## Abstract

**Background:** Modifiable unhealthy behaviors account for over two-thirds of new cases of noncommunicable diseases. Behavioral risk factor reduction is a potentially cost-effective means to improve long-term health outcomes. Although family serves as a pivotal cornerstone for fostering and maintaining individuals' health, the associations between family health (FH) and the proactive health risk management index (PHRMI) remain unclear.

**Objective:** This study aimed to construct a comprehensive index to measure the PHRMI and examine the mediating effect of health literacy on the association between FH and the PHRMI, as well as the moderating effect of family communication on the associations among the PHRMI, health literacy, and FH.

**Methods:** A cross-sectional questionnaire survey was conducted with 30,044 participants from 34 provinces or regions in China who were recruited using a multistage stratified sampling strategy from June 20, 2023, to August 31, 2023. This study constructed the PHRMI for the general population by encompassing BMI, physical activity (International Physical Activity Questionnaire–Short Form), depression (Patient Health Questionnaire-9), sleep quality (Brief version of the Pittsburgh Sleep Quality Index), smoking behavior, and drinking behavior. Further, we assessed FH (Short Form of the Family Health Scale), health literacy (Short-Form Health Literacy Questionnaire-4), and family communication (Family Communication Scale–Short Form). In addition, we collected the sociodemographic characteristics of the participants. We used model 4 of the IBM SPSS macro PROCESS to verify the mediating effect of health literacy between FH and the PHRMI, while model 7 was adopted to test the moderated mediation of family communication among the PHRMI, health literacy, and FH.

**Results:** Higher levels of FH were significantly associated with higher PHRMI levels (β=.710, 95% CI 0.669-0.752). Health literacy significantly mediated the association between FH and the PHRMI (β=.207, 95% CI 0.168-0.245), playing a partial mediating role. Family communication significantly moderated the association between FH and health literacy (β=.117, 95% CI 0.105-0.130). The simple slope analysis showed that higher levels of family communication exacerbated the effects of FH on health literacy. Subsequently, we performed a sensitivity analysis, and the main results aligned with the findings of prior studies. Nevertheless, the subgroup analysis revealed that the mediating effect of health literacy was not significant in the group aged >60 years (β=.066, 95% CI −0.024 to 0.157).

**Conclusions:** FH can be an important target that appears to be positively linked to proactive health risk management and health literacy. FH promotion for older adults should pay more attention to family or intergenerational communication.

family health; health literacy; proactive health risk management; middle-aged and older adults; health behavior

## Introduction

The presence of multiple health risk factors (environmental and occupational hazards, behavioral risks, and metabolic risks) exerts a cumulative negative influence on health [1]. From the perspective of the full life cycle, in addition to genetic factors, the accumulation of risk factors during the early stages of life exacerbates health hazards in the later stages of life [2,3]. Modifiable unhealthy behaviors, such as tobacco use,

XSL•FO
RenderX

consumption of foods high in saturated and trans fats, salt, and sugar, physical inactivity, and the harmful consumption of alcohol, account for more than two-thirds of all new cases of noncommunicable diseases and increase the risk of complications in individuals with noncommunicable diseases [4]. The rapid expansion and high incidence of chronic diseases worldwide, combined with population aging, have resulted in an increasing disease burden on individuals [5], families, and society [6]. Behavioral risk factor reduction is a potentially cost-effective means to improve long-term health outcomes and reduce the disease burden. Therefore, numerous countries have implemented policies to encourage individuals to actively practice a healthy lifestyle, aligning with the "proactive health" initiative actively promoted by China in recent years.

Despite being a novel concept proposed in 2015, proactive health has a lengthy research history concerning its concept and practice [7-11]. Most relevant research focuses on the connotation, subject matter, objectives, essential components, and implementation strategies of proactive health. Current academic discourse presents two main perspectives on the concept of proactive health [12]. First, based on the micro perspective of residents, proactive health is defined as guiding residents to identify and control risk factors [8], advocating self-active health management, and promoting the formation of healthy living habits [13]. Second, proactive health inherently leverages information technology to achieve its "proactive and full-lifecycle" characteristics in health management services [14]. From this perspective, proactive health is defined as health care professionals regularly monitoring residents' health risk indicators through means such as model design and platform construction [15], aiming to detect service needs early and intervene in the medical and health service process in advance. Despite the variations in conceptualizations of proactive health, scholars in China have reached a consensus on the identification and control of health risk factors within the core essence of proactive health. Some scholars have focused on special groups, such as adolescents [16], disabled older adults [17], patients with hypertension, patients with coronary heart disease [18], and others, to develop appropriate proactive health behavior measurement scales. The development approach mainly revolves around the specific health needs or unique health risk factors of the participants being assessed. For instance, proactive health management for adolescents [16] is composed of 5 dimensions: health responsibility, physical activity, nutritional diet, mental health, and self-discipline. In line with the above studies, we developed the proactive health risk management index (PHRMI), integrating the most common health risks for the general population. Proactive health risk management is defined as a resident's active engagement in health management activities encompassing psychological, dietary, exercise, sleep, and lifestyle aspects. It involves identifying and modifying detrimental habits to prevent health risks from the source, encouraging individuals to assume health management responsibilities, thereby comprehensively safeguarding individual and collective well-being. Risk factors were extracted based on the "four cornerstones of health" outlined in the "Victoria Declaration," namely "balanced diet," "moderate exercise," "smoking cessation and alcohol restriction," and "psychological balance" [19]. In addition, sleep of sufficient quality and duration is essential for good health [20] and reduces the risk of total mortality, obesity [21], cardiovascular disease [22,23], cerebrovascular diseases [24,25], and dementia. Therefore, sleep quality is incorporated as one of the components of the proactive health index.

Subsequently, this study aims to investigate family-level and individual-level determinants influencing the PHRMI. Entering the era of "Public Health 3.0," the family's role as a fundamental contributor to individual and community health remains unquestioned. The family, owing to its fundamental capacity to nurture, care for, protect, educate, and influence across the lifespan, serves as a pivotal cornerstone for fostering and maintaining individuals' health. Engaging families as proactive participants in health promotion initiatives can enhance family members' acceptance and use [19] and may facilitate longer-lasting and larger-scale behavioral changes [26]. Ho et al [27] have developed a more comprehensive conceptual framework for "family health" (FH) by using the Delphi method. The framework posits FH as a multifaceted resource arising at the family-unit level through the interplay of the members' health, their interactions, and the family's array of physical, social, emotional, economic, and medical resources. FH is a comprehensive construct that encompasses intrafamily dynamics, such as associations, communication, and the domestic environment, as well as the accessibility of social support and health resources. The influence of FH on proactive health, both in terms of its presence and magnitude, remains uncertain. Clarifying these ambiguities may have important implications for individual, clinical, and public health, especially amid the escalating incidence of chronic diseases [28].

Health literacy serves as a key measure reflecting an individual's accumulation of health knowledge and capabilities [29]. It is hypothesized that FH would result in a positive influence on health literacy, given that the family constitutes a primary environment through which health-related attitudes, behaviors, and competencies are developed. Existing studies have demonstrated that individuals with low health literacy are associated with inadequate health-related behaviors [30], leading to adverse health-related outcomes [31], including poorer general health [32], more hospitalizations [33], compromised self-management ability, less effective use of health services [34], and higher health care costs [35]. Although lower health literacy is often linked to poorer health outcomes, some patients with chronic diseases can successfully manage their conditions despite inadequate health literacy. The buffering effect of valuable resources and support from social networks appears to mitigate the negative impacts of low health literacy [36]. Humans, inherently endowed with social attributes, consistently inhabit a collective milieu characterized by diverse levels of social support and resource availability. Family-level resources and support are pivotal in an individual's social network. Research across Brazil, the United States, and China has established that family structure, income levels, and cohesion, along with other factors, significantly influence the development and maintenance of health literacy [37-39].

The enhancement of health literacy through FH promotion does not occur spontaneously but rather through dynamic interactions within familial systems. The circumplex model emphasizes that

XSL•FO
RenderX

family communication is considered a facilitating dimension and is essential for family cohesion and flexibility [40]. Conversation-oriented communication patterns significantly facilitate intermember health information exchange [41]. According to the "stimulus-awareness-internalization" pathway, family communication serves as a "stimulus" by facilitating information exchange and sharing [41-43]. This process enables individuals to receive health information and resources transmitted at the family level, subsequently internalizing them into cognitive components such as health literacy. Research has shown that better family communication is associated with better health status and higher cervical cancer literacy scores [37]. Another anorexia family therapy trial showed that family communication shifting from covert aggression to overt aggression during systemic family therapy significantly improved patients' eating attitudes [44]. The positive transformation of patients' eating attitudes and self-health cognition was promoted by coordinating the conflicts of health concepts within the family. Therefore, this study attempts to examine whether family communication plays a moderating role in the association between FH and health literacy.

Well-established evidence indicates that over two-thirds of the risk factors for chronic diseases stem from modifiable unhealthy behaviors [2,4,45]. Therefore, encouraging individuals to adopt a healthy lifestyle is crucial and urgent, with FH potentially serving as an effective intervention target. This study explores whether and how FH can enhance the PHRMI in China. We propose the following three hypotheses: (1) FH is positively associated with proactive health risk management, (2) the association between FH and the PHRMI is mediated by health literacy, and (3) family communication moderates the mediating effect of health literacy between FH and the PHRMI.

## Methods

### Sampling and Participants

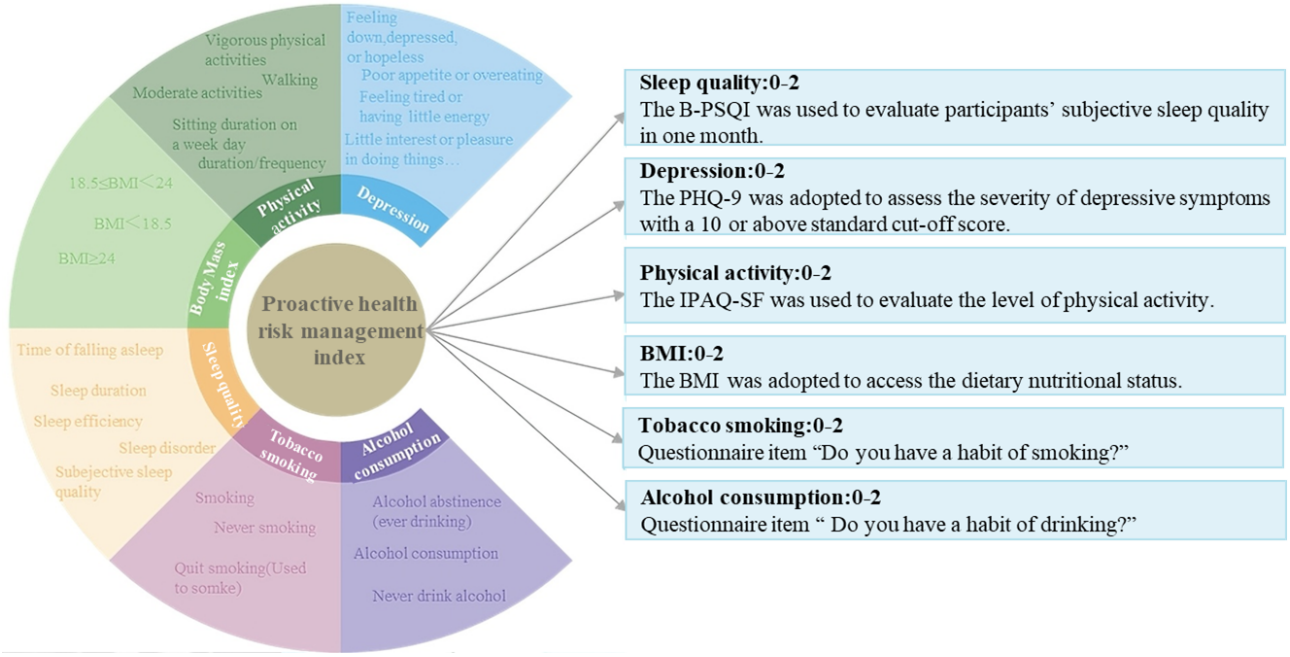
The data originated from a nationwide, representative, population-based survey conducted from June 20, 2023, to August 31, 2023, encompassing 150 cities from 23 provinces, 5 autonomous regions, 4 municipalities directly under the Central Government, and 2 special administrative regions in China [46,47]. To ensure the overall representativeness of the study population, the survey used a multistage sampling method, incorporating stratified sampling at various levels, including province, city, and community. During the first stage, the city selection included capital cities across China, and 2 to 12 cities were selected from each noncapital prefecture within every province and autonomous region, totaling 150 cities. The number of cities selected from each province was determined by the population size weight of that province. Moving on to the second stage, of the 150 municipalities sampled, the number of communities sampled within each municipality was proportional to the population base of the first-level administrative district. A total of 10 to 60 communities were sampled, with an urban-to-rural ratio of 3:2 in the municipalities sampled in each province, resulting in 800 communities. In the last stage, quota sampling was used at the community and village levels as well as at the individual level, using quotas that were determined based on sex and age attributes from the data of "The 7th National Census in 2021." The sample size was estimated to be 45,830. After implementing quota sampling, the final sample included 30,054 participants. This sample specifically accounted for attributes such as sex and age.

The survey protocol has been published [48]. Inclusion criteria for our survey include: (1) being aged 18 years or older, (2) holding the nationality of the People's Republic of China, (3) being permanent residents with annual travel of 1 month or less, (4) being able to complete the online questionnaire independently or with assistance, and (5) being able to understand each questionnaire item. Individuals who were delirious, suffering from cognitive dysfunction, participating in other similar research, or unwilling to participate were excluded. In this study, we excluded samples with missing data on critical study variables. Specifically, 10 participants were removed due to incomplete bedtime and wake-up time records, which precluded reliable assessment of their sleep quality.

### Ethical Considerations

This study was conducted in compliance with the ethical guidelines of the Declaration of Helsinki and received approval from the ethics research committee of the Shandong Provincial Hospital (SWYX:NO 2023 - 198). All data in this research did not involve participant compensation. All participants were required to sign informed consent prior to participating in the study. Meanwhile, we ensured the confidentiality of the collected data through anonymity and stringent security measures.

### Proactive Health Risk Management Index



Referring to previous relevant studies [49-51], PHRMIs were measured through a self-created comprehensive instrument, including BMI, physical activity, depression, sleep quality, smoking behavior, and drinking behavior. We defined the PHRMI as comprising 6 aspects, with its measurement based on the 4 cornerstones of health proposed by the World Health Organization. Given the detrimental health effects of tobacco smoking and alcohol consumption, we incorporated questions about smoking and drinking behavior, offering response options such as 0 ("yes, smoking or drinking"), 1 ("ever smoked or drank [quit]"), and 2 ("never smoked or drank"), alongside "Do you have a habit of smoking?" and "Do you have a habit of drinking?" The International Physical Activity Questionnaire–Short Form (IPAQ-SF) was used to evaluate the level of physical activity, assessing participants' vigorous activity, moderate activity, and walking activities in terms of frequency and duration from the previous week [52,53]. Previous studies have indicated a moderate-to-high reliability of IPAQ-SF across 12 countries, as well as the Chinese version. According to each participant's total metabolic equivalent–minute/week in walking, moderate, and vigorous activity for 7 days, we categorized them as high, moderate, and low physical activity and assigned the values "2," "1," or "0," respectively. The 9-item Patient Health Questionnaire was adopted to assess the severity of depressive symptoms [54], using a cutoff score of 10 or higher. We encoded Patient Health Questionnaire-9 scale scores of "15 or more" as "0," "5 to 14" as "1," and "less than 4" as "2." The Brief Version of the

XSL•FO
RenderX

Pittsburgh Sleep Quality Index (B-PSQI) was used to evaluate participants' subjective sleep quality over 1 month [55], and it has been proven to be a reliable and valid sleep-quality measure for the general population. This scale encompassed sleep efficiency, sleep latency, sleep duration, sleep disorders, and sleep quality, with a 5 or higher standard cutoff score. We encoded B-PSQI scale scores of "5 or more" as 0 and "less than 5" as 2. BMI was selected as an indicator for the examination of reasonable diet. Participants were classified as overweight (BMI≥24 kg/m$^2$), normal weight (18.5 kg/m$^2$≤BMI<24 kg/m$^2$), and underweight (BMI<18.5 kg/m$^2$), respectively. The indicator was coded as 0 (overweight or underweight) or 2 (normal weight). As shown in Figure 1, the total scores were summed to calculate a PHRMI score ranging from 0 to 12, where a higher score signifies better proactive health risk management.

**Figure 1.** Schematic diagram of the components of proactive health risk management, encompassing sleep quality (Brief version of the Pittsburgh Sleep Quality Index [B-PSQI]), depression (Patient Health Questionnaire-9 [PHQ-9]), physical activity (International Physical Activity Questionnaire–Short Form [IPAQ-SF]), BMI, tobacco smoking, and alcohol consumption.

## Assessment of FH

FH was measured using the Short Form of the Family Health Scale [56], which was modified to align with China's national conditions and cultural characteristics. The scale has been validated and proven to be reliable and effective. It contains four dimensions: (1) family healthy lifestyle; (2) FH resources; (3) family, social, or emotional health processes; and (4) family external social support. The 3 dimensions (7 items) are scored on a Likert-5 scale ranging from 1 (strongly disagree) to 5 (strongly agree), except for "family health resources" (3 items). Scores ranged from 10 to 50 points, with a high score indicating higher levels of FH. The Cronbach α for the sample was 0.807, and the Kaiser-Meyer-Olkin value was 0.879, both indicating acceptable reliability and validity.

## Assessment of Health Literacy

The mediator variable in this study was health literacy, assessed by a 4-item version of the Short-Form Health Literacy Questionnaire-4. The simplified health literacy scales, derived from the Short-Form Health Literacy Questionnaire-12 [57], demonstrated good reliability and validity and were reliable and effective tools for assessing the health literacy of the Chinese population. The total score ranges from 4 to 16, with a higher score indicating better levels of health literacy.

## Assessment of Family Communication

Family communication was the moderator in this study, assessed using the Family Communication Scale-Short Form (FCS-SF). For example, participants were asked, "Family members can discuss things calmly with each other." Items were scored on a 5-point scale from 1 to 5, from 1 ("strongly disagree") to 5 ("strongly agree"). The sum of scores on the FCS-SF, ranging from 4 to 20 points, indicates better communication between family members with higher scores. The Cronbach α for the FCS-SF was 0.926 in this study.

## Covariates

Covariates were identified initially based on relevant research and general knowledge, including age, sex, nationality, education level, family type, and employment status. Enrolled covariates were analyzed subsequently for intergroup differences using the bilateral 2-tailed Student *t* test or one-way ANOVA. Covariates were considered for inclusion as potential confounders in the final models if significant differences between the groups were observed. The final demographic characteristics included age, sex (1="male" and 2="female"), nationality (1="Han nationality" and 2="nationality minority"), educational level (1="illiterate or semi-illiterate"; 2="junior high school and below"; 3="secondary technical school, senior high school, and college for professional training"; and 4="Bachelor's degree and higher"), residence (1="urban" and

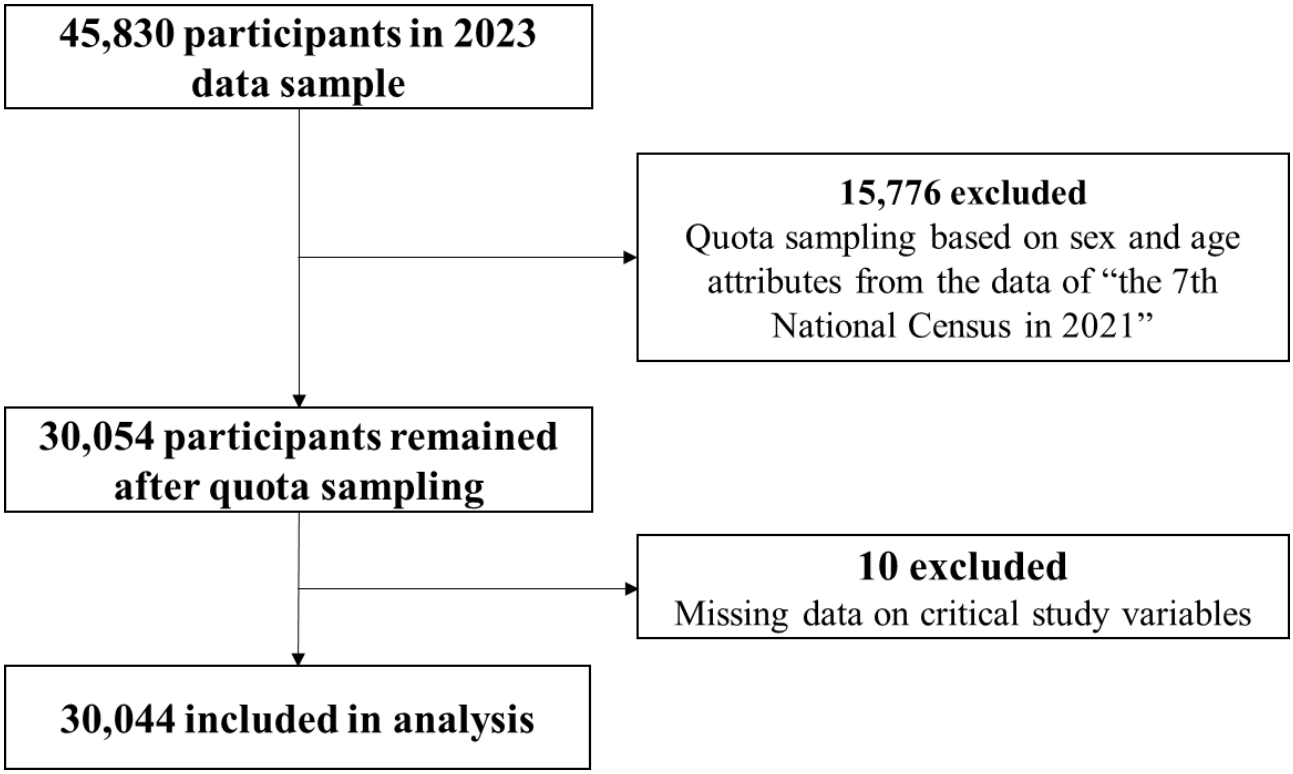
XSL•FO
RenderX

2="rural"), family type (1="core family," 2="backbone family," 3="joint family," 4="conjugal family," 5="single-parent family," and 6="other family"), household income monthly per capita (1="≤￥3000" [US $421], 2="￥3001-￥6000" [US $421-US $841], and 3="≥￥6001" [US $841]), children (0="no" and 1="yes"), and insurance (0="no" and 1="yes"). Age and self-assessment of social status (scoring 0-7) were set as continuous variables.

### Statistical Analysis

Demographic characteristics, FH, PHRMIs, health literacy, and family communication of participants were summarized using frequencies (percentages) or means and SDs. The disparity in PHRMIs across different groups was analyzed using the 2-tailed Student *t* test and one-way ANOVA. We used SPSS 26.0 (IBM Corp) and the Hayes [58] SPSS macro program PROCESS to test the mediating effect using model 4. If the coefficient *a* (representing the association between X and M), *b* (the mediator's effect on Y), and *c* (the relationship between X and Y) in the regression model including X, M, and Y were statistically significant, this indicated that the mediating effect was significant. Next, we constructed a new model containing the aforementioned variables and the product term of the moderator and independent variable to verify the moderating effect of family communication. Finally, the PROCESS macro for SPSS was used to examine whether family communication moderated the direct and indirect effects of FH on the PHRMI. All statistical analyses were conducted using SPSS 26.0. In addition, all models controlled for covariates, and the significance level was set at a *P* value of <.05 for all the hypothesis tests [59].

### Sensitivity and Subgroup Analysis



To validate the results, we conducted a sensitivity analysis. Specifically, we replaced depression with generalized anxiety disorder as a measure of the mood component and recalculated the PHRMI. Following this adjustment, we repeated the aforementioned statistical analysis steps to ascertain whether the direct and indirect effects remained statistically significant. In addition, subgroup analysis was used to explore the heterogeneity of PHRMIs. Considering the wide age spectrum of participants (aged 18-106 y), we further stratified the age cohorts to compare the association between familial health and proactive health levels across different age groups, as well as to examine the mediating role of health literacy.

## Results

### Sample Characteristics

The process for screening participants is shown in Figure 2. A total of 30,044 participants were included in the final analysis. All participants had a mean age of 43.99 (SD 16.55) years, ranging from 18 to 106 years, with 15,004 (49.90%) males and 15,040 (50.10%) females. Most participants were married (n=19,391, 64.50%), lived in urban areas (n=20,728, 69.00%), and reported having a Bachelor's degree or higher (n=10,609, 35.30%). The mean scores for FH and the PHRMI were 39.86 (SD 6.15) and 5.88 (SD 1.78), respectively. Subsequently, we performed an analysis of intergroup differences to assess the disparity in PHRMIs across demographic variables, using a 2-tailed *t* test and one-way ANOVA. Significant differences were found among various demographic groups, including sex, nationality, education level, and residence (Table 1).

**Figure 2.** Flowchart of participant selection in the 2023 Psychology and Behavior Investigation of Chinese Residents for this study, conducted from June 20, 2023, to August 31, 2023.

## Mediation Analyses

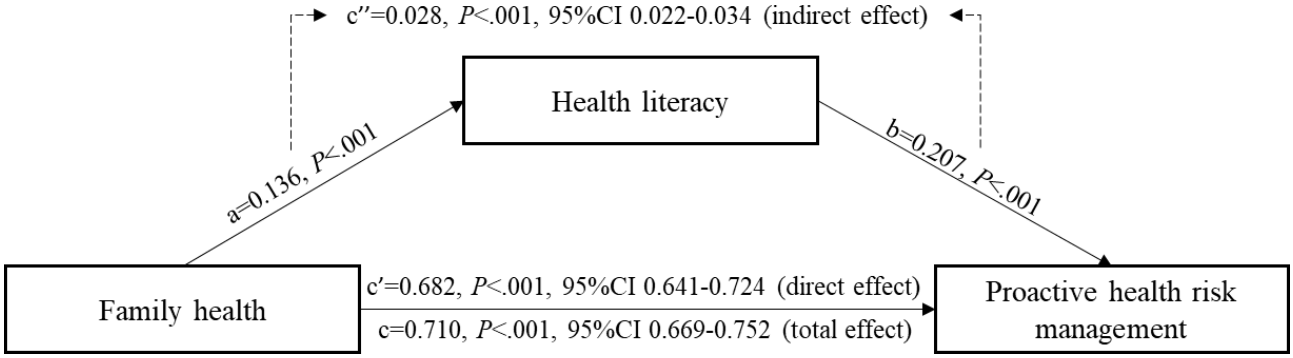
Model 4 is a simple mediating model in SPSS macro PROCESS compiled by Hayes. We adopted to test the mediating effect of health literacy on the association between FH and the PHRMI, while controlling for age, gender, nationality, education level, family type, employment status, income, children, marital status, insurance, residence, self-assessment of social status, and registered permanent residence. Model 1 of Table 2 shows that the positive predictive effect of FH on the PHRMI was significant (β=.710, 95% CI 0.669-0.752). Model 2 of Table 2 shows that FH had a significant positive predictive effect on health literacy (β=.136, 95% CI 0.124-0.148), while health literacy also had a significant positive predictive effect on the PHRMI (β=.207, 95% CI 0.168-0.245). Moreover, when the mediating variable was added, the direct predictive effect of FH on the PHRMI was still significant (β=.682, 95% CI 0.641-0.724), as shown in model 3 in Table 2. In addition, the upper and lower bounds of the bootstrapped 95% CI for the direct effect of FH on proactive health risk management and the mediating effect of health literacy did not include zero in Figure 3, indicating that the mediating effect was significant (indirect effect=0.028; *P*<.001). The results implied that the association between FH and the PHRMI was partially mediated by health literacy.

**Table .** Results of the mediating effect of health literacy in the association between family health (FH) and the proactive health risk management index (PHRMI) in the cross-sectional study based on the 2023 Psychology and Behavior Investigation of Chinese Residents (N=30,044). These models incorporated covariates, including age, gender, nationality, education level, family type, employment status, income, children, marital status, insurance, residence, self-assessment of social status, and registered permanent residence.

| Predictors | Model 1[a] (DV[b]=PHRMI) | Model 2[c] (DV=HL[d]) | Model 3[e] (DV=PHRMI) |
|---|---|---|---|
| FH, β (95% CI) | .710 (0.669-0.752) | .136 (0.124-0.148) | .682 (0.641-0.724) |
| HL, β (95% CI) | —[f] | — | .207 (0.168-0.245) |

[a]$F_{13,\ 30,030}$=166.605, *P*<0.001, $R^2$=0.109.

[b]DV: dependent variable.



[c]$F_{13,\ 30,030}$=226.421, *P*<0.001, $R^2$=0.142.

[d]HL: health literacy.

[e]$F_{14,\ 30,029}$=164.701, *P*<0.001, $R^2$=0.112.

[f]Not applicable.

**Figure 3.** Mediating model of the effect of family health on proactive health risk management via health literacy in this cross-sectional study based on the Psychology and Behavior Investigation of Chinese Residents (2023; N=30,044). "a" represents the coefficient between family health and health literacy; "b" represents the coefficient between health literacy and proactive health risk management; and "c" represents the total coefficient when combined direct coefficient (c') and from family health and proactive health risk management and indirect coefficient (c") between them via health literacy.

## Moderated Mediation Analyses

To verify the moderated mediation model while controlling for all covariates, we used model 7 of the SPSS macro PROCESS compiled by Hayes. The results of the family communication moderation test are shown in Table 3 and Figure 4. After putting family communication into the model, the product (interaction term) of FH and family communication had a significant predictive effect on health literacy (β=.117, 95% CI 0.105-0.130), as shown in model 4 of Table 3. The result showed that family communication played a moderating role in the association between FH and health literacy. Higher levels of

XSL•FO
RenderX

family communication exacerbated the effects of FH on health literacy, as evidenced by the fact that the linear slope for higher levels of family communication is steeper than that for lower levels in Figure 4. Furthermore, the effect size estimate for the moderated mediating effect was 0.024, and the 95% CI was (0.019-0.031), excluding 0, which also supported the existence of a moderated mediation effect in this model.

**Table .** Results of the moderated mediation model of family communication and health literacy in the association between family health (FH) and the proactive health risk management index (PHRMI) in this cross-sectional study (2023, China; N=30,044). All models incorporated covariates.

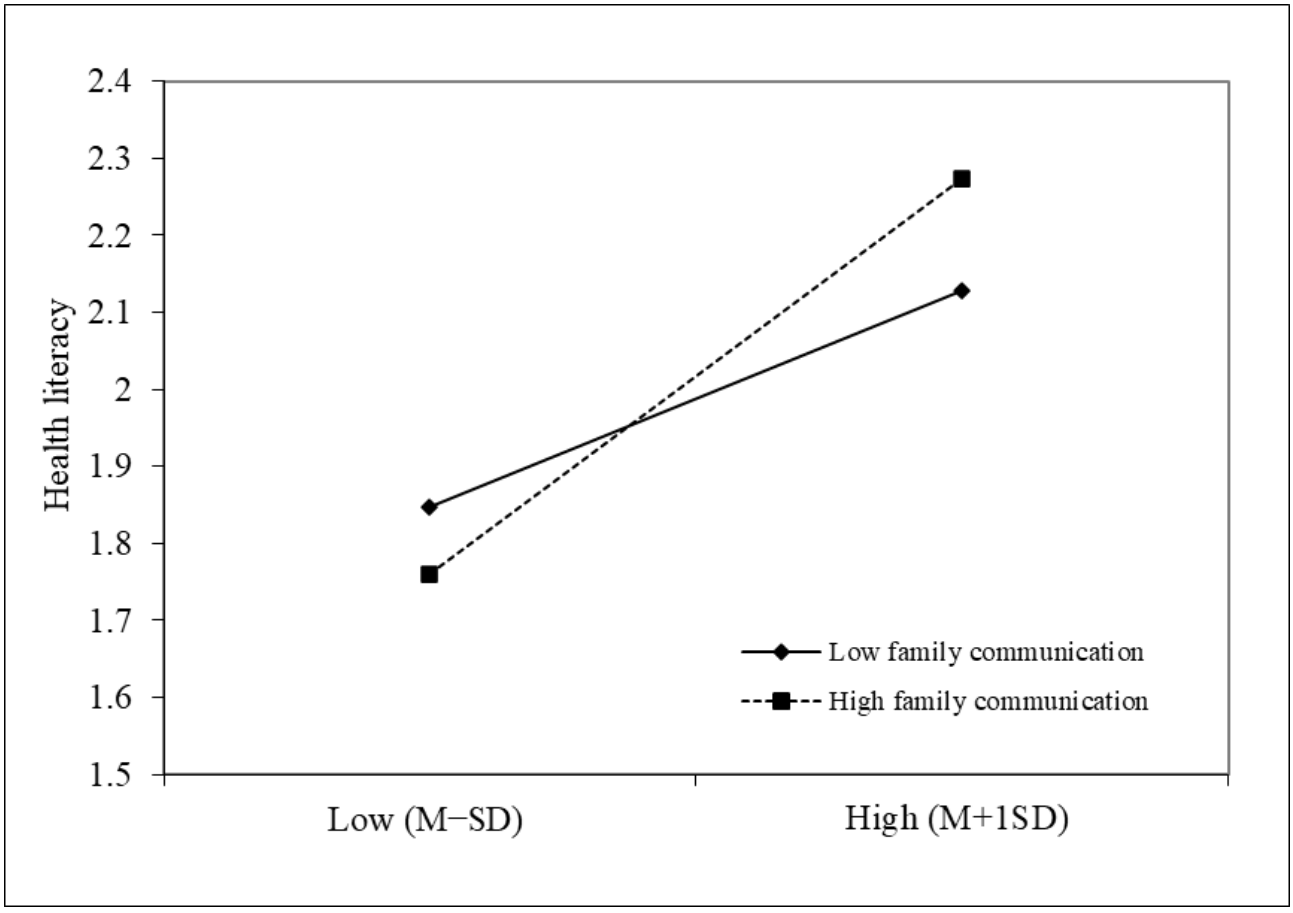
| Predictors | Model 4[a] (DV[b]=HL[c]), β (95% CI) | Model 5[d] (DV=PHRMI[e]), β (95% CI) |
|---|---|---|
| FH | .140 (0.126-0.153) | .682 (9.641-0.724) |
| HL | —[f] | .207 (0.168-0.245) |
| FC[g] | .029 (0.019-0.153) | — |
| FH×FC[h] | .117 (0.105-0.130) | — |

[a]$F_{15, 30,028}$=224.369; $R^2$=0.152.

[b]DV: dependent variable.

[c]HL: health literacy.

[d]$F_{14, 30,029}$=164.701; $R^2$=0.112.



[e]PHRMI:proactive health risk management index

### Sensitivity Analysis

In the sensitivity analysis (Table S2 in Multimedia Appendix 1), we assessed proactive health risk management using generalized anxiety disorder instead of depression. The result was consistent with that of the aforementioned analysis. Upon replacing depression with generalized anxiety disorder, the results revealed that better FH was associated with better health literacy (β=.198, 95% CI 0.160-0.236) and further increased proactive health risk management (β=.630, 95% CI 0.589-0.671), with a significant mediating effect. The moderating influence of family communication on the association between FH, health literacy, and the PHRMI was not assessed in this study, as variations in proactive health risk management did not affect the moderating effect of family communication.

### Subgroup Analysis

To clarify further the association between FH and the PHRMI, we performed subgroup analyses in different age groups, including "aged 18 - 44 years," "aged 45 - 59 years," and "aged 60 years and older." First, the positive associations between FH and the PHRMI were significant in all subgroups (for those aged 18 - 44 y: β=.708, 95% CI 0.650-0.767; for those aged 45 - 59 y: β=.653, 95% CI 0.574-0.731; for those aged ≥60 y: β=.732, 95% CI 0.637-0.827). Notably, the mediating effect of health literacy remained significant in individuals aged 18 to 44 and 45 to 59 years. However, for those aged 60 years or older, the association between health literacy and the PHRMI (β=.073, 95% CI −0.016 to 0.161) and the mediating effect of health literacy between FH and the PHRMI (β=.066, 95% CI −0.024 to 0.157) was not significant. The details are presented in Table S2 in Multimedia Appendix 1.

## Discussion

### Principal Findings

This study revealed that increased FH was linked to an increased PHRMI (β=.710; *P*<.001). Health literacy acted as a mediator in this relationship (β=.207; *P*<.001). Notably, while both the direct and indirect paths reached statistical significance, their magnitudes differed substantially. The strong direct association of FH with the PHRMI dominated the mediation pathway. Furthermore, higher-level family communication shows a small but statistically significant positive association with health literacy (β=.029; *P*<.001) while simultaneously intensifying the promoting effect of FH on it (β=.117; *P*<.001).

### Comparison With Prior Work

The study confirms a significant effect of family elements on an individual's health behaviors or outcomes. This aligns with the findings of most existing studies. Previous studies have already shown that various elements of family, such as family structure [60], sibling relationships [61], family social status [62], FH climate [63], family social capital [64], and so on, influence an individual's health. A similar effect also reflects on the influence on health behavior [65-68]. However, few studies have integrated family-level socialization dynamics, as described in family system theories [69], and explored the association between them and health or health behaviors. This critical deviation may lead to misjudging the role of family in members' health, limiting our ability to develop health promotion programs, policies, and goals and even blurring intervention priorities [70]. In this study, we used FH, encapsulating structure, function, and social network, which moves beyond examining isolated family factors to capture the holistic, systemic dynamics emphasized in family system theories. We discovered the positive association between FH and the PHRMI, aligning with a prior study [38]. In contrast, this study aims to examine the association between FH and clustered health behaviors, while the other focuses on exploring the mediating role of four independent health behaviors between FH and frailty. Currently, little research has examined how family-level integrated elements affect clustered health behaviors. A key innovation of this study is the construction of the PHRMI, encompassing important health risk factors. To some extent, it decreases the interdependencies among health behaviors that are often overlooked in single health behavior research. Consequently, this strengthens the argument that fostering overall FH may be a potent strategy for promoting proactive health behavior changes [71,72].

Higher health literacy is associated with increased participation in healthy behavior [30]. This research extends the outcome variables of health literacy by demonstrating that health literacy is positively associated with the PHRMI. In addition, individuals with lower FH tend to exhibit lower health literacy. Another cross-sectional survey in China also confirmed the positive association between FH and health literacy [73]. One possible explanation is that individuals with fewer family resources or family support may lack confidence and thus be unable to independently address health difficulties and manage health risk factors. In addition, health literacy mediates the positive association between FH and the PHRMI. Notably, the mediation analysis showed that the mediator only accounted for 4% of the total effect of FH on the PHRMI, suggesting a relatively modest mediated effect. FH is a complex and comprehensive concept influenced by multiple factors across family and individual domains. Complex familial interactions affect and shape individual health behavior through a variety of underlying mechanisms [74]. While our findings support the association between health literacy and proactive health risk management, exploring additional clinical, psychological, or physiological pathways remains an important direction for future research. On the other hand, family communication moderated the mediating effect of health literacy between FH and the PHRMI. This means the positive association between FH and health literacy was enhanced as family communication levels increased. The circumplex model proposes that families with a balance of cohesion and communication are more likely to set and achieve goals [75] by effectively integrating family members' individuality and independence. Therefore, a focus on both the family and the individual for health promotion could be more effective than efforts targeted solely at the individual.

Regarding the effects of variation among different age groups, subgroup analysis results showed that FH had a stronger positive effect on the PHRMI among older adult individuals compared to younger ones. Presumably, this result is due to the fact that older adults receive health information from a relatively singular

XSL•FO
RenderX

source [76,77]. As age increases, due to both subjective and objective factors such as the lack of credible internet-based health information sources [78], low-level electronic health literacy [79,80], and declines in cognitive [81,82] and physical function [83], the ability of older adults to discriminate health information gradually declines [84]. Therefore, they prefer to trust health interventions recommended by trusted family members [85]. In addition, consistent with previous studies, males tend to exhibit poorer health behaviors. Males' PHRMI scores are lower than females' at any age, indicating the need to strengthen males' health interventions in particular. We find that low self-assessed social status and resource-limited economic status are associated with lower FH and PHRMIs. Self-assessed social status was statistically associated with health literacy and the PHRMI, which is consistent with previous studies**.** Our study provides further empirical evidence that health interventions are not only about health but also about improving one's economic and social status. For instance, evidence from China shows that the national program to stabilize poverty alleviation has a significant health benefit, particularly for marginal poverty-prone households and people in resource-limited areas.

### Limitations

There are some limitations to this study that need further investigation in future research. First, although this study designed the proactive health risk management score using validated scales and indicators, the weighting coefficients between indicators were not addressed in the calculation process. Second, the cross-sectional research design means that causality cannot be deduced from the results. Future research could adopt a longitudinal design to explore the causal association between FH and proactive health risk management. Ultimately, some of the scales used to construct the proactive health risk management score in this paper, such as the B-PSQI and the IPAQ-SF, were completed by patients relying on their recall; this may introduce bias compared to the real situation. Future research could consider collecting objective indicators for the exercise and sleep dimensions.

### Conclusions

In conclusion, FH can be an important intervention target that appears to be positively linked to proactive health risk management. The mediating role of health literacy suggests its potential as a pathway through which improved FH may correspond to enhanced proactive health risk management. Our study provides evidence that maintaining FH is advantageous for promoting healthy behavior in Chinese individuals, particularly within the older adult population. Meanwhile, in the context of the family, health interventions should address a wider range of familial factors, such as family communication, family healthy lifestyle, FH resource accessibility, and family external social support, rather than focusing solely on health-related interventions.

## Acknowledgments

The authors are extremely grateful to all participants who took part in the study for their time and involvement. The authors would also like to thank the survey team for conducting the survey and cleaning the data.

## Funding

This work was supported by the National Key Research and Development Program of China (grant: 2023YFC3606400 and 2022YFE0133000), National Nature Foundation of China (grant 72004073 and 72374079), and Research Project of Humanities and Social Sciences of the Ministry of Education (grant 20YJC630134). The funder had no involvement in the study design; the data collection, analysis, and interpretation; or the writing of the manuscript.

## Data Availability

The data used in this study are publicly accessible at Psychology and Behavior Investigation of Chinese Residents (PBICR) [86]. The PBICR data are managed by the Psychology and Behavior Investigation of Chinese Residents Project Team and are not publicly available. Researchers interested in accessing PBICR data for replication or further analysis need to submit a data request to the project team (email: pbicr_zgjmxlyxwdc@163.com).

## Authors' Contributions

All authors reviewed and edited the manuscript. Y Wei and ST conceptualized the study. YW performed data analysis and wrote the original draft. Y Wu, HD, KZ, JS, HQ, and CW contributed to the writing of the manuscript. ST was responsible for funding acquisition. All authors had full access to all the data in the study and had final responsibility for the decision to submit for publication.

Co-corresponding author: Yibo Wu, School of Public Health, Peking University, No.38, Xueyuan Road, Beijing 100191, China, bjmuwuyibo@outlook.com

## Abstract

**Background:** Although recovery is a central tenet of the US substance use disorder service delivery system, empirical research on youth recovery remains limited and underdeveloped. Notably, no population-based representative surveys, either in the United States or internationally, currently assess recovery status among secondary school–aged youth (aged 14-18 years). Consequently, little is known about how many youth identify as being in recovery or about their characteristics and needs.

**Objective:** This study presents the first statewide representative estimate of adolescent self-reported recovery (ASR), derived from a large Midwestern state in the United States.

**Methods:** We used data from the 2024 Illinois Youth Survey, a weighted, statewide representative survey of students from 8th, 10th, and 12th grades across Illinois. We examined the prevalence of ASR with a widely used single-item question, “Do you consider yourself to be in recovery?” The question was presented after an instruction directing students to consider only substance use when responding. We estimated the prevalence of ASR and conducted descriptive analyses to characterize this group.

**Results:** Among the 6871 participating students from the 10th and 12th grades, the prevalence of ASR was 3.3% (95% CI 2.6%-4.1%). Among participants with ASR, 51.1% (118/231) were female, 39% (90/231) identified as Latino or Latina, 38.1% (88/231) identified as White, and 13% (30/231) identified as Black or African American. The average age of participants with ASR was 16.5 (SD 1.14) years. Participants with ASR were demographically diverse, and a little over half received free or reduced-price lunch.

**Conclusions:** Findings suggest that financial recovery capital may be particularly important for participants with ASR. This study provides the first population-based estimate of the prevalence of ASR and underscores the importance of including recovery status in large-scale surveys to inform and strengthen recovery support systems.

recovery; adolescents; substance use disorder; epidemiology; recovery capital

## Introduction

Recovery is undoubtedly an organizing principle of the US substance use disorder (SUD) service delivery system. For instance, the US Surgeon General’s report has a dedicated chapter on recovery [1], and federal and state agencies have the word “recovery” appearing in their organization names (eg, the Substance Abuse and Mental Health Services Administration houses an Office of Recovery). Additionally, nationally representative epidemiological studies have measured substance use recovery among adults. On the basis of a study that used data from the National Survey of Drug Use and Health, about 8% of US adults consider themselves to be in substance use recovery [2].

Focusing on recovery as an organizing concept for care is part of a broader effort to frame SUD—a clinically diagnosable condition with substance use—as a treatable health condition. Additionally, the recovery movement seeks to destigmatize the millions of Americans who have recovered from SUD. Finally, there has been increasing attention on what supports are required to both initiate and maintain recovery [1].

Major advances have been made toward these goals. Historically, public stigma toward addiction and misperceptions about treatment effectiveness may have clouded health professionals’ willingness to treat patients with addiction. However, since the early 2000s, researchers have shown that treatment outcomes for people with SUD are similar to, and sometimes better than, those for other chronic health care conditions [3]. Major initiatives such as the implementation of the screening, brief intervention, and referral to treatment model

XSL•FO
RenderX

in primary care have also moved SUD treatment into mainstream health care and improved SUD case identification [4]. However, the opioid crisis in the United States revealed a fissure in health care provision for SUD, with very low rates of efficacious medications being prescribed for persons with opioid use disorders [5].

Regarding stigma reduction, researchers have focused on identifying stigmatizing terms [6,7] that can be avoided by professionals. One clear term to avoid is "substance abuse," which has been associated with professionals viewing persons with SUD as in need of punitive responses [7] and as dangerous [6]. Because of findings like these, some state agencies have removed "substance abuse" from their agency names. Another focus of destigmatizing recovery involves identifying potential workplace discrimination. For example, one national survey found that people remain leery of hiring individuals even when they are in recovery [8], signaling that additional work must be done to frame SUD as a treatable health condition.

Finally, there are many efforts to improve the infrastructure to maintain recovery once it is achieved. Two examples include the development of recovery community organizations and collegiate recovery programs, which both provide support for recovery maintenance [9,10]. While the former are community centers run by people in recovery through many programs (ie, antistigma events, support groups, and training of peer recovery specialists), the latter are specialized programs in universities designed to provide social support to college students (ie, support groups and sober tailgates). Additionally, many health care systems have integrated persons with lived experience into paraprofessional roles to help support those entering recovery [11]. All these efforts are part of an overall movement toward creating a recovery-oriented system of care that prizes lived experience, provides recovery support, and destigmatizes people with SUD.

However, with few exceptions, what is known about the pathways into and benefits of recovery is almost entirely based on adult research. Some progress has been made in adapting adult-focused models of recovery support for adolescents. For example, recovery high schools congregate adolescents who have entered recovery and could benefit from intense, structured social support [12,13]. Another model of adolescent recovery support is the alternative peer group model, which emphasizes sober recreation, peer support, and linkage to services [14]. While promising, both of these models are not widely available, which is likely driven by the fact that there are no nationally representative epidemiological data on the number of youth in recovery who may benefit from such supports [1].

The purpose of this study is to obtain a more accurate estimate of the prevalence of adolescent self-reported recovery (ASR) than that reported in prior studies. This could help policymakers better assess the need for structured recovery support for younger adolescents. This study used a weighted random sample of students from 10th and 12th grade in a Midwestern US state, which improves upon prior estimates. For example, to our knowledge, only 1 prior study estimated ASR, but it was not representative of the state from which the sample was drawn. It is estimated that 4.9% of 10th graders and 4.6% of 12th graders (roughly aged 16-18 years) may consider themselves to be in recovery [15]. In this study, we address a major weakness of the prior study by using 2024 data from the same statewide survey, which is representative. Thus, this study is the first statewide representative estimate of ASR to be conducted.

## Methods

### Ethical Considerations

Human subjects approval for the primary study was obtained from the authors' institutional review board (University of Illinois; IRB24-0832), which included authorization to analyze and disseminate aggregated findings for secondary analyses such as this study. This study was approved for a waiver of parental consent, with parental notification and opt-out procedures in place. Schools were instructed not to survey students whose parents had opted them out of the survey and to provide such students with an alternative activity. However, the research team did not receive data on the number of students whose parents declined their participation in the survey.

### Study Description

The data used in this study come from the 2024 Illinois Youth Survey (IYS), a biennial survey administered to students in grades 8, 10, and 12. Participation was open to all schools in Illinois. Schools were recruited through a variety of mechanisms, including direct emails to principals and other school contacts from previous survey administrations, telephone calls, online newsletters and press releases, and conference exhibits (eg, the Illinois Principals' Association conference). Those who opted to participate registered online and were sent instructions on distributing parent notifications, instructions on administering the survey across grades at the school, teacher or proctor instructions to be read aloud to students on survey day, and login information for the online survey. Schools administered the survey on a date of their choosing between January 2024 and June 2024, and students completed the survey on school-issued devices during scheduled classroom periods. Some schools, especially larger schools, are surveyed over a few days or a week.

### Data Validation

Multiple procedures were applied to ensure internal consistency and data quality [16]. Internal consistency was evaluated by cross-validating related items (eg, past 30-day vs past-year substance use). For instance, respondents who reported alcohol use in the past month but not in the past year were classified as inconsistent and the corresponding survey items were recoded as missing. Following these checks, 12.4% of surveys were invalidated. Surveys were removed if respondents (1) endorsed the use of a fictitious drug (1%), (2) completed fewer than 40% of survey items (9%), or (3) selected 2 of the lowest honesty options (2.8%). Some surveys met more than one exclusion criterion, resulting in overlap.

### Sampling Procedures and School Participation

While participation in the IYS was open to all schools, the data used for this study were gathered from schools randomly

XSL•FO
RenderX

selected to comprise a statewide representative sample (refer to sampling procedures explained in subsequent sections). The sampling frame excluded very small schools (fewer than 16 students per grade) and all specialized institutions, such as alternative and charter schools, which may differ from traditional public schools in student composition.

During the 2024 administration cycle, a total of 10,490 surveys were collected from 154 sampled schools, including 74 middle schools and 80 high schools. Student participation rates varied across schools, with median participation rates of 81.5% (IQR 71.9%-86.5%) in middle schools and 55.3% (IQR 34.5%-69.2%) in high schools. This is consistent with participation rates in recent nationally representative surveys, which have dropped since the COVID-19 pandemic [17]. Participating schools included 60 from suburban Chicago, 29 from Chicago, 34 from other urban areas, and 31 from rural Illinois. To ensure adequate representation across grade-by-region strata, schools were oversampled at recruitment. Consequently, the target number of participating schools was achieved in most strata, and all participating schools were retained for analysis. Sampling weights were applied to account for differential probabilities of selection and participation.

The IYS uses a 2-stage, stratified cluster sampling design to generate a statewide representative sample of Illinois public schools serving students from 8th, 10th, and 12th grades. Schools were stratified by geographic region (Chicago, suburban Chicago, other urban or suburban counties, and rural counties) and grade level (8th, 10th, and 12th), yielding 12 strata to account for variation in student distribution across the state. In the first stage, schools were randomly selected within each stratum using a probability-proportional-to-size approach, accounting for differences in grade-level enrollment. In the second stage, all eligible students within selected schools were invited to participate, rather than sampling classrooms, to reduce logistical constraints and minimize within-class clustering. Within each participating school and grade, up to 50 completed surveys were randomly selected; schools with fewer than 50 respondents contributed all completed surveys [18-20]. This approach ensured equal selection probabilities across grades.

Survey weights were constructed to account for differential selection probabilities at the school and student levels. An additional absenteeism-adjustment factor was applied, giving greater weight to students with higher levels of school absence due to the known association between absenteeism and substance use [21]. Final weights were normalized to preserve the original sample size. When used with the specified survey design (including stratification), they yield estimates representative of the statewide public school population.

The 2024 IYS weighted dataset consisted of 10,490 students from 154 sampled schools. For this study, we focused on the subset of students (n=6986) from 10th and 12th grades who were administered the recovery status item. This study provides the first population-based estimate of the prevalence of ASR in Illinois. We hypothesized that the prevalence of ASR would be lower than that reported for adults in recovery.

## Measures

The IYS functions primarily as a prevention survey, with most items adapted from the Communities That Care Survey [22]. It includes a wide range of demographic measures, risk factors for initiating substance use, detailed substance use and consequence items, and a variety of other health and safety measures.

The primary variable of interest in this study was self-identified recovery status. Students were asked a single yes-or-no question, “Do you consider yourself to be in recovery?”, which has been used in prior adult research [2,19]. To avoid confusion with mental health recovery, this item appeared within a section clearly labeled: “The following questions are about recovery from substance use.” As done in other adult and adolescent research, immediately before the recovery item, students were asked, “Besides nicotine, did you used to have a problem with drugs or alcohol, but no longer do?” [2,15,19]. An affirmative response to this item is indicative of problem resolution but is not considered indicative of being in recovery.

## Analyses

All analyses accounted for the complex sampling design of the IYS and were conducted in both SPSS (version 31.0; IBM Corp) and Stata (version 19.1; StataCorp). Descriptive statistics, including prevalence estimates and 95% CIs, were calculated using the survey design and sampling weights to obtain design-adjusted SEs.

Missing data were minimal for demographic variables (<1.5%) and for the recovery item (3.5%). To evaluate the missing data mechanism, we conducted the Little Missing Completely at Random test on analytic variables, which did not indicate evidence against missing completely at random ($\chi^2_{50}$=63.94; $P$=.09). However, given the strong conceptual and empirical links between recovery status and related substance use behaviors, multiple imputations were conducted under the more general missing-at-random assumption. The imputation model incorporated a broad set of alcohol-related and marijuana-related measures to improve the plausibility of missing at random and the quality of imputed recovery estimates.

Recovery prevalence estimates were calculated overall and by grade level. Descriptive characteristics of youth who identified as being in recovery are also presented.

## Analytic Sample

Among the 6986 students from 10th and 12th grades, we applied a consistency check to ensure the validity of self-reported recovery status. Students (115/6986, 1.6%) who indicated never having used substances on the age-of-first-use item but simultaneously endorsed being in recovery were classified as inconsistent and excluded from the analysis. This step was taken to improve the accuracy of the recovery prevalence estimates. After applying this exclusion, the final analytic, unweighted sample included 6871 students.

## Results

### Weighted Prevalence of Recovery by Grade

The weighted prevalence of youth who self-identified as being in recovery is presented in Table 1. Overall, 3.3% (231/6909; 95% CI 2.6%-4.1%) of students from 10th and 12th grades reported being in recovery, while 96.6% (6678/6909) reported not being in recovery. When examined by grade level, recovery prevalence was 3.3% (120/3592; 95% CI 2.4%-4.2%) among 10th graders and 3.3% (111/3317; 95% CI 2.4%-4.5%) among 12th graders. In both grades, more than 96% of students reported not being in recovery.

**Table .** Weighted prevalence of adolescent self-reported recovery (ASR) (N=6871).

| Grade | Participants with ASR, n (%) | 95% CI[a] | Adolescents not reporting recovery, n (%) |
|---|---|---|---|
| 10th | 120 (3.3) | 2.4-4.2 | 3472 (96.6) |
| 12th | 111 (3.3) | 2.4-4.5 | 3206 (96.6) |

[a]95% CIs correspond to the prevalence estimates of ASR and are based on pooled results from multiple imputed analyses.

### Weighted Prevalence of Recovery by Demographic Groups and Characteristics

Table 2 presents the weighted prevalence of ASR by demographic factors and characteristics of the participants with ASR. Among the 231 participants with ASR, the mean age was 16.5 (SD 1.14) years. Recovery prevalence was higher among female participants (n=118, 3.8%) than among male participants (n=110, 2.8%), with a small proportion preferring not to answer.

**Table .** Weighted prevalence and characteristics of adolescent self-reported recovery (ASR) (n=231)[a].

| Variables | Participants with ASR, n (%) | Prevalence of ASR, % (95% CI) |
|---|---|---|
| Sex | | |
| Female | 118 (51.1) | 3.8 (2.8-4.8) |
| Male | 110 (47.6) | 2.8 (2.0-3.5) |
| Prefer not to answer | 3 (1.3) | —[b] |
| Race | | |
| White | 88 (38.1) | 2.2 (1.5-3.0) |
| Black or African American | 30 (13.0) | 4.2 (1.8-6.5) |
| Latino or Latina | 90 (39.0) | 5.3 (3.5-7.2) |
| Asian American | 10 (4.3) | — |
| Other | 13 (5.6) | — |
| Grade | | |
| 10th | 120 (52.1) | 3.3 (2.4-4.2) |
| 12th | 111 (47.9) | 3.3 (2.4-4.5) |
| Region | | |
| Suburban Chicago | 123 (53.2) | 3.2 (2.5-4.0) |
| Chicago | 40 (17.3) | 4.3 (1.7-6.8) |
| Other urban or suburban areas | 33 (14.3) | 2.3 (1.2-3.5) |
| Rural areas | 35 (15.2) | 4.9 (2.9-6.9) |
| Free or reduced-price lunch | | |
| Free lunch | 116 (50.2) | 4.3 (3.2-5.5) |
| Reduced-price lunch | 13 (5.6) | 3.4 (1.3-5.4) |
| Neither | 102 (44.2) | 2.4 (1.5-3.3) |

[a]Mean age for participants with ASR was 16.5 (SD 1.14) years.

[b]Prevalence and CIs are not shown for cells with small sample sizes due to limited precision.

By race, Latino or Latina youth had the highest prevalence of ASR (5.3%), followed by Black or African American youth (4.2%) and White youth (2.2%). Sample sizes for Asian American and other racial groups were too small to support

XSL•FO
RenderX

reliable estimates. Although White youth had a lower prevalence of ASR, they accounted for a substantial share of the total ASR population (88/231, 38.1%) due to their larger representation in the overall student population. In contrast, Latino or Latina youth, who had the highest prevalence of ASR (5.3%), comprised a disproportionately large share of the ASR population (90/231, 39%) relative to their representation in the student population.

The prevalence of ASR was comparable across grades, with estimates of 3.3% among 10th graders and 3.3% among 12th graders, and the proportion of participants with ASR was approximately evenly split between the two grades (120/231, 52.1% and 111/231, 47.9%, respectively).

Regional differences in prevalence of ASR were observed, with the highest prevalence in rural areas (4.9%), followed by Chicago (4.3%), suburban Chicago (3.2%), and other urban or suburban areas (2.3%). Among all participants with ASR, most were from suburban Chicago (123/231, 53.2%).

Regarding socioeconomic status, as indicated by free or reduced-price lunch status, the highest prevalence of ASR was among those receiving free lunch (4.3%), followed by those receiving reduced-price lunch (3.4%). The prevalence of ASR was lowest among youth not receiving any lunch assistance (2.4%). Approximately half (116/231, 50.2%) of all participants with ASR received free lunch.

## Discussion

### Principal Findings

In this Midwestern US state, 3.3% of adolescents self-reported being in recovery. Based on the total number of students in the 10th and 12th grades in Illinois, that equates to about 4375 tenth graders and 4455 twelfth graders. Comparably, about 4% to 8% of adults in the United States indicate that they are in recovery [2,23]. This is consistent with our hypothesis that adolescent self-reported recovery would be lower than estimates for adults, owing to fewer years of disordered use and fewer opportunities to make lifestyle changes associated with being in recovery.

Furthermore, we note that the overall prevalence rate of ASR here (3.3%) is lower than that previously reported for adolescents (4.3%) in the same state [15]. This could be because this study used a statewide representative sample, whereas the prior sample did not. Additionally, this study used more stringent data screening, excluding students who reported “never using” substances on items about age of onset but also reported being in recovery. In this study, this exclusion criterion lowered the overall prevalence estimate from 5.1% to 3.3%, a considerable difference. This finding highlights the importance for researchers measuring prevalence of ASR to incorporate validity checks.

On the basis of this and other work, we urge national epidemiological studies to start measuring youth recovery. First, these estimates will help improve the planning and development of recovery support services for adolescents. For example, recovery high schools, specially designed to support youth in recovery, are only available in some areas. These findings may support the plausibility of establishing a recovery high school in Chicago or its suburbs. Second, compared to small clinic-based studies of adolescent recovery, studies based on large epidemiological designs can capture a wide variety of recovery pathways, including nonabstinent recovery. There are many definitions of recovery [1]. Regrettably, we know little about nonabstinent youth in recovery [24], although small studies suggest that many youth are interested in this pathway [25].

Third, asking about youth recovery on epidemiological surveys may lead to new insights through the identification of recovery hot spots; that is, it would enable researchers to evaluate whether systems-level initiatives in recovery promotion (ie, recovery community organizations) are working. Emerging research has shown that county-level recovery ecosystems, measured by the presence of treatment, support groups, and recovery-friendly policies, predict ASR indirectly through parent and peer disapproval [26]. Given the need for community recovery capital [27] to support youth recovery, these findings support the validity of the item we used here and in prior research to measure recovery [15].

Finally, youth recovery may be a critical prevention indicator in the future. Although recovery is generally thought of as a treatment outcome in existing patient placement criteria for SUDs, youth recovery could also be conceptualized as a prevention indicator in the broader health context; that is, participants with ASR could reasonably be expected to experience better health outcomes in adulthood due to lifestyle choices associated with earlier recovery.

### Limitations

The following limitations apply to this study. First, the data were self-reported by adolescents, and it is unclear whether all students fully grasped the concept of recovery, despite the introductory heading clarifying that questions referred to substance use. While the survey contractor did not inquire whether schools used monitoring of school devices (ie, GoGuardian), schools were instructed to provide a private space for students to participate and were informed that the survey was anonymous. Research shows that group-administered computerized surveys can reduce reporting of socially undesirable topics due to concerns about confidentiality, even with anonymity assurances [28]. Nevertheless, it is possible that surveillance software used by schools resulted in underreporting. Future studies should track and transparently report whether schools use monitoring software. This would enable better sensitivity testing of its impact on reporting sensitive information.

Second, estimates for 12th graders in the Chicago strata may be less reliable due to small sample sizes at randomized schools and lower student participation. However, as the majority of students in Illinois (223,547/406,719, 55%) live in suburban school districts, the slightly higher recovery estimates in Chicago may only result in a slight upward bias in the statewide prevalence rate. Third, as this survey only included students who were present in school on the days of survey administration, it is a limitation that it does not include students who were absent or had left school. We do not know how this would affect ASR estimates. While absenteeism would affect substance use

XSL•FO
RenderX

estimates [21], participants with ASR may experience improvements in school attendance. Future research should clarify this phenomenon. Fourth, these findings are specific to Illinois public school 10th-grade and 12th-grade students and should not be extrapolated to other states or countries. Future research is needed to assess whether youth recovery prevalence differs nationally or internationally.

Fifth, because the data source is a prevention survey, some variables of interest are unavailable (eg, recovery supports and SUD diagnoses). However, we note that SUD screening scores were elevated among participants with ASR in our prior research [15], possibly supporting the validity of our single-item measure of recovery for adolescents. Finally, the statewide representative sample excluded small schools or specialized institutions, including alternative and charter schools. In sensitivity analyses, we found that alternative schools (in our nonweighted sample) had a higher prevalence of ASR. The exclusions of both absent students and students from alternative schools necessitate additional research on marginalized students. Such students are often less likely to attend school and are also overrepresented in alternative schools [29,30]. However, the overall impact on the state prevalence of the ASR estimate would be low because there are so few alternative schools. Nevertheless, although the data are representative of mainstream public schools, the prevalence estimates reported here may not fully generalize to all youth.

## Conclusions

Recovery is an organizing concept of the US SUD service delivery system, which is why it is peculiar that there is no national estimate of youth recovery. This statewide representative survey of a large Midwestern US state found that 3% of youth in 10th and 12th grades considered themselves to be in recovery. We strongly encourage the adoption of a recovery status item on national and international epidemiological studies involving adolescents under the age of majority. Doing so may lead to better recovery support planning, a better understanding of nonabstinent recovery pathways, more research on recovery hot spots, and improved understanding of whether youth recovery functions as both a treatment outcome and a protective factor for future health status.
